C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2), cell-based HTS platform to identify small molecule antiviral agents targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at the BSL-2 level were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV_B and HeV that can be used as a neutralization or entry inhibitor assay to measure neutralizing antibodies, or as a surrogate for generating virus escape mutants to neutralizing antibodies. Here, the F and G genes of NiV_B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV_B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[56] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 h at 37 °C. Each virus-mAb mixture (90 µL/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci are counted using the CTL Basic Count™ and an IC_{50} value is determined as the antibody concentration

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC_{50} values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

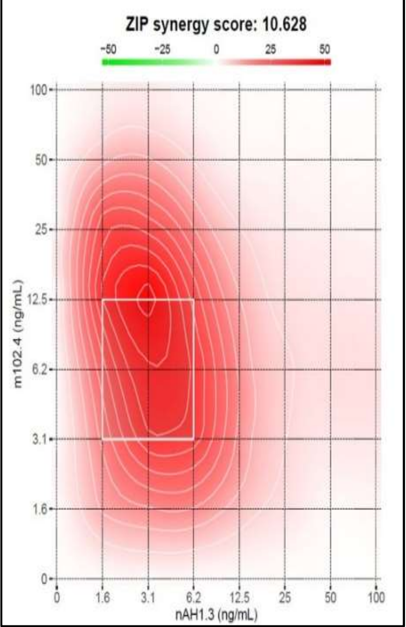

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

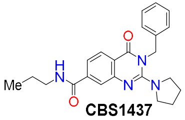
yielding 50% reduction in fluorescent foci versus control wells. **Table 1** shows the calculated IC_{50} values using rCedV chimeras vs. those determined by a conventional PRNT assay with authentic NiV-B and HeV, and they are remarkably within a 2-fold range.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[56] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[57] using a Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here.

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, *in vitro*, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to *in vivo* animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 μM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 μM, and 47 hits showed only minimal cytotoxicity at 33 μM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.

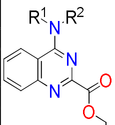


CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)
0.70	100	2.1	100	3.3

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 μM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 μM). **Table 3** shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14** (**Figure 4**), bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.



N	Comp ID	R^1	R^2	% inhib at 10 μM
1	**G577-0014**	H	3-chloro-4-methoxyphenyl	81
2	**G577-0016**	H	2,4-difluorophenyl	18
3	**G577-0021**	H	2-chloro-4-fluorophenyl	58
4	**G577-0022**	H	3-methoxyphenyl	46
5	**G577-0028**	Me	cyclohexyl	93
6	**G577-0084**	H	4-isopropylphenyl	85
7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
8	**G577-0112**	Me	2-methylphenyl	94

*methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent, **CBS1437**, as well as specific plans for developing the SARs.*

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The **Xu lab** has engineered and established transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies.[10] We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs from each cohort. We expect to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

D. RESEARCH DESIGN AND METHODS

D1. Aim 1: Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays.

D.1.1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 μM) and low cytotoxicity (CC_{50} >100 μM).

D.1.1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**G577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we will optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. We will also optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) to produce 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely, 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[58-59] as well as other methods.[60,61] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible. In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[62]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112**

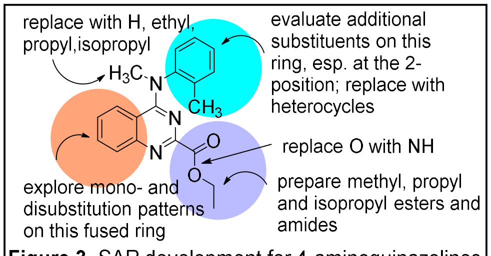


Figure 3. SAR development for 4-aminoquinazolines

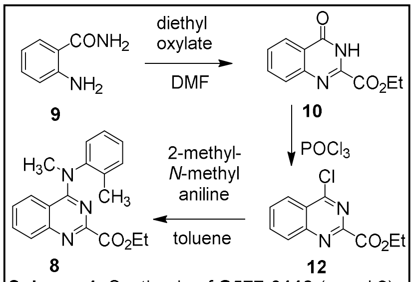

Scheme 1. Synthesis of **G577-0112** (cmpd **8**).

	G577-0386	**proposed cpd 13**	**proposed cpd 14**

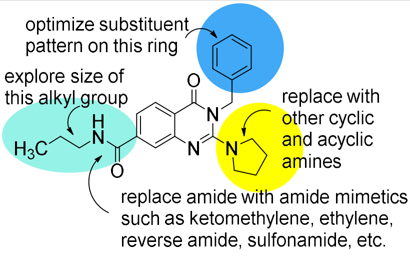

Figure 5. SAR development for **CBS1437**.

(compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester with an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scores have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding. In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. We have also researched and found additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

D.1.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5×10^4 cells per well will be treated with growth medium containing either DMSO or selected compound for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 µM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. The HTS will be performed in the **Rong Lab**. The libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including an Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used as a specificity control. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (EC_{50} values less than 10 µM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds <80% pure will be purified and retested.

D.1.1.3. Evaluation of antiviral activity of advanced candidates. Inhibitors will be tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2×10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 µM to 0.01 µM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to parallel control cultures of virus and DMSO. This work will be performed in the BSL-4 facility at UTMB (**Geisbert, Core D)**.

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Peet, Gaisina, and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds.

D.1.2. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with medium containing either DMSO or selected inhibitors at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by western blot techniques or viral RNA levels by q-RT-PCR. CedV specific antibodies against G F N and P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and performed using the ABI 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in **Aim 1** will also be used for antiviral target identification. *In vitro* selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[63,64] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a “drug resistant” virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any “drug resistant” virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inhibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.1.2.1. Assess the binding properties by surface plasmon resonance (SPR). The NiV polymerase (L protein and a phosphoprotein P, or RdRp complex) will be prepared using a previously published protocol[65]. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, and kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[66] RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab.**[67]

D.1.2.2. Structure determination of recombinant proteins with bound inhibitors by CryoEM. High-resolution structures of the NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compounds to be defined will be obtained using CryoEM by the **Veesler Lab** at the Arnold and Mabel CryoEM Center at the UW. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[68] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including Warp[69], cryoSparc[70], and RELION[71]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed using Rosetta which is developed at the UW. As cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[72-76], to explore the conformational landscape[77] of ligand binding events, and to capture conformational variability of intermediate states[78,79], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.1.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds.

*Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.1.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.

Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-Tox properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[80] Compounds with IC_{50} values ≥100 μM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds.[81] Compounds with >50% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed as previously described.[82] Compounds that do not prevent [^{3}H]dofetilide binding (IC_{50} >10 μM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method[83] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1×10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used.

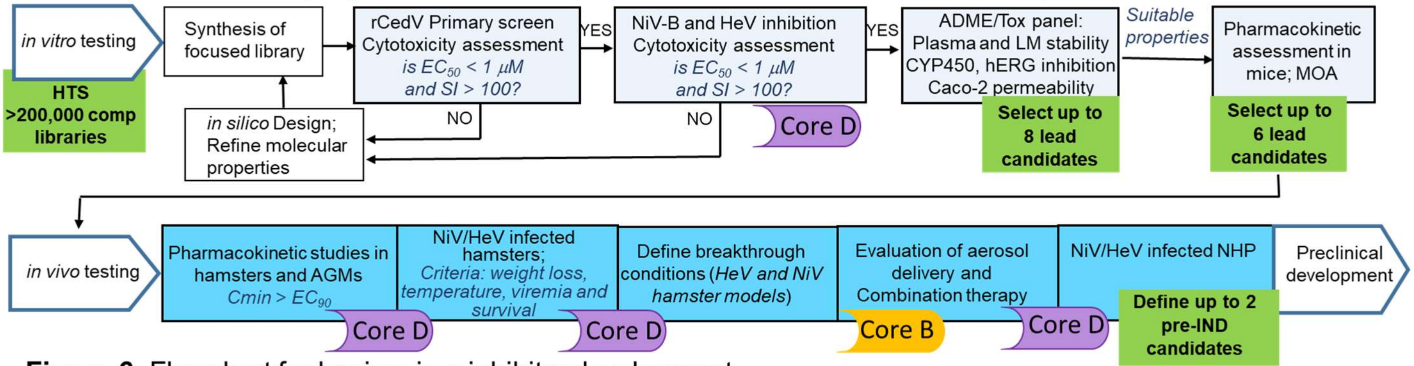

Figure 6. Flowchart for henipavirus inhibitor development.

The bacteria will be exposed to different dose levels and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes. **D.1.3.2. PK studies:** PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim. We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 6**).

D.2. AIM 2: Characterization of the potency and breadth of selected nanobodies.

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the **UTMB, BSL-4 Core D** to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data).** The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.2.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.2.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV (Bangladesh and Malaysia strains) and HeV (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[84-86] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.2.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit NiV and HeV, we will use a high-throughput neutralization assay (conducted in the **Broder lab**). This assay is based on GFP-encoding, recombinant replication-competent, Cedar henipavirus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bengladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,87] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described HeV variant.[88] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[89,90]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.2.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software, which runs 24 hours per day and enables automated targeting and image acquisition, while keeping a relational database of all micrographs to expedite subsequent processing.[91] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[68,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[84,86,92-94] mechanical stage tilting with gold grids[95,96] or detergents to modify surface tension[97]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[95,98-102] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[103-105] The NiV attachment (G) glycoprotein engages host receptors, and is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) (**Figure 7**), which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

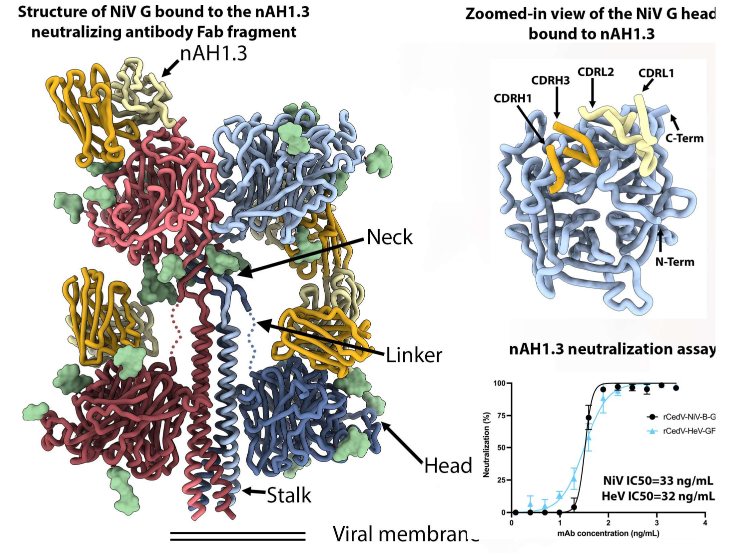

Figure 7. NiV G bound to the nAH1.3 neutralizing antibody Fab fragment. **A**) Ribbon diagram of the NiV G ectodomain bound to the broadly neutralizing nAH1.3 Fab fragment in two orthogonal orientations. Each of the four NiV G protomers is colored distinctly and resolved N-linked glycans are rendered as green surfaces. The nAH1.3 heavy and light chains are colored gold and yellow, respectively, and only the variable domains were modeled in density. The linkers connecting the neck to the two proximal head domains are shown as dashed lines due to weaker density in the cryoEM reconstruction. (**B**) Ribbon diagram of a NiV G head domain (blue) with the interacting nAH1.3 heavy and light chains CDRs rendered in gold and yellow. (**C**) nAH1.3-mediated neutralization of rCedV-NiV-B-GFP (black) and rCedV-HeV-GFP (blue).

D.2.2.1. High-resolution structural studies using X-ray crystallography. Some nanobodies might bind to regions that are intrinsically flexible, thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[106] and BUSTER-TNT.[107]

D.2.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[84-86,93,108,109]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[110-112] and high-resolution noise substitution prior to Fourier shell correlation calculations[113] to avoid overfitting. Atomic models will be assessed using Molprobity,[114] EMringer[115] and Privateer.[116] The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

D.2.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[117-119] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected *in vivo*, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting, which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in **Aim 2A**. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.3. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with the ABSL-3 and ABSL-4 Core (**Core D**) to evaluate lead candidate drugs and nanobodies *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM.[2,120] PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

D.3.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by the **UTMB Core (Core D)**. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of henipavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.3.2. *In vivo* testing of lead compounds NiV/HeV in infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV_B or HeV.[87,121-123] Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.3.4. Define breakthrough conditions for anti-henipavirus antiviral agents in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antiviral agents fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV.[87,121-123] Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.3.5. Combination therapy of anti-henipavirus antiviral agents in hamsters. This subaim will employ the most promising antiviral agents from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV.[87,121-123]Treatment with at least two different antiviral agents will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.3.6. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ $5x10^6$ PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by the ABSL-3 and ABSL-4 Core. Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by the **Aerosol Delivery Core** (see **Core B**) at various times after henipavirus infection.

D.3.7. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD) as previously described[41] or by small particle aerosol as previously described[42,124] with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV_B using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (TW Geisbert, C Broder, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by the **Aerosol Delivery Core** (see **Core B**) up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that **Core B** may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antiviral agents may not improve protective efficacy or extend the therapeutic window of the agents. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues.. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the continued outbreaks of NiV across a large global region requires urgent translational countermeasure research to establish a readiness for the next NiV or related pathogenic henipavirus outbreak. We have discovered antiviral leads that show promise against NiV and HeV, and lay out a detailed plan to optimize, develop, and test these drugs. We also initiate a new plan to develop and test antiviral nanobodies. Together with the expertise, resources and experience within this proposal, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the nonpathogenic Cedar henipavirus (CedV) is a useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline **CBS1435** was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50} values in the low μM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Viral polymerase-targeting lead molecules will be selected using NiV-B and HeV assays and mechanism of action (MOA) studies, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] Twenty-two cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antiviral agents approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus that is nonpathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will yield testable antiviral agents with potential pan-henipavirus effectiveness. Our collaborative team also has extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both viral polymerase-targeting small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays and SPR binding assay for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobody studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

For several decades, the major agents of emerged or newly identified infectious diseases in humans have been viruses of zoonotic origins.[11-13] Among these, two paramyxoviruses of importance are Nipah virus (NiV) and Hendra virus (HeV); the prototype species of the genus *Henipavirus* and are single-stranded, negative sense, enveloped RNA viruses.[14] HeV appeared in 1994, in an outbreak of severe respiratory disease in horses in Australia, with the death of 14 horses and their trainer.[15,16] NiV (Malaysia strain, NiV-M) appeared in an outbreak of encephalitis in pig farmers in Malaysia in 1998.[17,18] NiV outbreaks have since been seen in Bangladesh and India by a related strain NiV-Bangladesh (NiV-B).[19] Pteropid fruit bats are the major reservoir hosts for henipaviruses.[6,20] NiV and HeV have broad host tropism, infecting at least 18 species across 6 orders of mammals. Among these, NiV and HeV will cause a systemic and often fatal respiratory and/or neurological disease in at least 11 species including humans, with human fatality rates ranging from 40-100%.[2,21] A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.[22] However, CedV is not known to be zoonotic and has been shown to be nonpathogenic in HeV and NiV animal models.[22-24] Two additional henipaviruses are also known, Ghana bat virus and Mojiang virus, but only from sequence data.[25-27] Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and 3 outbreaks in India.[28] In 2014, an outbreak of NiV-M occurred in the Philippines with 9 fatalities of 11 human cases, with horse-to-human and human-to-human transmission.[29] The combined NiV case fatality rate is ~60% across a large region of Asia in five countries.[3] The recent 2018 NiV outbreak in Kerala, India was significant, occurring in a new geographic region, with a case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission, underscoring both the transmissibility and the lethal nature of this virus.[4]

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period of 1 to 2 weeks.[4,30] Acute NiV/HeV infection in people is systemic and likely via hematogenous viral spread from the respiratory system.[31] Disease onset is characterized by fever, myalgia, shortness of breath, and cough.[16,32] Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery.[30,33] The predominant clinical feature in the Malaysia outbreak was encephalitis, but respiratory symptoms were also common.[32,34] The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, 83% of cases had acute respiratory distress syndrome (ARDS).[4,35] The key findings of human NiV/HeV infection are wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected.[36,37] Human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset or relapsed encephalitis.[33,38] Relapsed encephalitis caused by NiV appears to be a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later,[39] NiV and HeV are biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents by several US agencies. Also, both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), the African green monkey (AGM), when delivered by small particle aerosol.[40-42] NiV and henipaviral diseases (HeV) are included on the WHO's Blueprint List of Priority Pathogens.[43] NiV is a potential pandemic threat because of its high case-fatality rates, capacity for human-to-human transmission and potential to mutate, and a human-adapted strain in a region of high population density, could lead to rapid spread.[44] *There are presently no approved vaccines or therapeutic modalities for NiV/HeV infections in people.*

The viral RNA-dependent-RNA polymerases of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been hampered by requirements of BSL-4 containment. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications at BSL-2 and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV.[7] Those leads provide the rationale for the current application. Our ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, that also allows for discovery across the whole replication cycle, not restricted to only the viral polymerase. Another well-exploited stage of virus infection is the attachment and entry process.[45] NiV/HeV possess two membrane anchored glycoproteins required for infection; one for attachment, the G glycoprotein, and the other for membrane fusion the F glycoprotein.[46] The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and all vaccine strategies.[28] Although an effective post-exposure human monoclonal antibody (mAb) therapy targeting the NiV and HeV G glycoprotein (m102.4) has been extensively examined,[47-51] its delivery must be within several days following infection in NHPs. An unexplored alternative but related antibody-based strategy are antiviral nanobodies. A nanobody, is an antibody fragment comprised of just a single monomeric variable antibody domain.[52] Nanobodies were first engineered from variable heavy chain domains of camelid heavy chain

antibodies (VHHs), and camelid VHHs retain full antigen specificity and are only a fraction of the size of a human antibody, and they have extended complementarity determining regions (CDRs) which can allow them to bind epitopes not normally accessible to conventional antibodies, such as conserved viral epitopes often masked by glycan shields.[10] Our expertise in henipavirus F and G structural and functional analyses together with anti-F and G mAb development and therapeutic application, will facilitate the development and testing of a new and understudied area of nanobody-based immunotherapeutic against NiV and HeV.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of the investigators in this proposal. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may well have activity across related members of the henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of a high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification. Finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole NiV or HeV immune sera shows cross-reactivity with CedV, however, such sera or even specific high-titer anti-CedV F or G antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins.[22] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and the largest polymerase in the order *Mononegavirale*, yet it shares high aa identity to NiV and HeV L proteins. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; aa identities of L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of identity, shared between CedV and that of NiV and HeV, suggests that antivirals that target the L polymerase, could be identified and also offer the possibility of identifying pan-henipavirus countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Several small molecule inhibitors have been validated *in vitro* using infectious HeV and NiV, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[53-55] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for *in vitro* production of various amounts and their rapid characterization. Nanobody development will be carried out by **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels.[10] Immunized mouse cohorts are in progress using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2.**

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and

characterize batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet, Irina Gaisina, and Terry Moore, UIC and Chicago BioSolutions Inc.** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule inhibitors of henipaviruses.

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2), cell-based HTS platform to identify small molecule antiviral agents targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at the BSL-2 level were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV_B and HeV that can be used as a neutralization or entry inhibitor assay to measure neutralizing antibodies, or as a surrogate for generating virus escape mutants to neutralizing antibodies. Here, the F and G genes of NiV_B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV_B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[56] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 h at 37 °C. Each virus-mAb mixture (90 µL/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci are counted using the CTL Basic Count™ and an IC$_{50}$ value is determined as the antibody concentration

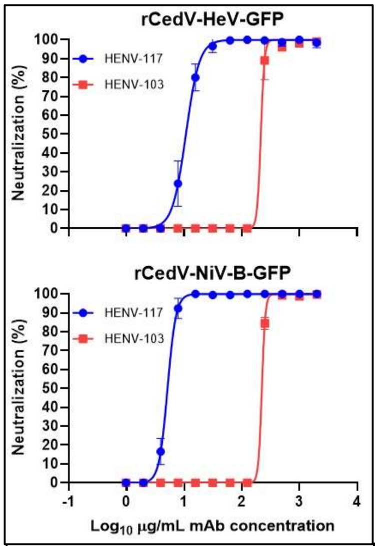

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC$_{50}$ values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

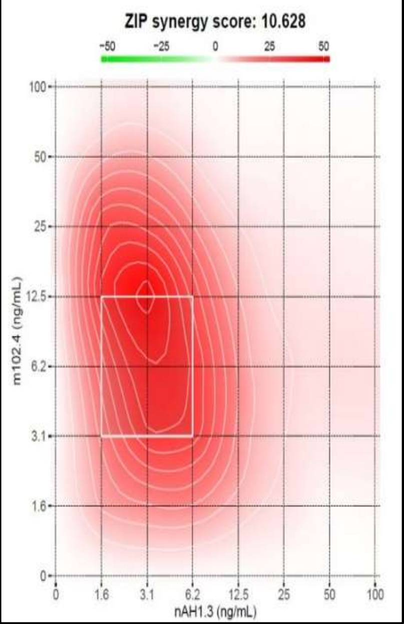

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

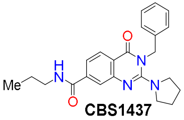
yielding 50% reduction in fluorescent foci versus control wells. **Table 1** shows the calculated IC_{50} values using rCedV chimeras vs. those determined by a conventional PRNT assay with authentic NiV-B and HeV, and they are remarkably within a 2-fold range.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[56] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[57] using a Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here.

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, *in vitro*, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to *in vivo* animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 μM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 μM, and 47 hits showed only minimal cytotoxicity at 33 μM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)
0.70	100	2.1	100	3.3

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

	N	Comp ID	R^1	R^2	% inhib at 10 μM
	1	**G577-0014**	H	3-chloro-4-methoxyphenyl	81
	2	**G577-0016**	H	2,4-difluorophenyl	18
	3	**G577-0021**	H	2-chloro-4-fluorophenyl	58
	4	**G577-0022**	H	3-methoxyphenyl	46
	5	**G577-0028**	Me	cyclohexyl	93
	6	**G577-0084**	H	4-isopropylphenyl	85
	7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
	8	**G577-0112**	Me	2-methylphenyl	94

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 μM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 μM). **Table 3** shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14** (**Figure 4**), bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss* *methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent, **CBS1437**, as well as specific plans for developing the SARs.*

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The **Xu lab** has engineered and established transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies.[10] We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs from each cohort. We expect to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

D. RESEARCH DESIGN AND METHODS

D1. Aim 1: Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays.

D.1.1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 μM) and low cytotoxicity (CC_{50} >100 μM).

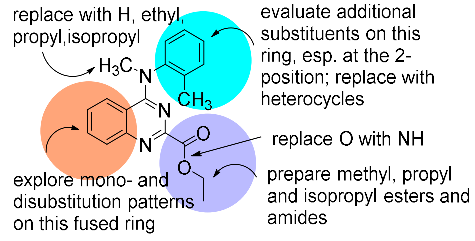


Figure 3. SAR development for 4-aminoquinazolines

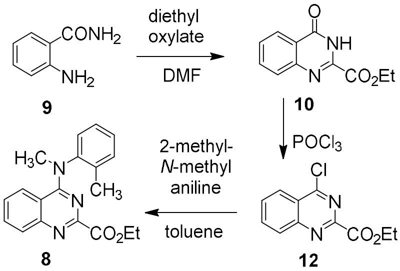

Scheme 1. Synthesis of **G577-0112** (cmpd **8**).

D.1.1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**G577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we will optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. We will also optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) to produce 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely, 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[58-59] as well as other methods.[60,61] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible. In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[62]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112**

	G577-0386	**proposed cpd 13**	**proposed cpd 14**
cLogP	2.87	2.40	4.04
solubility	-4.76	-4.63	-5.25
druglikeness	2.56	3.64	3.62
drug score	0.18	0.35	0.21

	proposed compound 15	**proposed cpd 16**	**proposed cpd 17**
cLogP	3.69	3.69	3.35
solubility	-4.90	-4.98	-4.63
druglikeness	3.75	4.51	4.83
drug score	0.38	0.23	0.41

Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

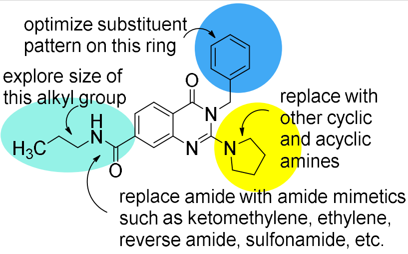

Figure 5. SAR development for **CBS1437**.

(compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester with an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scores have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding. In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. We have also researched and found additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

D.1.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of $2.5x10^4$ cells per well will be treated with growth medium containing either DMSO or selected compound for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. The HTS will be performed in the **Rong Lab**. The libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including an Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used as a specificity control. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (EC_{50} values less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds <80% pure will be purified and retested.

D.1.1.3. Evaluation of antiviral activity of advanced candidates. Inhibitors will be tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2×10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to parallel control cultures of virus and DMSO. This work will be performed in the BSL-4 facility at UTMB (**Geisbert, Core D)**.

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Peet, Gaisina, and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds.

D.1.2. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with medium containing either DMSO or selected inhibitors at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by western blot techniques or viral RNA levels by q-RT-PCR. CedV specific antibodies against G F N and P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and performed using the ABI 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in **Aim 1** will also be used for antiviral target identification. *In vitro* selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[63,64] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a “drug resistant” virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any “drug resistant” virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inhibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.1.2.1. Assess the binding properties by surface plasmon resonance (SPR). The NiV polymerase (L protein and a phosphoprotein P, or RdRp complex) will be prepared using a previously published protocol[65]. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, and kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[66] RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab.**[67]

D.1.2.2. Structure determination of recombinant proteins with bound inhibitors by CryoEM. High-resolution structures of the NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compounds to be defined will be obtained using CryoEM by the **Veesler Lab** at the Arnold and Mabel CryoEM Center at the UW. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[68] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including Warp[69], cryoSparc[70], and RELION[71]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed using Rosetta which is developed at the UW. As cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[72-76], to explore the conformational landscape[77] of ligand binding events, and to capture conformational variability of intermediate states[78,79], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.1.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate* ***advanced lead compounds*** *exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the* ***advanced lead compounds****.*

D.1.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-Tox properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[80] Compounds with IC_{50} values ≥100 μM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds.[81] Compounds with >50% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed as previously described.[82] Compounds that do not prevent [^{3}H]dofetilide binding (IC_{50} >10 μM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method[83] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1 × 10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella*

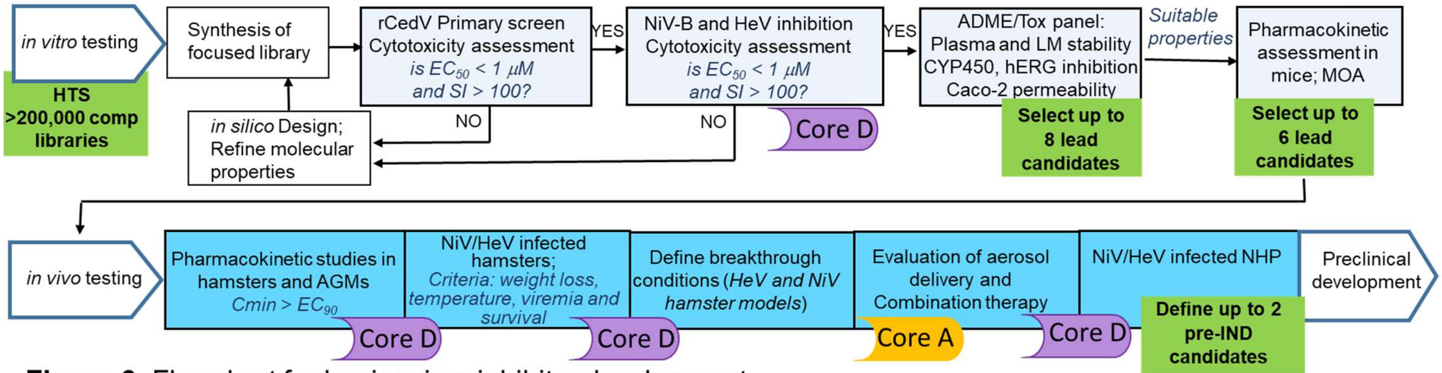

Figure 6. Flowchart for henipavirus inhibitor development.

typhimurium strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes. **D.1.3.2. PK studies:** PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim. We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 6**).

D.2. AIM 2: Characterization of the potency and breadth of selected nanobodies.

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the **UTMB, BSL-4 Core D** to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data).** The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.2.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.2.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV (Bengladesh and Malaysia strains) and HeV (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[84-86] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.2.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit NiV and HeV, we will use a high-throughput neutralization assay (conducted in the **Broder lab**). This assay is based on GFP-encoding, recombinant replication-competent, Cedar henipavirus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bengladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,87] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described HeV variant.[88] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[89,90]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.2.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software, which runs 24 hours per day and enables automated targeting and image acquisition, while keeping a relational database of all micrographs to expedite subsequent processing.[91] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[68,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[84,86,92-94] mechanical stage tilting with gold grids[95,96] or detergents to modify surface tension[97]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[95,98-102] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[103-105] The NiV attachment (G) glycoprotein engages host receptors, and is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) (**Figure 7**), which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

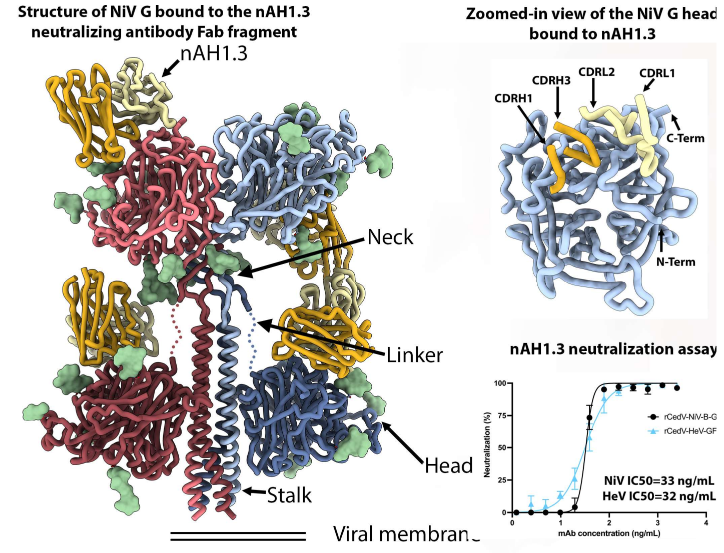

Figure 7. NiV G bound to the nAH1.3 neutralizing antibody Fab fragment. **A**) Ribbon diagram of the NiV G ectodomain bound to the broadly neutralizing nAH1.3 Fab fragment in two orthogonal orientations. Each of the four NiV G protomers is colored distinctly and resolved N-linked glycans are rendered as green surfaces. The nAH1.3 heavy and light chains are colored gold and yellow, respectively, and only the variable domains were modeled in density. The linkers connecting the neck to the two proximal head domains are shown as dashed lines due to weaker density in the cryoEM reconstruction. (**B**) Ribbon diagram of a NiV G head domain (blue) with the interacting nAH1.3 heavy and light chains CDRs rendered in gold and yellow. (**C**) nAH1.3-mediated neutralization of rCedV-NiV-B-GFP (black) and rCedV-HeV-GFP (blue).

D.2.2.1. High-resolution structural studies using X-ray crystallography. Some nanobodies might bind to regions that are intrinsically flexible, thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[106] and BUSTER-TNT.[107]

D.2.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[84-86,93,108,109]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[110-112] and high-resolution noise substitution prior to Fourier shell correlation calculations[113] to avoid overfitting. Atomic models will be assessed using Molprobity,[114] EMringer[115] and Privateer.[116] The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

D.2.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[117-119] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected *in vivo*, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting, which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in **Aim 2A**. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.3. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with the ABSL-3 and ABSL-4 Core (**Core D**) to evaluate lead candidate drugs and nanobodies *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM.[2,120] PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

D.3.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by the **UTMB Core (Core D)**. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of henipavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.3.2. *In vivo* testing of lead compounds NiV/HeV in infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV_B or HeV.[87,121-123] Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.3.4. Define breakthrough conditions for anti-henipavirus antiviral agents in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antiviral agents fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV.[87,121-123] Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.3.5. Combination therapy of anti-henipavirus antiviral agents in hamsters. This subaim will employ the most promising antiviral agents from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV.[87,121-123]Treatment with at least two different antiviral agents will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.3.6. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ $5x10^6$ PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by the ABSL-3 and ABSL-4 Core. Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by the **Aerosol Delivery Core** (see **Core A**) at various times after henipavirus infection.

D.3.7. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD) as previously described[41] or by small particle aerosol as previously described[42,124] with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV_B using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (TW Geisbert, C Broder, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by the **Aerosol Delivery Core** (see **Core A**) up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that **Core A** may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antiviral agents may not improve protective efficacy or extend the therapeutic window of the agents. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues.. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the continued outbreaks of NiV across a large global region requires urgent translational countermeasure research to establish a readiness for the next NiV or related pathogenic henipavirus outbreak. We have discovered antiviral leads that show promise against NiV and HeV, and lay out a detailed plan to optimize, develop, and test these drugs. We also initiate a new plan to develop and test antiviral nanobodies. Together with the expertise, resources and experience within this proposal, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the nonpathogenic Cedar henipavirus (CedV) is a useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline **CBS1435** was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50} values in the low μM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Viral polymerase-targeting l~~L~~ead molecules will be selected using NiV-B and HeV assays and~~,~~ mechanism of action (MOA) studies, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] Twenty-two cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antiviral agents approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus that is nonpathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will ~~potentially~~ yield testable antiviral agents with potential pan-henipavirus effectiveness. Our collaborative team also has extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both viral polymerase-targeting small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays and SPR binding assay for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobody studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

For several decades, the major agents of emerged or newly identified infectious diseases in humans have been viruses of zoonotic origins.[11-13] Among these, two paramyxoviruses of importance are Nipah virus (NiV) and Hendra virus (HeV); the prototype species of the genus *Henipavirus* and are single-stranded, negative sense, enveloped RNA viruses.[14] HeV appeared in 1994, in an outbreak of severe respiratory disease in horses in Australia, with the death of 14 horses and their trainer.[15,16] NiV (Malaysia strain, NiV-M) appeared in an outbreak of encephalitis in pig farmers in Malaysia in 1998.[17,18] NiV outbreaks have since been seen in Bangladesh and India by a related strain NiV-Bangladesh (NiV-B).[19] Pteropid fruit bats are the major reservoir hosts for henipaviruses.[6,20] NiV and HeV have broad host tropism, infecting at least 18 species across 6 orders of mammals. Among these, NiV and HeV will cause a systemic and often fatal respiratory and/or neurological disease in at least 11 species including humans, with human fatality rates ranging from 40-100%.[2,21] A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.[22] However, CedV is not known to be zoonotic and has been shown to be nonpathogenic in HeV and NiV animal models.[22-24] Two additional henipaviruses are also known, Ghana bat virus and Mojiang virus, but only from sequence data.[25-27] Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and 3 outbreaks in India.[28] In 2014, an outbreak of NiV-M occurred in the Philippines with 9 fatalities of 11 human cases, with horse-to-human and human-to-human transmission.[29] The combined NiV case fatality rate is ~60% across a large region of Asia in five countries.[3] The recent 2018 NiV outbreak in Kerala, India was significant, occurring in a new geographic region, with a case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission, underscoring both the transmissibility and the lethal nature of this virus.[4]

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period of 1 to 2 weeks.[4,30] Acute NiV/HeV infection in people is systemic and likely via hematogenous viral spread from the respiratory system.[31] Disease onset is characterized by fever, myalgia, shortness of breath, and cough.[16,32] Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery.[30,33] The predominant clinical feature in the Malaysia outbreak was encephalitis, but respiratory symptoms were also common.[32,34] The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, 83% of cases had acute respiratory distress syndrome (ARDS).[4,35] The key findings of human NiV/HeV infection are wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected.[36,37] Human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset or relapsed encephalitis.[33,38] Relapsed encephalitis caused by NiV appears to be a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later,[39] NiV and HeV are biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents by several US agencies. Also, both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), the African green monkey (AGM), when delivered by small particle aerosol.[40-42] NiV and henipaviral diseases (HeV) are included on the WHO's Blueprint List of Priority Pathogens.[43] NiV is a potential pandemic threat because of its high case-fatality rates, capacity for human-to-human transmission and potential to mutate, and a human-adapted strain in a region of high population density, could lead to rapid spread.[44] ***There are presently no approved vaccines or therapeutic modalities for NiV/HeV infections in people.***

The viral RNA-dependent-RNA polymerases of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been hampered by requirements of BSL-4 containment. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications at BSL-2 and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV.[7] Those leads provide the rationale for the current application. Our ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, that also allows for discovery across the whole replication cycle, not restricted to only the viral polymerase. Another well-exploited stage of virus infection is the attachment and entry process.[45] NiV/HeV possess two membrane anchored glycoproteins required for infection; one for attachment, the G glycoprotein, and the other for membrane fusion the F glycoprotein.[46] The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and all vaccine strategies.[28] Although an effective post-exposure human monoclonal antibody (mAb) therapy targeting the NiV and HeV G glycoprotein (m102.4) has been extensively examined,[47-51] its delivery must be within several days following infection in NHPs. An unexplored alternative but related antibody-based strategy are antiviral nanobodies. A nanobody, is an antibody fragment comprised of just a single monomeric variable antibody domain.[52] Nanobodies were first engineered from variable heavy chain domains of camelid heavy chain

antibodies (VHHs), and camelid VHHs retain full antigen specificity and are only a fraction of the size of a human antibody, and they have extended complementarity determining regions (CDRs) which can allow them to bind epitopes not normally accessible to conventional antibodies, such as conserved viral epitopes often masked by glycan shields.[10] Our expertise in henipavirus F and G structural and functional analyses together with anti-F and G mAb development and therapeutic application, will facilitate the development and testing of a new and understudied area of nanobody-based immunotherapeutic ~~for~~ against NiV and HeV.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of the investigators in this proposal. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may well have activity across related members of the henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of a high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification. Finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole NiV or HeV immune sera shows cross-reactivity with CedV, however, such sera or even specific high-titer anti-CedV F or G antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins.[22] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and the largest polymerase in the order *Mononegavirale*, yet it shares high aa identity to NiV and HeV L proteins. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; aa identities of L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of identity, shared between CedV and that of NiV and HeV, suggests that antivirals that target the L polymerase, could be identified and ~~perhaps~~ also offer the possibility of identifying pan-henipavirus countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Several small molecule inhibitors have been validated *in vitro* using infectious HeV and NiV, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[53-55] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for *in vitro* production of various amounts and their rapid characterization. Nanobody development will be carried out by **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels.[10] Immunized mouse cohorts are in progress using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2.**

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and

characterize batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet, Irina Gaisina, and Terry Moore, UIC and Chicago BioSolutions Inc.** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule inhibitors of henipaviruses.

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2), cell-based HTS platform to identify small molecule antiviral agents targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at the BSL-2 level were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV_B and HeV that can be used as a neutralization or entry inhibitor assay to measure neutralizing antibodies, or as a surrogate for generating virus escape mutants to neutralizing antibodies. Here, the F and G genes of NiV_B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV_B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[56] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 h at 37 °C. Each virus-mAb mixture (90 µL/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci are counted using the CTL Basic Count™ and an IC_{50} value is determined

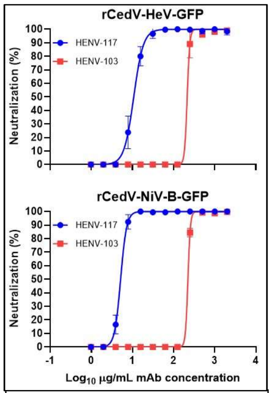

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC_{50} values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

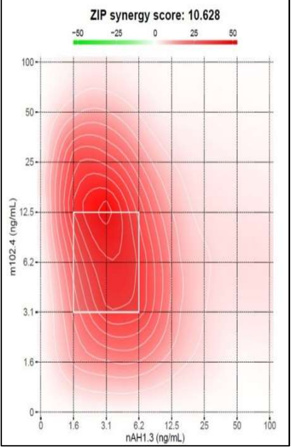

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

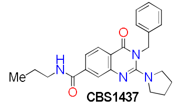
as the antibody concentration yielding 50% reduction in fluorescent foci versus control wells. **Table 1** shows the calculated IC$_{50}$ values using rCedV chimeras vs. those determined by a conventional PRNT assay with authentic NiV-B and HeV, and they are remarkably within a 2-fold range.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[56] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[57] using a Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here.

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, *in vitro*, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to *in vivo* animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC$_{50}$ (µM)	CC$_{50}$ (µM)	EC$_{50}$ (µM)	CC$_{50}$ (µM)	EC$_{50}$ (µM)
0.70	100	2.1	100	3.3

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

	N	Compound ID	R^1	R^2	% inhib at 10 µM
	**1**	**G577-0014**	H	3-chloro-4-methoxyphenyl	81
	2	**G577-0016**	H	2,4-difluorophenyl	18
	3	**G577-0021**	H	2-chloro-4-fluorophenyl	58
	4	**G577-0022**	H	3-methoxyphenyl	46
	5	**G577-0028**	Me	cyclohexyl	93
	6	**G577-0084**	H	4-isopropylphenyl	85
	7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
	8	**G577-0112**	Me	2-methylphenyl	94

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC$_{50}$ values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC$_{50}$ value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM). **Table 3** shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14** (**Figure 4**), bearing an unsubstituted cyclohexyl

Commented [CB1]:
Make texts in all the tables SMALLER

Commented [CB2]:
Make texts in all the tables SMALLER

group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent,* ***CBS1437****, as well as specific plans for developing the SARs.*

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The Xu lab has engineered and established transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies.[10] We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs from each cohort. We expec~~cep~~t to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC$_{50}$ <1 μM) and low cytotoxicity (CC$_{50}$ >100 μM).

D1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**G577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as “ADME handles” to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we will optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. We will also optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc.

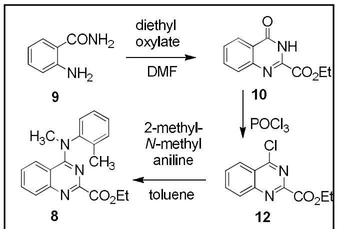
Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.



Scheme 1. Synthesis of **G577-0112** (cmpd **8**).

In **Scheme 1** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) to produce 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely, 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[58-59] as well as other methods.[60,61] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.

In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[62]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester with an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scores have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding. In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. We have also researched and found additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

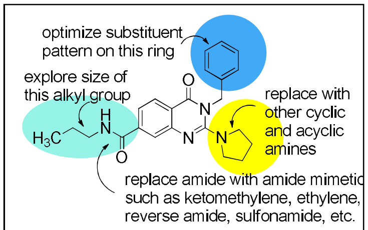


Figure 5. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5×10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. The HTS will be performed in the **Rong Lab**.These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including an Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used ~~again a~~as a specificity control. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (EC_{50} values less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation.*

Formatted: Font: Bold

Cytotoxicity Assessment and Ranking. We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" as described previously[97] in a 96-well format. The ratio of CC$_{50}$/EC$_{50}$ is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds <80% pure will be purified and retested.

D.1.3. Evaluation of antiviral activity of advanced candidates. Inhibitors will be tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2×10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to parallel control cultures of virus and DMSO. This work will be performed in the BSL-4 facility at UTMB (**Geisbert, Core D**).

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Peet, Gaisina, and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds.

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with medium containing either DMSO or selected inhibitors at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by western blot techniques or viral RNA levels by q-RT-PCR. CedV specific antibodies against G F N and P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and performed using the ABI 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in **Aim 1** will~~can~~ also be used~~exploited~~ for antiviral target identification. *In vitro* selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[63,64] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a "drug resistant" virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any "drug resistant" virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inhibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The NiV polymerase (L protein and a phosphoprotein P, or RdRp complex) will be prepared using a previously published protocol(**ref**). Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_{D}) to the RdRp protein, and kinetics [association rate constants (k_{a}), and dissociation rate constants (k_{d})] as previously described.[65] ~~Prefusion-stabilized~~ RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 µM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_{D}) will be calculated as $K_{\mathrm{D}} = k_{\mathrm{d}}/k_{\mathrm{a}}$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab (ref)**.

Formatted: Font: Bold

D.2.3. Structure~~tructure~~ determination of recombinant proteins with bound inhibitors by ~~by X-Ray crystallography and~~ CryoEM. High-resolution structures of the NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compounds to be defined will be obtained using ~~both x-ray crystallography and~~ CryoEM by ~~Dr.~~the **Veesler Lab** at the Arnold and Mabel CryoEM Center at the UW. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands~~.~~ ~~Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization~~. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[66] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including Warp[67], cryoSparc[68], and RELION[69]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed using Rosetta which is developed at the UW. As cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[70-74], to explore the conformational landscape[75] of ligand binding events, and to capture conformational variability of intermediate states[76,77], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches.

Formatted: Font: Bold

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp.) to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[78] Compounds with IC_{50} values ≥100 µM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[79] Compounds with >30% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed

in a [^{3}H] dofetilide-binding assay as previously described.[80] using SHSY5Y cells. Compounds that do not prevent [^{3}H]dofetilide binding (IC_{50} >10 μM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method[81] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1×10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

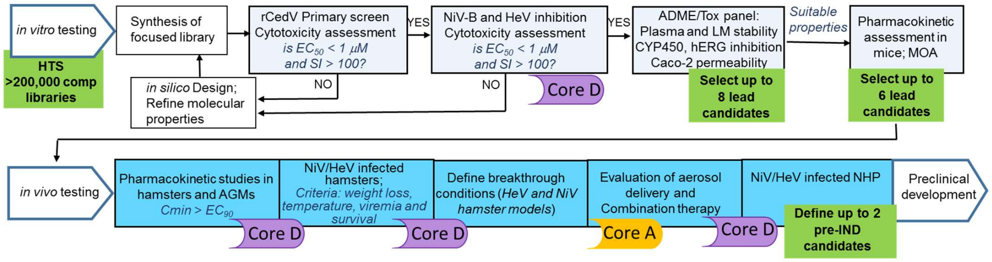

Figure 6. Flowchart for henipavirus inhibitor development. NOT FINAL

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 6**).

Formatted: Space After: 3 pt

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies.

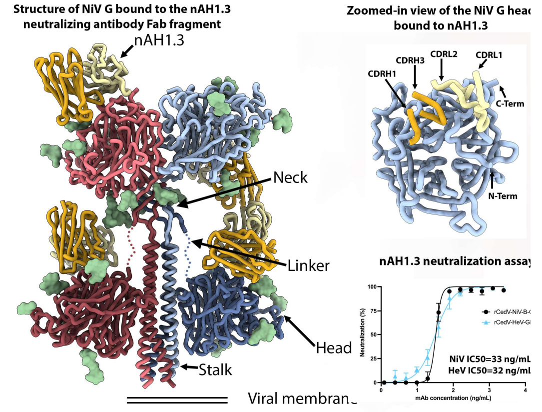
Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the **UTMB, BSL-4 Core D** to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data).** The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV (Bengladesh and Malaysia strains) and HeV (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[82-84] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit NiV and HeV, we will use a high-throughput neutralization assay (conducted in the **Broder lab**). This assay is based on GFP-encoding, recombinant replication-competent, Cedar henipavirus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bangladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,85] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described HeV variant.[86] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[87,88]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.



A) Ribbon diagram of the NiV G ectodomain bound to the broadly neutralizing nAH1.3 Fab fragment in two orthogonal orientations. Each of the four NiV G protomers is colored distinctly and resolved N-linked glycans are rendered as green surfaces. The nAH1.3 heavy and light chains are colored gold and yellow, respectively, and only the variable domains were modeled in density. The linkers connecting the neck to the two proximal head domains are shown as dashed lines due to weaker density in the cryoEM reconstruction. (**B**) Ribbon diagram of a NiV G head domain (blue) with the interacting nAH1.3 heavy and light chains CDRs rendered in gold and yellow. (**C**) nAH1.3-mediated neutralization of rCedV-NiV-B-GFP (black) and rCedV-HeV-GFP (blue).

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software, which runs 24 hours per day and enables automated targeting and image acquisition, while keeping a relational database of all micrographs to expedite subsequent processing.[89] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[66,67] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the

epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[82,84,90-92] mechanical stage tilting with gold grids[93,94] or detergents to modify surface tension[95]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[93,96-100] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[101-103]
The NiV attachment (G) glycoprotein engages host receptors, and is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3), which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some nanobodies might bind to regions that are intrinsically flexible, thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[104] and BUSTER-TNT.[105]

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[82-84,91,106,107]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[108-110] and high-resolution noise substitution prior to Fourier shell correlation calculations[111] to avoid overfitting. Atomic models will be assessed using Molprobity,[112] EMringer[113] and Privateer.[114] The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[115-117] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected *in vivo*, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting, which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in **Aim 2A**. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with the ABSL-3 and ABSL-4 Core (**Core D**) to evaluate lead candidate drugs and nanobodies *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM.[2,118] PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV$_B$ and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV$_B$ and HeV infected AGM models.

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by the **UTMB Core (Core D)**. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC$_{90}$ in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of henipavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV in infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV$_B$ or HeV.[85,119-121] Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antiviral agents in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antiviral agents fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV.[85,119-121] Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.5.4. Combination therapy of anti-henipavirus antiviral agents in hamsters. This subaim will employ the most promising antiviral agents from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV.[85,119-121]Treatment with at least two different antiviral agents will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ 5×10^6 PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by the ABSL-3 and ABSL-4 Core. Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by the **Aerosol Delivery Core** (see **Core A**) at various times after henipavirus infection.

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD) as previously described[41] or by small particle aerosol as previously described[42,122] with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV_B using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (TW Geisbert, C Broder, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by the **Aerosol Delivery Core** (see **Core A**) up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that **Aerosol Delivery Core (Core A)** may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antiviral agents may not improve protective efficacy or extend the therapeutic window of the agents. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of NiV infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next NiV or other related pathogenic henipavirus outbreaks. We have discovered two differentiated series of compounds that show early promise as agents that have potential for treating NiV infections, and we have designed a series of optimized druglike candidates for future preparation and development.

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the nonpathogenic Cedar henipavirus (CedV) is a useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline **CBS1435** was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50} values in the low µM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] Twenty-two cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antiviral agents approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus that is nonpathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antiviral agents with potential pan-henipavirus effectiveness. Our collaborative team also has extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobody studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

Over the past 40 years the major etiological agents of emerged or identified infectious diseases in humans have been viruses.[11] Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV).[12,13] In 1994, HeV caused an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer.[14,15] NiV was the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998. Spread of NiV infections typically requires direct contact with an infected source, and transmission can occur between people and from animals to people. Symptoms may culminate in a severe respiratory and/or neurological disease that is often fatal. Complications of the infection can result in relapsed encephalitis following recovery. On September 5, 2021, a twelve-year-old boy in the Indian state of Kerala died after contracting NiV infection. During the process of transporting him to medical centers for a diagnosis, twenty-three health care workers exposed to this boy also died, which underscores both the transmissability and the lethal nature of this virus. *There is presently no vaccine or small molecule therapeutics that have been developed for NiV infections.* Pteropid bats appear to be the major reservoir hosts for henipaviruses.[6,16] HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%.[2,17]

NiV and HeV are classified as biosafety level-4 (BSL-4) restricted pathogens and both remain transboundary threats to livestock and people throughout South Asia and Australia. NiV and henipaviral diseases have been categorized by the World Health Organization (WHO) as an epidemic threat needing urgent research and countermeasure development and are included in the WHO R&D Blueprint list of priority pathogens with epidemic potential.[18] Presently, there are no prophylactic or therapeutic treatment options for henipavirus infections approved for use in humans. A subunit vaccine, Equivac® HeV, has been available for use in horses in Australia since 2012[19] for the prevention of HeV infection. This equine vaccine received full registration by the Australian Pesticides and Veterinary Medicines Authority in 2015, with all vaccinated horses receiving a microchip with a database being maintained and is the first commercially deployed vaccine against a BSL-4 agent.[20] Although a human monoclonal antibody (mAb) m102.4 has successfully completed a phase I safety trial in Australia,[21] developing vaccines or therapeutics against henipaviruses for use in people remains a high priority. Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of several vaccine strategies.[2] Although an effective post-exposure human monoclonal antibody (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been extensively examined,[22-26] it must be administered within several days following lethal infection in animal challenge models. In contrast, however, antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of biosafety level-4 (BSL-4) containment. Recently, a third isolate, namely, Cedar virus (CedV) has been added to the *Henipavirus* genus.[27] However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease and resides in nature in the same bat host species as HeV.[27,28] Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences,[29,30] but HeV, NiV, and CedV are the only virus isolates reported.

We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and have identified several inhibitory compounds that were further validated with the infectious NiV-Bangladesh (NiV-B) strain. The validated compounds provide the foundation for the current application.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of the investigators in this proposal. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may well have activity across related members of the henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice

Commented [CB1]: This section needs fixing.

I am sending separate section. AFTER i cut it down more as you suggest./

that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of a high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification. Finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole NiV or HeV immune sera shows cross-reactivity with CedV, however, such sera or even specific high-titer anti-CedV F or G antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins. [27] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and the largest polymerase in the order *Mononegavirale*, yet it shares high aa identity to NiV and HeV L proteins. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; aa identities of L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of identity, shared between CedV and that of NiV and HeV, suggests that antivirals that target the L polymerase, could be identified and perhaps also offer the possibility of identifying pan-henipavirus countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Several small molecule inhibitors have been validated *in vitro* using infectious HeV and NiV, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[31-33] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for *in vitro* production of various amounts and their rapid characterization. Nanobody development will be carried out by **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels.[10] Immunized mouse cohorts are in progress using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2.**

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and characterize batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet, Irina Gaisina, and Terry Moore, UIC and Chicago BioSolutions Inc.** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule inhibitors of henipaviruses.

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2), cell-based HTS platform to identify small molecule antiviral agents targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at the BSL-2 level were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV$_B$ and HeV that can be used as a neutralization or entry inhibitor assay to measure neutralizing antibodies, or as a surrogate for generating virus escape mutants to neutralizing antibodies. Here, the F and G genes of NiV$_B$ (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV$_B$-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[34] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 h at 37 °C. Each virus-mAb mixture (90 µL/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci are counted using the CTL Basic Count™ and an IC$_{50}$ value is determined as the antibody concentration yielding 50% reduction in fluorescent foci versus control wells. **Table 1** shows the calculated IC$_{50}$ values using rCedV chimeras vs. those determined by a conventional PRNT assay with authentic NiV-B and HeV, and they are remarkably within a 2-fold range.

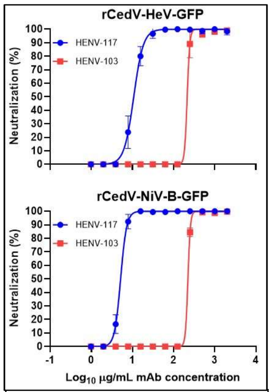

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC$_{50}$ values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[34] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[35] using a Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here.

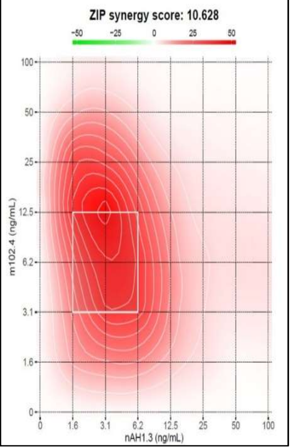

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

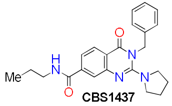
Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from

Aim 2; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, *in vitro*, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to *in vivo* animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (µM)	CC_{50} (µM)	EC_{50} (µM)	CC_{50} (µM)	EC_{50} (µM)
0.70	100	2.1	100	3.3

In Table 2 is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM).

Table 3 shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14,** bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent, **CBS1437**, as well as specific plans for developing the SARs.*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

	N	Compound ID	R^1	R^2	% inhib at 10 µM
	**1**	**G577-0014**	H	3-chloro-4-methoxyphenyl	81
	2	**G577-0016**	H	2,4-difluorophenyl	18
	3	**G577-0021**	H	2-chloro-4-fluorophenyl	58
	4	**G577-0022**	H	3-methoxyphenyl	46
	5	**G577-0028**	Me	cyclohexyl	93
	6	**G577-0084**	H	4-isopropylphenyl	85
	7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
	8	**G577-0112**	Me	2-methylphenyl	94

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The Xu lab has engineered and established transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies.[10] We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs

Commented [CB2]: Make texts in all the tables SMALLER

Commented [CB3]: Make texts in all the tables SMALLER

Commented [CB4]: I do not see where these numbered compounds (14, 16, 18) are in the table?

from each cohort. We except to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 µM) and low cytotoxicity (CC_{50} >100 µM).

D1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**G577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we will optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. We will also optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a brief synopsis of the general method used for the synthesis of 4-aminoquinazolines. The specific procedures for the three steps vary, but all initiate with anthranilamides. This general route will allow us to prepare compounds with varied R_1, R_2 and R_3 groups as well as compounds with substituents that replace the carboethoxy functionality at the 2-position. Several anthranilamides are commercially available, which will allow us to initially access starting materials with a variety of R_3 groups. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[36-37] as well as other methods.[38,39] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.

Commented [CB5]: Compound 8 in Table 3 is G577-0112 not "F"

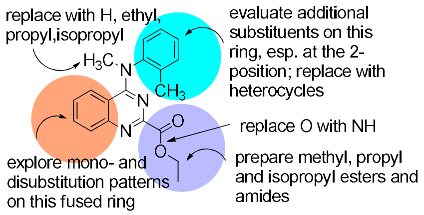


Figure 3. SAR development for 4-aminoquinazolines

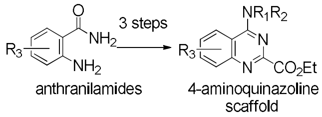
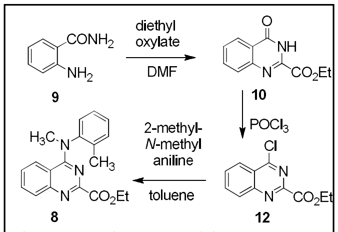


Scheme 1. General synthesis for 4-aminoquinazolines.



Scheme 2. Synthesis of **G577-0112** (cmpd **8**).

In **Scheme 2** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) to produce 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely, 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline.

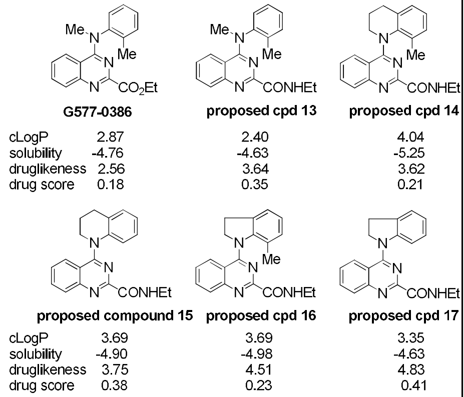


Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[40]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester with an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scores have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding. In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. We have also researched and found additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

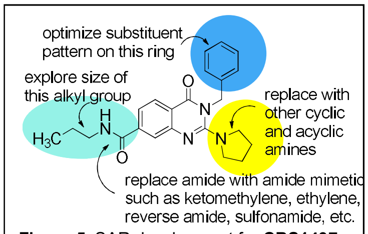

Figure 5. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5×10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 µM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including an Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 µM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSV-G-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (EC_{50} values less than 10 µM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds <80% pure will be purified and retested.

D.1.3. Evaluation of antiviral activity of advanced candidates. Inhibitors will be tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2×10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to parallel control cultures of virus and DMSO. This work will be performed in the BSL-4 facility at UTMB (**Geisbert, Core D)**.

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Peet, Gaisina, and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds.

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with medium containing either DMSO or selected inhibitors at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by western blot techniques or viral RNA levels by q-RT-PCR. CedV specific antibodies against G F N and P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and performed using the ABI 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in **Aim 1** can also be exploited for antiviral target identification. *In vitro* selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[41,42] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a “drug resistant” virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any “drug resistant” virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inhibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The NiV polymerase (L protein and a phosphoprotein P) will be prepared using a previously published protocol. Biacore T200 and Biacore

8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, and kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[43] Prefusion-stabilized RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 µM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab**.

D.2.3. Structure determination of recombinant proteins with bound inhibitors by X-Ray crystallography and CryoEM. High-resolution structures of the NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compounds to be defined will be obtained using both x-ray crystallography and CryoEM by the **Dr. Vessler Lab**. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. Initial crystallization screens will be set up robotically using in-house Gryphon crystallization robotics. Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization. X-ray data collection will be done where? Crystal structures will be determined by molecular replacement using existing structures as search models. For inhibitors binding to regions other than above or if co-crystals cannot be obtained, cryo-EM will be used to determine the complex structure. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[44] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including cryoSparc[45], EMAN[46], and RELION[47]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed by molecular dynamics (MD) studies. While cryo-EM can provide access to the near-atomic resolution structures of large biomolecular systems, in their near native environment, MD can be used to reveal its dynamic behavior and refine low-resolution regions of cryo-EM reconstructions[48,49]. Furthermore, as X-ray/cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional inhibitors as they become available), MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[50-54], to explore the conformational landscape[55] of ligand binding events, and to capture conformational variability of intermediate states[48,56], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches. David, please look at this section. Make necessary corrections.

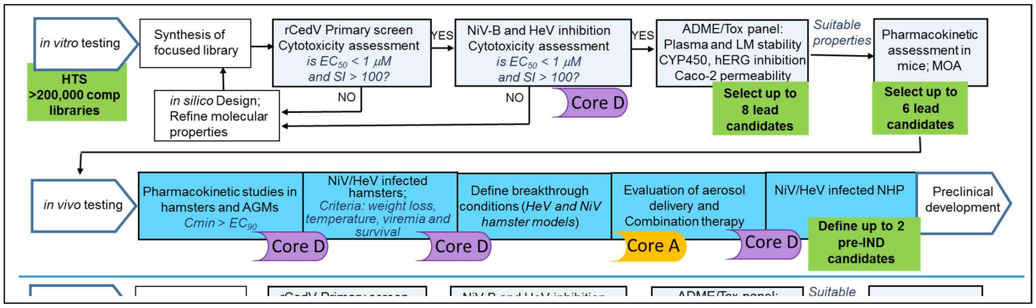
Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate* ***advanced lead compounds*** *exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the* ***advanced lead compounds****.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp.) to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[57] Compounds with IC_{50} values ≥100 µM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[58] Compounds with >30% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed in a [^{3}H] dofetilide-binding assay as previously described.[59] using SHSY5Y cells. Compounds that do not prevent

[^{3}H]dofetilide binding (IC_{50} >10 µM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method[60] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1×10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.



Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 6**).

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies.

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the **UTMB, BSL-4 Core D** to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data).** The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV (Bengladesh and Malaysia strains) and HeV (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[61-63] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

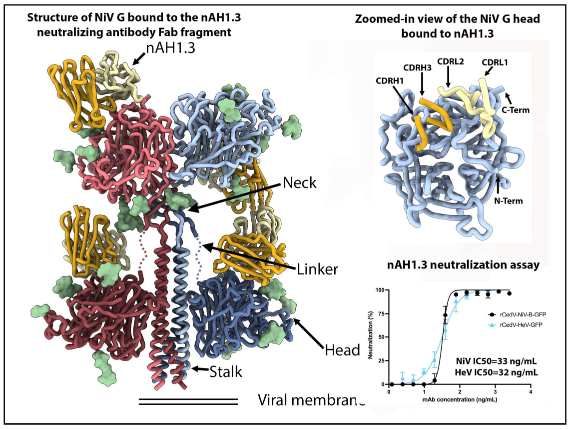
D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit NiV and HeV, we will use a high-throughput neutralization assay (conducted in the **Broder lab**). This assay is based on GFP-encoding, recombinant replication-competent, Cedar henipavirus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bangladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,64] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described HeV variant.[65] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[66,67]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software, which runs 24 hours per day and enables automated targeting and image acquisition, while keeping a relational database of all micrographs to expedite subsequent processing.[68] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[44,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[61,63,70-72] mechanical stage tilting with gold grids[73,74] or detergents to modify surface tension[75]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened



resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[73,76-80] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[81-83]

The NiV attachment (G) glycoprotein engages host receptors, and is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3), which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some nanobodies might bind to regions that are intrinsically flexible, thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[84] and BUSTER-TNT.[85]

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[61-63,71,86,87]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[88-90] and high-resolution noise substitution prior to Fourier shell correlation calculations[91] to avoid overfitting. Atomic models will be assessed using Molprobity,[92] EMringer[93] and Privateer.[94] The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[95-97] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected *in vivo*, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting, which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in **Aim 2A**. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with the ABSL-3 and ABSL-4 Core (**Core D**) to evaluate lead candidate drugs and nanobodies *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM.[2,98] PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV$_B$ and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV$_B$ and HeV infected AGM models.

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by the **UTMB Core (Core D)**. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC$_{90}$ in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of henipavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV in infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV$_B$ or HeV.[64,99-101] Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antiviral agents in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antiviral agents fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV.[64,99-101] Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.5.4. Combination therapy of anti-henipavirus antiviral agents in hamsters. This subaim will employ the most promising antiviral agents from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV.[64,99-101]Treatment with at least two different antiviral agents will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ 5x10^6 PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by the ABSL-3 and ABSL-4 Core. Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by the **Aerosol Delivery Core** (see **Core A**) at various times after henipavirus infection.

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD) as previously described[102] or by small particle aerosol as previously described[103,104] with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV_B using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (TW Geisbert, C Broder, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by the **Aerosol Delivery Core** (see **Core A**) up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that **Aerosol Delivery Core (Core A)** may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antiviral agents may not improve protective efficacy or extend the therapeutic window of the agents. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of NiV infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next NiV or other related pathogenic henipavirus outbreaks. We have discovered two differentiated series of compounds that show early promise as agents that have potential for treating NiV infections, and we have designed a series of optimized druglike candidates for future preparation and development.

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the non-pathogenic Cedar henipavirus (CedV) is useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline CBS1435 was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50}s in the low µM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class ~~also aerosol delivery of~~ nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

Over the past 40 years the major etiological agents of emerged or identified infectious diseases in humans have been viruses.[11] Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV).[12,13]~~.~~ In 1994, HeV caused an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer.[14,15] NiV was the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998. Spread of NiV infections typically requires direct contact with an infected source, and transmission can occur between people and from animals to people. Symptoms may culminate in a severe respiratory and/or neurological disease that is often fatal. Complications of the infection can result in relapsed encephalitis following recovery. On September 5, 2021, a twelve-year-old boy in the Indian state of Kerala died after contracting ~~the Nipah virus~~NiV infection. During the process of transporting him to medical centers for a diagnosis, twenty-three health care workers exposed to this boy also died, which underscores both the transmissibility and the lethal nature of this virus. *There is presently no vaccine or small molecule therapeutics that have been developed for NiV infections.* Pteropid bats appear to be the major reservoir hosts for henipaviruses.[6,16]~~.~~ HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%.[2,17]~~.~~

NiV and HeV are classified as biosafety level-4 (BSL-4) restricted pathogens and both remain transboundary threats to livestock and people throughout South Asia and Australia. NiV and henipaviral diseases have been categorized by the World Health Organization (WHO) as an epidemic threat needing urgent research and countermeasure development and are included in the WHO R&D Blueprint list of priority pathogens with epidemic potential.[18]~~.~~ Presently, there are no prophylactic or therapeutic treatment options for henipavirus infections approved for use in humans. A subunit vaccine, Equivac® HeV, has been available for use in horses in Australia since 2012[19] for the prevention of HeV infection. This equine vaccine received full registration by the Australian Pesticides and Veterinary Medicines Authority in 2015, with all vaccinated horses receiving a microchip with a database being maintained and is the first commercially deployed vaccine against a BSL-4 agent.[20]~~.~~ Although a human monoclonal antibody (mAb) m102.4 has successfully completed a phase I safety trial in Australia,[21]~~,~~ developing vaccines or therapeutics against henipaviruses for use in people remains a high priority. Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of several vaccine strategies.[2]~~.~~ Although an effective post-exposure human monoclonal antibody (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been extensively examined,[22-26]~~,~~ it must be administered within several days following lethal infection in animal challenge models. In contrast, however, antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of biosafety level-4 (BSL-4) containment. Recently, a third isolate, namely, Cedar virus (CedV) has been added to the *Henipavirus* genus.[27]~~.~~ However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease and resides in nature in the same bat host species as HeV.[27,28]~~.~~ Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences,[29,30]~~,~~ but HeV, NiV, and CedV are the only virus isolates reported.

We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and have identified several inhibitory compounds that were further validated with the infectious NiV-Bangladesh (NiV-B) strain. The validated compounds provide the foundation for the current application.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice

Commented [CB1]: This section needs fixing.

I am sending separate section. AFTER i cut it down more as you suggest./

that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole ~~inactivated~~ NiV or HeV immune sera ~~will~~ shows cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G ~~glycoprotein~~ antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins. [27] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and ~~it is also~~ the largest polymerase in the order *Mononegavirale*, yet it ~~still~~ shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; ~~the~~ aa identities of ~~the important~~ L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of ~~protein~~ identity, ~~overall,~~ shared between CedV~~,~~ and that of NiV and HeV, suggests that antiviral~~ agent~~s that target ~~for example,~~ the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus ~~antiviral~~ countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] ~~Indeed, s~~Several small molecule inhibitors have been validated in vitro using infectious HeV and NiV~~ in BSL-4~~, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[31-33] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. ~~In collaboration~~Nanobody development will be carried out by~~ with~~ **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels~~,~~.[10] ~~we have several I~~Iimmunized mouse cohorts are in progress ~~now underway using native-like oligomeric recombinant~~using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2**. ~~in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.~~

Formatted: Font: Bold

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company

engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule ~~entry~~ inhibitors of henipaviruses~~Nipah~~.

Formatted: Space After: 3 pt

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2 ~~containment~~), cell-based HTS platform to identify small molecule antivirals targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at BSL-2 were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV-B and HeV that can be used as a neutralization ~~tool~~ or entry inhibitor assay to measure neutralizing antibodies ~~or sera~~, or as a surrogate for generating virus escape mutants to ~~F or G~~ neutralizing antibodies. Here, the F and G genes of NiV-B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV-B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared ~~(rCedV-NiV-B and rCedV-HeV)~~. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[34] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 hrs at 37~~-~~°C. Each virus-mAb mixture (90 µl/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci ~~were~~ are counted using the CTL Basic Count™ and an IC$_{50}$ is determined as the antibody concentration ~~at which there was a~~yielding 50% reduction in fluorescent foci versus ~~untreated~~ control wells. **Table 1** shows the calculated ~~EC$_{50}$~~ IC$_{50}$ values using rCedV chimeras vs. those determined by conventional PRNT assay with authentic NiV-B and HeV ~~in BSL-4~~, and they are remarkably within a 2-fold range.

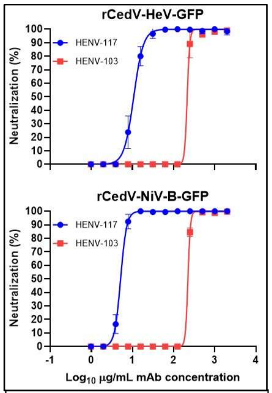

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC$_{50}$ values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS ~~neutralization~~ assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[34] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[35] using a

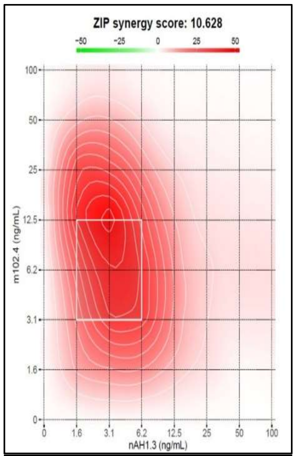

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

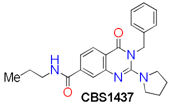
Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here. ~~m102.4 and nAH1.3 indicate here.~~

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, in vitro, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to in vivo animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (µM)	**CC_{50} (µM)**	**EC_{50} (µM)**	**CC_{50} (µM)**	**EC_{50} (µM)**
0.70	100	2.1	100	3.3

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM).

Table 3 shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14,** bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent, **CBS1437**, as well as specific plans for developing the SARs.*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

	N	Compound ID	R^1	R^2	% inhib at 10 µM

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The Xu lab has engineered and established transgenic mice that produce

VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies(REF). We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs from each cohort. We except to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

Commented [CB5]: Xu, J. et al. Nanobodies from camelid mice and llamas neutralize SARS-CoV-2 variants. Nature 595, 278-282, doi:10.1038/s41586-021-03676-z (2021).

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 µM) and low cytotoxicity (CC_{50} >100 µM).

D1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**F577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as “ADME handles” to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. In addition, we will optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be more chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a brief synopsis of the general method used for the synthesis of 4-aminoquinazolines. The specific procedures for the three steps vary, but all initiate with anthranilamides. This general route will allow us to prepare compounds with varied R_1, R_2 and R_3 groups as well as compounds with substituents that replace the carboethoxy functionality at the 2-position. Several anthranilamides are commercially available, which will allow us to initially access starting materials with a variety of R_3 groups. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[36-37] as well as other methods.[38,39] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.

Commented [CB6]: Compound 8 in Table 3 is G577-0112 not “F”

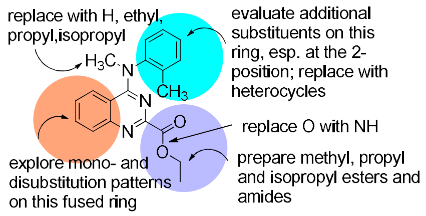

Figure 3. SAR development for 4-aminoquinazolines

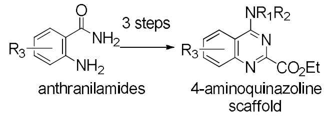
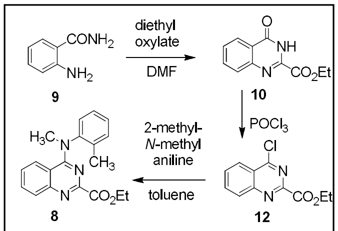


Scheme 1. General synthesis for 4-aminoquinazolines.



Scheme 2. Synthesis of **G577-0112** (cmpd **8**).

In **Scheme 2** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) produces 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline.

Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[40]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester to an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scres have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding.

In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. Additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

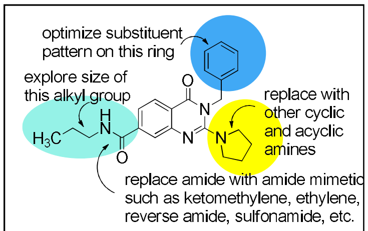

Figure 5. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5 x 10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation ~~(PerkinElmer, Waltham, MA) as per the manufacturer's instructions~~. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T ~~cells~~ and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

<u>*Screening Libraries.*</u> These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions,**

Inc. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSV-G-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (potent inhibitor, EC_{50} less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" ~~(Promega, Madison, WI)~~ as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds ~~found to be~~ <80% pure will be purified and retested.

D.1.3. Evaluation of ~~protective properties~~antiviral activity of ~~the~~ advanced candidates. ~~in the henipavirus infectious assays~~ Inhibitors will be ~~done~~ tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2 × 10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to ~~that from~~ parallel control cultures ~~with~~ of virus and DMSO ~~vehicle only~~. This work will be performed in the BSL-4 facility at UTMB ~~(by the~~ **Geisbert ~~Lab (Core ?~~BSL-4 Core lead)** .

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Gaisina and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy ~~based on a~~using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or ~~the additional~~other HTS hits identified ~~with the HTS of the~~using the expanded libraries of compounds ~~for defining lead compounds for advancement~~.

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with ~~cell growth~~ medium containing either DMSO or selected furopyrimidines at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by ~~standard~~ western blot techniques or viral RNA levels by ~~quantitative real time polymerase chain reaction assays (~~q-RT-PCR~~)~~. CedV specific antibodies against ~~the attachment (~~G~~) and fusion (~~F~~) that were generated in the~~ ~~**Broder Lab**~~ ~~and antibodies to CedV~~ N and ~~CedV~~ P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and ~~. The one-step reaction will be~~ performed using the ~~Applied Biosystems (~~ABI~~)~~ 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies,

Formatted: Space After: 3 pt

Formatted: Font: Bold

HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in ~~the small molecule inhibitor identification assays (~~**Aim 1**~~)~~ can also be exploited for antiviral target identification. In vitro selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants~~ viruses~~. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[41,42] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a "drug resistant" virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any "drug resistant" virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L ~~polymerase~~ gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The ~~Nipah~~ NiV polymerase (L protein and a phosphoprotein P) will be prepared using a previously published protocol. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[43] Prefusion-stabilized RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab**.

Formatted: Space After: 3 pt

D.2.3. Structure determination of recombinant proteins with bound inhibitors by X-Ray crystallography and CryoEM. High-resolution structures of the ~~Nipah~~ NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compound to be developed will be obtained using both x-ray crystallography and CryoEM by Dr. Vessler Lab. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. Initial crystallization screens will be set up robotically using in-house Gryphon crystallization robotics. Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization. X-ray data collection will be done where? Crystal structures will be determined by molecular replacement using existing structures as search models. For inhibitors binding to regions other than above or if co-crystals cannot be obtained, cryo-EM will be used to determine the complex structure. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[44] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including cryoSparc[45], EMAN[46], and RELION[47]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed by molecular dynamics (MD) studies. While cryo-EM can provide access to the near-atomic resolution structures of large biomolecular systems--in their near native environment, MD can be used to reveal its dynamic behavior and refine low-resolution regions of cryo-EM reconstructions[48,49]. Furthermore, as X-ray/cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[50-54], to explore the conformational landscape[55] of ligand binding events, and to capture conformational variability of intermediate states[48,56], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches. David, please look at this section. Make necessary corrections.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp.)~~, Woburn, MA)~~ to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[57] Compounds with IC$_{50}$ values ≥100 µM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[58] Compounds with >30% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed in a $[^3H]$ dofetilide-binding assay as previously described~~ by Finlayson *et al*~~.[59] using SHSY5Y cells. Compounds that do not prevent $[^3H]$dofetilide binding (IC$_{50}$ >10 µM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method ~~as described by Gres *et al*.~~[60] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1 × 10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will

Formatted: Space After: 3 pt

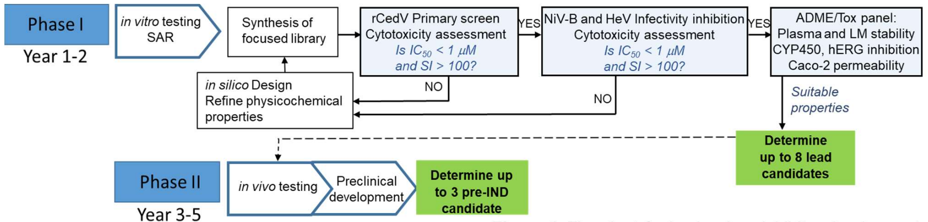

Figure 4. Flowchart for henipavirus inhibitor development

Will be MODIFIED **Figure 5**

be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 5**).

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies.

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the ~~core???~~ UTMB, BSL-4 Core to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data**). The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV ~~pah virus~~ (Bangladesh and Malaysia strains) and ~~Hendra~~ HeV ~~virus~~ (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[61-63] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with ~~Nipah and Hendra virus~~NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit ~~Nipah virus and Hendra virus~~NiV and HeV, we will use a high-throughput neutralization assay ~~developed in the~~ (conducted in the **Broder lab**). This assay is based on ~~green fluorescent protein (~~GFP~~)~~-encoding, recombinant replication-competent, Cedar ~~(~~henipa~~)~~virus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bangladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,64] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described ~~Hendra virus~~HeV variant.[65] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond ~~Nipah and Hendra viruses~~NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[66,67]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against ~~Nipah virus and Hendra virus~~NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software which runs 24 hours per day and enables automated targeting and image acquisition while keeping a relational database of all micrographs to expedite subsequent processing.[68] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[44,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[61,63,70-72] mechanical stage tilting with gold grids[73,74] or detergents to modify surface tension[75]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[73,76-80] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[81-83]

Formatted: Font: Bold

The ~~Nipah virus~~NiV attachment (G) glycoprotein engages host receptors, is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the ~~Nipah virus~~NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some ~~of the~~ nanobodies might bind to regions that are intrinsically flexible thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[84] and BUSTER-TNT.[85]~~.~~

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[61-63,71,86,87]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[88-90] and high-resolution noise substitution prior to Fourier shell correlation calculations[91] to avoid overfitting. Atomic models will be assessed using Molprobity,[92]~~,~~ EMringer[93] and Privateer.[94]~~.~~ The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[95-97] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected in vivo, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in Aim 2A. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with the **ABSL-3 and ABSL-4 Core** (Core D) to evaluate lead candidate drugs and nanobodies~~s~~ *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in ~~a~~ well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster ~~(refs)~~ and AGM (refs 1, 2~~s~~). PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

Formatted: Font: Bold

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed ~~by Core D~~by the UTMB Core. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of heniavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ $5x10^6$ pfu of NiV_B or HeV (refs 3-6). Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight

Formatted: Superscript

Formatted: Highlight

loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antivirals fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV (refs 3-6). Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

Formatted: Highlight

D.5.4. Combination therapy of anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6~~5x10^5~~ PFU of NiV or HeV (refs 3-6). Treatment with at least two different antivirals will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

Formatted: Superscript

Formatted: Highlight

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ 5x10^6 PFU of NiV$_B$~~-B~~ or HeV as determined in henipavirus dose confirmation studies conducted by the **ABSL-3 and ABSL-4 Core** ~~Core D~~ (see Core D). Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by the **Aerosol Delivery Core**~~Core X~~ (see Core A~~X~~) at various times after henipavirus infection.

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD)~~MAD system~~ as previously described (ref 7) or by small particle aerosol as previously described (refs 8, 9) with a uniformly lethal challenge dose (~ ~~-~~20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV$_B$ using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (TW Geisbert, C Broder, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by the **Aerosol Delivery Core**~~Core X~~ (see Core A)up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Formatted: Font: Bold

Potential Pitfalls and Alternative Strategies. It is possible that **Aerosol Delivery Core (Core A)** ~~X~~ may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antivirals may not improve protective efficacy or extend the therapeutic window of antivirals. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and ~~monoclonal antibodies~~mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.~~.~~

Formatted: Not Highlight

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of ~~Nipah virus~~NiV infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next ~~Nipah virus~~NiV or other related pathogenic henipavirus outbreaks. We *have discovered two differentiated series of compounds that show early promise as agents that have potential for treating ~~Nipah virus~~NiV infections, and we have designed a series of optimized druglike candidates for future preparation and development.*

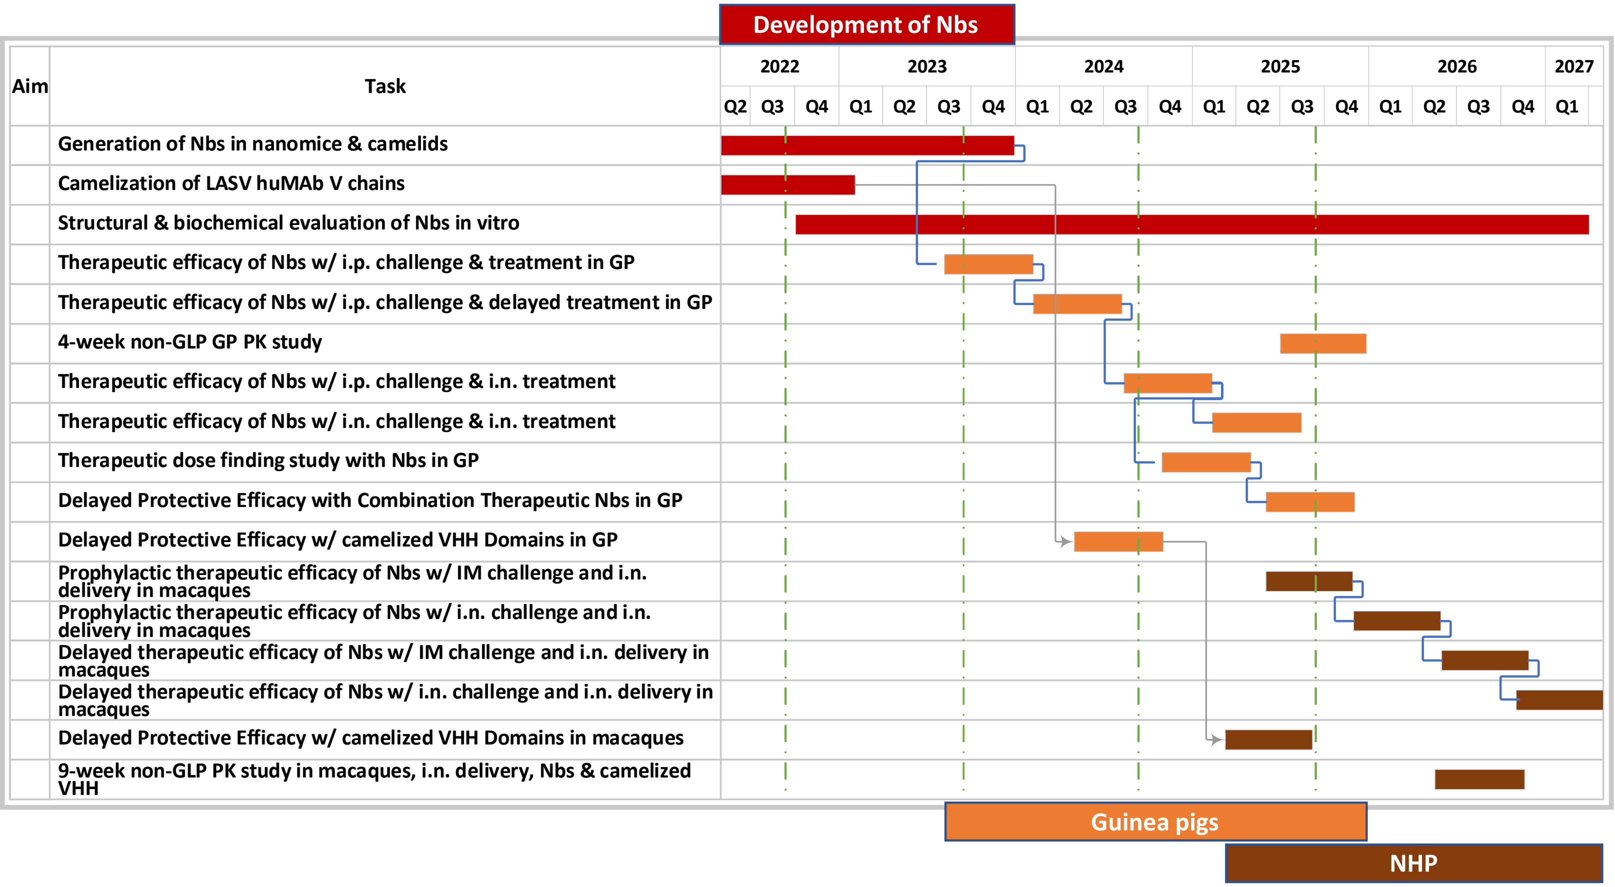
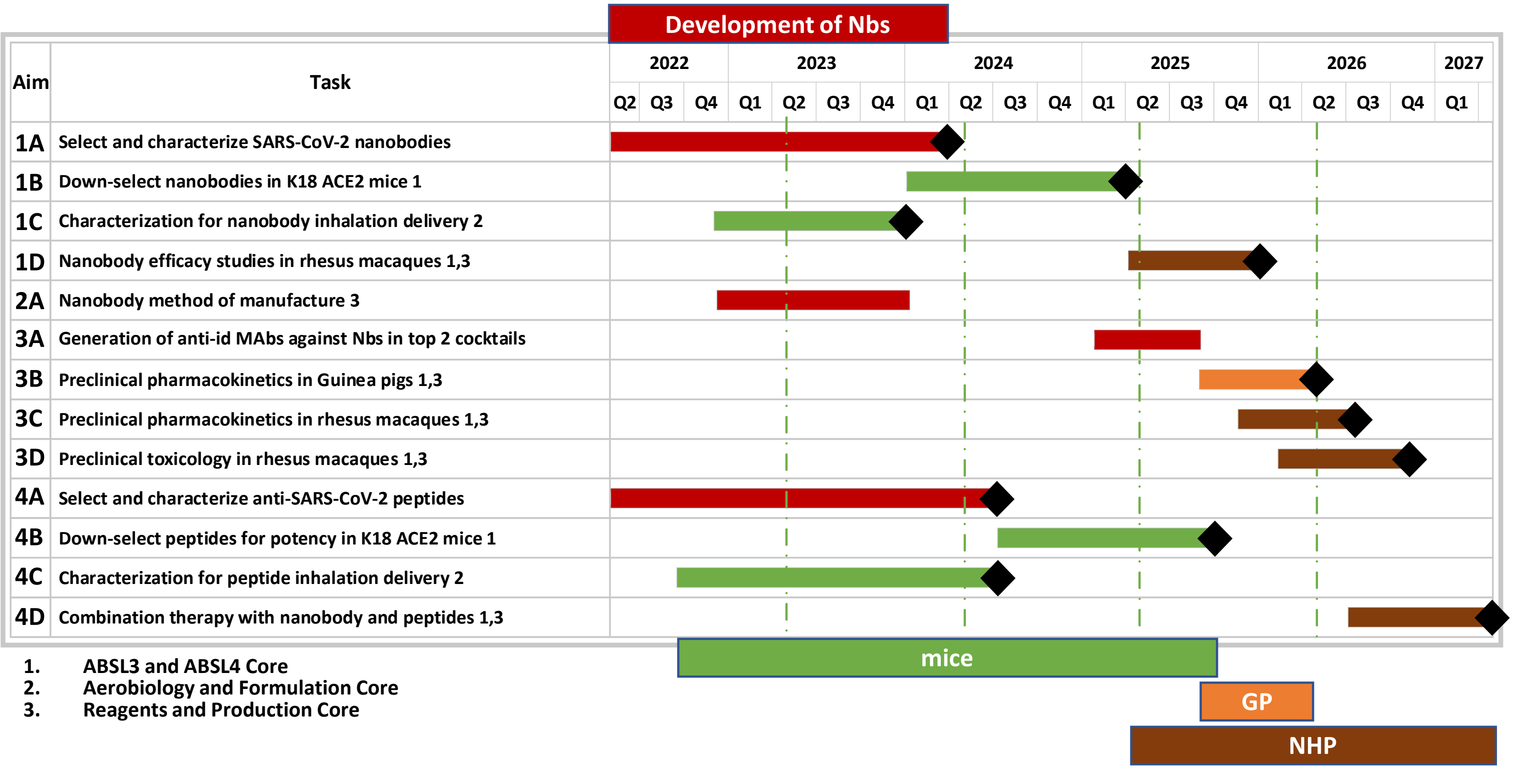
RAViD Center Project 2: Structure-guided development of nanobody therapeutics against Arenaviruses



Aim	Task
	Generation of Nbs in nanomice & camelids
	Camelization of LASV huMAb V chains
	Structural & biochemical evaluation of Nbs in vitro
	Therapeutic efficacy of Nbs w/ i.p. challenge & treatment in GP
	Therapeutic efficacy of Nbs w/ i.p. challenge & delayed treatment in GP
	4-week non-GLP GP PK study
	Therapeutic efficacy of Nbs w/ i.p. challenge & i.n. treatment
	Therapeutic efficacy of Nbs w/ i.n. challenge & i.n. treatment
	Therapeutic dose finding study with Nbs in GP
	Delayed Protective Efficacy with Combination Therapeutic Nbs in GP
	Delayed Protective Efficacy w/ camelized VHH Domains in GP
	Prophylactic therapeutic efficacy of Nbs w/ IM challenge and i.n. delivery in macaques
	Prophylactic therapeutic efficacy of Nbs w/ i.n. challenge and i.n. delivery in macaques
	Delayed therapeutic efficacy of Nbs w/ IM challenge and i.n. delivery in macaques
	Delayed therapeutic efficacy of Nbs w/ i.n. challenge and i.n. delivery in macaques
	Delayed Protective Efficacy w/ camelized VHH Domains in macaques
	9-week non-GLP PK study in macaques, i.n. delivery, Nbs & camelized VHH

RAViD Center Project 3: Aerosol delivery of nanobodies and peptides for coronaviruses



Aim	Task
1A	Select and characterize SARS-CoV-2 nanobodies
1B	Down-select nanobodies in K18 ACE2 mice 1
1C	Characterization for nanobody inhalation delivery 2
1D	Nanobody efficacy studies in rhesus macaques 1,3
2A	Nanobody method of manufacture 3
3A	Generation of anti-id MAbs against Nbs in top 2 cocktails
3B	Preclinical pharmacokinetics in Guinea pigs 1,3
3C	Preclinical pharmacokinetics in rhesus macaques 1,3
3D	Preclinical toxicology in rhesus macaques 1,3
4A	Select and characterize anti-SARS-CoV-2 peptides
4B	Down-select peptides for potency in K18 ACE2 mice 1
4C	Characterization for peptide inhalation delivery 2
4D	Combination therapy with nanobody and peptides 1,3

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the non-pathogenic Cedar henipavirus (CedV) is useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline CBS1435 was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50}s in the low µM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC$_{50}$ value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class ~~also aerosol delivery of~~ nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

Over the past 40 years the major etiological agents of emerged or identified infectious diseases in humans have been viruses.[11] Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV).[12,13]~~.~~ In 1994, HeV caused an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer.[14,15] NiV was the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998. Spread of NiV infections typically requires direct contact with an infected source, and transmission can occur between people and from animals to people. Symptoms may culminate in a severe respiratory and/or neurological disease that is often fatal. Complications of the infection can result in relapsed encephalitis following recovery. On September 5, 2021, a twelve-year-old boy in the Indian state of Kerala died after contracting ~~the Nipah virus~~NiV infection. During the process of transporting him to medical centers for a diagnosis, twenty-three health care workers exposed to this boy also died, which underscores both the transmissability and the lethal nature of this virus. *There is presently no vaccine or small molecule therapeutics that have been developed for NiV infections.* Pteropid bats appear to be the major reservoir hosts for henipaviruses.[6,16]~~.~~ HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%.[2,17]~~.~~

NiV and HeV are classified as biosafety level-4 (BSL-4) restricted pathogens and both remain transboundary threats to livestock and people throughout South Asia and Australia. NiV and henipaviral diseases have been categorized by the World Health Organization (WHO) as an epidemic threat needing urgent research and countermeasure development and are included in the WHO R&D Blueprint list of priority pathogens with epidemic potential.[18]~~.~~ Presently, there are no prophylactic or therapeutic treatment options for henipavirus infections approved for use in humans. A subunit vaccine, Equivac® HeV, has been available for use in horses in Australia since 2012[19] for the prevention of HeV infection. This equine vaccine received full registration by the Australian Pesticides and Veterinary Medicines Authority in 2015, with all vaccinated horses receiving a microchip with a database being maintained and is the first commercially deployed vaccine against a BSL-4 agent.[20]~~.~~ Although a human monoclonal antibody (mAb) m102.4 has successfully completed a phase I safety trial in Australia,[21]~~,~~ developing vaccines or therapeutics against henipaviruses for use in people remains a high priority. Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of several vaccine strategies.[2]~~.~~ Although an effective post-exposure human monoclonal antibody (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been extensively examined,[22-26]~~,~~ it must be administered within several days following lethal infection in animal challenge models. In contrast, however, antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of biosafety level-4 (BSL-4) containment. Recently, a third isolate, namely, Cedar virus (CedV) has been added to the *Henipavirus* genus.[27]~~.~~ However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease and resides in nature in the same bat host species as HeV.[27,28]~~.~~ Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences,[29,30]~~,~~ but HeV, NiV, and CedV are the only virus isolates reported.

We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and have identified several inhibitory compounds that were further validated with the infectious NiV-Bangladesh (NiV-B) strain. The validated compounds provide the foundation for the current application.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice

Commented [CB1]: This section needs fixing.

I am sending separate section. AFTER i cut it down more as you suggest./

that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole ~~inactivated~~ NiV or HeV immune sera ~~will~~ shows cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G ~~glycoprotein~~ antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins.[27] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and ~~it is also~~ the largest polymerase in the order *Mononegavirale*, yet it ~~still~~ shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; ~~the~~ aa identities of ~~the important~~ L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of ~~protein~~ identity, ~~overall,~~ shared between CedV~~,~~ and that of NiV and HeV, suggests that antiviral~~ agent~~s that target ~~for example,~~ the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus ~~antiviral~~ countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] ~~Indeed, s~~Several small molecule inhibitors have been validated in vitro using infectious HeV and NiV~~ in BSL-4~~, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[31-33] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. ~~In collaboration~~Nanobody development will be carried out by~~ with~~ **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels~~,~~.[10] ~~we have several l~~Iimmunized mouse cohorts are in progress ~~now underway using native-like oligomeric recombinant~~using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2**. ~~in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.~~

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company

engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule ~~entry~~ inhibitors of henipaviruses~~Nipah~~.

Formatted: Space After: 3 pt

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2 ~~containment~~), cell-based HTS platform to identify small molecule antivirals targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at BSL-2 were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV-B and HeV that can be used as a neutralization ~~tool~~ or entry inhibitor assay to measure neutralizing antibodies ~~or sera~~, or as a surrogate for generating virus escape mutants to ~~F or G~~ neutralizing antibodies. Here, the F and G genes of NiV-B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV-B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared ~~(rCedV-NiV-B and rCedV-HeV)~~. All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[34] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 hrs at 37~~-~~°C. Each virus-mAb mixture (90 µl/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci ~~were~~ are counted using the CTL Basic Count™ and an IC_{50} is determined as the antibody concentration ~~at which there was a~~yielding 50% reduction in fluorescent foci versus ~~untreated~~ control wells. **Table 1** shows the calculated ~~EC_{50}~~ IC_{50} values using rCedV chimeras vs. those determined by conventional PRNT assay with authentic NiV-B and HeV ~~in BSL-4~~, and they are remarkably within a 2-fold range.

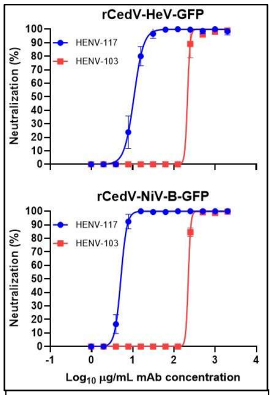

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC_{50} values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS ~~neutralization~~ assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[34] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[35] using a

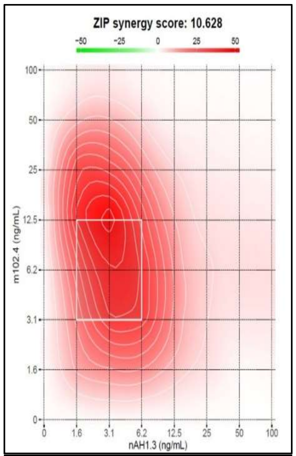

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

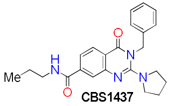
Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as shown here. ~~m102.4 and nAH1.3 indicate here.~~

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, in vitro, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to in vivo animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC$_{50}$ (µM)	**CC$_{50}$ (µM)**	**EC$_{50}$ (µM)**	**CC$_{50}$ (µM)**	**EC$_{50}$ (µM)**
0.70	100	2.1	100	3.3

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC$_{50}$ values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC$_{50}$ value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM).

Table 3 shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14,** bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent, **CBS1437**, as well as specific plans for developing the SARs.*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

C2.2.3. Generation of Nipah and Hendra G and F nanobodies. We recently initiated a collaborative project in nanobody development against NiV and HeV, as well as other henipavirus glycoproteins, with Dr. Jianliang Xu (**RAViD, Nanobody Core Lead**). The Xu lab has engineered and established transgenic mice that produce

VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, and has published on the power and utility of anti-SARS-CoV-2 nanobodies(REF). We have already initiated the immunizations of several nanomouse cohorts using native-like oligomeric recombinant sF (**Veesler lab**) and sG glycoproteins (**Broder lab**) of NiV-B and HeV. Immune responses are excellent and sera measured by ELISA using the immunogens. The first of these cohorts will be processed in the coming weeks, and the Xu lab will be constructing phage libraries of polyclonal VHHs from each cohort. We except to be able to make rapid progress in **Aim 2**, in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

Commented [CB5]: Xu, J. et al. Nanobodies from camelid mice and llamas neutralize SARS-CoV-2 variants. Nature 595, 278-282, doi:10.1038/s41586-021-03676-z (2021).

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 μM) and low cytotoxicity (CC_{50} >100 μM).

D1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**F577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. In addition, we will optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be more chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a brief synopsis of the general method used for the synthesis of 4-aminoquinazolines. The specific procedures for the three steps vary, but all initiate with anthranilamides. This general route will allow us to prepare compounds with varied R_1, R_2 and R_3 groups as well as compounds with substituents that replace the carboethoxy functionality at the 2-position. Several anthranilamides are commercially available, which will allow us to initially access starting materials with a variety of R_3 groups. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[36-37] as well as other methods.[38,39] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.

Commented [CB6]: Compound 8 in Table 3 is G577-0112 not "F"

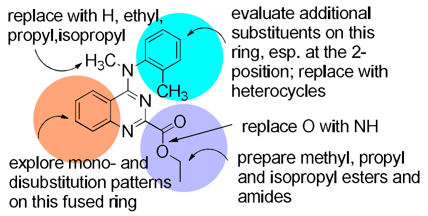

Figure 3. SAR development for 4-aminoquinazolines

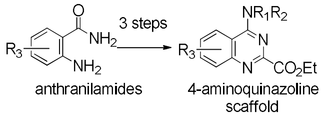
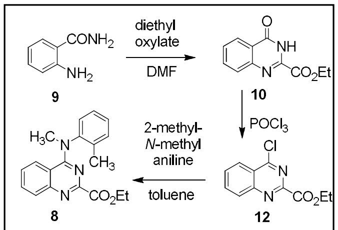


Scheme 1. General synthesis for 4-aminoquinazolines.



Scheme 2. Synthesis of **G577-0112** (cmpd **8**).

In **Scheme 2** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) produces 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline.

Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[40]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester to an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scres have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding.

In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. Additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

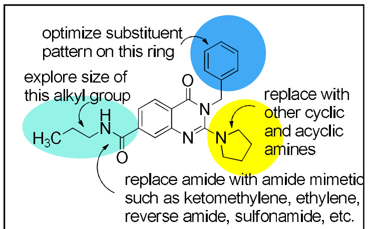

Figure 5. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5×10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation ~~(PerkinElmer, Waltham, MA) as per the manufacturer's instructions~~. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T ~~cells~~ and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions,**

Inc. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSV-G-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (potent inhibitor, EC_{50} less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" ~~(Promega, Madison, WI)~~ as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds ~~found to be~~ <80% pure will be purified and retested.

D.1.3. Evaluation of ~~protective properties~~antiviral activity of ~~the~~ advanced candidates. ~~in the henipavirus infectious assays~~ Inhibitors will be ~~done~~ tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2 × 10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to ~~that from~~ parallel control cultures ~~with~~ of virus and DMSO ~~vehicle only~~. This work will be performed in the BSL-4 facility at UTMB (~~by the~~ **Geisbert ~~Lab (Core ?~~BSL-4 Core lead)** .

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Gaisina and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy ~~based on a~~using a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or ~~the additional~~other HTS hits identified ~~with the HTS of the~~using the expanded libraries of compounds ~~for defining lead compounds for advancement~~.

Formatted: Space After: 3 pt

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with ~~cell growth~~ medium containing either DMSO or selected furopyrimidines at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by ~~standard~~ western blot techniques or viral RNA levels by ~~quantitative real time polymerase chain reaction assays (~~q-RT-PCR~~)~~. CedV specific antibodies against ~~the attachment (~~G~~) and fusion (~~F~~) that were generated in the **Broder Lab** and antibodies to CedV-~~N and ~~CedV-~~P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene, and ~~. The one-step reaction will be~~ performed using the ~~Applied Biosystems (~~ABI~~)~~ 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies,

Formatted: Font: Bold

HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** ***Target identification for small molecules.*** The rCedV tools used in ~~the small molecule inhibitor identification assays (~~**Aim 1**~~)~~ can also be exploited for antiviral target identification. In vitro selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants~~ viruses~~. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[41,42] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a "drug resistant" virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any "drug resistant" virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L ~~polymerase~~ gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The ~~Nipah~~ NiV polymerase (L protein and a phosphoprotein P) will be prepared using a previously published protocol. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[43] Prefusion-stabilized RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab**.

Formatted: Space After: 3 pt

D.2.3. Structure determination of recombinant proteins with bound inhibitors by X-Ray crystallography and CryoEM. High-resolution structures of the ~~Nipah~~ NiV RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compound to be developed will be obtained using both x-ray crystallography and CryoEM by Dr. Vessler Lab. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. Initial crystallization screens will be set up robotically using in-house Gryphon crystallization robotics. Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization. X-ray data collection will be done where? Crystal structures will be determined by molecular replacement using existing structures as search models. For inhibitors binding to regions other than above or if co-crystals cannot be obtained, cryo-EM will be used to determine the complex structure. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[44] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including cryoSparc[45], EMAN[46], and RELION[47]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed by molecular dynamics (MD) studies. While cryo-EM can provide access to the near-atomic resolution structures of large biomolecular systems--in their near native environment, MD can be used to reveal its dynamic behavior and refine low-resolution regions of cryo-EM reconstructions[48,49]. Furthermore, as X-ray/cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[50-54], to explore the conformational landscape[55] of ligand binding events, and to capture conformational variability of intermediate states[48,56], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches. David, please look at this section. Make necessary corrections.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp.)~~, Woburn, MA)~~ to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[57] Compounds with IC_{50} values ≥100 μM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[58] Compounds with >30% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed in a [^{3}H] dofetilide-binding assay as previously described~~ by Finlayson *et al*~~.[59] using SHSY5Y cells. Compounds that do not prevent [^{3}H]dofetilide binding (IC_{50} >10 μM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method ~~as described by Gres *et al*.~~[60] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1 × 10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will

Formatted: Space After: 3 pt

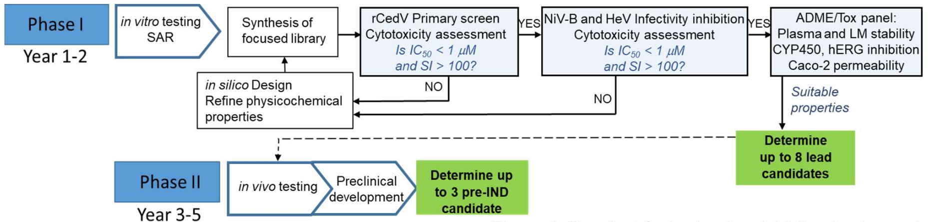

Figure 4. Flowchart for henipavirus inhibitor development

Will be MODIFIED **Figure 5**

be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 5**).

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies.

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. **Aim 1** will also collaborate with the ~~core???~~ UTMB, BSL-4 Core to evaluate lead candidates with authentic NiV and HeV and also in vivo in **Aim 3**. Batteries of nanobodies to the F and G glycoproteins of NiV and HeV will be isolated from phage libraries constructed using cohorts of nanomice immunized with sF and sG recombinant glycoproteins (**C2.2.3. Preliminary Data**). The Core will conduct preliminary characterizations on binding and specificities and then provide purified nanobody panels to the **Veesler** and **Broder labs** for detailed studies.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth.

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including NiV ~~pah virus~~ (Bengladesh and Malaysia strains) and ~~Hendra~~ HeV ~~virus~~ (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[61-63] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with ~~Nipah and Hendra virus~~NiV and HeV glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit ~~Nipah virus and Hendra virus~~NiV and HeV, we will use a high-throughput neutralization assay ~~developed in the~~ (conducted in the **Broder lab**). This assay is based on ~~green fluorescent protein (~~GFP~~)~~-encoding, recombinant replication-competent, Cedar ~~(~~henipa~~)~~virus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bengladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins (see: C.2.1. Preliminary Data).[7,64] This platform is safe, enabling utilization at BSL-2 compared to BSL-4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the **Broder lab** recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described ~~Hendra virus~~HeV variant.[65] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond ~~Nipah and Hendra viruses~~NiV and HeV (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[66,67]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against ~~Nipah virus and Hendra virus~~NiV and HeV. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition.

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software which runs 24 hours per day and enables automated targeting and image acquisition while keeping a relational database of all micrographs to expedite subsequent processing.[68] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[44,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[61,63,70-72] mechanical stage tilting with gold grids[73,74] or detergents to modify surface tension[75]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[73,76-80] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[81-83]

Formatted: Font: Bold

Formatted: Font: Bold

The ~~Nipah virus~~NiV attachment (G) glycoprotein engages host receptors, is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the ~~Nipah virus~~NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some ~~of the~~ nanobodies might bind to regions that are intrinsically flexible thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[84] and BUSTER-TNT.[85]~~.~~

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[61-63,71,86,87]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[88-90] and high-resolution noise substitution prior to Fourier shell correlation calculations[91] to avoid overfitting. Atomic models will be assessed using Molprobity,[92]~~,~~ EMringer[93] and Privateer.[94]~~.~~ The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails.

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[95-97] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected in vivo, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in Aim 2A. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with Core D to evaluate lead candidates *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in a well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster ~~(refs)~~ and AGM (refs). PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

Commented [CB7]:
Animal Challenge Models of Henipavirus Infection and Pathogenesis
T. W. Geisbert, H. Feldmann and C. C. Broder
Curr Top Microbiol Immunol 2012 Vol. 359 Pages 153-77
DOI: 10.1007/82_2012_208

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed ~~by Core D~~by the UTMB Core. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of heniavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV_B or HeV (refs). Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antivirals fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV (refs). Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.5.4. Combination therapy of anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^5$ PFU of NiV or HeV (refs). Treatment with at least two different antivirals will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ $5x10^6$ PFU of NiV~~-~~B or HeV as determined in henipavirus dose confirmation studies conducted by Core D (see Core D). Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by Aerosol Delivery Core~~Core X~~ (see Core X) at various times after henipavirus infection.

Formatted: Not Superscript/ Subscript

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the MAD system as previously described (ref) or by small particle aerosol as previously described (refs) with a uniformly lethal challenge dose (~~~-~~20,000 PFU of NiV or HeV. The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by **Aerosol Delivery Core**~~Core X~~ up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Formatted: Font: Bold

Potential Pitfalls and Alternative Strategies. It is possible that **Aerosol Delivery Core**~~ X ~~may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antivirals may not improve protective efficacy or extend the therapeutic window of antivirals. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and ~~monoclonal antibodies~~mAbs to protect animals against lethal henipavirus disease to de-risk this Aim.

Formatted: Font: Bold

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of ~~Nipah virus~~NiV infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next ~~Nipah virus~~NiV or other related pathogenic henipavirus outbreaks. We have discovered two differentiated series of compounds that show early promise as agents that have potential for treating ~~Nipah virus~~NiV infections, and we have designed a series of optimized druglike candidates for future preparation and development.

and length

As soon as Irina gets another version everyone should please at least check their sections. I have added the missing sections on nanobody development and sources
to preliminary data and to Aim 2 Vessler.

Then we need to remove all hanging sentences to tighten and save space

I am rewriting the background (Yellow highlighted here) as I said earlier. It is not
the version from Sunday and has major errors.

General, Aim #1 needs to be cut down, either by detail or removing some figures,
It is too long and out of balance with Aim 2 and 3 in scope.

Do you need refs for Tom's section Aim 3 ? I can do that also

Did all of you send your consortium letter of agreement to Chris and Bob?

Irina is doing this lifting here now, if someone wants to make
a list of bullets of the major AIMS and SubAIMS we can sent
to Bob and Luis and Luis said

he make our missing Gantt chart for us
We need this or the attached ppt file list

AUTHENTICATION OF KEY BIOLOGICAL AND/OR CHEMICAL RESOURCES

RESUME AND SUMMARY OF DISCUSSION: This application proposes to investigate the drivers of spillover events of henipaviruses from bats to domesticated animals to humans in Bangladesh. The characterization of the routes of transmission and molecular and serological analyses to assess exposure to henipaviruses is highly significant and addresses an important knowledge gap. The Principal Investigator (PI) and the investigative team are strong with complimentary expertise and a record of previous successful collaborations and are well-positioned to carry out the proposed studies. Additional strengths of this well put together application are its data collection and analysis and the use of camera trapping observations to determine interactions between domesticated animals with bats. A number of weaknesses were identified. Some reviewers expressed concern about the lack of detail for the secondary antibodies in the multiplex assay or what the expected benchmarks are for success of this assay. There was also considerable concern related to the biosafety level of the henipavirus, which is a BSL-3/BSL-4 pathogen. Questions were raised whether this was adequately addressed in the application. For example, inactivation of the samples, the human transmission risk to study personnel handling the virus in the different work environments, and appropriate biohazard containment at one of the institutions that only has a BSL-2 facility. Overall, the weaknesses dampened the enthusiasm of the review committee.

DESCRIPTION (provided by applicant): Until and unless we better understand and prevent spillovers of bat-borne viruses into intermediate hosts and humans, we will be severely limited in our ability to stop pandemics. Henipaviruses are bat-borne, RNA viruses that spillover through this route. Nearly half of all reported human henipavirus infections have been associated with contact with sick domesticated animals, though our understanding of drivers of henipavirus spillovers and specific transmission pathways remains severely limited. Building on preliminary data about bat, domesticated animal and human infections, this multidisciplinary study integrates epidemiology, ecology, and anthropology, will identify spillover pathways for henipaviruses into domesticated animals in Bangladesh and the risk they pose to human health. Our first aim is to identify drivers of henipavirus spillovers into domesticated animals in Faridpur, Bangladesh. We will use multiplex pan-henipavirus assays to identify infections in Pteropus medius bats and domesticated animals living nearby this roost through cross-sectional and prospective studies. Combined with intensive studies of bat-domesticated animal interactions and weather data, we will build statistical models to identify the relative contribution of each of these factors. Our second aim is to describe which henipaviruses are being transmitted from bats to domesticated animals. Serologic studies of animals in Bangladesh show that they are frequently infected with non-Nipah henipaviruses. Through surveillance for and sampling of sick domesticated animals, we will describe the specific viruses that spillover from bats in Faridpur. Our third aim is to determine the risk of henipavirus transmission from domesticated animals to humans. We hypothesize that undetected henipavirus spillovers in humans are occurring through contact with sick domesticated animals and will conduct cross-sectional and prospective serosurveys of humans who have close contact with sick animals in Faridpur. We remain ignorant about henipavirus spillovers through intermediate hosts – including the specific viruses spilling over, the frequency and distribution of spillovers, and the pathways of transmission – at our own peril. The knowledge gained from this study will be immediately applicable to human and animal health programs in Bangladesh and other countries where henipaviruses circulate in bats. By learning about which henipaviruses infect humans, and how they are infected, we can advise public health surveillance programs on how to optimize detection and epidemiologic investigation of cases across Bangladesh. Our investigations about spillovers in Faridpur can also be scaled- up to other areas of Bangladesh and countries where henipaviruses circulate in bats so that we can truly begin to appreciate the scale of henipavirus spillovers in the global landscape.

PUBLIC HEALTH RELEVANCE: We remain ignorant about bat henipavirus spillovers through intermediate hosts – including the specific viruses spilling over, the frequency and distribution of spillovers, and the pathways of transmission – at our own peril. Until and unless we better understand and prevent spillovers of bat-borne viruses into intermediate hosts and humans, we will be severely limited in our ability to stop pandemics. The knowledge gained from this study will be immediately applicable to human and animal health programs because if we know which henipaviruses infect humans and domesticated animals, and how they are infected, we can advise public health surveillance programs on how to optimize detection and prevention of infections.

CRITIQUE 1:

Significance: 2
Investigator(s): 1
Innovation: 2
Approach: 2
Environment: 1

Overall Impact: The proposed project aims to improve our current understanding of Henipavirus spillovers from animals to humans. Henipaviruses are a highly relevant viral group that have been associated with significant mortality outbreaks in humans. Importantly, in most cases human infections have been associated to contact with an animal reservoir including wild animals (e.g., bats) or domestic livestock species (e.g., pigs). The proposed study will investigate risk factors and drivers of henipavirus spillovers into humans, identify which henipaviruses are being transmitted to humans and determine the risk of transmission of henipavirus from domestic animals to humans. The project will be conducted in a henipavirus endemic area in Bangladesh and will involve field epidemiological investigations as well as prospective sample collection and testing of both human and animals in close contact. This is a highly relevant study, especially when considering the context of the current COVID-19 pandemic. Identification and characterization of pathways of henipavirus spillover is critical to devise strategies that could help to prevent the next epidemic or pandemic.

1. Significance:

Strengths

- This is a field study that will investigate spillover events of henipaviruses from animals to humans in a setting that has seen multiple outbreaks in humans.
- The study will involve field epidemiology-, ecology-, and anthropology and will focus on sampling of both humans and animals that live in henipavirus endemic areas.
- The investigators propose to look at multiple animal species that are raised in the target study area in Bangladesh.
- Outcomes of the study will clearly help and improve our understanding of the factors and risks associated with spillover events of henipaviruses into humans.
- The study will identify the henipaviruses that have the potential to spill over into humans.

Weaknesses

- Most henipavirus outbreaks described to date, have been linked to palm tree sap contact or ingestion. The study will target several domestic animal species that may not serve as intermediate hosts.

2. Investigator(s):

Strengths

- The team of investigators is very strong and have a good track record of collaboration.
- Experience in conducting the proposed field epi studies is well documented and the PI and Co-PI have active and ongoing collaborations.
- The PI has first-hand knowledge of the institution in Bangladesh that will be conducting the field trial in the henipavirus endemic area.

Weaknesses

- None noted.

3. Innovation (2):

Strengths

- The study will undertake an interdisciplinary approach to dissect and improve understanding of spillover events of henipaviruses between animals and humans.
- This will involve field-based surveillance in both humans and animals.

Weaknesses

- None noted.

4. Approach:

Strengths

- The project will include epidemiological investigations, field observation of animal and human behavior and sample collection and testing.
- Molecular and serological tests will be used to assess exposure to known henipaviruses.
- Epidemiological data will be linked to behavioral data and testing data collected in the field.

Weaknesses

- The assays employed will only target known nipaviruses. The study and work would benefit from unbiased pathogen detection approaches (e.g., sequencing) at least in samples collected from sick people and humans or a subset of those.

5. Environment:

Strengths

- The infrastructure available in the U.S. and in Bangladesh are excellent and the team has a good track record of collaboration and international interactions.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- Well-articulated human subjects document was provided and all potential issues related to protection of human subjects has been well thought out.

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically
- Race/Ethnicity: Distribution justified scientifically
- For NIH-Defined Phase III trials, Plans for valid design and analysis:
- Inclusion/Exclusion Based on Age: Distribution justified scientifically

Vertebrate Animals:

Yes, all criteria addressed

- Use of animals in the project is well justified.

Biohazards:

Acceptable

- All institutions involved have the infrastructure in place to handle potentially zoonotic henipaviruses. Work in the U.S. will be conducted at a high biocontainment facility.

Applications from Foreign Organizations:

Justified

- Well-articulated and justified plan to collaborate on with an institution located in a henipavirus endemic area.

Select Agents:

Acceptable

Resource Sharing Plans:

Acceptable

- Resource sharing plan well described and follows NIH guidelines.

Authentication of Key Biological and/or Chemical Resources:

Acceptable

Budget and Period of Support:

Recommend as Requested

CRITIQUE 2:

Significance: 3
Investigator(s): 3
Innovation: 3
Approach: 6
Environment: 7

Overall Impact: This is an application from a complementary team of investigators led by an experienced early-stage investigator working in an scientific environment that is partially suitable to the project. The project is highly significant and innovative. The team proposes to identify drivers of henipavirus spillovers into domesticated animals, describe which viruses are being transmitted from bats to domesticated animals and lastly, they will serosurvey people to predict possible transmission. Swabs, urine, and blood samples will be collected from bats and from domesticated animals. A major weakness was identified in the Approach as the project entails a human transmission risk to the personnel conducting the study in the field in Bangladesh and appropriate biocontainment conditions are not listed for the sample collection part of the work. Benchmarks for success are not discussed. The likelihood that this project will exert a sustained powerful influence in the field is moderate.

1. Significance:

Strengths

- The significance of this project is very high. It addresses a critical barrier to progress in the field: understanding the nature and frequency of spillover events of RNA viruses which have high genomic mutation rates that favor onward transmission into humans. The goal of the current application is to focus on transmission of henipaviruses (which include Nipah and Hendra viruses) from bats to domesticated animals to humans.
- The work described will address gaps in knowledge in the field and there is strong scientific premise for the project. They propose to use a multiplex pan-henipavirus assay to investigate exposure to these infections across multiple animal species, including humans.

Weaknesses

- None noted.

2. Investigator(s):

Strengths

- This early-stage investigator PI is well suited to this project in terms of experience, expertise and leadership.
- The collaborators have complementary and integrated expertise.
- All established investigators have ongoing records of accomplishments that have advanced the field.

Weaknesses

- None noted.

3. Innovation:

Strengths

- The application challenges current research paradigms as it attempts to simultaneously identify and explain transmission pathways of henipaviruses from bats to intermediate hosts and from intermediate hosts to humans.
- Current human henipaviruses surveillance exclude human infections acquired through contact with sick animals.

Weaknesses

- None noted.

4. Approach:

Strengths

- The team proposes to identify drivers of henipavirus spillovers into domesticated animals, describe which viruses are being transmitted from bats to domesticated animals and lastly, they will serosurvey people to predict possible transmission. Swabs, blood, and urine samples will be collected from bats (urine to check for virus shedding) and from domesticated animals.
- The overall strategy and analysis are well reasoned, and potential problems of the study are discussed for each aim.
- A study timeline/milestones is provided.

Weaknesses

- One major weakness was identified in the methodology. Nipah Virus is a select agent BSL-3/BSL-4 pathogen and Nipah virus shedding in urine has been detected repeatedly in longitudinal surveys of bats in Faridpur District in Bangladesh. Although in the select agent section there’s one sentence on sample collection into a solution containing trizol, there’s not enough biocontainment discussed in the approach to reassure that this work will not inadvertently produce a patient zero for a new pandemic virus. This project entails a considerable human transmission risk to the personnel conducting the study in the field due to exposure to bat excretions and large numbers if multiple infected domestic animals and specific measures for personal protection are not mentioned in the Approach for Aims 1 and 2, which are the major risk factors for collection of samples at the interface of bat/human and infected domesticated animal/human.
- Benchmarks for success are not discussed.

5. Environment.

Strengths

- None noted.

Weaknesses

- The associated institution in Bangladesh does not have appropriate biosafety level facilities (minimum BSL3) to handle the samples they propose to collect and test.
- Equipment is not listed.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- Human serosurveys in native environment.

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically
- Race/Ethnicity: Distribution justified scientifically
- For NIH-Defined Phase III trials, Plans for valid design and analysis: Not applicable
- Inclusion/Exclusion Based on Age: Distribution justified scientifically
- Males, females, children, non-Hispanic Asians will be included.

Vertebrate Animals:

Yes, all criteria addressed

- The face page of the application states No Vertebrate Animals but they addressed this issue.

Biohazards:

Unacceptable

- They propose to capture and sample swabs, urine, and blood from bats and domesticated animals in Bangladesh and use multiplex pan-henipavirus assays to identify infections in bats and domesticated animals. Henipaviruses pose a meaningful pandemic threat. Since there will be exposure of humans to potentially new unknown bat viruses, and they will acquire samples in solution containing trizol before being processed in BSL2 at least a plan to safeguard the personal protection of the people doing the field work needs to be explained.

Applications from Foreign Organizations:

Justified

- Work to be conducted in Bangladesh.

Select Agents:

Unacceptable

- Nipah virus is a select agent to be handled in BSL-3/4 conditions. The facility in Bangladesh that will handle samples at interfaces of bat/human can only handle BSL-2 containment.

Resource Sharing Plans:

Acceptable

Authentication of Key Biological and/or Chemical Resources:

Unacceptable

- All the secondary antibodies used for each one of the species proposed for serosurveys, including bats, must be authenticated. This section was not addressed.

Budget and Period of Support:

Recommend as Requested

CRITIQUE 3:

Significance: 2
Investigator(s): 1
Innovation: 2
Approach: 2
Environment: 1

Overall Impact: The investigators propose a study to investigate routes of spillover of henipaviruses from bats to domestic animals to humans. The study is justified by prior work suggesting that a key route of exposure to henipaviruses is via domestic animals and a gap in the scientific understanding of what contributes to these spillover events. The research includes the collection of ecological, environmental, and anthropological data, as well as sero-surveillance in bats, domestic animals and humans, and sequencing virus obtained from bats and sick domestic animals. The study is well-designed to address the research questions both in terms of the study location, the excellent research team, and the design of data collection and analysis. The investigator's greatest challenges are the many unknowns about henipavirus spillovers which will require the team to be agile (the proposal has well-reasoned contingency plans). However, this is also strong justification for the proposed work. The team is well positioned to carry-out the proposed research and improve our understanding of henipavirus transmission.

1. Significance:

Strengths

- Henipaviruses are a model system for studying spillover of viruses into human populations. The proposed research will shed light on pathways by which henipaviruses move from wild to domestic animal populations and cross over to humans.

- The proposed research can help inform how to improve surveillance systems for emerging henipaviruses, which are currently focused, at least in Bangladesh, on human symptomatic surveillance.

Weaknesses

- The generalizability to other emerging pathogens is unclear as the spillover pathways may vary by pathogen. Nonetheless the wild animal to domestic animal to human pathway has historically been a key route of disease emergence.

2. Investigator(s):

Strengths

- The investigator team is well-positioned to conduct the proposed research.

Weaknesses

- None noted.

3. Innovation:

Strengths

- The proposed research focuses on the wild animal/domestic animal interface which is an important but poorly characterized route of pathogen emergence.
- The integration of diverse data streams is novel and can help fill gaps left by studies focused only on a single host species.

Weaknesses

- None noted.

4. Approach:

Strengths

- The bat and domestic animal surveillance is well-designed, providing temporal data.
- The proposed analyses clearly make use of the data collected and are appropriate for the study aims.
- The qualitative studies in SA1 will add a rich data source that is particularly important given the number of unknowns.
- Camera trapping to assess animal contacts is a key strength to allow objective measurement of this feature.
- The sequencing and phylogenic analysis of samples collected from bats and domestic animals is a key strength and will allow the researchers to assess the relatedness of viruses found in animal and bat populations.

Weaknesses

- The investigators may want to consider chipping or tagging bovines, as they are harder to consistently identify over time than they indicate in their proposal.
- It is unclear how/whether mobile animal or human populations such as the mobile pigs they mention will be surveyed as it is plausible they play a role in transmission.

5. Environment:

Strengths

- The study location is excellent as it is likely a region with concentration of henipaviruses and high human – domestic animal – bat exposures.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- Acceptable

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically
- Race/Ethnicity: Distribution justified scientifically
- For NIH-Defined Phase III trials, Plans for valid design and analysis: Not applicable
- Inclusion/Exclusion Based on Age: Distribution justified scientifically
- Will restrict to ages 5 and older. This is scientifically and logistically justified.

Vertebrate Animals:

Yes, all criteria addressed

- Adequate protections for all field staff to prevent virus exposure when handling animals will be paramount.

Biohazards:

Acceptable

- This is addressed in the select agent section.

Applications from Foreign Organizations:

Justified

- There is a partnership with ICDDR,B in Bangladesh which is necessary for the proposed research.

Select Agents:

Acceptable

- The project involves works with Nipah and other henipaviruses.

Resource Sharing Plans:

Acceptable

Authentication of Key Biological and/or Chemical Resources:
Acceptable

Budget and Period of Support:
Recommend as Requested

THE FOLLOWING SECTIONS WERE PREPARED BY THE SCIENTIFIC REVIEW OFFICER TO SUMMARIZE THE OUTCOME OF DISCUSSIONS OF THE REVIEW COMMITTEE, OR REVIEWERS' WRITTEN CRITIQUES, ON THE FOLLOWING ISSUES:

PROTECTION OF HUMAN SUBJECTS: Acceptable

INCLUSION OF WOMEN PLAN: Acceptable

INCLUSION OF MINORITIES PLAN: Acceptable

INCLUSION ACROSS THE LIFESPAN: Acceptable

COMMITTEE BUDGET RECOMMENDATIONS: The budget was recommended as requested.

BIOHAZARDS: Unacceptable

SELECT AGENTS: Unacceptable

AUTHENTICATION OF KEY BIOLOGICAL AND/OR CHEMICAL RESOURCES: Unacceptable

NIH has modified its policy regarding the receipt of resubmissions (amended applications).See Guide Notice NOT-OD-18-197 at https://grants.nih.gov/grants/guide/notice-files/NOT-OD-18-197.html. The impact/priority score is calculated after discussion of an application by averaging the overall scores (1-9) given by all voting reviewers on the committee and multiplying by 10. The criterion scores are submitted prior to the meeting by the individual reviewers assigned to an application, and are not discussed specifically at the review meeting or calculated into the overall impact score. Some applications also receive a percentile ranking. For details on the review process, see http://grants.nih.gov/grants/peer_review_process.htm#scoring.

Subject: comments on henipavirus RO1
Date: Wednesday, November 3, 2021 12:13:40 PM
Attachments: 1R01AI168287-01.pdf

Colleagues,

We've received scores and comments on our RO1. Score was 31, 21st percentile. We need to be around 10-14th percentile to be funded. So, not too bad for our first submission.

Two reviewers scored the proposal very high. Reviewer #2 is very cranky about biosafety issues. Hopefully, we can address these in the next submission. I'll meet with the Program Officer soon to see if she has any insights.

There are also some concerns about validating the serology tests, which was predictable. Perhaps we can think of ways to address that as well.

The plan is to resubmit at the next deadline in Feb.

Feeling hopeful.
Emily

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the non-pathogenic Cedar henipavirus (CedV) is useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline CBS1435 was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50}s in the low μM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

Commented [d1]: This is unlikely to be the case (at least for the nanobodies)

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 µm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and also aerosol delivery of nanobodies. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

Over the past 40 years the major etiological agents of emerged or identified infectious diseases in humans have been viruses.[11] Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV)[12,13]. In 1994, HeV caused an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer.[14,15] NiV was the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998. Spread of NiV infections typically requires direct contact with an infected source, and transmission can occur between people and from animals to people. Symptoms may culminate in a severe respiratory and/or neurological disease that is often fatal. Complications of the infection can result in relapsed encephalitis following recovery. On September 5, 2021, a twelve-year-old boy in the Indian state of Kerala died after contracting the Nipah virus. During the process of transporting him to medical centers for a diagnosis, twenty-three health care workers exposed to this boy also died, which underscores both the transmissability and the lethal nature of this virus. *There is presently no vaccine or small molecule therapeutics that have been developed for NiV infections.* Pteropid bats appear to be the major reservoir hosts for henipaviruses[6,16]. HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%[2,17].

NiV and HeV are classified as biosafety level-4 (BSL-4) restricted pathogens and both remain transboundary threats to livestock and people throughout South Asia and Australia. NiV and henipaviral diseases have been categorized by the World Health Organization (WHO) as an epidemic threat needing urgent research and countermeasure development and are included in the WHO R&D Blueprint list of priority pathogens with epidemic potential [18]. Presently, there are no prophylactic or therapeutic treatment options for henipavirus infections approved for use in humans. A subunit vaccine, Equivac® HeV, has been available for use in horses in Australia since 2012 [19] for the prevention of HeV infection. This equine vaccine received full registration by the Australian Pesticides and Veterinary Medicines Authority in 2015, with all vaccinated horses receiving a microchip with a database being maintained and is the first commercially deployed vaccine against a BSL-4 agent [20]. Although a human monoclonal antibody (mAb) m102.4 has successfully completed a phase I safety trial in Australia [21], developing vaccines or therapeutics against henipaviruses for use in people remains a high priority. Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of several vaccine strategies[2]. Although an effective post-exposure human monoclonal antibody (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been extensively examined[22-26], it must be administered within several days following lethal infection in animal challenge models. In contrast, however, antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of biosafety level-4 (BSL-4) containment. Recently, a third isolate, namely, Cedar virus (CedV) has been added to the *Henipavirus* genus[27]. However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease and resides in nature in the same bat host species as HeV[27,28]. Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences[29,30], but HeV, NiV, and CedV are the only virus isolates reported.

We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and have identified several inhibitory compounds that were further validated with the infectious NiV-Bangladesh (NiV-B) strain. The validated compounds provide the foundation for the current application.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice

that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole inactivated NiV or HeV immune sera will show cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G glycoprotein antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins. [27] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and it is also the largest polymerase in the order *Mononegavirale*, yet it still shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; the aa identities of the important L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This high degree of protein identity, overall, shared between CedV, and that of NiV and HeV, suggests that antiviral agents that target for example, the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus antiviral countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Indeed, several small molecule inhibitors have been validated in vitro using infectious HeV and NiV in BSL-4, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support Aim 1 to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[31-33] Nanobodies can be isolated using the same phage library construction methods and phage panning procedure routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. In collaboration with **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, [10] we have several immunized mouse cohorts now underway using native-like oligomeric recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in Aim 2 in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of Aim 3. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in Aim 3. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company

engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule entry inhibitors of Nipah.

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2 containment), cell-based HTS platform to identify small molecule antivirals targeting henipavirus replication without the requirement for BSL-4 containment.[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with that of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera use guidelines and procedures at BSL-2 were reviewed and approved by the USU, Institutional Biosafety Committee (IBC) in accordance with NIH guidelines. These replication competent rCedV chimeras create a very rapid and robust surrogate infection assay for NiV-B and HeV that can be used as a neutralization tool or entry inhibitor assay to measure neutralizing antibodies or sera, or as a surrogate for generating virus escape mutants to F or G neutralizing antibodies. Here, the F and G genes of NiV-B (2010 Faridpur isolate) and HeV (2008 Redlands isolate) were synthesized and inserted into our pOLTV5-rCedV anti-genome plasmid. For the HTS neutralization assay, a turbo-GFP gene was inserted between the CedV P and M genes. Each chimera (rCedV-NiV-B-GFP and rCedV-HeV-GFP) were rescued as previously described.[8] Other versions without reporter genes have also been prepared (rCedV-NiV-B and rCedV-HeV). All virus stocks are cloned and genomes confirmed by NGS. Typically, large stocks are prepared and frozen as single use aliquots. Show in **Figure 1** is an example of how these chimeras are used in a virus neutralization test, referred to as a fluorescent reduction neutralization test (FRNT) using two human NiV/HeV cross-reactive anti-G mAbs (HENV-103 and -117) as previously described.[34] Briefly, Vero 76 cells are used in black walled clear bottom 96-well plates, mAbs are serially diluted in medium, and equal volumes of medium containing rCedV-NiV-B or rCedV-HeV are added to each mAb dilution for a final concentration of 2000 PFU, incubated for 2 hrs at 37 °C. Each virus-mAb mixture (90 µl/well) is added to the pre-seeded Vero 76 cells in triplicate and the assay run for just another 24 h followed by 4% formaldehyde fixation, washing and then scanning using a CTL S6 analyzer. Fluorescent foci were counted using the CTL Basic Count™ and an IC_{50} is determined as the antibody concentration at which there was a 50% reduction in fluorescent foci versus untreated control wells. **Table 1** shows the calculated EC_{50} values using rCedV chimeras vs. those determined by conventional PRNT assay with authentic NiV-B and HeV in BSL-4, and they are remarkably within a 2-fold range.

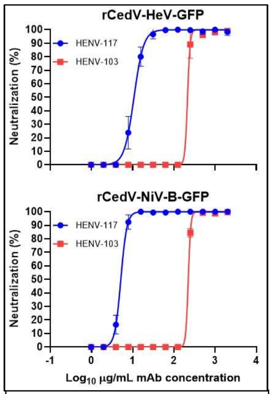

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.

IC50 (ng/mL)	HeV	rCedV-HeV	NiVB	rCedV-NiVB
HENV-103	445	216	507	238
HENV-117	14	11	15	6

Table 1. IC_{50} values of cross-reactive anti-G human mAbs HENV-103 and -117) as determined by rCedV chimera FRNT assay and NiV-B and HeV conventional PRNT assay.

In addition to conventional single agent neutralization tests, the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras can also be used in rapid HTS neutralization assays to measure synergistic activities of inhibitors, such as antibodies or drugs. The synergistic neutralizing activity of the HENV-103 and HENV-117 mAbs were described utilizing the rCedV chimera assay.[34] Shown in **Figure 2** is a neutralization synergy assay conducted with mAbs m102.4 and nAH1.3 (both NiV/HeV cross-reactive anti-G mAbs) where they are individually diluted 2-fold in a 7x7 concentration matrix. The diluted mAbs are added 1:1 to 4000 PFU per well of rCedV-NiV-B-GFP and the assay essentially carried out as above, with percent neutralization calculated by normalizing foci to a virus only control. Matrices are imported into SynergyFinder and analyzed Neutralization synergy was calculated by comparing treatment to virus only control wells. Values were imported into SynergyFinder software[35] using a

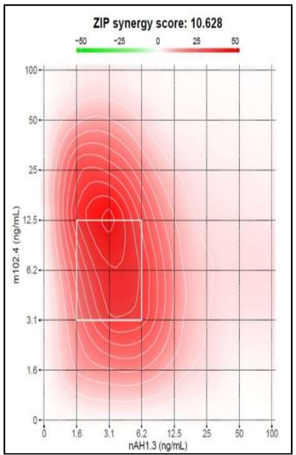

Figure 2. Synergy map with calculated synergy score using the zero interactions potency (ZIP) model generated by SynergyFinder for neutralization of rCedV-NiV-B-GFP by serially diluted m102.4 and nAH1.3 mAbs.

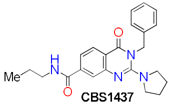
Zero Interactions Potency (ZIP) statistical model; delta scores >10 indicate likely synergy as m102.4 and nAH1.3 indicate here.

Antiviral evaluation and combination testing of small molecules and nanobodies. These rCedV-based tools and rCedV chimera viruses will allow for rapid antiviral activity assessment and an ability to measure synergistic antiviral activities for both small molecule inhibitors derived from **Aim 1** and nanobodies derived from **Aim 2**; and will also allow the novel approach of testing small molecules and nanobody combinations in a rapid and quantitative manner, in vitro, to select best-in-class candidates for both monotherapeutic and combination therapeutic modalities prior to in vivo animal model testing.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called "SMART Set") was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM.

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.



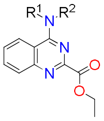
CBS1437

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (µM)	CC_{50} (µM)	EC_{50} (µM)	CC_{50} (µM)	EC_{50} (µM)
0.70	100	2.1	100	3.3

In **Table 2** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437**. Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM).

Table 3 shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14,** bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent,* ***CBS1437****, as well as specific plans for developing the SARs.*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.



N	Compound ID	R^1	R^2	% inhib at 10 µM
1	**G577-0014**	H	3-chloro-4-methoxyphenyl	81
2	**G577-0016**	H	2,4-difluorophenyl	18
3	**G577-0021**	H	2-chloro-4-fluorophenyl	58
4	**G577-0022**	H	3-methoxyphenyl	46
5	**G577-0028**	Me	cyclohexyl	93
6	**G577-0084**	H	4-isopropylphenyl	85
7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
8	**G577-0112**	Me	2-methylphenyl	94

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 μM) and low cytotoxicity (CC_{50} >100 μM).

D1.1. Synthetic Chemistry. In **Figure 3** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**F577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. In addition, we will optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be more chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a brief synopsis of the general method used for the synthesis of 4-aminoquinazolines. The specific procedures for the three steps vary, but all initiate with anthranilamides. This general route will allow us to prepare compounds with varied R_1, R_2 and R_3 groups as well as compounds with substituents that replace the carboethoxy functionality at the 2-position. Several anthranilamides are commercially available, which will allow us to initially access starting materials with a variety of R_3 groups. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[36-37] as well as other methods.[38,39] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.

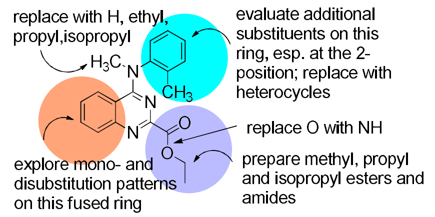


Figure 3. SAR development for 4-aminoquinazolines

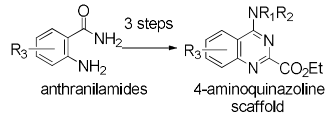
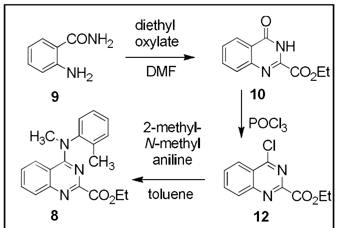


Scheme 1. General synthesis for 4-aminoquinazolines.



Scheme 2. Synthesis of **G577-0112** (cmpd **8**).

In **Scheme 2** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) produces 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline.

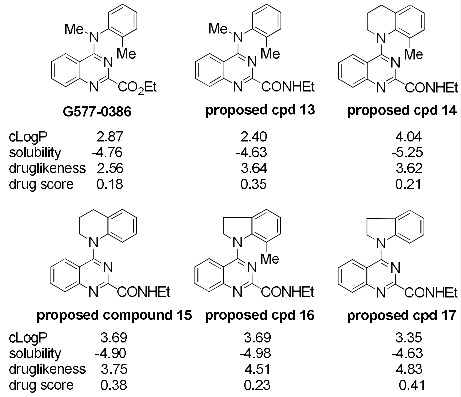


Figure 4. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

In **Figure 4** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[40]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester to an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scres have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding.

In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. Additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

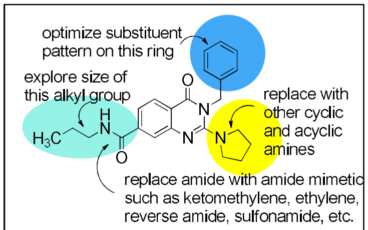

Figure 5. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5 x 10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation (PerkinElmer, Waltham, MA) as per the manufacturer's instructions. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T cells and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of > 150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. *Hit Selection Algorithm.* A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSV-G-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (potent inhibitor, EC_{50} less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. *Hit Validation, Cytotoxicity Assessment and Ranking.* We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" (Promega, Madison, WI) as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. *Hit Quality Control and Identity Assurance.* The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds found to be <80% pure will be purified and retested.

D.1.3. Evaluation of protective properties of the advanced candidates in the henipavirus infectious assays will be done as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2 × 10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to that from parallel cultures with virus and DMSO vehicle only. This work will be performed in the BSL-4 facility at UTMB by the **Geisbert Lab (Core ?)** .

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Gaisina and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy based on a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or the additional HTS hits identified with the HTS of the expanded libraries of compounds for defining lead compounds for advancement.

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with cell growth medium containing either DMSO or selected furopyrimidines at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by standard western blot techniques or viral RNA levels by quantitative real time polymerase chain reaction assays (q-RT-PCR). CedV specific antibodies against the attachment (G) and fusion (F) that were generated in the Broder Lab and antibodies to CedV-N and CedV-P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene. The one-step reaction will be performed using the Applied Biosystems (ABI) 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus. *Target identification for small molecules.*** The rCedV tools used in the small molecule inhibitor identification assays (**Aim 1**) can also be exploited for antiviral target identification. In vitro selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutant viruses. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[41,42] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a “drug resistant” virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any “drug resistant” virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L polymerase gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inibitors using authentic NiV-B and HeV in BSL-4 by the UTMB Core.

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The Nipah polymerase (L protein and a phosphoprotein P) will be prepared using a previously published protocol. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[43] Prefusion-stabilized RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab**.

D.2.3. Structure determination of recombinant proteins with bound inhibitors by X-Ray crystallography and CryoEM. High-resolution structures of the Nipah RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compound to be developed will be obtained using both x-ray crystallography and CryoEM by Dr. Vessler Lab. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. Initial crystallization screens will be set up robotically using in-house Gryphon crystallization robotics. Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization. X-ray data collection will be done where? Crystal structures will be determined by molecular replacement using existing structures as search models. For inhibitors binding to regions other than above or if co-crystals cannot be obtained, cryo-EM will be used to determine the complex structure. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[44] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including cryoSparc[45], EMAN[46], and RELION[47]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed by molecular dynamics (MD) studies. While cryo-EM can provide access to the near-atomic resolution structures of large biomolecular systems--in their near native environment, MD can be used to reveal its dynamic behavior and refine low-resolution regions of cryo-EM reconstructions[48,49]. Furthermore, as X-ray/cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[50-54], to explore the conformational landscape[55] of ligand binding events, and to capture conformational variability of intermediate states[48,56], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches. David, please look at this section. Make necessary corrections.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp., Woburn, MA) to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[57] Compounds with IC_{50} values ≥100 μM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[58] Compounds with >30% recovery (1 h) will be considered

for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed in a [^{3}H] dofetilide-binding assay as described by Finlayson *et al.*[59] using SHSY5Y cells. Compounds that do not prevent [^{3}H]dofetilide binding (IC$_{50}$ >10 μM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method as described by Gres *et al*.[60] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P$_{app}$) greater than 1 × 10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian chromosomal aberration test**: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C$_{0}$, C$_{max}$, T$_{1/2}$, T$_{max}$, and F(%) will be determined. Depending on the estimation of T$_{max}$, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

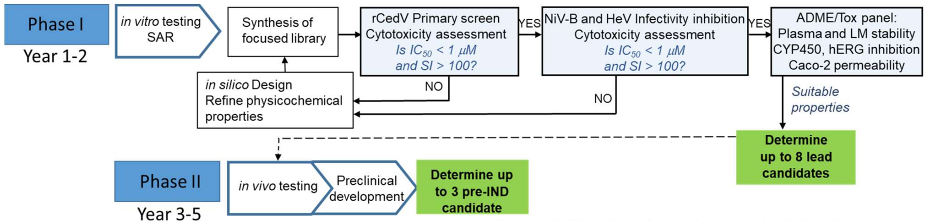

Figure 4. Flowchart for henipavirus inhibitor development

Will be MODIFIED **Figure 5**

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 5**).

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. Aim 1 will also collaborate with the core??? to evaluate lead candidates *in vivo*.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including Nipah virus (Bangladesh and Malaysia strains) and Hendra virus (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[61-63] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with Nipah and Hendra virus glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit Nipah virus and Hendra virus, we will use a high-throughput neutralization assay developed in the Broder lab. This assay is based on green fluorescent protein (GFP)-encoding, replication-competent, Cedar (henipa)virus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bangladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins.[7,64] This platform is safe, enabling utilization at BSL2 compared to BSL4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the Broder lab recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described Hendra virus variant.[65] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond Nipah and Hendra viruses (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[66,67]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against Nipah virus and Hendra virus. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The Veesler lab is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The Veesler lab has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software which runs 24 hours per day and enables automated targeting and image acquisition while keeping a relational database of all micrographs to expedite subsequent processing.[68] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[44,69] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[61,63,70-72] mechanical stage tilting with gold grids[73,74] or detergents to modify surface tension[75]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[73,76-80] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[81-83]

The Nipah virus attachment (G) glycoprotein engages host receptors, is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the Nipah virus G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some of the nanobodies might bind to regions that are intrinsically flexible thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[84] and BUSTER-TNT[85].

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[61-63,71,86,87]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[88-90] and high-resolution noise substitution prior to Fourier shell correlation calculations[91] to avoid overfitting. Atomic models will be assessed using Molprobity[92], EMringer[93] and Privateer[94]. The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[95-97] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected in vivo, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in Aim 2A. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with Core D to evaluate lead candidates *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in a well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster (refs) and AGM (refs). PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by Core D. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of heniavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV_B or HeV (refs). Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antivirals fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV (refs). Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.5.4. Combination therapy of anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^5$ PFU of NiV or HeV (refs). Treatment with at least two different antivirals will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ $5x10^6$ PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by Core D (see Core D). Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by Core X (see Core X) at various times after henipavirus infection.

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the MAD system as previously described (ref) or by small particle aerosol as previously described (refs) with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV. The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by Core X up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that Core X may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antivirals may not improve protective efficacy or extend the therapeutic window of antivirals. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and monoclonal antibodies to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of Nipah virus infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next Nipah virus outbreaks. We have discovered two differentiated series of compounds that show early promise as agents that have potential for treating Nipah virus infections, and we have designed a series of optimized druglike candidates for future preparation and development.

Irina, Lijun

try putting this rCedV tools into the preliminary data
it covers chimeras to replace the published rCedV-Luc description and existing figure 1 which we should remove. the chimera prelim data supports high throughput nanobody assessment, and synergy assay (which can be mentioned in Aim 1 drugs, and Aim 2 nanobodies.

also there is some text for resistance selection and genome sequencing for target identification if needed somewhere

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and also aerosol delivery of nanobodies. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

Over the past 40 years the major etiological agents of emerged or identified infectious diseases in humans have been viruses.[11] Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV)[12,13]. In 1994, HeV caused an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer.[14,15] NiV was the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998. Spread of NiV infections typically requires direct contact with an infected source, and transmission can occur between people and from animals to people. Symptoms may culminate in a severe respiratory and/or neurological disease that is often fatal. Complications of the infection can result in relapsed encephalitis following recovery. On September 5, 2021, a twelve-year-old boy in the Indian state of Kerala died after contracting the Nipah virus. During the process of transporting him to medical centers for a diagnosis, twenty-three health care workers exposed to this boy also died, which underscores both the transmissability and the lethal nature of this virus. *There is presently no vaccine or small molecule therapeutics that have been developed for NiV infections.* Pteropid bats appear to be the major reservoir hosts for henipaviruses[6,16]. HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%[2,17].

NiV and HeV are classified as biosafety level-4 (BSL-4) restricted pathogens and both remain transboundary threats to livestock and people throughout South Asia and Australia. NiV and henipaviral diseases have been categorized by the World Health Organization (WHO) as an epidemic threat needing urgent research and countermeasure development and are included in the WHO R&D Blueprint list of priority pathogens with epidemic potential [18]. Presently, there are no prophylactic or therapeutic treatment options for henipavirus infections approved for use in humans. A subunit vaccine, Equivac® HeV, has been available for use in horses in Australia since 2012 [19] for the prevention of HeV infection. This equine vaccine received full registration by the Australian Pesticides and Veterinary Medicines Authority in 2015, with all vaccinated horses receiving a microchip with a database being maintained and is the first commercially deployed vaccine against a BSL-4 agent [20]. Although a human monoclonal antibody (mAb) m102.4 has successfully completed a phase I safety trial in Australia [21], developing vaccines or therapeutics against henipaviruses for use in people remains a high priority. Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of several vaccine strategies[2]. Although an effective post-exposure human monoclonal antibody (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been extensively examined[22-26], it must be administered within several days following lethal infection in animal challenge models. In contrast, however, antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of biosafety level-4 (BSL-4) containment. Recently, a third isolate, namely, Cedar virus (CedV) has been added to the *Henipavirus* genus[27]. However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease and resides in nature in the same bat host species as HeV[27,28]. Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences[29,30], but HeV, NiV, and CedV are the only virus isolates reported.

We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and have identified several inhibitory compounds that were further validated with the infectious NiV-Bangladesh (NiV-B) strain. The validated compounds provide the foundation for the current application.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice

that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole inactivated NiV or HeV immune sera will show cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G glycoprotein antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins. [27] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and it is also the largest polymerase in the order *Mononegavirale*, yet it still shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; the aa identities of the important L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This high degree of protein identity, overall, shared between CedV, and that of NiV and HeV, suggests that antiviral agents that target for example, the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus antiviral countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Indeed, several small molecule inhibitors have been validated in vitro using infectious HeV and NiV in BSL-4, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support Aim 1 to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[31-33] Nanobodies can be isolated using the same phage library construction methods and phage panning procedure routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. In collaboration with **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels, [10] we have several immunized mouse cohorts now underway using native-like oligomeric recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in Aim 2 in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of Aim 3. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in Aim 3. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company

engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule entry inhibitors of Nipah.

C.2.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2 containment), cell-based HTS platform to identify small molecule antivirals targeting henipavirus replication without the requirement for BSL-4 containment. A reverse genetics approach was used to generate rCedV expressing luciferase (rCedV-Luc). A firefly luciferase (Luc) gene was inserted between CedV P and M genes in the rCedV anti-genome clone by standard restriction digest and ligation methods to yield the luciferase reporter rCedV full-length genome plasmid (**Figure 1A**). Successful rescue of rCedV-Luc was demonstrated by observing multiple syncytia on Vero E6 cells inoculated with freeze-thawed cell culture supernatants from BSR-T7/5 cells transfected with rCedV-Luc anti-genome and helper plasmids (yellow box in **Figure 1B**). The growth kinetics of rCedV-Luc to rCedV was compared (**Figure 1C**). Vero E6 cells were infected with either rCedV or rCedV-Luc at an MOI of 0.01. At 24 h intervals, supernatants from infected cells were collected and analyzed by plaque assay for infectious viral titers. At all-time points examined, no statistically significant differences were observed between rCedV and rCedV-Luc, indicating that the recombinant viruses have similar growth kinetics. In parallel, infected cells were lysed and analyzed for intracellular luciferase activity. As seen in **Figure 1C** (blue axis), increasing luciferase activity was detected that reached saturation at ~1 × 108 relative luciferase units (RLU) at 72 hpi (blue dashed line). The increase in luciferase signal correlated with the increase in infectious viral titers. These results indicated that introduction of the luciferase reporter gene did not interfere with the growth of the recombinant virus and that luciferase activity is an indicator of viral genome expression.

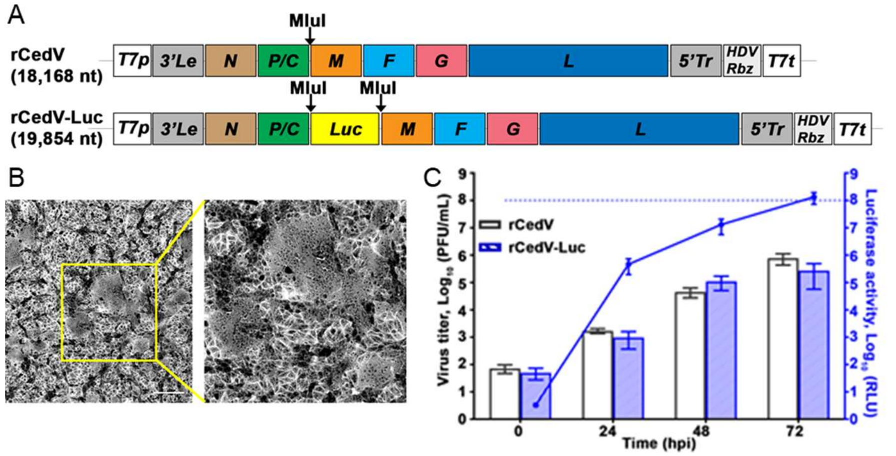

Figure 1. Characterization of recombinant CedV expressing luciferase. A) The firefly luciferase (*Luc*) gene was inserted at the unique MluI restriction site between the *P* and *M* genes to produce rCedV-Luc. B) Vero E6 cells infected with rCedV-Luc C) Vero E6 cells infected with either rCedV or rCedV-Luc at an MOI of 0.01. At 0, 24, 48 and 72 hpi. Viral titers determined by plaque assay and calculated as PFU/ml

Table 1. High throughput screening assay parameters

Assay Parameters	96-well format	384-well format
Z'	0.6 ± 0.02	0.5 ± 0.2
%CV	13.3 ± 1.14	14 ± 0.05
S/B	$> 10^3$	> 40

Table 2. Inhibition of rCedV and NiV-B by the HTS hit **CBS1437**.

CedV (293T)		CedV (Vero)		NiV-B (Vero)
EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)	CC_{50} (μM)	EC_{50} (μM)
0.70	100	2.1	100	3.3

The optimization of cell type, virus MOI, and incubation time was conducted to develop an assay suitable for HTS antiviral screening is described in our recently published manuscript.[7] Shown in **Table 1** are the results of further optimization of the HTS assay and resulting parameters in both 96- and 384-well formats. Z' scores ≥ 0.5, high S/B ratios and CV < 20% were recorded, indicating a robust sensitive high-throughput assay. These data demonstrated that the rCedV-Luc platform is suitable for HTS-based hit identification.

C.2.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from ChemDiv library by the UIC medicinal chemists and called “SMART Set”) was used for a pilot HTS to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative analogs for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 μM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 μM, and 47 hits showed only minimal cytotoxicity at 33 μM.

In **Table 1** is shown a representative quinazoline compound from our quinazoline series of rCedV inhibitors, designated as **CBS1437** (**Table 2**). Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Compound **CBS1437** was also evaluated in the infectious NiV (NiV-B) assay and found to have an EC_{50} value of 3.3 µM. An important reason for producing the data shown in **Table 2** was to validate the primary screening data that was gathered from the rCedV HTS assay. Thus, we concluded that our HTS approach was a valid method for defining NiV inhibitors. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein. This hit showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5 (0% inhibition at 12.5 µM).

Table 3 shows eight additional inhibitors in the quinazoline series, namely 4-aminoquinazolines, that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 3**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **14,** bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **14** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the two *n*-propyl compounds (**16** and **18**) are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, which may be worth exploring with a larger set of derivatives. It is clear that additional compounds in our 4-aminoquinazoline series (**Table 3**) would provide excellent opportunities for further optimization of the inhibitory activities. *In the Research Plan we discuss methods for the preparation of new 4-aminoquinazolines in addition to compounds in a backup series defined by our validation agent,* ***CBS1437****, as well as specific plans for developing the SARs.*

Table 3. Antiviral activity of 4-amino-quinazoline-2-carboxylates **1-8** in the rCedV luciferase reporter virus assay.

	N	Compound ID	R^1	R^2	% inhib at 10 µM
	**1**	**G577-0014**	H	3-chloro-4-methoxyphenyl	81

	4	**G577-0022**	H	3-methoxyphenyl	46
	5	**G577-0028**	Me	cyclohexyl	93
	6	**G577-0084**	H	4-isopropylphenyl	85
	7	**G577-0111**	*n*-propyl	4-fluorophenyl	86
	8	**G577-0112**	Me	2-methylphenyl	94

C3. Any data on monobodies?

D. RESEARCH DESIGN AND METHODS

D1. Aim 1A. Synthesize diverse analogs of the 4-aminoquinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 µM) and low cytotoxicity (CC_{50} >100 µM).

D1.1. Synthetic Chemistry. In **Figure 2** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **8** (**F577-0112**). Substituent changes on the core fused scaffold will involve exploration of mono- and disubstitution substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. In addition, we will optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be more chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 1** is shown a brief synopsis of the general method used for the synthesis of 4-aminoquinazolines. The specific procedures for the three steps vary, but all initiate with anthranilamides. This general route will allow us to prepare compounds with varied R_1, R_2 and R_3 groups as well as compounds with substituents that replace the carboethoxy functionality at the 2-position. Several

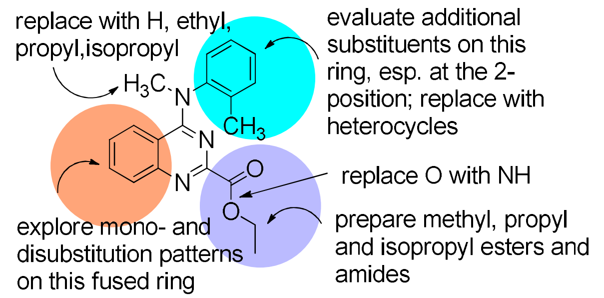

Figure 2. SAR development for 4-aminoquinazolines

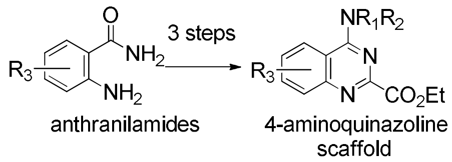
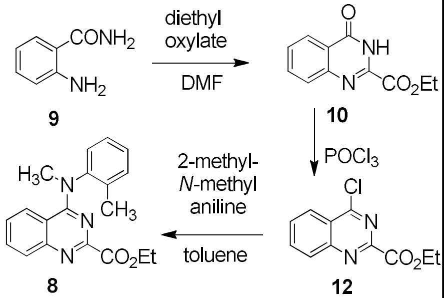
anthranilamides are commercially available, which will allow us to initially access starting materials with a variety of R_3 groups. A variety of methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[34-35] as well as other methods.[36,37] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible.



Scheme 1. General synthesis for 4-aminoquinazolines.

In **Scheme 2** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **9** is heated with diethyl oxalate in a solution of dimethylformamide (DMF) produces 2-carboethoxyquinazoline-4-one (**10**) in a condensation/cyclization process. Treatment of **10** with phosphorous oxychloride next provides a reactive intermediate, namely 2-carboethoxy-4-chloroquinazoline-4-one (**12**), which affords the specific inhibitor **G577-0112** (compound **8**) after a displacement reaction with 2-methyl-*N*-methylaniline.



Scheme 2. Synthesis of **G577-0112** (cmpd **8**).

In **Figure 3** is shown a set of proposed compounds related to **G577-0112** (compound **8**) for which we show parameters calculated using Actelion OSIRIS software[38]. The proposed compounds (**13** through **17**) generally show improved druglikeness and drug scores (and other parameters) with respect to **G577-0112** (compound **8**), and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester to an amide by substituting NH for O, to provide proposed new compound **13**. In progressing through the constrained compounds **14** through **17**, improvement of parameters culminates with the indoline derivative **17**, whose druglikeness and druglike scres have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **14** and **15** and indolines **16** and **17**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding.

	G577-0386	**proposed cpd 13**	**proposed cpd 14**
cLogP	2.87	2.40	4.04

drug score	0.38	0.23	0.41

Figure 3. Proposed inhibitors of rCedV based on Actelion OSIRIS predicted parameters.

In **Figure 4** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 4**, since amides are subject to metabolic cleavage. Additional synthetic methods are available for the construction of both 4-aminoquinazolines and 2,3,7-trisubstituted quinazolin-4-ones.

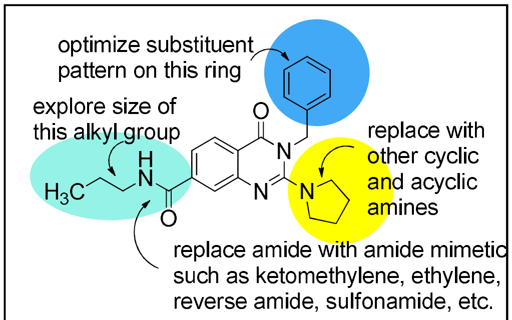

Figure 4. SAR development for **CBS1437**.

D.1.2. Evaluate efficacy of various derivatives in the 4-aminoquinazoline and the quinazolin-4-one series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5 x 10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation (PerkinElmer, Waltham, MA) as per the manufacturer's instructions. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T cells and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in the **Broder Lab.**

Screening Libraries. These libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of > 150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be purchased by **Chicago BioSolutions, Inc**. _Hit Selection Algorithm._ A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSV-G-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (potent inhibitor, EC_{50} less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. _Hit Validation, Cytotoxicity Assessment and Ranking._ We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" (Promega, Madison, WI) as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. _Hit Quality Control and Identity Assurance._ The hits will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds found to be <80% pure will be purified and retested.

D.1.3. Evaluation of protective properties of the advanced candidates in the henipavirus infectious assays will be done as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2×10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to that from parallel cultures with virus and DMSO vehicle only. This work will be performed in the BSL-4 facility at UTMB by the **Geisbert Lab (Core ?)** .

Pitfalls and alternate strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Gaisina and Moore.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy based on a different reaction sequence. Should we encounter a scaffold-related problem with our 4-aminoquinazoline scaffold, we will switch to our backup quinazolin-4-one scaffold or the additional HTS hits identified with the HTS of the expanded libraries of compounds for defining lead compounds for advancement.

D.2.1. Aim 1B. Investigate the mechanism of action (MOA) of the replication inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: **1) Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells**. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with cell growth medium containing either DMSO or selected furopyrimidines at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by standard western blot techniques or viral RNA levels by quantitative real time polymerase chain reaction assays (q-RT-PCR). CedV specific antibodies against the attachment (G) and fusion (F) that were generated in the Broder Lab and antibodies to CedV-N and CedV-P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene. The one-step reaction will be performed using the Applied Biosystems (ABI) 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; **2) Determine the stage(s) of inhibition of 4-aminoquinazolines and quinazolin-4-ones in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; **3) Analyze escape mutants against the advanced lead compounds with Cedar virus.** Escape mutants provide information on potential targets of small molecule inhibitors as well as the potential for development of drug resistance in the field. We will generate escape mutant rCedV viruses that are resistant to the identified lead compounds and determine the rate at which resistance is developed to our inhibitors. In so doing, we will also identify protein coding as well as regulatory sequences that are altered. HEK293T cells will be infected with rCedV virus at MOI of 1 in the presence of the inhibitors at 10 times the IC_{50} values of each of the compounds. At 72 hpi, viral supernatant will be passaged in Vero cells at MOI of 0.01 in the presence of increasing concentrations of compound for >5 passages to obtain the escape mutants. The escape mutants will be plaque purified and subjected to whole-genome sequencing. The identified mutation(s) will be introduced into the rCedV anti-genome cDNA and upon successful incorporation of the mutation, the mutant rCedV will be rescued and sequenced to ensure retention of the introduced mutation. The rescued mutant rCedV will be fully characterized as described.[8]

D.2.2. Assess the binding properties by surface plasmon resonance (SPR). The Nipah polymerase (L protein and a phosphoprotein P) will be prepared using a previously published protocol. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[39] Prefusion-stabilized RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (0.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab**.

D.2.3. Structure determination of recombinant proteins with bound inhibitors by X-Ray crystallography and CryoEM. High-resolution structures of the Nipah RdRp complex with key inhibitors such as **CBS1437** and the advanced lead compound to be developed will be obtained using both x-ray crystallography and CryoEM by Dr. Vessler Lab. It is expected that these structures will be determined and will reveal the atomic level details of how our inhibitors interact with the polymerase and inhibit its activity, which will be highly informative for developing potent high-affinity ligands. Initial crystallization screens will be set up robotically using in-house Gryphon crystallization robotics. Biophysical techniques such as native mass spectrometry and thermal shift assays, light scattering, and fluorophore analysis to measure protein stability and folding are routine and will be used to ensure that bound compounds are not destabilizing domain structures to prevent crystallization. X-ray data collection will be done where? Crystal structures will be determined by molecular replacement using existing structures as search models. For inhibitors binding to regions other than above or if co-crystals cannot be obtained, cryo-EM will be used to determine the complex structure. For EM studies, we will utilize automated data collection software to facilitate throughput. In brief, data will be processed using the Appion[40] pipeline, which keeps track of all data and processing steps. All data will be processed using multiple single particle EM software packages, including cryoSparc[41], EMAN[42], and RELION[43]. Purified complexes will be deposited onto grids, blotted, and cryo-plunged into liquid ethane to preserve them in a thin layer of vitreous buffer. Images of the complexes will be collected using automated image acquisition software under low dose conditions. Structures generated by cryo-EM will be refined and reconstructed by molecular dynamics (MD) studies. While cryo-EM can provide access to the near-atomic resolution structures of large biomolecular systems--in their near native environment, MD can be used to reveal its dynamic behavior and refine low-resolution regions of cryo-EM reconstructions[44,45]. Furthermore, as X-ray/cryo-EM structures of polymerase in complex with key inhibitors (i.e., **CBS1437** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[46-50], to explore the conformational landscape[51] of ligand binding events, and to capture conformational variability of intermediate states[44,52], which can be crucial to gain mechanistic knowledge of biological function, but remain out of reach through experimental approaches. David, please look at this section. Make necessary corrections.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Broder, Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory 4-aminoquinazolines or quinazoline-4-ones.

D.3. Aim 1C. Evaluation of pharmacokinetics/toxicokinetics of the advanced lead compounds. *Milestone: Designate **advanced lead compounds** exhibiting optimal ADME properties in vitro: stability to liver microsomes, low CYP isoform inhibition, Caco-2 permeability, and devoid of hERG channel affinity. Before investigating the efficacy of the compounds in vivo (Aim 3), PK studies will be performed to determine an optimal dosing regimen for the efficacy studies with the **advanced lead compounds**.*

D.3.1. Select NiV-B inhibitors with *in vitro* ADME properties suitable for whole animal testing.
Rationale: Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. We will assess several critical *in vitro* ADME-T properties and prioritize compounds accordingly. **CYP450 inhibition.** The CYP450 inhibition assays will be carried out using the CYP3A4, and CYP2D6 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp., Woburn, MA) to rapidly screen for potential inhibitors of the principal drug metabolizing cytochrome P450 enzymes.[53]

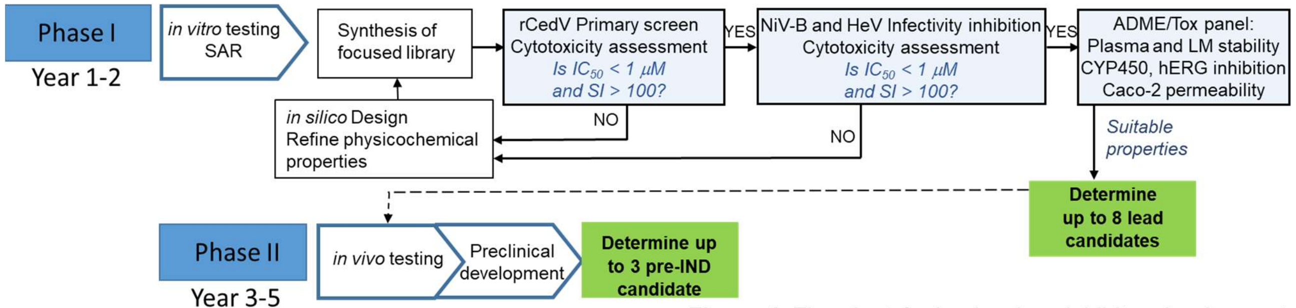

Figure 4. Flowchart for henipavirus inhibitor development

Will be MODIFIED **Figure 5**

Compounds with IC$_{50}$ values ≥100 µM for CYP isoforms will be prioritized for further advancement. **Rat/Human Liver Microsome Stability**. Rat and human liver microsome preparations will be used to evaluate the metabolic stability of compounds by the method of Kuhnz *et al*.[54] Compounds with >30% recovery (1 h) will be considered for further advancement. **hERG channel blockade.** The ability of compounds to block the hERG channel will be assessed in a [^{3}H] dofetilide-binding assay as described by Finlayson *et al.*[55] using SHSY5Y cells. Compounds that do not prevent [^{3}H]dofetilide binding (IC$_{50}$ >10 µM) will advance. **Cellular permeability.** Drug absorption through the intestinal epithelium is critical to good oral bioavailability. We will use the Caco-2 method as described by Gres *et al*.[56] to evaluate the potential for oral bioavailability of the lead inhibitors. Compounds exhibiting a Caco-2 permeability value (P_{app}) greater than 1×10^{-6} cm/sec will be prioritized. **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels of the compound up to a solubility-limiting level in the presence or absence of rat liver enzymes (rat S9 liver fraction) acting in the normal process of metabolism and any reverse mutations will be determined. ***In vitro* mammalian**

chromosomal aberration test: The purpose of this study is to evaluate the clastogenic potential of the compound based on its ability to induce chromosome aberrations in human peripheral blood lymphocytes.

D.3.2. PK studies: Naïve male/female mice (equal number, 3 groups of 36 animals total) will be treated with a single dose via i.v., i.p., or oral gavage administration and blood will be collected and processed to obtain plasma and serum from three animals/group/time point at up to 12 time points through 24 h post dose. Two doses will be used to establish the drug exposure-dose range relationship: the estimated efficacious dose (ED), based upon preliminary data at 25 mg/kg i.p. or p.o. and an observable adverse effect dose (OAED) (to be determined). Compounds of interest will be extracted from biological specimens by protein precipitation, analyzed on a triple-quadruple mass spectrometer (LC-MS/MS) and quantified using an internal standard method with a minimum of a five-point calibration curve. PK parameters including AUC, C_0, C_{max}, $T_{1/2}$, T_{max}, and F(%) will be determined. Depending on the estimation of T_{max}, PK study time points can be further adjusted to reach more accurate calculations of AUC. Plasma concentration will be established to support dosage selection for efficacy studies. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

Potential Pitfalls and Alternative Strategies. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc. and Reaction Biology, Corp., and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim.

We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds**, which will allow for the future selection of a preclinical candidate (**Figure 5**).

D.4. AIM 2: Characterization of the potency and breadth of selected nanobodies

Rationale: Aim 2A will investigate the binding properties, cross-reactivity and inhibition of the nanobodies targeting henipavirus F and G glycoproteins to assess potency and breadth of neutralization. Aim 1 will also collaborate with the core??? to evaluate lead candidates *in vivo*.

D.4.1. AIM 2A. Evaluation of nanobody cross-reactivity, neutralization potency and breadth

D.4.1.1. ELISA and biolayer interferometry assessment of cross-reactivity. The **Veesler lab** has a panel of prefusion-stabilized F ectodomain trimers and G ectodomain tetramers recombinantly expressed in mammalian cells, including Nipah virus (Bangladesh and Malaysia strains) and Hendra virus (both ancestral and the newly described variant) with and without avi-tag for biotinylation.[57-59] These proteins were used to vaccinate transgenic mice for nanobody production and will be used for downstream screening of the nanobody libraries and for exploring cross-reactivity with Nipah and Hendra virus glycoproteins and with more distantly related henipaviruses using high-throughput ELISA assays. Biolayer interferometry analysis of binding kinetics and affinity will be carried out for the most promising nanobodies selected by ELISAs to enable ranking them based on binding affinities and cross-reactivity.

D.4.1.2. Chimeric virus neutralization assays. To evaluate the ability of the nanobodies to inhibit Nipah virus and Hendra virus, we will use a high-throughput neutralization assay developed in the Broder lab. This assay is based on green fluorescent protein (GFP)-encoding, replication-competent, Cedar (henipa)virus (rCedV) chimeras in which the native glycoproteins are substituted with the NiV-B (rCedV-NiV-B-GFP, Bengladesh strain) or the HeV (rCedV-HeV-GFP) F and G glycoproteins.[7,60] This platform is safe, enabling utilization at BSL2 compared to BSL4 for authentic viruses, and has been thoroughly validated and shown to faithfully recapitulate the data obtained with NiV-B and HeV with both monoclonal antibodies and vaccine-elicited polyclonal sera. This method was used to support the preclinical development of G-specific antibodies[5]. Furthermore, the Broder lab recently developed a rCedV-HeVv-GFP using reverse-genetics to study the antigenic properties of a newly described Hendra virus variant.[61] These assays will enable ranking each nanobody based on their neutralization potency and breadth to assist downstream selection. For nanobodies for which cross-reactivity will be detected beyond Nipah and Hendra viruses (e.g. CedV), their inhibitory activity will be tested against authentic CedV. Finally, these chimeric virus neutralization assays can be implemented for viruses for which no isolates are available (as is the case for henipaviruses discovered through metagenomics in bats or other animals).[62,63]

Rigor and reproducibility. All plasmids are purchased from Genescript and delivered with sequencing certificates. Each batch of recombinant glycoprotein and pseudovirus is quality-controlled based on reactivity with or inhibition by well-characterized reagents such as monoclonal antibodies and electron microscopy imaging. All data will be obtained using multiple replicate measurements using independent batches of proteins and viruses and performed by multiple individuals to ensure the reproducibility of our assays.

Anticipated results. This aim will assist the selection of the most promising individual nanobodies with broad and potent neutralizing activity against Nipah virus and Hendra virus. The top candidates will be further studied structurally and functionally and evaluated for *in vivo* efficacy.

D.4.2. AIM 2B: Studies of molecular basis of nanobody-mediated viral inhibition

Rationale: Aim 2B will explore the structural basis of target recognition by the nanobodies to provide an atomic-level understanding of binding and inhibition which will be validated using functional assays. This structural framework will be used to guide the design of nanobody cocktails with enhanced neutralization potency, breadth and resistance to escape mutations. The Veesler lab is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with NiV or HeV F and G glycoproteins to visualize recognition at the atomic level and inform further optimization of target binding affinity. The Veesler lab has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software which runs 24 hours per day and enables automated targeting and image acquisition while keeping a relational database of all micrographs to expedite subsequent processing.[64] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[40,65] Complexes of nanobodies with glycoproteins will be vitrified and imaged using cryoEM to visualize directly the epitopes targeted by the different nanobodies. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[57,59,66-68] mechanical stage tilting with gold grids[69,70] or detergents to modify surface tension[71]. Some of the nanobodies might not recognize the glycoproteins rigidly leading to conformational heterogeneity and dampened resolution. We will overcome this using workflows developed in-house specifically for that purpose for previously characterized miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[69,72-76] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[77-79]

The Nipah virus attachment (G) glycoprotein engages host receptors, is the basis of a commercially available horse vaccine and entered phase I clinical trials for use in humans with funding from the Coalition for Epidemic Preparedness Initiatives. The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the Nipah virus G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

D.4.2.1. High-resolution structural studies using X-ray crystallography. Some of the nanobodies might bind to regions that are intrinsically flexible thereby limiting resolution using cryoEM. We have already encountered such cases with coronavirus fusion machinery-directed antibodies binding to linear epitopes in the spikes. We will overcome these challenges by determining high-resolution crystal structures of the nanobodies bound to their cognate epitopes, similar to the strategy we used to obtain structural information of the B6 and S2P6 antibodies bound to several β-coronavirus stem helices. Refinement of atomic models will use both Phenix[80] and BUSTER-TNT[81].

D.4.2.2. Functional analysis of nanobodies. The mechanism(s) of viral inhibition of each nanobody inferred from the the structural data will be validated using receptor binding, F cleavage and membrane fusion assays we previously implemented for henipaviruses and coronaviruses.[57-59,67,82,83]

Potential Pitfalls and Alternative Strategies. In the unlikely event we encounter protein complexes that cannot be vitrified using any of the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which has been specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). This device is available at the UW Arnold and Mabel Beckman cryoEM center, which **Dr. Veesler** co-directs.

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the formulation of cocktails. This work will also demonstrate the mechanism(s) of action of nanobodies leading to inhibition of viral entry.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[84-86] and high-resolution noise substitution prior to Fourier shell correlation calculations[87] to avoid overfitting. Atomic models will be assessed using Molprobity[88], EMringer[89] and Privateer[90]. The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the designed nanobodies and their targets which will enable iterative optimization of binding affinity, cross-reactivity and the design of nanobody cocktails.

D.4.3. AIM 2C. Structure-guided formulation of nanobody cocktails

Rationale: The formulation of mAb cocktails has become a widely used and successful approach to prevent or treat infections with RNA viruses. For instance, although the individual Regeneron 10933 (casirivimab) and 10987 (imdevimab) mAbs are affected by a range of residue substitutions detected in SARS-CoV-2 clinical isolates, the two-mAb cocktail proved more resilient to escape mutations.[91-93] Because experimental passaging of NiV and HeV with low concentrations of neutralizing mAbs can favor the emergence of neutralization escape mutants, although none were ever detected in vivo, we will formulate and test neutralizing nanobody cocktails that targets multiple, yet distinct and conserved, antigenic sites on the NiV and HeV F and G glycoproteins.

The separation of receptor engagement and membrane fusion functions on two distinct glycoproteins represent a unique opportunity for implementing multi-pronged targeting which has not been evaluated previously. We will combine multiple, distinct F-specific, G-specific and F/G-specific nanobodies based on classification of their antigenic sites resulting from our structural studies, biolayer interferometry and competition ELISA data. CedV chimera-based neutralization assays will be used to characterize the cocktails and compare them side-by-side to individual constituting nanobodies with matched composition, as described in Aim 2A. Readouts for down-selection will include maximal neutralization potency and breadth and structural characterization will be used to ensure that multi-pronged binding occurs as designed and to guide future rounds of optimization if necessary.

Anticipated results. The outcome of this aim will be the generation and down-selection of nanobody cocktails with broad and potent neutralizing activity against NiV and HeV ready to be tested for *in vivo* protection.

D.5. AIM 3: Evaluation of lead compounds *in vivo*.

Rationale: Aim 3 will collaborate with Core D to evaluate lead candidates *in vivo*. A critical aspect of antiviral discovery that is often overlooked is the early stage testing of lead compounds in a well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster (refs) and AGM (refs). PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs and nanobodies will be used in NiV_B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV_B and HeV infected AGM models.

D.5.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed by Core D. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of heniavirus disease. Lead compounds which demonstrate good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will be used to select doses and dosing regimens for the subsequent protection studies in AGMs.

D.5.2. *In vivo* testing of lead compounds NiV/HeV infected hamsters. The *in vivo* activity of the most potent compounds from Aims 1 and 2 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 pfu of NiV_B or HeV (refs). Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs or nanobodies. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for further analysis in the Subaims below.

D.5.3. Define breakthrough conditions for anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising drugs from Aim 1 and nanobodies from Aim 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antivirals fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^6$ PFU of NiV or HeV (refs). Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.5.4. Combination therapy of anti-henipavirus antivirals in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 where breakthrough conditions have been defined in D.5.3. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ $5x10^5$ PFU of NiV or HeV (refs). Treatment with at least two different antivirals will be administered beginning at a time point where substantial breakthrough was shown in D.5.3 for each individual antiviral in D.5.3 to determine if combining at least two different antivirals improves survival. Group sizes may be increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

D.5.5. Evaluation of aerosol delivery of antivirals against aerosol exposure in hamsters. This subaim will employ the most promising antivirals from Aims 1 and 2 individually or in combinations to determine 1) if aerosol delivery can improve efficacy or extend the therapeutic window versus parenteral delivery and 2) if antivirals can protect against small particle aerosol exposure. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated by aerosol exposure with up to ~ $5x10^6$ PFU of NiV_B or HeV as determined in henipavirus dose confirmation studies conducted by Core D (see Core D). Treatments with drugs, nanobodies, or combinations of drugs and/or nanobodies will be initiated by i.v., i.p., or aerosol delivery following optimization by Core X (see Core X) at various times after henipavirus infection.

D.5.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the MAD system as previously described (ref) or by small particle aerosol as previously described (refs) with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV. The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion or aerosol following optimization by Core X up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Potential Pitfalls and Alternative Strategies. It is possible that Core X may experience difficulties in optimizing aerosol delivery of drugs and/or nanobodies. Likewise, it is possible that aerosol delivery of antivirals may not improve protective efficacy or extend the therapeutic window of antivirals. We will also assess conventional parenteral delivery routes (as noted in the subaims above) which were previously shown for remdesivir and monoclonal antibodies to protect animals against lethal henipavirus disease to de-risk this Aim.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

In summary, the emergence and re-emergence of Nipah virus infections throughout the world, coupled with its high fatality rate, provide very significant motivation for the preparation of small molecule inhibitors of this virus to create a readiness for the next Nipah virus outbreaks. We have discovered two differentiated series of compounds that show early promise as agents that have potential for treating Nipah virus infections, and we have designed a series of optimized druglike candidates for future preparation and development.

Chris, I'm still working on it, and this is my current version. I had to use an old one for Tom's edits.
Still need to fix refs in your "Background" portion to be able to put it in.
Although, it seems even longer than the one in the submitted Alabama grant.
Would it be possible to reduce it a little bit?

And I'll use the new figures that you just sent us.
Thanks.

Subject: rCedV

Irina, Lijun

try putting this rCedV tools into the preliminary data
it covers chimeras to replace the published rCedV-Luc description and existing
figure 1 which we should remove. the chimera prelim data supports high throughput
nanobody assessment, and synergy assay (which can be mentioned in Aim 1 drugs, and Aim 2
nanobodies.

also there is some text for resistance selection and genome sequencing for
target identification if needed somewhere

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV)(REF). NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality(REF). Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission(REF). Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors(REF). 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers(REF). As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis{Marsh, 2012 #2}. We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS)(REFS). We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity(REF). These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and also aerosol delivery of nanobodies. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

RESEARCH STRATEGY

A) Background and Significance

Over the past 40 years the major etiological agents of emerged or newly identified infectious diseases in humans have been viruses{Desselberger, 2000 #1}. Among these, two zoonotic paramyxoviruses of particular importance are Nipah virus (NiV) and Hendra virus (HeV) which are the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae* and are single-stranded, negative sense, enveloped RNA viruses.{Wang, 2013 #1} HeV was discovered first in 1994, in an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer{Murray, 1995 #109;Selvey, 1995 #110}. NiV (Malaysia strain NiV-M) was discovered a few years later as the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998(REF). NiV outbreaks have also been recorded in Bangladesh and India by a closely related strain NiV-Bangladesh (NiV-B)(REF). Pteropid bats are the major reservoir hosts for henipaviruses{Clayton, 2013 #3;Halpin, 2011 #58}. HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, NiV and HeV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%{Broder, 2013 #11;Geisbert, 2012 #13}. A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.{Marsh, 2012 #2} However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease{Lieu, 2015 #642;Marsh, 2012 #2}(REF). Two additional henipaviruses are also recognized, Ghana bat virus and Mojiang virus, but are known only from sequence data{Wu, 2014 #4;Drexler, 2012 #5}(REF). Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and three outbreaks in India (reviewed(REF)). In 2014, an outbreak of NiV-M encephalitis occurred in the Philippines with 9 fatalities of 11 human cases, along with horse-to-human and human-to-human transmission{Ching, 2015 #66}.The combined NiV case fatality rate is ~60% across a large region of South Asia and Southeast Asia in five countries(REF). The recent 2018 NiV outbreak in Kerala, India was significant, having occurred in a new geographic region, a high case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission, underscoring both the transmissibility and the lethal nature of this virus{Arunkumar, 2018 #927}.

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period estimated to be 1 to 2 weeks(REF). Acute NiV/HeV infection in people is systemic and likely via hematogenous spread of the virus from the respiratory system(REF). Disease onset is characterized by fever, myalgia, shortness of breath, and cough(REF). Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery from infection(REF). The predominant clinical feature in the NiV-M outbreak in Malaysia was encephalitis, but respiratory symptoms were also common, with fever, cough, and headache(REF). The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, India, 83% of cases presented with acute respiratory distress syndrome (ARDS)(REF). The key findings of human NiV/HeV infection are a wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected(REF). However, human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset encephalitis or a relapsed encephalitis in patients who previously recovered(REF). Relapsed encephalitis caused by NiV appears to result from a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later(REF). NiV and HeV are also biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents, infecting both humans and economically important livestock by several US Government agencies and both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), the African green monkey (AGM) when delivered by small particle aerosol(REF). NiV and henipaviral diseases (HeV) are also included on the WHO's Blueprint List of Priority Pathogens(REF). NiV stands out as a potential pandemic threat because of its associated high case-fatality rates, capacity for human-to-human transmission, potential to mutate, and if a human-adapted strain were to infect communities in South Asia, the high regional population densities could lead to rapid infection spread(REF). *There is presently no approved vaccines or therapeutic modalities for preventing or treating NiV/HeV infections in people.*

The viral RNA-dependent-RNA polymerase of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been significantly hampered due to requirements of BSL-4 containment in research and development process. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase

(rCedV-Luc) for high-throughput screening (HTS) applications at BSL-2 containment and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV(REF). Those validated lead compounds provide a foundation and rationale for the current application. This ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, allowing for inhibitor discovery across the virus replication cycle, and not restricted to only the viral polymerase. Another well-exploited stage of virus infection that has been successfully targeted is virus attachment and entry(REF). Henipaviruses possess two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion(REF). The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of all vaccine strategies(REF). Although an effective post-exposure human monoclonal antibody (mAb) therapy targeting the NiV and HeV G glycoprotein (m102.4) has been extensively examined{Mire, 2016 #322;Geisbert, 2014 #154;Xu, 2013 #152;Bossart, 2011 #153;Bossart, 2009 #125}, it must be administered within several days following a lethal virus challenge in NHP models. An unexplored alternative but related antibody-based therapeutic strategy against henipavirus infection are antiviral nanobodies. A nanobody, also termed single-domain antibody (sdAb), is an antibody fragment comprised of just a single monomeric variable antibody domain(REF). Nanobodies were first engineered from variable heavy chain domains of camelid heavy chain antibodies (VHHs), and camelid VHHs retain full antigen specificity and are only a fraction of the size of mouse or human antibody, and they also have extended complementarity determining regions (CDRs) which can allow them to bind epitopes that are not normally accessible to conventional antibodies such as conserved viral epitopes that are often masked by glycan shields(REF). Here, our expertise in recombinant henipavirus F and G glycoprotein structural and functional analysis together with anti-F and G mAb development and their therapeutic application, will facilitate the development and testing of a new and understudied area of nanobody-based countermeasures for combating NiV and HeV.

B) Innovation

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. Indeed, all aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). First, the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. Second, our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice that produce VHHs (nanobodies). Third, together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. Fourth, the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Cedar henipavirus. The closely related henipavirus, Cedar henipavirus (CedV), was recovered from *Pteropus* flying fox urine samples in Australia and shown to be nonpathogenic (REF). CedV was isolated in BSL-4 containment, but there was potential to use it a surrogate system for the study of pathogenic henipaviruses at BSL-2. We developed a reverse genetics system for designing and rescuing recombinant CedV (rCedV) (REF). Interestingly, unlike HeV and NiV that use only ephrin-B2 and ephrin-B3 as entry receptors, CedV displays a broader ephrin usage profile, employing human ephrin-B2, ephrin-B1, ephrin-A2 and ephrin-A5 and murine-A1 for infection(REF). However, CedV is nonpathogenic in the well-accepted experimental animal models of HeV and NiV infection and disease including the hamster, ferret, and AGM(REF). CedV attenuation has been attributed to the lack of an RNA editing site in the *P* gene for the production of the interferon antagonist proteins, V and W(REF).

Small molecule antiviral drug discovery. Anti-whole inactivated NiV or HeV immune sera will show cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G glycoprotein antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins (REF). Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and it is also the largest polymerase in the order *Mononegavirale*, yet it still shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; the aa identities of the important L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This high degree of protein identity, overall, shared between CedV, and that of NiV and HeV, suggests that antiviral agents that target for example, the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus antiviral countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication (REF). Indeed, several small molecule inhibitors have been validated in vitro using infectious HeV and NiV in BSL-4, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support Aim 1 to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials(REFs). Nanobodies can be isolated using the same phage library construction methods and phage panning procedure routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. In collaboration with Dr. Jianliang Xu (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels(REF), we have several immunized mouse cohorts now underway using native-like oligomeric recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in Aim 2 in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

Nanobodies from camelid mice and llamas neutralize SARS-CoV-2 variants
Jianliang Xu et al.,

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of Aim 3. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in Aim 3. Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV)(REF). NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality(REF). Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission(REF). Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors(REF). 22 cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antivirals approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers(REF). As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus non-pathogenic in well-established animal models of NiV and HeV pathogenesis{Marsh, 2012 #2}. We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS)(REFS). We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an IC_{50} value of 3.3 μm against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will potentially yield testable antivirals with potential pan-henipavirus effectiveness. Our collaborative team also has an extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity(REF). These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and also aerosol delivery of nanobodies. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobodies studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

RESEARCH STRATEGY

A) Background and Significance

Over the past 40 years the major etiological agents of emerged or newly identified infectious diseases in humans have been viruses{Desselberger, 2000 #1}. Among these, two zoonotic paramyxoviruses of particular importance are Nipah virus (NiV) and Hendra virus (HeV) which are the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae* and are single-stranded, negative sense, enveloped RNA viruses. {Wang, 2013 #1} HeV was discovered first in 1994, in an outbreak of severe respiratory disease in horses in Brisbane, Australia, resulting in the deaths of 14 horses and their trainer{Murray, 1995 #109;Selvey, 1995 #110}. NiV (Malaysia strain NiV-M) was discovered a few years later as the causative agent of a significant outbreak of severe encephalitis in pig farmers in Malaysia in 1998(REF). NiV outbreaks have also been recorded in Bangladesh and India by a closely related strain NiV-Bangladesh (NiV-B)(REF). Pteropid bats are the major reservoir hosts for henipaviruses{Clayton, 2013 #3;Halpin, 2011 #58}. HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bat hosts. Among these animals, NiV and HeV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with human fatality rates ranging from 40-100%{Broder, 2013 #11;Geisbert, 2012 #13}. A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.{Marsh, 2012 #2} However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease{Lieu, 2015 #642;Marsh, 2012 #2}(REF). Two additional henipaviruses are also recognized, Ghana bat virus and Mojiang virus, but are known only from sequence data{Wu, 2014 #4;Drexler, 2012 #5}(REF). Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and three outbreaks in India (reviewed(REF)). In 2014, an outbreak of NiV-M encephalitis occurred in the Philippines with 9 fatalities of 11 human cases, along with horse-to-human and human-to-human transmission{Ching, 2015 #66}.The combined NiV case fatality rate is ~60% across a large region of South Asia and Southeast Asia in five countries(REF). The recent 2018 NiV outbreak in Kerala, India was significant, having occurred in a new geographic region, a high case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission, underscoring both the transmissibility and the lethal nature of this virus{Arunkumar, 2018 #927}.

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period estimated to be 1 to 2 weeks(REF). Acute NiV/HeV infection in people is systemic and likely via hematogenous spread of the virus from the respiratory system(REF). Disease onset is characterized by fever, myalgia, shortness of breath, and cough(REF). Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery from infection(REF). The predominant clinical feature in the NiV-M outbreak in Malaysia was encephalitis, but respiratory symptoms were also common, with fever, cough, and headache(REF). The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, India, 83% of cases presented with acute respiratory distress syndrome (ARDS)(REF). The key findings of human NiV/HeV infection are a wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected(REF). However, human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset encephalitis or a relapsed encephalitis in patients who previously recovered(REF). Relapsed encephalitis caused by NiV appears to result from a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later(REF). NiV and HeV are also biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents, infecting both humans and economically important livestock by several US Government agencies and both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), the African green monkey (AGM) when delivered by small particle aerosol(REF). NiV and henipaviral diseases (HeV) are also included on the WHO's Blueprint List of Priority Pathogens(REF). NiV stands out as a potential pandemic threat because of its associated high case-fatality rates, capacity for human-to-human transmission, potential to mutate, and if a human-adapted strain were to infect communities in South Asia, the high regional population densities could lead to rapid infection spread(REF). *There is presently no approved vaccines or therapeutic modalities for preventing or treating NiV/HeV infections in people.*

The viral RNA-dependent-RNA polymerase of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been significantly hampered due to requirements of BSL-4 containment in research and development process. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase

(rCedV-Luc) for high-throughput screening (HTS) applications at BSL-2 containment and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV(REF). Those validated lead compounds provide a foundation and rationale for the current application. This ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, allowing for inhibitor discovery across the virus replication cycle, and not restricted to only the viral polymerase. Another well-exploited stage of virus infection that has been successfully targeted is virus attachment and entry(REF). Henipaviruses possess two membrane anchored glycoproteins involved in virus entry; one mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion(REF). The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and also the main focus of all vaccine strategies(REF). Although an effective post-exposure human monoclonal antibody (mAb) therapy targeting the NiV and HeV G glycoprotein (m102.4) has been extensively examined{Mire, 2016 #322;Geisbert, 2014 #154;Xu, 2013 #152;Bossart, 2011 #153;Bossart, 2009 #125}, it must be administered within several days following a lethal virus challenge in NHP models. An unexplored alternative but related antibody-based therapeutic strategy against henipavirus infection are antiviral nanobodies. A nanobody, also termed single-domain antibody (sdAb), is an antibody fragment comprised of just a single monomeric variable antibody domain(REF). Nanobodies were first engineered from variable heavy chain domains of camelid heavy chain antibodies (VHHs), and camelid VHHs retain full antigen specificity and are only a fraction of the size of mouse or human antibody, and they also have extended complementarity determining regions (CDRs) which can allow them to bind epitopes that are not normally accessible to conventional antibodies such as conserved viral epitopes that are often masked by glycan shields(REF). Here, our expertise in recombinant henipavirus F and G glycoprotein structural and functional analysis together with anti-F and G mAb development and their therapeutic application, will facilitate the development and testing of a new and understudied area of nanobody-based countermeasures for combating NiV and HeV.

B) Innovation

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of this proposal's investigators. Indeed, all aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet and Irina Gaisina, Chicago BioSolutions** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core Lead). First, the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may will have activity across related members of henipavirus genus. Second, our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice that produce VHHs (nanobodies). Third, together with newly created rCedV chimeras and the establishment of high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. Fourth, the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification, and finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Cedar henipavirus. The closely related henipavirus, Cedar henipavirus (CedV), was recovered from *Pteropus* flying fox urine samples in Australia and shown to be nonpathogenic (REF). CedV was isolated in BSL-4 containment, but there was potential to use it a surrogate system for the study of pathogenic henipaviruses at BSL-2. We developed a reverse genetics system for designing and rescuing recombinant CedV (rCedV) (REF). Interestingly, unlike HeV and NiV that use only ephrin-B2 and ephrin-B3 as entry receptors, CedV displays a broader ephrin usage profile, employing human ephrin-B2, ephrin-B1, ephrin-A2 and ephrin-A5 and murine-A1 for infection(REF). However, CedV is nonpathogenic in the well-accepted experimental animal models of HeV and NiV infection and disease including the hamster, ferret, and AGM(REF). CedV attenuation has been attributed to the lack of an RNA editing site in the *P* gene for the production of the interferon antagonist proteins, V and W(REF).

Small molecule antiviral drug discovery. Anti-whole inactivated NiV or HeV immune sera will show cross-reactivity with CedV, however such sera or even specific high-titer anti-CedV F or G glycoprotein antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins (REF). Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and it is also the largest polymerase in the order *Mononegavirale*, yet it still shares high aa identity to NiV and HeV L protein. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; the aa identities of the important L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This high degree of protein identity, overall, shared between CedV, and that of NiV and HeV, suggests that antiviral agents that target for example, the L polymerase, could be identified and perhaps also offer the possibility of pan-henipavirus antiviral countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication (REF). Indeed, several small molecule inhibitors have been validated in vitro using infectious HeV and NiV in BSL-4, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support Aim 1 to optimize our current best-in-class leads and also screen large libraries of antiviral compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials(REFs). Nanobodies can be isolated using the same phage library construction methods and phage panning procedure routinely employed for mAb discovery, which allows for in vitro production of various amounts and their rapid characterization. In collaboration with Dr. Jianliang Xu (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels(REF), we have several immunized mouse cohorts now underway using native-like oligomeric recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in Aim 2 in generating and characterizing diverse panels of nanobodies to the F and G glycoproteins of NiV and HeV.

Nanobodies from camelid mice and llamas neutralize SARS-CoV-2 variants
Jianliang Xu et al.,

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of Aim 3. In addition, we expect to discover, and well-characterize, batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in Aim 3. Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.

Dear Irina / Iijun
and All
I know you have been working on AIm 1 and David on Aim 2

I said i was revising the Aims page, and working on the bkg and innovation.

Please integrate the attached, which is also a V3 revision to Aims page, into this Doc you just sent, before folks start editing.

Again. as we discussed. UIC will be the holder of the final format and reff generation. So the tedious bit here is the ref insertions into the BKG and Innovation.

I am not sure how all think to move forward from here, regards to editing and working on one document

I will work on Prelim data on nanos and SNT chimera assay tomorrow. with some figs to add
cb

SPECIFIC AIMS.

The COVID-19 pandemic caused by SARS-CoV-2 continues to profoundly impact individuals, communities, and nations. SARS-CoV-2 is rapidly evolving, demonstrating a capacity to persist and cause disease despite effective vaccines. There is a profound need for new antivirals for SARS-CoV-2 and particularly orally bioavailable antivirals for prophylaxis and early treatment. For over 20 years, our NIH-supported studies have advanced understanding of the functions and inhibitors of the CoV replicase, specifically the nsp12 RNA-dependent RNA polymerase (nsp12-RdRp) and the nsp14 proofreading exoribonuclease (nsp14-ExoN), both highly conserved and critical functions for CoV replication and RNA synthesis. Since 2014, our program has led IND-enabling preclinical studies for remdesivir and molnupiravir, including *in vitro* and *in vivo* efficacy, potency, toxicity, mechanism of action (MOA), resistance and combination studies. Thus, our capabilities are well established for coronavirus inhibitor hit identification and lead development using relevant *in vitro* and *in vivo* models, in conjunction with iterative chemical design and modification with industry and academic labs.

In this program, we propose to use novel design and chemistry to: *1)* develop inhibitor hit compounds and validate leads targeting nsp12-RdRp (and cofactors nsp7,8) and nsp14-ExoN (and cofactor nsp10); and *2)* advance available and newly identified priority leads through *in vitro*, *in vivo*, and chemical studies toward oral formulation and IND-ready potent, oral drugs active against SARS-CoV-2 and other present and future zoonotic CoVs.

Aim 1. dentification and Selection of Hit and Lead Compounds Targeting the SARS-CoV-2 nsp12-RdRp and nsp14-ExoN Complexes. *The objective of this aim is to define hit compounds suitable for chemical modification, validation, and advancement to lead optimization*. **Part 1** will test novel nucleoside analogs (NAs) targeting the nsp12-RdRp. In **Part 2**, chemical libraries will be screened for selective activity using *in vitro* biochemical assays against defined components of the replicase core complex, nsp12-7-8, and nsp14-10. **Part 3** will test inhibitors of two-metal-ion-dependent (TMID) enzymes that have demonstrated inhibition of nsp14-ExoN and CoV replication. In **Part 4,** high-impact hits identified using continuous human respiratory cell cultures (A549-hACE2, Calu-3) will be validated in primary human airway epithelial (HAE) cells and against multiple human and model animal CoVs. Hits will be prioritized for lead advancement based on potency, activity in primary cells types, selectivity index, and amenability to SAR and oral administration.

Aim 2. Lead Development for Mechanism of Action (MOA), Viral Determinants of Activity and Resistance, and Combination Testing. *The objective of this aim is to rapidly move validated hits through rigorous* in vitro *testing and further lead advancement to* in vivo *studies*. In **Part 1**, SARS-CoV-2 will be passaged for resistance to lead inhibitors, followed by testing of isolates showing phenotypic resistance in quantitative assays of potency and efficacy, replication kinetics, and cytopathic effect. Viral genomes will be sequenced to define candidate determinants of resistance and known and novel drug targets in nsp12, nsp14, and across the genome. Prioritized candidate mutations will be introduced into isogenic backgrounds of SARS-CoV2 to test and confirm putative drug targets and resistance determinants. This information will be fed to the Structure and Analysis cores to further explore mechanism of action. In **Part 2**, passaged virus populations and engineered mutants will be tested for cross-resistance or increased sensitivity to compounds of similar or different chemical classes and for relative fitness vs. wild-type SARS-CoV-2 in direct co-infection competition experiments. In **Part 3**, lead compounds will be tested in combinations with remdesivir, molnupiravir, and other novel leads from this program to determine whether their interactions are synergistic, additive, or antagonistic.

Aim 3. Lead Evaluation in Rodent Models of Zoonotic CoV Replication, Pathogenesis, Disease, Transmission, and Persistence. *The objective of this aim is to use established, robust, murine and hamster models for SARS-CoV-2, SARS-CoV, and MERS-CoV infection to determine lead efficacy* in vivo. In **Part 1**, validated leads (prioritizing established oral formulations) will be tested in wild-type, young, adult mice at different times of infection for impact on viral replication, disease, and pathology. In **Part 2**, a hamster model will be used to test lead efficacy in a different host species and prevention of transmission to uninfected contacts. In **Part 3**, compounds demonstrating activity in young, immunocompetent mice will be tested in aged and immunocompromised (RAG -/- and MuMT-/- strains) mice for capacity to ameliorate replication and disease in animals predisposed to severe infection. In **Part 4**, the potential and genetic basis for *in vivo* development of SARS-CoV-2 and SARS-CoV resistance to advanced leads will be explored using virus isolated from immunocompromised mice that progress to persistent infection.

RESEARCH STRATEGY

SIGNIFICANCE AND IMPACT.

SARS-CoV-2 and other zoonotic coronaviruses (CoVs) cause devastating disease and remain uncontrolled. During the past 20 years, five novel CoVs have emerged to cause severe illness in new hosts, three of which are human respiratory pathogens: severe acute respiratory syndrome (SARS)-CoV (2002-2004), Middle East respiratory syndrome (MERS)-CoV (2012-present), and SARS-CoV-2 (2019-present)[7-9]. Viruses similar to SARS-CoV, MERS-CoV, and SARS-CoV-2 have been found in reservoir species such as bats and pangolins[10-14]. Thus, in addition to the current pandemic that has killed 1 in 500 Americans, all evidence indicates that new CoV emergence will continuously threaten global health at the animal-to-animal, animal-to-human, and human-to-human interfaces. Potent, broad-spectrum, resistance-averting, and orally-administered antivirals are thus urgently needed to prevent and treat SARS-CoV-2 and allow rapid response to future high-consequence zoonotic CoVs as vaccines and other countermeasures are developed.

The CoV replicase as a target of antiviral drug development. CoVs contain the largest positive sense single-strand RNA of any known human virus, ranging from 28-32 kb in length (Fig. 1). CoV RNA genome replication and subgenomic mRNA transcription are mediated by the replicase nonstructural proteins 1-16 (nsps 1-16) which are translated from input genome RNA as large replicase polyproteins[15] and processed by viral proteases in nsp3 and nsp5 into intermediate and mature nsps 1-16 containing known or predicted functions in RNA synthesis and modification[15-18]. Biochemical, genetic, protein-interaction, cryo-EM, and crystallographic structure studies of replicase components all support a model of a multi-protein replicase holoenzyme with polymerase, RNA-modification, and proofreading functions containing at a minimum nsps 7-8-9-10-12-13-14 (Fig. 1). The **nsp12-RNA-dependent-RNA-polymerase** (**nsp12-RdRp**) is the central component in the RNA synthesis and modification machinery. The nsp12-RdRp folds into canonical "fingers-palm-thumb" domains forming the active-site cleft, which contains SDD metal-coordinating catalytic residues, as well as a novel "NiRAN" domain harboring nucleotidyl and guanylyl transferase activities. The nsp12-RdRp has multiple demonstrated interacting proteins and cofactors, including nsp7, nsp8, nsp9, nsp13, and the bifunctional nsp14-exoribonuclease/ N7-methyltransferase[19-21]. The Denison lab has been a world leader in studies of the **nsp14-exoribonuclease** (**nsp14-ExoN**) and has shown nsp14-ExoN to have critical roles in virus replication, genomic and subgenomic RNA synthesis, high-fidelity replication (RNA-dependent RNA proofreading), RNA recombination, innate immune antagonism, and native resistance to nucleoside analogs (NAs)[19,20,22-28]. The CoV replicase thus constitutes a holoenzyme with arrayed critical enzymatic functions and cofactors that are vulnerable to perturbation by precisely acting small-molecule antivirals.

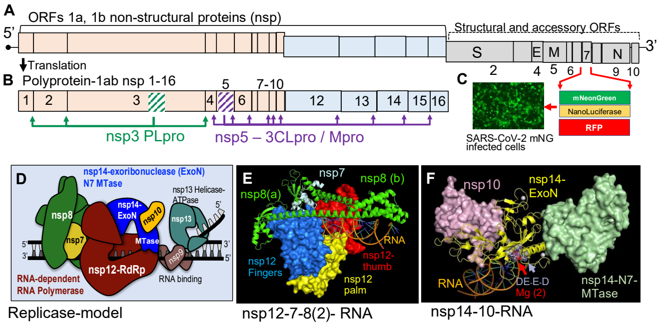

Figure 1. Coronavirus replicase protein expression, reporters, organization and structures of nsp12-7-8 and nsp14-10 subcomplexes. (**A**) Genome organization of SARS-CoV-2. (~30kb ss (+)RNA genome). (**B**) Translation of ORF1ab replicase polyprotein 1ab and processing of nonstructural proteins 1-16 (nsp1-16) by viral encoded proteases nsp3-PLpro and nsp5-3Clpro (Mpro). (**C**) Engineered reporters in SARS-CoV-2 ORF7 for analysis of replication and inhibition: mNeonGreen, mNG; nanoluciferase; red fluorescent protein (RFP)[3,4]. Similarly, reporters for SARS-CoV[5] and MERS-CoV [6] are available. (**D**) Model of known interactions and proposed holoenzyme of the CoV replicase including: nsp12-RdRp; nsp7-8, required nsp12-RdRP cofactors; nsp14-exoribonuclease and N7 methyltransferase (ExoN, N7MTase); nsp10, required nsp14 cofactor. (**E**) Structure of nsp12-RdRp and nsp7/8 cofactors and RNA (PDB 6YYT). Domains of core nsp12-RdRp are shown: blue, fingers; yellow, palm; red, thumb. NiRAN domain not shown. The molecules of nsp8 (green) and nsp7 (light blue) required for nsp12 activity are shown, as well as location of RNA. (**F**) Structure of nsp14, required nsp10 cofactor, and RNA molecule (PDB 7N0B). Locations of active Mg^{2+} (2) (red) and coordinating DE-E-D residues (blue) are indicated.

Research team focus on next-generation inhibitors, oral formulations, and combinations. Prior to the COVID-19 pandemic, very few labs were focused on fundamental CoV biology and fewer still on CoV antiviral drug development. Our CoV antivirals program in the NIAID-U19-supported "Antiviral Drug Discovery and Development Center" (AD3C) between 2014 and 2020 advanced two nucleoside analog (NA) antivirals through preclinical development into IND: remdesivir (Veklury, Gilead Sciences) and molnupiravir (NHC, MK-4482 / EIDD-2801, Emory Institute for

Drug Development). Both showed remarkable potency and efficacy against CoVs, including SARS-CoV-2, and both target the nsp12-RdRp[29-32]. Due in large part to our preclinical development contributions, remdesivir was rapidly moved into human trials and remains the only FDA-approved direct-acting antiviral (DAA) for SARS-CoV-2. Yet, the remdesivir requirement for IV administration limited the scope of trials and its subsequent indications to hospitalized and severely ill patients[33], which excludes treatment of COVID-19 cases comprising the vast majority of infections. Similarly, our studies supported use of the orally bioavailable NA, molnupiravir, now in advanced-stage clinical trials[34]. The recent announcement by MERCK that the phase 3 trial was terminated due to clear benefit of molnupiravir over placebo for prevention of hospitalization and severe disease (awaiting publication and FDA review) is highly encouraging and supportive of our studies in vitro and in animals and demonstrates our ability to identify oral inhibitors of CoV replication and disease. We have shown that both remdesivir and molnupiravir present high genetic barriers to resistance, but just as clearly we have shown that resistance can emerge against either drug[31,32]. Thus, it is imperative to establish additional antiviral strategies for all stages of infection—early, late, and post-exposure prophylaxis—and to include combinations of DAAs to improve outcomes and prevent emergence of resistance.

INNOVATION

Discovery of chemical matter for testing. Multiple parallel and highly innovative approaches will be used to develop hits and identify and optimize leads (see below for team integration and expertise), including: *1)* novel NA chemistry (Arbutus [AR]) and modifications (University of Southern California [USC]); *2)* structure-based design and modification of two-metal-ion-dependent (TMID) enzyme inhibitors active against nsp14-ExoN (University of Connecticut [UConn]); *3)* biochemical screening of active nsp12-7-8 and nsp14-10 replicase subcomplexes against massive compound libraries (Southern Research [SR]); and *4)* integrated molecular modeling, cryo-EM, NMR, crystallography, and fragment-based screening of hits or chemically modified leads (SR Cores).

Established pathways for hit identification and lead development. We have well-established and effective strategies for testing inhibitor efficacy, potency, and toxicity across multiple CoVs and cell lines, which will allow for rapid and accurate assessment of candidate hits meriting modification and/or advancement. Further, we will merge rational drug design and discovery approaches to identify candidate resistance mutations and relevant mutation linkages[25,31] in linear but extensively cross-linked workflows to achieve high-throughput hit evaluation and refinement, rapid down-selection, and seamless progression of our best leads though comprehensive functional analyses *in vitro* and *in vivo.* These approaches include: *1)* numerous relevant *in vitro* systems of HCoV infection utilizing continuous and primary human airway cells[30,35,36]; *2)* physiologic *in vivo* models of HCoV disease[35,37-41]; *3)* precision biochemical assays of priority targets in the viral replicase[1,2]; *4)* a panel of well characterized epidemic and endemic HCoVs [6,12,13,30,40-45]; *5)* reverse-genetics systems for human endemic, zoonotic, and pre-epidemic CoVs[4,6,12,13,42,43,46]; and *6)* deep- and long-read next-generation sequencing (NGS) methods [25].

RESEARCH TEAM

CoV research team and integration of expertise. This project proposes a highly synergistic collaboration incorporating novel target and drug discovery and chemistry, biochemistry, structural biology, and *in vitro* and *in vivo* preclinical models of infection (Fig. 2). The **Denison lab** at **Vanderbilt University Medical Center** (**VUMC**) has been a leader in CoV research for over 30 years and in preclinical development of remdesivir and molnupiravir[29-32,47,48]. The Denison lab houses longstanding fundamental research programs in the virology and genetics of the CoV replicase, particularly nsp12-RdRp and nsp14-ExoN, across SARS-CoV-2, MERS-CoV, and SARS-CoV and the highly tractable animal beta-CoV, murine hepatitis virus (MHV). The Denison lab was the first to confirm and characterize the CoV unique RNA-proofreading function of nsp14-ExoN and its critical role in virus fidelity, replication, and intrinsic resistance to classes of NAs[22,23,32,49-51]. The **Menachery lab** at the **University of Texas Medical Branch** (**UTMB**) will perform hit validation and lead development *in vitro* and *in vivo*. They have established robust small animal models for SARS-CoV-2, SARS-CoV, MERS-CoV, and bat-CoV infection[6,12,13,40-45], including animal-adapted strains of SARS-CoV-2 for use in native mice--young, aged, and immunocompromised animals[40]. Further, they have established models in hamsters for studies of SARS-CoV-2 replication, pathology, and transmission[35,38,39]. In addition to animal models, UTMB has long-standing expertise in highly relevant *in vitro* primary cell-culture systems, including air-liquid-interface (ALI) human airway epithelial (HAE) cultures[35]. Their well-established reverse genetics for multiple CoVs, including SARS-CoV-2, allows for testing of resistance mutations in mouse-adapted viral genetic backgrounds. Finally, Andrew Routh, PhD (UTMB) is an expert in deep sequencing analysis and has developed pipelines for analysis of RNA-seq and long-read (nanopore MinION) data in collaboration with the Denison lab, showing the role of CoV nsp14-ExoN in CoV recombination[25].

Expertise in fundamental CoV biology, replication, and pathogenesis at VUMC and UTMB is complemented by decades of experience and demonstrated success in novel antiviral discovery, chemistry, and development. The **Weller and Wright labs at UConn** have long-standing expertise in viral exonucleases and have established novel approaches for developing inhibitors of TMID enzymes, specifically against viral exonucleases. They have collaborated with the Denison lab to identify exonuclease-targeted compounds that demonstrate inhibition of SARS-CoV-2. **SR will direct the Medicinal Chemistry** (**MedChem**) **Core, Analysis Core, and Structure Core. SR** will perform screening of large libraries in defined biochemical assays of nsp12-7-8 and nsp14-10 to identify hits with potential for active-site and allosteric inhibition of those complexes. In addition, they have established lead compounds of unknown mechanism that will serve as initial development candidates at VUMC and UTMB. The **McKenna lab at USC** has established an approach for tunable chemical modifications to increase the potency and metabolism of NAs. They also will contribute modified NAs with significant *in vitro* efficacy for hit-to-lead validation and development. **AR** is an established company whose scientific director is Michael Sofia, a discoverer of sofosbuvir. Dr. Sofia and his research team have ongoing programs on antivirals against both hepatitis B virus and CoVs. AR has generated a panel of anti-CoV NAs with activity against HCoV-OC43 and/or SARS-CoV-2; these will be tested for hit identification and lead development in collaboration with AR. The drug-development programs are highly integrated and will work with the MedChem Core in the conduct of structure-activity refinement (SAR), biochemical testing, structure determination, modeling, and modifications.

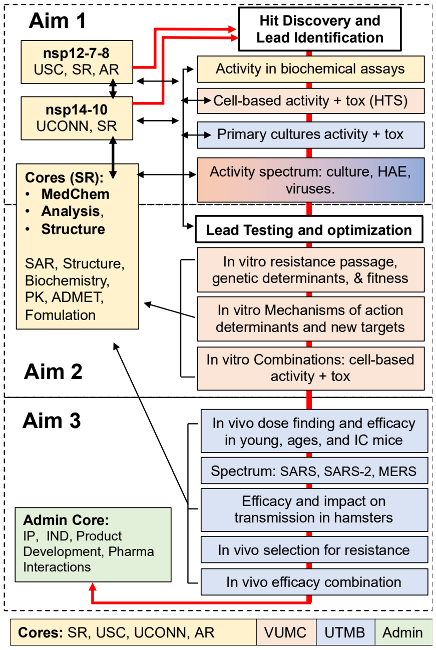

Figure 2. Experimental design and integration of programs for hit discovery and lead development. Schematic of experimental design, hit discovery and validation, and lead development through *in vitro* and *in vivo* testing. Cores: MedChem, Analysis and Structure; SR, Southern Research; USC, McKenna lab (Univ. Southern California); UCONN, Weller/Wright labs, (Univ. Connecticut); AR, Arbutus Biopharma; VUMC, Denison Lab (Vanderbilt University Medical Center); UTMB, Menachery lab (University of Texas Medical Branch); Admin, Admin Core.

Project 1 interactions and with other projects. Project 1 has been designed as an integrated, iterative workflow across the partnering scientific teams and cores. We will promptly communicate about leads that target proteins and functions conserved across virus families. Combination treatments built from leads not only carry the potential to improve breadth, potency, and resistance profiles against CoVs, but also might create bridge regimens effective against disparate virus families. Thus, the preclinical development program for CoV antivirals will promote progress across all AD3C-2 AVIDD projects and potentially define novel, broad-spectrum antivirals.

SCIENTIFIC PREMISE, EXPERIMENTAL RIGOR, AND CONSIDERATION OF RELEVANT BIOLOGICAL VARIABLES

The scientific premise of this program is that small-molecule antivirals, singly and in combination and designed for oral administration, are essential for the control of current (SARS-CoV-2 and MERS-CoV) and future zoonotic CoV epidemics. Additionally, we propose that broad-spectrum therapies can be developed that target more than one virus and more than one virus family to maximize their benefit to global public health. We are committed to conducting rigorous, unbiased, and transparent research that generates repeatable and reproducible data amenable to statistically verifiable outcomes as part of comprehensive laboratory quality assurance. Cell lines, including primary cells, will be routinely monitored for purity by histological analysis of cell morphology and testing for contaminants (e.g., *Mycoplasma*). To reduce biological variability of *in vitro* antiviral analyses, we will perform assays using multiple complementary cell types (continuous cell lines and primary cells) and methods (reporter gene expression, infectious virus production, and viral RNA quantification by RT-qPCR). Experimental animals will be purchased through standard vendors that maintain genotypic control of their colonies. If non-commercially available animals are required, genetic backgrounds will be determined using state-of-the-art genotyping arrays. Any mutant animal strain used in this project will be confirmed within each cohort using validated diagnostic assays. To safeguard reproducibility across the scientific community, we will make novel virus strains, vectored viral cDNAs, and engineered cell lines available through BEI and Addgene.

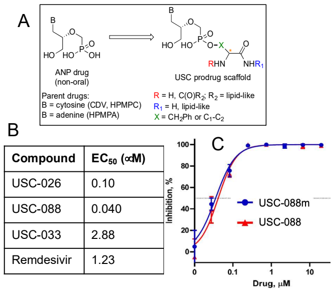
APPROACH

SPECIFIC AIM 1. Identification and Selection of Hit and Lead Compounds Targeting the SARS-CoV-2 nsp12-RdRp and nsp14-ExoN.

Rationale. The objective of this aim is to define hit compounds for chemical modification, in vitro validation, and advancement to lead optimization. These studies focus on the critical conserved replicase complex, specifically nsp12-RdRp, nsp14-ExoN, and cofactors. However, all proteins that assemble in the functional replicase complex and required for RNA synthesis and modification are potential targets that may emerge during the course of the study.

Part 1. NA chemistry and targeting the nsp12-RdRp.

NA modifications for nsp12-RdRp inhibition. Modified NAs have the potential for both enhanced and more universal cell penetration as well as increased efficacy and potential oral bioavailability. **USC** has designed and synthesized a series of NAs[52] (Fig. 3), one of which, USC-088, shows 30x higher potency than remdesivir against a clinical isolate of SARS-CoV-2 in Vero E6 cells (IC_{50} = 0.04 μM; CC_{50} >100 μM). USC-088 incorporates a unique promoiety platform created at USC that provides versatile chemical 'tunability' to enhance the potency and PK properties of antiviral nucleoside phosphonates and phosphates (Fig. 3). In support of Project 1, they will develop this potential lead and its back-up, USC-026. USC-088 and USC-026 will be tested for activity against SARS-CoV-2 in continuous and primary cells (Part 4) and further developed and characterized in Aim 2. Concurrently, USC will collaborate with the **MedChem Core** to perform SAR, ADME, and PK in animal models, with the goal of obtaining an orally effective final lead compound. USC-088 and USC-026 or a lead derived therefrom by SAR will be made available for evaluation to other projects as a broad-spectrum antiviral RdRp inhibitor. The pro-moiety platform will also be applied to enhance potency[53] and oral bioavailability[54-56] of emerging nucleoside/nucleotide leads from Project 1 and MedChem Core.



Compound	EC_{50} (∝M)
USC-026	0.10
USC-088	0.040
USC-033	2.88
Remdesivir	1.23

Figure 3. A) Tunable prodrug scaffold to enhance potency, tissue selectivity, and oral bioavailability. CDV and HPMPA are shown as antiviral nucleoside examples. **B)** Compound activity against SARS CoV-2 in Vero E6 cells (McKenna, USC). **C**) *In vitro* activity profile of USC-88 (two synthetic batches to demonstrate reproducibility) against SARS-CoV-2.

Novel NA inhibitors from structure-based design and pharmacophore screening. Through structure-based modeling and medicinal chemistry approaches, the chemistry team at **Arbutus (AR)** has synthesized or identified novel NAs as candidate broad-spectrum inhibitors of nsp12-RdRp. AR has complemented In-house *de novo* design with *in silico* pharmacophore-based pre-screening of compound libraries to triage a diverse set of known NA inhibitors to be tested against CoVs. In the AR development pipeline, systematic modifications are introduced to trigger antiviral activity and favorable selectivity toward virus vs. host cells. Any identified hits are elaborated further based on emerging SAR and through structure-based computational modeling. Hits validated using SARS-CoV-2-infected Vero cells and/or other CoV-infected cell systems with low micromolar EC_{50} values and no cytotoxicity in the efficacy range will be evaluated in continuous and primary cells (VUMC and UTMB). Results will be communicated with AR for their analysis of desirable drug-like properties, including stability and solubility (See Letter). Advancement of potential leads through Aims 2 and 3 (VUMC) will occur in parallel and iteratively with SAR to improve stability, solubility, and cell permeability for oral bioavailability (AR). Subsequent ADMET and PK analyses will be conducted at AR. Mechanism-of-action (MOA) studies of lead molecules will be performed using synthesized triphosphate metabolites and nsp12-RdRp enzymatic assays (AR).

Part 2. Biochemical high-throughput screening of nsp12-7-8 and nsp14-10 complex inhibitors.

Current Lead Compounds. The existing and productive collaboration between **VUMC and SR** has yielded 4 compounds based on viral cytopathic effect (CPE) screening against SARS-CoV in Vero-E6 cells (Fig 4) The compounds demonstrate >3 log virus titer reduction. sub-μM potency against SARS-CoV-2 in A549 cells at VUMC. These are currently progressing through SAR in the MedChem Core and will immediately be studied *in vitro* and *in vivo* as leads. Because mechanism is unknown, we will pursue passage / resistance / sequencing studies to determine if these leads are virus-targeted and, if so, the specific protein(s) with which they interact.

Assay	Target Values						SRI-45975	**SRI-46488**	**SRI-46944**	**SRI-46897**
SARS-CoV EC_{50} (μM) (Vero E6-CPE)	<1	1.0	0.209	0.179	0.13
CC_{50} (μM) [SI]	>30	>30 [>30]	>30 [>140]	>30 [>165]	>30 [>230]
SARS-CoV-2 EC_{50} (μM) (A549-hACE2)	<1	0.65	0.102	0.003	0.088
Virus Titer Reduction (VTR) ($\log_{10}$)	>2	2.98	3.08	2.938	2.589

Figure 4. Existing Lead Inhibitors from Southern Research. Compounds identified by previous CPE-based library screening demonstrate activity against both SARS-CoV (VeroE6) and SARS-CoV-2 (A549), meeting criteria for progression as leads according to EC50, CC_{50}, SI, and virus titer reduction.

Biochemical Screening for Novel Inhibitors. Going forward in this proposal, **SR** will not further pursue viral CPE-based screening; in this project SR will deploy biochemical assays using SARS-CoV-2 replicase subunits: nsp12-7-8 as an active polymerase complex and nsp14-10 as an active exoribonuclease/N7-methyltransferase assay. **A) The nsp12-7-8 complex.** A functionally active SARS-CoV-2 RdRp comprised of recombinant nsp12-7-8 has been reported[1] and will be used (Fig. 5, panel A). This assay will enable high-throughput screening for compounds that directly target polymerase activity. The system has the advantage of targeting the core synthetic complex and thus will capture active compounds specific for the nsp12-RdRp active site as well as allosteric or other inhibitors of nsp12, 7 or 8. Hits that advance with priority in Aim 1 will be subjected to MOA studies in Aim 2 and iterative SAR and structural analyses at SR. **B) The nsp14-10 complex**. Nsp14-ExoN function may require or be facilitated or modified by the small non-enzymatic nsp10[57]. Complexes of nsp14-10 have been confirmed to show ExoN function when expressed and purified from bacteria [2,24,26,27,58]. A SARS-CoV-2 nsp14-10 ExoN functional assay sensitive to dsRNA digestion by ExoN will be employed[2] (Fig. 5, panel B). The complex will be screened against the same library as the nsp12-7-8 complex, with similar potential to detect both direct and indirect inhibitors (allosteric and disruption of protein interactions). Further, this biochemical testing approach using nsp12-7-8 and nsp14-10 complexes will allow protein-focused evaluation of confirmed and new hits identified from AR, USC, and UConn libraries.

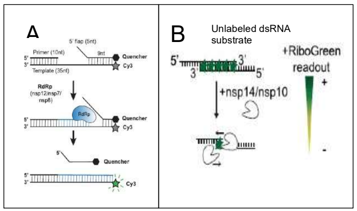

Figure 5. A) FRET-based SARS-CoV-2 recombinant nsp12/7/8 RdRp strand- displacement assay. Figure from (1). **B)** RiboGreen recombinant SARS-CoV-2 nsp14-10 exoribonuclease assay. Figure from (2).

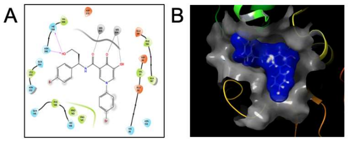
PART 3. TMID enzyme inhibitors of nsp14-ExoN (UConn).

The large size of CoV genomes and inherent error-prone nature of the viral RdRp necessitate a proofreading step (mediated by the ExoN domain of nsp14) to avoid buildup of lethal mutations in progeny genomes[59,60]. The nsp14-ExoN activity also renders CoVs resistant to many classic NAs via ExoN-mediated excision of the mispaired base[24]. Inhibitors of ExoN function are therefore expected to be directly antiviral and are also anticipated to strongly synergize with NAs such as ribavirin and remdesivir [32,49-51]. ExoN belongs to a large superfamily of DE-D-D exonucleases (DE-E-D in CoVs), whose catalytic functions are orchestrated by two Mg^{2+} atoms[16,60]. Both DNA and RNA viruses encode such TMID enzymes, many of which have been shown to perform essential roles in nucleic acid metabolism (e.g., HIV integrase[61-63] and influenza endoribonuclease[64,65]). Despite a common two-metal dependent mechanism, TMID enzymes differ considerably in the overall active site architecture, offering opportunities to engineer both potency and selectivity. The **Weller/Wright labs (UConn)** have developed a small-molecule platform to target viral TMID enzymes and generate novel antivirals, now extended to nsp14-ExoN in collaboration with the Denison lab at VUMC. The high-resolution structure of the nsp10-nsp14 complex enabled rapid virtual screening of a TMID-focused library developed by the Weller/Wright lab. Compounds were flexibly docked to the active site using Schrodinger Maestro Suite, and the resulting poses were ranked by docking score and fit. Visual inspection of top-scoring complexes revealed the promise of a subset of inhibitors, which made contacts in the deeper regions of the active site while retaining key interactions with the metal centers. Figure 6 shows a representative *in silico* complex of one such inhibitor, DDI-117 docked to ExoN. Eight of the compounds were tested for inhibition of ExoN activity using a gel-based assay to monitor cleavage of a ssRNA substrate. While six of the derivatives showed no effect on ExoN activity, two compounds reduced activity significantly. Next, we evaluated direct binding to ExoN protein by measuring the thermal shift



C

Compound	EC50 (µM) SARS-CoV-2	CC50 (µM) (SI)	VTR max $\log_{10}$
DDI 116	~ 0.94	4.11 (4.3)	>2.5
DDI 117	0.18	2.93 (16.3)	~ 2

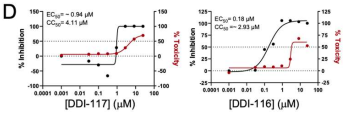


Figure 6. Structure-based compounds against nsp14-ExoN inhibit SARS-CoV-2 (Weller-Wright, UConn). **A)** Ligand plot showing key interactions between DDI-117 and ExoN. **B)** Surface plot of DDI-117 in the ExoN active site (based on PDB:7DIY). **C)** Activity of DDI-116 and DDI-117 against SARS-CoV-2 in human A549-hACE2 cells. CC_{50}: cytotoxicity. SI: selectivity index (CC_{50}/EC_{50}). VTR max: maximum virus titer reduction. **D)** Inhibition and cytotoxicity data used to generate EC_{50} and CC_{50}.

of unlabeled protein in the presence of 20-fold excess of inhibitor (Tycho, Nanotemper). Both DDI-117 and DDI-116 produced a pronounced shift in the inflection temperature (ΔTi = 1.1°C), indicative of significant stabilization of the protein:ligand complex, while two structurally related but inactive compounds had no effect. These four compounds were tested at VUMC to determine anti-SARS-CoV-2 activity in culture. DDI-117 and DDI-116 demonstrated low micromolar level antiviral activity with an SI of >5, while the others exhibited no antiviral activity.

These validated hists demonstrate direct target engagement, functional inhibition, and antiviral activity in cell culture, providing a strong foundation for the ongoing Weller/Wright ExoN inhibitor program. This program will use a combination of structure-based lead optimization, *in vitro* analysis, biophysical evaluations, functional analysis, and antiviral activity to generate an evolving SAR model. Refinements will be made to induce improvements in potency and selectivity at **UConn** and in collaboration with the **MedChem, Structure, and Analysis Cores**. For example, additional contacts with proximate, conserved residues including Pro141, Pro142, His95, Gln145, Gln104, and Phe146 will be pursued. Candidates demonstrating good levels of antiviral activity in cell culture (EC_{50} < 2.5 µM) and an acceptable SI (> 30) will be recommended for synergy testing with nucleoside inhibitors, formulation studies, and *in vivo* evaluation in collaboration.

Part 4. *In vitro* hit determination and validation.

Hit testing in continuous cell lines. Compounds from parts 1-3 above will be tested in SARS-CoV-2-infected cells using recombinant virus expressing mNeonGreen (mNG), nanoluciferase, and red fluorescent protein (RFP) (Fig. 1). We will employ Calu-3 (human lung adenocarcinoma), A549-ACE2 (human lung adenocarcinoma), and Huh-7 (human hepatocellular carcinoma) cells using approaches we have previously reported for remdesivir and molnupiravir[30-32] and as described for preliminary studies with SR compounds and UConn TMID enzyme inhibitors. The use of multiple cell types is important to address potential differences in cell penetration or metabolism, as we observed with remdesivir and its parent compound GS-441524 in Vero and A549 cells[30]. Cultures will be infected in multiple replicates and then left untreated, treated with carrier (such as DMSO), or treated with compound in carrier at concentration ranges designed to either establish or directly test the needed range for a 10-point analysis to calculate potency ($\log_{10}$ virus titer reduction [VTR]) and efficacy (EC_{50}). Virus replication will be initially quantified using luminescence or fluorescence, followed by confirmation with qRT-PCR and/or plaque assay. Parallel uninfected cells will be similarly treated across a broad range of drug concentrations to determine cytotoxicity (CC_{50}) using CellTiter-Glo luminescence assay. Data will be used to calculate compound selectivity index (SI = EC_{50}/CC_{50}) and compared between cell types. Compounds with EC_{50} <10 µm and SI >10 will be considered for further analysis, with priority on compounds demonstrating EC_{50} <2 µM and SI >50. While not a chief criterion, we will further prioritize compounds that show VTR >2 $\log_{10}$. However, compounds with higher EC_{50}s and/or promising feasibility based on modeling, docking, or other assays may be considered for further testing if they are especially relevant and good candidates for SAR.

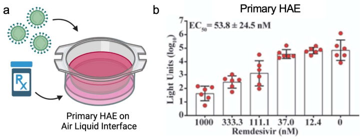

Figure 7. Human airway cultures for anti-SARS-CoV-2 testing. **a)** Primary human airway epithelia (HAE) cultures will be infected with reporter-expressing CoVs and treated with candidate drugs. **b)** Remdesivir was tested in nanoluciferase-SARS-CoV-2-infected HAE cultures. EC_{50} value is shown. Each dot represents one replicate data point.

Hit validation in physiologically relevant primary cells against SARS-CoV-2 and determination of breadth of activity. Compounds of significant interest from testing in continuous cell lines will be assessed for efficacy, potency, and cytotoxicity in SARS-CoV-2-infected primary HAE cultures using methods established in the M**enachery lab at UTMB**[35] (Fig. 7). In this system, Cultures are established from explanted tracheal/bronchial cells on air-liquid-interface (ALI) transwells, which allows differentiation into ciliated cells as natural targets of infection. Cells are infected at the apical surface and may be treated with drug either from the apical or basal compartments depending on formulation, cell penetration, and metabolism. Efficacy, potency, cytotoxicity, and SI will be determined. Compounds also will be examined for breadth of activity in HAE cultures infected with SARS-CoV and MERS-CoV.

Prioritization, capacity, lead identification, optimization, and advancement. We will prioritize initial hits based on multiple factors including potency, activity in primary cell types, SI, potential for SAR, and development potential for oral administration. Prioritized compounds will be further developed within this Aim and down-selected to a top-performing pool of leads for testing in Aim 2. We have significant capacity between VUMC and UTMB for evaluation and validation of up to 20 hits per month, and we are positioned to advance 10 compounds annually into detailed *in vitro* and *in vivo* studies. We have already identified multiple compounds (Figs. 3, 4, 6) satisfying basic criteria for advancement Those will enter studies in Aim 2, and possibly Aim 3, as the pipeline of new hit compounds and validated hits from parts 1-3 above progress. Thus, we anticipate a fully established pipeline of drug candidates, from novel discovery to hit validation to lead optimization at project inception, which will continue toward IND-enabling studies over the course of the project.

SPECIFIC AIM 2: Lead Development for Mechanism of Action (MOA), Viral Determinants of Activity and Resistance, and Combination Testing.

Rationale. The objective of this aim is to rapidly move advanced hits and validated leads through rigorous in vitro virologic assays to define MOA, phenotypic and genotypic resistance, and functional interactions with other priority compounds; inform additional SAR; and guide other modifications based on structural and biophysical analyses, leading to Go/No-Go decisions on progression of leads to in vivo testing.

Published and preliminary results supporting feasibility and capacity. Studies at VUMC over the past eight years have established approaches for lead development that define MOA, resistance, and novel protein determinants and combination studies of NAs, including remdesivir and molnupiravir[29,31,32]. These studies have been IND-enabling and supported advancement of remdesivir (RDV) and molnupiravir (MPV) into clinical trials. We have shown: **1)** RDV and MPV demonstrate high barriers to resistance and follow different genetic pathways impacted by MOA. **2)** Introduction of two nsp12-RdRp mutations associated with MHV resistance to RDV into WT MHV reconstitutes the resistance phenotype, and homologous mutations introduced into SARS-CoV confer RDV resistance[32]. **3)** Resistance of MHV to RDV results in ***increased sensitivity*** to MPV[29] (Fig. 8). **4)** Combination treatment with MPV and RDV show no antagonism and are at least additive in their anti-CoV activity (unpublished-score 1.72). These findings support our proposal that multiple NAs targeting nsp12-RdRp alone or with other replicase inhibitors may be useful combinations to enhance efficacy and limit emergence of resistance.

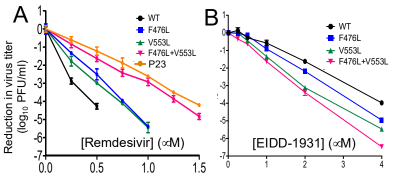

Figure 8. Remdesivir resistance mutations from MHV confer *increased* sensitivity to molnupiravir parent compound EIDD-1931. **A)** Remdesivir-mediated reduction in murine hepatitis virus (MHV) titer. Wildtype MHV (WT, black). Virus passaged 23 times in the presence of remdesivir (P23, orange). nsp12-RdRP resistance mutations F476L (blue), V553I (green) or both (magenta) in the WT MHV genetic background. **B)** EIDD-1931-mediated reduction in titers of viruses from panel A.

Part 1. Identification of resistance determinants. We will serially passage SARS-CoV-2 and MHV in A549-hACE2 and murine delayed brain tumor (DBT) cells, respectively, in the presence of leads to select for resistance. This parallel approach allows for analysis of the trajectory of resistance development along different genetic pathways taken by distantly related beta-CoVs in different cell types. We will serially passage virus in the presence of increasing concentrations of lead compounds in three parallel lineages for each virus and cell type to allow for selection of alternative pathways to resistance. Vehicle-passaged lineages will serve as controls for drug-independent cell-culture adaptations. Passaged virus populations displaying phenotypic resistance, including increased viral titers and CPE at higher drug concentrations, will be tested in EC_{50} and VTR assays to quantify the level of resistance.

Part 2. Sequence analysis, confirmation of targets, determinants of resistance, and biochemical and structural implications. Viruses demonstrating resistance phenotypes (e.g., increased CPE and infectious titers) will be analyzed by combined RNA-seq and long-read RNA sequencing (nanopore MinION) at **VUMC and UTMB (See Routh letter)** to confirm or define targets, mechanism of action (MOA), candidate resistance mutations, and novel physical or functional linkages in known or unpredicted interacting viral proteins or genetic elements. We will initially examine RNA from cells infected with population virus, which represents total diversity of potential mutations selected over passage. If multiple mutations are identified in a known or putative target, additional studies will determine whether mutations occur singly or in specific combinations (i.e., genetic linkage), including selection and sequencing of plaque isolates and MinION sequencing to define mutation haplotypes in sub-lineages or individual genomes. Single and combination mutations that have emerged to dominate WT sequences will be engineered in isogenic clones of SARS-CoV-2 to test/confirm drug targets and candidate resistance mutations. Confirmed mutations impacting resistance or MOA will be engineered at conserved homologous positions of MERS-CoV, MHV, and other beta- and alpha-CoVs to test for shared resistance determinants across divergent CoVs. Finally, confirmed mutations impacting resistance or MOA will be submitted to collaborators and to the Structure Core for potential structural determination and to the Analysis Core for testing in defined biochemical nsp12/7/8 or nsp14-10 systems.

Part 3. Impact of resistance mutations on viral fitness and susceptibility to other compounds. Our previous studies have shown that CoV passage in the presence of an inhibitory drug can select specific resistance mutations and may concurrently select for epistatic (compensatory) or adaptive mutations, which can impact virus replication, fitness, resistance, and general sensitivity to multiple compounds[31,32,50,51]. **1) Replication.** Viruses will be compared in side-by-side replicate assays during single-cycle (high multiplicity of infection [MOI]) and multiple-cycle (low MOI) replication in the presence and absence of compounds. Replication curves will reveal changes in eclipse period, exponential growth kinetics, time to maximum replication, and peak titer. **2) Competitive fitness.** SARS-CoV-2 passaged populations and isogenic clones containing engineered confirmed mutations will be co-infected with WT virus containing a silent (synonymous) barcode of up to 8 nucleotides, which allows quantitative comparison of WT and mutant virus abundances by qRT-PCR using specific primers and probes[51]. WT and mutant viruses will be inoculated onto cells at ratios of 1:1, 1:9, and 9:1, followed by five serial passages of culture supernatants and qRT-PCR for WT and mutant virus in supernatant and total infected-cell RNA at each passage level. Based on our long experience, we predict that selection of resistance mutations in the replicase will confer a fitness cost (less competitive) compared to vehicle-passaged virus in the absence of compound and display distinct replication advantages against all viruses in presence of drug. **3) Resistance/sensitivity to other compounds with similar or different targets.** We will assess the sensitivity of drug-resistant mutants to other leads targeting the same and different proteins. These experiments will define the potential for cross-resistance and sensitivity to leads with distinct target specificities—e.g., nsp14-ExoN inhibitors vs. nsp12-RdRp resistance mutations—and guide selection of combinations.

Part 4. Combination testing. An important goal of this program is to define interactions between lead compounds and establish a basis in support of - or rationale against - combination therapy for CoVs as a strategy to increase potency and prevent emergence of resistance. Most basically, it is critical to establish that a compound does not broadly antagonize other compounds and/or exacerbate cellular toxicity. On the other hand, additivity or synergy with other compounds would favor advancement of a lead. Leads advancing from preceding sections will be tested in two-way dose matrices, initially with clinical-stage and approved anti-CoV DAAs (e.g., remdesivir, molnupiravir, protease inhibitors GC376 and PF-07321332, and then with combinations of compounds targeting nsp12/7/8 and nsp14-10 complexes or individual proteins. Synergy testing will be performed in technical and biological replicates, beginning with EC_{50} concentrations centered in the six-point dose-response curve. Combinations that display neutrality in toxicity assays and either additive or synergistic efficacy as defined by the BLISS synergy score[66] will be prioritized for testing *in vivo*.

SPECIFIC AIM 3. Lead evaluation in rodent models of zoonotic CoV replication, pathogenesis, disease, transmission, and persistence.

Rationale. In vivo models of CoV infection offer a critical, complex system to evaluate drug efficacy[67]. Robust mouse and hamster models have been established at **UTMB** for SARS-CoV, SARS-CoV-2, and MERS-CoV infection. In addition, these systems can be tailored to evaluate drug efficacy against transmission, in aged models, and in immune compromised states. This approach will provide crucial insights into how a drug performs in limiting disease and spread in healthy and vulnerable populations. The models also will allow iterative testing for route of drug administration, formulation, and testing of combinations.

Part 1. Utilize mouse models of SARS-CoV-2, SARS-CoV, and MERS-CoV infection to explore how drug treatment via different routes alters viral replication and pathogenesis. In this sub-aim, we will use established mouse infection models for SARS-CoV-2[40], SARS-CoV[41], and MERS-CoV[37] to explore drug efficacy *in vivo*. Each of these murine models of CoV infection recapitulate key elements of human disease and allow examination of how a drug impacts virus replication, disease progression, and recovery. **Mouse models.** Both SARS-CoV and MERS-CoV models of infection have been previously established and use mouse-adapted

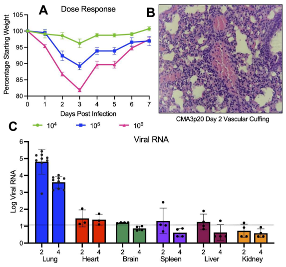

Figure 9. Mouse-adapted SARS-CoV-2 model. A) Dose response of 10 week old BALB/C mice infected with 10^4 (green), 10^5 (blue), or 10^6 (pink) PFU of SARS-CoV-2 CMA3. **B)** Immune infiltration in the lung 2 days post-infection with 10^5 PFU SARS-CoV-2. **C)** Viral RNA in various tissues following 10^5 PFU SARS-CoV-2 infection. Dashed line indicates lower limit of quantification.

strains to demonstrate viral replication in respiratory tissues and significant disease in terms of weight loss, respiratory function, and damage to the lung[37,41]. Our group at UTMB has generated a mouse-adapted SARS-CoV-2 strain (CMA3p20) that induces dose-dependent weight loss, immune infiltration/lung damage, and virus replication limited to the respiratory tract (Fig. 9)[40]. For SARS-CoV and SARS-CoV-2, these studies utilize standard laboratory strains (BALB/C, C57BL/6), while the MERS-CoV model employs human DPP4 transgenic mice[37]. Importantly, these CoV mouse models do not produce disease in off-target tissues like the CNS as seen with human ACE2 transgenic mice[68]. As such, these models provide a more physiologically relevant system to evaluate drug efficacy in the respiratory tract following infection. **Route of treatment.** The mouse models offer several avenues for drug administration. We will utilize two routes for each target drug. The first route will be decided based on expected efficacy (intranasal [i.n.], intraperitoneal [i.p.], intravenous [i.v.], inhalation). In addition, we will also use on oral delivery (gavage) to facilitate transfer to studies in humans. **Evaluation of viral load.** Initial studies will examine the impact a drug has on virus replication in the respiratory tract. In mice, we focus on viral titer found in the upper (trachea) and lower (lung) airways. We anticipate effective drugs will yield a reduction >1 $\log_{10}$ in viral titer relative to control. In addition to plaque assays, lobes of the lung will be examined for changes in viral RNA and antigen staining. From each of these parameters, the impact of the drug on viral load will be comprehensively evaluated. **Disease parameters.** In addition to viral load, we will evaluate the impact of drug treatment on CoV-induced disease. The most common metric, weight loss, will be examined over a 7-day time course with peak disease occurring between days 2-5 post-infection. We also will survey changes in disease score (ruffled fur, hunching, diminished movement) and use whole body plethysmography (WBP) to evaluate changes to respiratory function[69]. Finally, we will utilize histopathology (H&E) to examine immune-cell infiltration and lung damage in the presence of drug treatment. **Experimental design.** Drug efficacy will be evaluated in CoV models in the following order: SARS-CoV-2, SARS-CoV, and MERS-CoV. Briefly, 10 week-old C57BL/6 (SARS-Cov-2, SARS-CoV) or transgenic DPP4 (MERS-CoV) mice will be treated with the drug of interest or vehicle control starting 1 day prior to infection and continued throughout the time course of infection (Fig. 10). Animals subsequently will be infected with a dose of virus inducing up 20% weight loss and evaluated over a 7-day time course. Subsets of mice will be euthanized at days 2, 4, and 7 for determination of viral replication (lung and trachea), viral RNA (lung), and histopathology (lung). We anticipate an effective drug will have a significant impact on viral replication (reduction >1 $\log_{10}$), reduction in weight loss (>10% [absolute magnitude]), improved respiratory function, and/or diminished damage/immune infiltration in the lung. Targets validated with the most sensitive route (i.e., i.v., i.p., inhalation) or oral administration will be evaluated for therapeutic treatment commencing after infection. Because a priority is for development of orally available drugs, any lead advancing through *in vitro* studies that has known oral formulation will be prioritized and immediately tested by oral gavage administration.

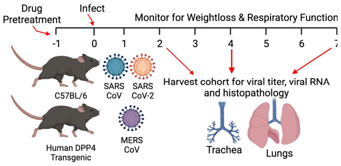

Figure 10. Drug efficacy testing in murine CoV models of infection. Mice will be treated with target drug or vehicle control beginning at day -1 and infected, monitored, euthanized for tissue harvest at days 2, 4, and 7.

Commented [CJ1]: Add panel labeling to figure (A., B., C.) Also, correct statement re. dashed line in panel C?

Part 2. Examine drug efficacy in the SARS-CoV-2 hamster model: impact on airway replication, lung damage, disease induction, and transmission. We will utilize the golden Syrian hamster, a second model of SARS-CoV-2 infection, to evaluate efficacy of a drug at limiting CoV replication, disease, and spread. **Hamster model.** Similar to mice, the golden Syrian hamster provides an *in vivo* model that recapitulates key elements of human disease, including replication limited to the airway, disease with non-adapted SARS-CoV-2 strains, and immune infiltration and damage to the lung. Importantly, the model also evaluates how drug treatment impacts virus transmission. Overall, our group has had significant experience utilizing the hamster model to evaluate fundamental aspects of SARS-CoV-2 biology and impact of variants[35,38,39]. **Route of treatment.** Paralleling the mouse studies, we will pursue two routes for drug treatment. The first approach will use best-efficacy route (i.n., i.p., i.v., or inhalation). Subsequent studies will focus on oral delivery (gavage). Selected routes will be informed by efficacy data from mouse studies. **Evaluation of viral load.** We will evaluate viral replication in both lower (lung) and upper (trachea) airways. In addition, we will determine viral titers in nasal washes as a proxy for transmission capacity[38,39]. We also will examine changes in viral RNA and antigen staining in the lung in the presence of drug treatment. **Disease parameters.** Drug-treated and control hamsters will be evaluated for changes in disease by weight loss, disease score, and histopathology. We will perform WBP in the hamster model by leveraging current equipment available in the animal BSL3. **Transmission.** One advantage of the hamster model of SARS-CoV-2 over mice is the capacity to evaluate changes in transmission between animals. While mice fail to transmit virus even via contact, our group has demonstrated efficient transmission of SARS-CoV-2 in the hamster model[38,39]. In this study, we will use drug- and mock-treated hamsters infected with barcoded SARS-CoV-2 as donor animals (Fig. 11). We will subsequently expose infected hamsters to naïve hamsters and evaluate transmission efficiency under drug treatment using NGS (see Letter Andrew Routh). **Experimental design.** 4-6 week old male golden Syrian hamsters will be treated with drug of interest or vehicle 1 day prior to infection with SARS-CoV-2 and continued throughout the experimental time course. Hamsters will be evaluated over a 7-day time course, with subsets euthanized at days 2, 4, and 7 for assessment of viral replication, viral RNA, and histopathology. We anticipate an effective drug will reduce viral replication (>1 $\log_{10}$) and weight loss (>10% [absolute magnitude]), improve respiratory function, and/or diminish lung damage and immune infiltration. Treatments that result in reduced viral replication or improved disease outcomes will be further evaluated for changes in transmission. Finally, targets validated by sensitive routes (i.n., i.v., i.p., inhalation) will tested for oral dosing using same design.

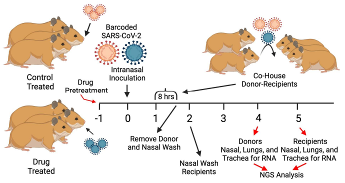

Figure 11. Drug impact on SARS-CoV-2 transmission. Drug- and mock-treated animals infected with barcoded SARS-CoV-2 will be co-housed with naïve animals and transmission evaluated by NGS.

Part 3. Evaluate drug efficacy in reducing disease in the susceptible aged mouse model of CoV infection. Based on demographic data from SARS-CoV-2, SARS-CoV, and MERS-CoV outbreaks, CoV infection causes increased mortality in aged human populations, an age-dependent susceptibility is recapitulated in our mouse models of SARS-CoV and SARS-CoV-2 pathogenesis[70,71]. Therefore, these aging models allow evaluation of drug efficacy in a critical, susceptible population. **Aged mouse model.** While young C57BL/6 mice (10 weeks old) are relatively resistant to SARS-CoV infection, aged mice (20 months) have significantly more disease in terms of weight loss, immune infiltration, and respiratory dysfunction (Fig. 12). Similar age-dependent disease has been observed following SARS-CoV-2 infection of mice[70]. Importantly, drug treatments that reduce or disrupt virus replication may have augmented efficacy in aging mouse models and show utility in treating CoV-mediated disease in this susceptible population. **Viral load and disease parameters.** We anticipate changes in viral replication will be similar between young and aged mice. However, we predict drug treatment will have an increased impact in aged mice due to exacerbated disease. We will focus on several disease readouts to mark improved outcomes, including weight loss, disease course, and survival over a 7-day time period. We will also utilize WBP to evaluate changes in respiratory function with and without drug treatment. Finally, histopathology of the lung will provide insight into damage and immune infiltration in the presence of drug treatment. **Experimental Design.** Aged C57BL/6 mice (14-20 months) will be treated with the drug of interest or vehicle control 1 day prior to infection. Animals will be subsequently infected with mouse-adapted SARS-CoV (MA15) or SARS-CoV-2 (CMA3p20) and evaluated over a 7-day time course. Subsets of mice will be euthanized at days 2, 4, and 7 for analyses of viral replication, viral RNA, and histopathology. We expect treated aged mice will experience a reduction in weight loss (>10% [absolute magnitude), improved respiratory function, and/or diminished damage and immune infiltration in the lung.

Commented [CJ2]: Will treatment continue throughout the infection course?

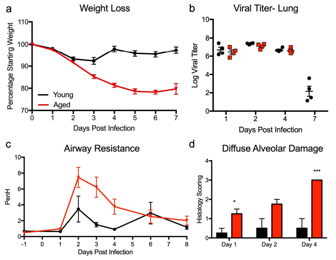

Figure 12. Age-dependent disease in mouse models of SARS-CoV. Young (10 week-old, black) and aged (20 month old, red) C57BL/6 mice infected with 10^4 PFU of SARS-CoV MA15 were monitored for **a)** weight loss, **b)** viral titer in the lung, **c)** airway resistance (penH) by WBP and **d)** diffuse alveolar damage by histopathology.

Part 4. Determine drug efficacy and viral resistance generation in immune compromised mouse models. In addition to aged populations, immunocompromised people represent a major vulnerable population to CoV disease, and specific genetic knockout mouse models recapitulate similar immune deficiencies as found in humans. These models will be used to evaluate drug efficacy as well as define potential routes for drug

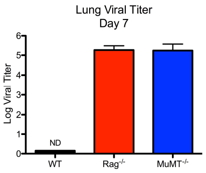

Figure 13. CoV clearance requires adaptive immunity. WT mice clear SARS-CoV by day 7. Mice lacking lymphocytes (Rag-/-) or only B-cells (MuMT-/-) fail to clear SARS-CoV, permitting continued replication.

resistance produced in persistently infected *in vivo* models. **Immune compromised mouse model.** Previous work with mice lacking both B- and T-cell immunity (RAG-/-) or B cells immunity alone (MuMT-/-) has demonstrated persistent infection with SARS-CoV lasting >30 days post-initial challenge[72] (Fig. 13). As such, these mouse models correspond to persistent infection with SARS-CoV-2 observed in immunocompromised humans[73]. Importantly, immune compromised mouse models provide an avenue to explore drug efficacy in a vulnerable population, which often respond poorly to vaccines[74,75]. In addition, the persistent infection model provides an *in vivo* system to explore drug resistance that can expand on *in vitro* studies. **Evaluation of viral load.** We will evaluate virus replication in drug-treated immunocompromised mice over an extended timeline—early (day 2), intermediate (day 7), and extended (day 30) intervals post-infection. We will focus on the lungs in these animals and evaluate viral replication, RNA, and antigen staining in parallel. **Disease parameters.** Previous studies with SARS-CoV demonstrated that, although RAG-/- and MuMT-/- fail to clear virus over time, the disease phenotypes are consistent with WT mice in terms of disease and damage. Therefore, while we will evaluate weight loss, disease score, and histopathology, we do not anticipate significant changes in disease relative to young mice in Part 1. For SARS-CoV-2, the immune compromised model development is ongoing and may reveal distinction in disease that will be pursued as indicated by specific phenotypes. **Resistance mutations.** Consistent with *in vitro* resistance testing, immunocompromised mice used in these studies will allow exploration of the generation of resistance *in vivo*. Using the day 30 samples from persistently infected mice, we will work with Dr. Andrew Routh (see letter) to examine coding changes in the SARS-CoV and SARS-CoV-2 genomes that may contribute to drug resistance. **Experimental Design.** RAG-/- and MuMT-/- mice will be treated with the drug of interest or vehicle control 1 day prior to infection and continued throughout the 30-day time course. Animals will be subsequently infected with either SARS-CoV (MA15) or SARS-CoV-2 (CMA3) and evaluated over a 30-day time course. Subsets of mice will be euthanized at days 2, 7, and 30 for viral replication (lung and trachea), viral RNA (lung), and histopathology (lung). We anticipate an effective drug will have a significant impact on viral replication (reduction >1 log$_{10}$), even in the absence of adaptive immune responses. We do not anticipate significant changes to disease parameters between WT and mutant animals in the SARS-CoV model. For SARS-CoV-2, model development will inform measurable changes to pathogenesis. For resistance, we will focus on virus-coding mutations found at late time points (days 15 and 30), and these mutations will be cross-referenced to Aim 2 results to identify unique and shared features of *in vitro*- and *in vivo*-selected resistance. Critical mutations will be engineered in isogenic backgrounds for in vitro testing and for direct testing of impact of mutations on virus fitness (**VUMC**), attenuation in vivo **(UTMB)**, and in biochemical systems with the **Structure and Analysis Cores** for impact on protein function and sensitivity to the compound in question.

Expected outcomes, potential challenges, and alternative strategies. Our group has extensive experience with *in vivo* models of coronavirus infection[12,13,38-40,76-82]. We anticipate each activity in Aim 3 will be successful based on robust animal model systems, well-established experimental design, and prior experience with the proposed studies. We predict that targets advancing to this aim will show efficacy in both the hamster and mouse models of infection. In addition, the transmission and aged models will provide important insights into the use of these drugs in a metric of spread and a key, susceptible population, respectively. While the models are well characterized, the oral dosing and candidate formulations may require optimization to improve efficacy and may vary across CoV strains. Similarly, while we anticipate generation of resistance, failure to induce resistance *in vivo* would be a positive result, suggesting limited escape from the candidate tested. Absence of resistant mutants, while unlikely, would obviate the need for studies to characterize attenuation of resistant viruses in immune competent animals.

PROJECT DEVELOPMENT PLAN. The table below shows the stages of development. It is broadly useful to look at overall process but less so in regards to specific compounds and our high priority of identifying and rapidly advancing compounds with broad efficacy and potential for oral administration. With the ongoing pandemic, our demonstrated expertise, and the highly integrated labs (VUMC, UTMB, UCONN, SR), collaborators (Arbutus, USC) and Cores (MedChem, Structure, Analysis) we are positioned for rapid-cycle iteration on validated hits and advanced leads to improve potency, physical properties, and toxicity profiles via combination of structural analyses, biochemical assays, and medicinal chemistry. All requisite capabilities exist within Project 1 consortium. Importantly, we start with multiple validated hits from USC, Arbutus, UConn that will enter Aims 1 and 2 and even Aim 3. We will constantly review and prioritize / reprioritize compounds to continue to develop novel approaches while rapidly advancing those most promising.

Based on the monthly progress meetings and annual project reviewers, the AD3C-2 Center will prioritize promising projects and drug candidate for fast-track development. Compounds with *in vivo* efficacy, desired PK, and good safety profile will be prioritized for preclinical development and IND profiling. Please refer the details for the Product Development Plan in the OVERALL write-up of the application.

SPECIFIC AIMS

Hendra virus (HeV) and Nipah virus (NiV) are members of the genus *Henipavirus* (family *Paramyxoviridae*) that can cause severe respiratory illness and encephalitis in animals and humans. Both viruses are among the deadliest human pathogens known to man with case fatality rates up to 100% for the Bangladesh strain of NiV (NiV$_B$). Significantly, multiple rounds of person-to-person transmission of NiV$_B$ is also possible. Cedar henipavirus (CedV) is the only other henipavirus isolate and also the only known non-pathogenic henipavirus, and has been recently demonstrated to be an effective surrogate platform for henipavirus antiviral drug discovery and tool for countermeasure research. There are no approved vaccines or therapeutics for disease caused by HeV or NiV. This proposal focuses on developing antiviral countermeasures to combat the pathogenic henipaviruses which today includes HeV and two distinct NiV strains, NiV$_B$ and NiV Malaysia (NiV$_M$). Genevant Sciences, Inc. has considerable experience developing RNA interference (RNAi) therapeutics against highly pathogenic viruses, with demonstrated efficacy in nonhuman primate (NHP) models of infection. The RNAi therapeutics approach utilizes Genevant's lipid nanoparticle (LNP) platform which stabilizes encapsulated small interfering RNA (siRNA) ensuring effective delivery to target cells. Aim 1 will focus on developing RNAi strategies to combat henipaviruses. A second antiviral discovery approach will focus on compounds that target the replication complex of henipaviruses. This approach is supported by the previous results that the polymerase inhibitor remdesivir can confer protection to animals against NiV$_B$ demonstrating the promise of this class of drugs. Here, Aim 2 will perform high-throughput screening (HTS) using a large library of compounds with an established HTS assay employing a replication competent authentic henipavirus platform (CedV) to identify additional lead antiviral candidates. Aim 3 will focus on combination therapy which is known to be highly effective for combating other viral pathogens, and also one that limits the potential emergence of drug resistance. This uniquely different and targeted combination approach will utilize the most potent antivirals identified in Aims 1 and/or 2 and could provide an effective and complementary treatment of henipavirus infection that is more effective than each therapeutic modality alone. Specifically, we will pursue the following three aims:

Aim 1. Develop and optimize siRNA for protection against Hendra and Nipah viruses. A battery of siRNAs against conserved regions of the L, N, P, M, G, and F genes of HeV, NiV$_M$, and NiV$_B$ will be designed and evaluated for antiviral activity *in vitro*. The most promising candidates will be formulated in LNP targeting different cell types. Pharmacokinetic and biodistribution studies will be performed in hamsters. Protective efficacy of lead candidates will be evaluated in hamster models of henipavirus disease when administered at various times after exposure and by different routes of delivery. Dosing and delivery regimens will be evaluated in hamsters, and the most promising siRNAs will be assessed in a proof-of-concept protective efficacy in African green monkey (AGM) models of HeV and NiV$_B$.

Aim 2. Develop and optimize replication complex inhibitors against Hendra and Nipah viruses. Libraries of drugs predicted to have activity against the replication complex of henipaviruses will be screened using a novel surrogate virus system based on the henipavirus Cedar virus (CedV) which has significant homology to both HeV and NiV. This system utilizes recombinant CedV encoding luciferase (rCedV-Luc) and will be used at BSL-2 for high-throughput screening (HTS) of a library of up to 100,000 compounds. Lead candidates will then be screened against wild type HeV and NiV *in vitro*. Pharmacokinetic and biodistribution studies will be performed in hamsters on inhibitors showing *in vitro* activity against wild type henipaviruses. Protective efficacy of lead drugs will be performed in hamster models of HeV and NiV infection. Antivirals showing strong protective efficacy may be optimized in collaboration with the Chemistry Core. Following optimization of dosing and delivery regimens in hamsters the most promising antivirals will be assessed for protective efficacy in AGM models of HeV and NiV$_B$. In order to leverage existing data showing that remdesivir protected a small cohort of AGMs when given very shortly after exposure to NiV$_B$, studies will be performed to determine the therapeutic window for remdesivir in AGMs exposed to HeV and NiV$_B$, i.e., can remdesivir be given at the onset of clinical disease or at advanced stages of illness and still have a beneficial effect?

Aim 3. Develop combination therapy of broad-spectrum siRNA-conjugate therapeutics and/or replication complex inhibitors against Hendra and Nipah viruses. The most promising antivirals from Aims 1 and/or 2 targeting different antigenic sites will be combined and assessed for enhanced efficacy in henipavirus-infected cells and hamsters. The objectives of these studies will be to determine if the combinatorial approach will confer 1) improved antiviral efficacy over that seen with each therapeutic alone; and 2) improved efficacy when treatment is initiated either at, or even after, the prodromal phase.

RESEARCH STRATEGY

(a) Significance. Hendra virus (HeV) and Nipah virus (NiV) are enveloped, single-stranded negative-sense RNA viruses and the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae*[1-3]. NiV and HeV are bat-borne paramyxoviruses that are distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality. Henipaviruses are capable of infecting at least 18 animal species across six orders of mammals, including bats[4,5]. HeV was first recognized in 1994 as the cause of an outbreak that led to fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra, Australia. To date, HeV has appeared in Eastern Australia on 62 occasions causing the death or euthanasia of more than 100 horses, two HeV antibody-positive and euthanized dogs, and 4 fatalities of 7 human cases[6,7]. The horse is the predominant target host acquiring HeV infection from virus-shedding bats and is also the source of human infection. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts[8,9]. NiV was later recognized as the agent causing a large outbreak of encephalitis among pig farmers in Malaysia in 1998/1999. Although NiV from Malaysia (NiV_M) has not re-emerged in Malaysia, nearly annual outbreaks of human cases of NiV infection have been recorded since 2001 in Bangladesh and a few in India caused by NiV-Bangladesh (NiV_B)[10]. The outbreaks of NiV^B have had notably higher human fatality rates ranging from 75-100%, along with the direct food-borne transmission of NiV from bats to humans and significant human-to-human transmission of NiV infection[11]. Evidence of NiV has also been detected in cattle, goats, and pigs[12]. However, in 2014, an outbreak of NiV encephalitis (attributed to the NiV-Malaysia strain) occurred in the Philippines with 9 fatalities of 11 human encephalitic cases and an influenza-like illness in another 6 individuals, one also with meningitis[13]. The Philippines outbreak involved horse-to-human and human-to-human transmission of NiV infection as well as apparent lethal infections of both cats and dogs. A more recent 2018 NiV_B outbreak in Kerala, India, occurred in a new geographic region far from the locations in Bangladesh and India where all prior appearances have occurred and had a high case fatality - 91%, with 22 of 23 cases the result of human-to-human infection transmission at three different hospital locations[14]. A fatal case of NiV_B was reported in Kerala in September of 2021 causing concern of another potential outbreak[15]. Together, there have been over 650 cases of human NiV infection with a combined ~60% case fatality rate, in South Asia and Southeast Asia across five countries[16]. The observations that the NiV_M and NiV_B strains reportedly display differences in case fatality rates and human-to-human transmission are interesting as there is 91.8% nucleotide homology between the genomes[17].

HeV and NiV are classified as Biosafety Level (BSL)-4 pathogens because of the high mortality rates associated with infection, the lack of effective medical countermeasures, and the ease of transmission. In addition to causing morbidity and mortality as a naturally acquired infection, HeV and NiV are also categorized as Category C priority pathogens by several US Government agencies because of the concern for deliberate misuse. Along this line NIV_M and NiV_B cause lethal infection in nonhuman primates (NHPs) when delivered by small particle aerosol[18,19]. Importantly, NiV and henipaviral diseases were recently included on the World Health Organization's (WHO) Blueprint List of Priority Pathogens[20] while NiV was also included on the Coalition for Epidemic Preparedness Innovations (CEPI) list of Priority Diseases[21]. As a result of the unprecedented global pandemic of COVID-19 there is heightened concern regarding respiratory pathogens. Consequently, in March of 2020 the US CDC recommended that NiV be added to the list of Tier 1 Select Agents[22]. Characteristics of NiV enhancing its global pandemic potential include: humans are susceptible; NiV is capable of person-to-person transmission; it is an RNA virus with potential to mutate, and if a human-adapted strain were to infect communities in South Asia, high population densities and global interconnectedness would rapidly spread the infection[23].

Currently, there are no approved human vaccines or therapeutics for NiV or HeV disease. While substantial progress has been made in developing preventive vaccines against NiV and HeV[24-29], with a soluble glycoprotein-based vaccine in Phase I clinical trials[30], the development of postexposure treatments has lagged behind. A variety of antiviral therapies have been explored to combat NiV and HeV infection with some assessed in animal challenge models, including ribavirin, chloroquine, polyIC12U, and heptad peptide fusion inhibitors but all with none to limited effectiveness[31]. The most effective postexposure treatments identified to date that have been assessed in the gold standard African green monkey (AGM) models have been remdesivir[32] and the human monoclonal antibody (mAb) m102.4[33-35]. Remdesivir was shown to completely protect AGMs from lethal NiV_B disease when treatment was initiated 24 hours after virus exposure and before the onset of viremia or clinical disease. The human mAb m102.4, which targets the henipavirus G glycoprotein, has shown more promise in the AGM model. Specifically, m102.4 completely protected AGMs against HeV or NiV_B when treatment was initiated beginning 3 days after virus exposure[33,35] and against NiV_M when treatment was initiated as late as 5 days after virus exposure[34]. In addition, m102.4 has also been employed under compassionate use protocols to treat HeV patients in Australia and a potential exposure in the US[30]. However, while m102.4 completely protected AGMs when initiated beginning 5 days after exposure to NiV$_M$ it was unable to protect any AGMs when initiated beginning 5 days after exposure to NiV$_B$[35] supporting views that NiV$_B$ is more pathogenic in humans and AGMs. Importantly, while NiV$_M$ causes disease and lethality in AGMs it is not uniformly lethal while NiV$_B$ causes uniform lethality in AGMs under the same test conditions[35]. A current major gap in preclinical postexposure treatment studies is the lack of any antiviral modality to show protective efficacy in animal models when treatment is initiated at the onset of clinical signs for HeV and NiV$_B$ or at more advanced stages of clinical illness.

Henipaviruses have a negative sense, single-stranded RNA genome that is 18,234 nucleotides in length for HeV[36], 18,246 nucleotides in length for NiV$_M$[37] or 18,252 nucleotides in length for NiV$_B$[17]. The genome consists of six genes, namely, N, P, M, F, G and L[36,37]. The N gene encodes the nucleoprotein that is essential for genome replication and packaging[38]. The P gene encodes the phosphoprotein (P), which is essential for genome replication[38], and three additional proteins termed C, V, and W that appear to have pathogenic roles[39]. The M gene encodes the matrix protein that is required for viral particle formation and budding[40,41]. The F gene encodes the fusion protein that allows for fusion of the viral and host cell membranes in viral entry[42]. The G gene encodes the glycoprotein, which is the viral attachment protein that recognizes the host ephrin-B2 and ephrin-B3 receptors expressed on a variety of cell types including endothelial cells, neurons, pulmonary alveolar Type II epithelial cells, and dendritic cells that are highly conserved among many mammalian species[43-45]. The L gene encodes the large viral RNA-dependent RNA polymerase[9,37]. All of these genes and gene products serve as potential targets for therapeutic interventions. This proposal focuses on developing antivirals that can provide broad protection against all medically relevant henipaviruses by 1) developing and optimizing small interfering RNAs (siRNA) directed against genes important for henipavirus replication and assembly; 2) developing and optimizing small molecules inhibitors of the henipavirus replication complex; and 3) combining the most promising antivirals for improved antiviral efficacy over that seen with an individual therapeutic.

(b) Innovation.

siRNA and LNP. siRNAs are powerful, sequence-specific reagents able to suppress gene expression through the process of RNAi. The siRNA approach described in this proposal provides a significant new antiviral strategy that enables targeting of multiple viral genomes and virally-derived mRNA molecules. Development and optimization of this technology has the potential to lead to an effective "one-stop" treatment against NiV and HeV. Genevant's liver targeting LNP platform is a clinically validated technology that enabled the FDA approval of the first RNAi drug (Onpattro™)[46]. They have shown promising results in clinical trials targeting hepatitis B virus, and more recently been successfully deployed in clinical trials for mRNA-LNP vaccines designed against SARS-CoV-2 with Pfizer recently obtaining US FDA licensure. Moreover, in a previous collaboration with UTMB Genevant (formerly Arbutus) developed LNP-siRNA therapeutics that demonstrated complete protection against Ebola, Sudan, and Marburg viruses in guinea pigs and NHPs[47-53]. As with this proposal, that work began with siRNA screening and lead identification, progressing through to proof of concept studies in NHPs during a 5 year term. siRNAs have also shown *in vitro* efficacy against henipaviruses[54,55]. Together, these results strongly support the applicability of an siRNA-LNP approach to addressing pathogenic henipaviruses.

siRNA Delivery. Genevant's technology platform is based on specialized lipid nanoparticles (LNP) capable of efficient encapsulation and delivery of nucleic acids (**Figure 1**). LNP are comprised of a proprietary combination of various lipid components and novel cationic lipids[56]. The spontaneous vesicle formation process is highly efficient, and typically 90-95% of the siRNA are encapsulated within these lipid particles. The resulting LNP are filter-sterilized, and ready-for-injection vials can be stored refrigerated for many months. LNP particles are 50-90 nm in diameter and serum stable, rendering them suitable for parenteral administration. In addition, the feasibility of pulmonary delivery of nucleic acid payload with LNP has been demonstrated by our group and others[57-59]. The small size of LNP allows them to be entrapped in aerosolized droplets that can easily be deposited deep in the lungs. Thus, LNP provide a means of transporting nucleic acid drugs to the appropriate target tissues and target cells in a much more efficient and pharmacologically active manner than is achieved by administering the nucleic acid alone. It does this by: 1) providing protection from nuclease degradation in the bloodstream, 2) permitting administration via several different routes; 3) allowing accumulation in target tissues and 4) providing a means of siRNA entry into the cellular cytoplasm for RNAi activity. The LNP delivery platform

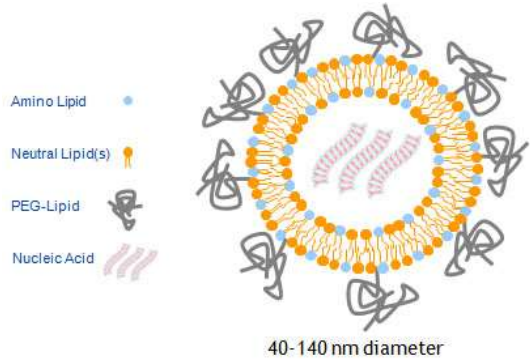

Figure 1. Schematic of LNP.

can be readily adapted as needed to target new or divergent agents by incorporation of different siRNAs, and the delivery of multiple siRNAs (a "cocktail") within a single LNP is a powerful tool for targeting different critical nodes within a single disease or to enable broad spectrum antiviral activity.

Henipaviruses have a broad cellular tropism. The early targets of NiV and HeV infection are respiratory epithelial and endothelial cells[60,61]. Multiple sources of data indicate that LNP are effectively delivered to these cells in preclinical species[57-59]. Genevant has demonstrated that LNP lipid components can be designed and combined in a rational manner to modulate the pharmacology of the resulting particle, allowing optimization of formulations for new applications[62,63]. LNP pharmacology is particularly influenced by the polyethylene glycol (PEG)-lipid and cationic lipid structures and content. Changes to the LNP bilayer have provided up to 10-fold improved target knockdown in rodents and NHPs[64]. Engineering of lipid components should also allow redirection of LNP to other cells, including extra hepatic. Genevant has already developed LNP formulations that can withstand nebulization for delivery to the airway epithelium, and further optimization should enhance delivery efficiency. **Immunostimulation.** Many types of nucleic acids, including siRNAs, are potent activators of the mammalian immune system[65]. Immune activation represents an undesirable side effect due to the toxicities induced by unwarranted cytokine expression and inflammation. The potential of siRNA-based drugs to activate the immune system and elicit downstream effects such as antibody responses is an area of concern in the evaluation of both safety and efficacy. These responses to nucleic acids may further be amplified through the use of delivery vehicles that facilitate the cellular uptake of the siRNA (such as LNP). Genevant's work developing siRNAs for therapeutic applications has shown that siRNA chemical modifications confer nuclease resistance and prevent recognition of siRNA by the innate immune system[66]. These chemically modified siRNAs have improved tolerability and reduced off-target effects (relative to siRNAs composed of native RNA chemistry) in an animal model of hepatitis B infection[67]. Genevant's "minimal modification" strategy involves the incorporation of 2'-OMe nucleotides into siRNAs - this approach has been demonstrated to abrogate the induction of the immune response and associated toxicities in primary human cell cultures, mice and NHPs, indicating the preservation of the inhibitory mechanism across species[68].

Preliminary studies.

b.1 Design of Specific siRNAs Using Bioinformatic Algorithms. Genevant is experienced in designing active and specific siRNAs for targets using the Whitehead site (http://jura.wi.mit.edu/bioc/siRNAext/) based on thermodynamic criteria, known to be a major factor in siRNA efficacy. We have successfully designed siRNAs targeting both endogenous and viral genes using this method[50-54,69,70]. Recently, we have improved our design by adopting a proprietary bioinformatic algorithm with more advanced off-target analysis for higher specificity. This algorithm allows off-target sequence alignment with all known transcripts for a given species. It also compares the seed region of siRNAs with known microRNAs for evaluating potential microRNA-like off-target effects. In addition, single nucleotide polymorphism (SNP) will also be investigated for each of the nucleotide in the siRNA to estimate potential loss of activity risk. Using this algorithm, we have successfully identified active siRNAs *in vivo* for multiple programs. In this research project, we will apply our siRNA design experience to identify specific siRNA candidates for NiV and HeV.

b.2 *In vitro Screen* of Virus Targeting siRNA with Dual Luciferase Reporter (DLR) Assay. *In vitro* screening of antiviral siRNAs is challenging with live viral infection models, particularly for viruses in Risk Groups 3 or 4 that requires specialized facilities for handling. The DLR assay has been identified as an effective strategy to enable early-stage siRNA screening that mitigates this risk. This nonviral screening system involves transfection of plasmid vectors for firefly and *Renilla* luciferase. The viral gene fragments containing the siRNA targeting sites will be inserted between the two luciferase genes. siRNA knock down of target mRNA is reflected by a concomitant decrease in the (downstream) *Renilla* luciferase luminescence, which is normalized to luminescence produced by firefly luciferase (itself a measure for cell transfection efficiency). Genevant harnesses this assay for multiple antiviral siRNA screen efforts such as HBV, Ebola, Marburg, etc. In this research proposal, we will synthesis luciferase reporter constructs containing the NiV and HeV viral gene targets and screen designed anti-NiV/HeV siRNAs using DLR assay.

b.3 Delivery of Luciferase mRNA LNP via Aerosolization. The aerosolized approach is complicated by the mucosal barrier of the respiratory epithelium, which facilitates ciliary clearance of foreign particulates. LNP typically comprise four lipid components: an ionizable lipid, a PEG-conjugated lipid, cholesterol, and a phospholipid. To identify an initial LNP for delivery to lung epithelium, we employed a nucleic acid reporter payload (luciferase mRNA) and tested different combinations of each for their ability to withstand nebulization (PennCentury microsprayer) and impart functional delivery and expression of the nucleic acid payload. Luciferase biodistribution was visualized by luminescence imaging (**Figure 2**) and activity was assessed with a luciferase enzymatic assay (**Figure 3**). We found that variations in the identity and proportions of the lipid

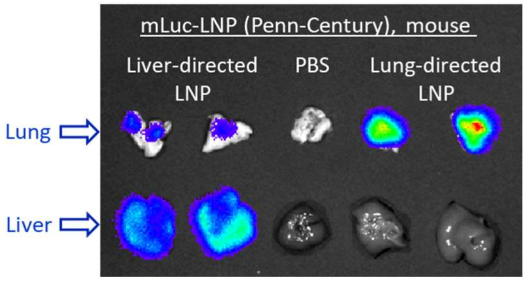

Figure 2. *Ex vivo* imaging of tissues from animals treated with PBS, a lung-directed, or liver-directed LNP.

components strongly influence the ability to mediate delivery. LNP F demonstrated localized expression in the lung, with high luciferase activity in this target organ compared to the liver. In later studies, we moved from intratracheal (i.t.) delivery to nebulization (Aerogen Aeroneb Solo device). Nebulizers are commonly used for the treatment of respiratory diseases because of their ability to disperse drug formulations into small aerosol droplets that are inhaled into the airway through a mouthpiece. Animals in these studies were exposed to LNP in a nebulization chamber. Luciferase expression was predominantly reported in the lung, whereas i.t. administration (Penn Century) often resulted in expression in the airway bifurcation. IVIS whole body imaging showed localized distribution of luciferase in the lung following nebulization (**Figure 4**). Although bioluminescence differed visually between left lung (1 lobe) and right lung (4 lobes), we confirmed that both lungs have similar luciferase activity. Furthermore, we hypothesized that rapid clearance would improve tolerability profile of the LNP formulation. Thus, we designed and used biodegradable lipids with structural motifs that are rapidly hydrolyzed to facilitate rapid clearance. As confirmed by Mass Spectrometry (MS) analysis, very low levels of the parent ionizable lipid were present in the lungs at 6h and 24h post-nebulization (**Figure 5**).

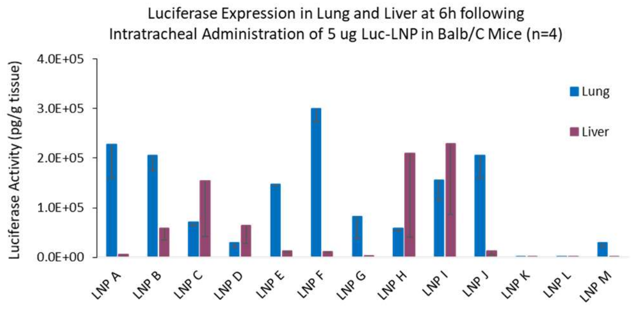

Figure 3. Example of a formulation screen in naïve mice.

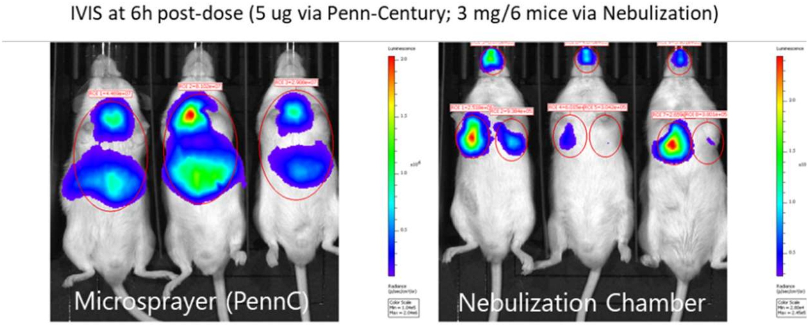

Figure 4. IVIS whole body imaging of mice at 6h following aerosolized delivery of luciferase mRNA LNP.

Delivery of siRNA LNP via intravenous administration to target specific cell types in the liver. Although our work with lung delivery has been focused on delivery to the lung epithelium, we have demonstrated in another application that LNPs can be designed to selectively target different cell types in the liver following intravenous (i.v.) administration. As an example, we have developed LNPs that target hepatic stellate cells (HSCs) in the liver and demonstrated that they accumulate to a much lesser degree in hepatocytes (the usual target of LNP in the liver). A sustained 12-month screening effort of our proprietary lipids and compositions resulted in the identification of LNP M3, a considerably more effective formulation for silencing the HSC-specific gene target RELN. It showed minimal activity against hepatocyte (TTR) or endothelial cell (TIE-2) targets (**Figure 6**). Conversely, LNP A is far more effective for targeting hepatocytes and LNP G was effective against all 3 cell-specific gene targets. A similar screening approach could be used to identify LNP compositions that target the lung endothelium, using TIE-2 siRNA.

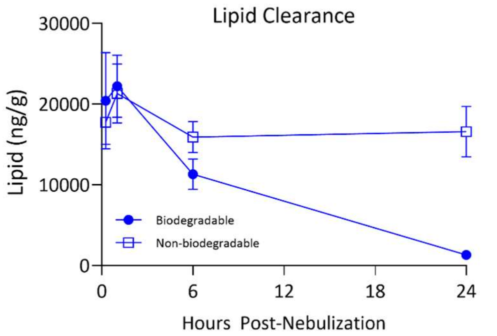

Figure 5. Clearance of parent ionizable lipid following aerosolized delivery to mice.

b.4. Antiviral drug discovery. Antiviral drug discovery for HeV and NiV has been significantly hampered due to requirements of BSL-4 containment. However, the recently discovered Cedar virus (CedV), which shares significant homology to both NiV and HeV and the third member of the *Henipavirus* genus, has allowed us to circumvent the BSL-4 requirement for henipavirus drug discovery, because CedV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease, and thus designated as a BSL-2 agent. We have recently optimized a recombinant CedV encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications and performed a pilot HTS to identify small molecule inhibitors using the recombinant CedV[71]. Importantly, several small molecule inhibitors (**Figure 7**) have been validated *in vitro* using infectious HeV and NiV in the BSL-4 facility, demonstrating the proof-of-concept feasibility of using this CedV-based surrogate HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for the current drug discovery project. Particularly, our furopyrimidine-based hit **Z2** was found to have an EC_{50} value of 0.5 µM. In Table 2 are shown additional inhibitors in the furopyrimidine series that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). In the Research Plan we discuss methods for the preparation of new compounds in each series as well as specific plans for developing the SARs. Our recombinant CedV HTS system will be used to support Aim 2.

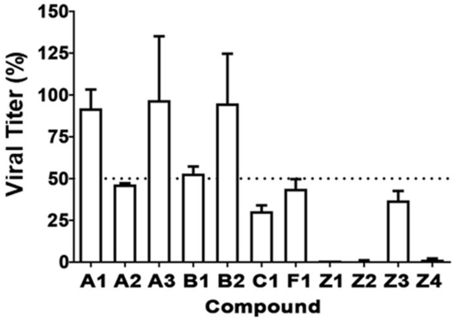

Figure 7. Inhibition of NiV_B replication Vero 76 cells measured by virus titer reduction assay (% infection relative to the DMSO control).

Table 1. Validation of rCedV-based HTS assay hits for inhibition of NiV_B.

Hit	CedV (293T)		CedV (Vero)		NiV_B (Vero)
	IC_{50} (µM)	CC_{50} (µM)	IC_{50} (µM)	CC_{50} (µM)	IC_{50}(µM)
Z1	0.70	100	2.1	100	3.3
Z2	0.78	37	13.2	100	0.5

b.5. Combination therapy. Combining antiviral drugs with different mechanisms of action is one possible strategy for limiting drug resistance and may have synergistic or additive effects that can improve outcome. Combination therapies became a standard of care for treating HIV and HCV infections and have been more commonly used to treat chronic viral infection. However, we recently showed that a combination of a polymerase inhibitor (remdesivir) with a human mAb targeting a surface glycoprotein had a substantial and statistically significant effect in extending the therapeutic window for treated Marburg virus infection of NHPs[72]. In brief, rhesus monkeys are protected against lethal Marburg virus infection when treatment with either a human mAb (MR186-YTE; 100%), or remdesivir (80%), is initiated 5 days post-inoculation (dpi) with Marburg while no animals survive when either treatment is initiated alone beginning 6 dpi. However, by combining MR186-YTE with remdesivir beginning 6 dpi, significant protection (80%) is achieved, thereby extending the therapeutic window. This new data shows that combination therapy may also have utility against acute viral infections.

(c) Approach

Research Strategy:

Respiratory epithelial cells, endothelial cells, and neurons are important cellular targets of NiV and HeV[73-88]. In addition, dendritic cells and macrophages can be infected and disseminate henipaviruses[79,86]. Temporal studies in animal models show that henipaviruses initially infect respiratory epithelium, spread to other cells such as endothelial cells, and eventually to neurons[75,76]. Once henipaviruses infect neurons therapeutic intervention is difficult. A goal of Aim 1 is to develop siRNAs that can target henipavirus genes associated with replication and assembly and deliver these siRNAs to primary cellular targets in order to slow the ability of henipaviruses to gain access to the CNS and improve survival. In addition to liver-based targets and indications, Genevant has been working to expand LNP delivery to extrahepatic tissues, including lung. Here we will seek to apply these advances, identifying potent and cross-species active NiV/HeV targeting siRNAs for pulmonary delivery to both endothelium and epithelium. Aim 2 is focused on replication complex inhibitors. Some of these inhibitors will be developed within this project while other antivirals will be provided by Arbutus and Gilead. Currently, Arbutus has actively engaged in the discovery and development of broad spectrum small-molecule inhibitors against the RNA-dependent RNA polymerase of coronaviruses, including that of SARS-CoV-2. Since the active site of these viral enzymes can be highly conserved, antiviral compounds discovered from this program may also exhibit inhibitory effect across multiple RNA viruses. Representative compounds from the different sub-series will be evaluated by the HTS Core for antiviral effect against henipaviruses. Confirmed hits will be elaborated to develop SAR, with assistance from structure-based computational modeling. Lead compounds with promising antiviral and pharmacokinetics profiles will be progressed into testing against viral infection in animal models to determine *in vivo* efficacy.

Aim 1. Develop and optimize siRNA for protection against Hendra and Nipah viruses. We have three Subaims under Aim 1 that together are focused on the development of broad spectrum, non-immunostimulatory siRNAs targeting NiV and HeV genes associated with replication and assembly. They will be encapsulated in a single LNP to form a postexposure therapeutic and tested in hamsters and NHPs for protection against NiV and HeV. We will first identify the most efficacious siRNAs against four different genes (L, N, P, M) of one or more NiV and/or HeV strains (**Subaim 1.1**). These will subsequently be combined into a tri- or quadripartite siRNA cocktail to confer activity against potential mutations of the virus. siRNAs displaying the strongest anti-NiV/HeV activity will be incorporated into selected novel LNP to enable their delivery to the lung endothelium and/or epithelium. In parallel, we will select and formulate a shortlist of novel lipid compositions for lung delivery (both intravenously to endothelium and aerosolized to the epithelium) (**Subaim 1.2**). Emphasis will be placed on those with proven high potency in other applications and biodegradable functionality to provide the best tolerability profile. LNP will be screened in naïve rodents using model siRNA (TIE2 for endothelium, e-Cadherin for epithelium). The best LNP will be combined with the NiV/HeV siRNA from Subaim1.1 and assessed in hamsters and NHPs challenged with NiV and HeV (**Subaim 1.3**).

1.1. Design and *In vitro* screening of siRNAs targeting NiV/HeV L, N, P and M proteins. The goal of Aim 1 is to design, screen, and select lead siRNAs targeting NiV and HeV viral genes. siRNAs targeting each viral gene will be designed using bioinformatic algorithms and screened through *in vitro* dual luciferase reporter (DLR) assays. 2’-OMe chemical modifications will be applied to the lead siRNA candidates to mitigate immunostimulatory effect while maintain the gene silencing potency. siRNAs targeting the conserved regions of viral genes will be prioritized for candidates down selection. For viral genes with short sequence length and low homology between NiV and HeV or among different viral strains in the same species, siRNAs targeting one or more dominant strains will also be screened as potential cocktail component. The viral gene targets we selected include the L pol (L), which provides the RNA-dependent RNA polymerase activity of the polymerase complex, and which is necessary for all viral RNA synthesis. The second target is the nucleocapsid (N) protein that facilitates the functional transition of the viral polymerase from a viral transcriptase to a viral replicase during viral replication. In addition, the polymerase cofactor phosphoprotein (P) and virion budding coordinator matrix protein (M) are also promising anti-NiV/HeV targets. ***Design of siRNAs targeting NiV/HeV L, N, P and M proteins.*** Using proprietary bioinformatic algorithms, siRNA will be designed targeting NiV/HeV L, N, P and M genes. Viral gene sequences of all clinically relevant NiV and HeV species will be obtained from NCBI Entrez viral genome sequence databases. If available, conserved regions of each viral gene will be identified for siRNA design. For viral genes with low cross-species homology, the sequence from dominant clinic species will be used. The siRNA targeting specificity will be assessed by aligning with human, NHP and rodent transcriptomes and seed sequence comparison with known human, NHP and rodent microRNAs. Specificity of both sense and antisense strand will be analyzed. ***In vitro screening of unmodified NiV/HeV siRNA.*** For each gene target, a pool of 48 of bioinformatically designed siRNA candidates with high specificity will be synthesized for *in vitro* activity screening using DLR assay. This nonviral screening system involves transfection of plasmid vectors for firefly and *Renilla* luciferase. The viral gene fragments containing the siRNA targeting sites will be inserted at the 3’ end of *Renilla* luciferase gene. siRNA knock down of target mRNA is reflected by a decrease in *Renilla* luciferase luminescence, which is normalized to luminescence produced by firefly luciferase (itself a measure for cell transfection efficiency). Two rounds of screening will be performed, including a 2-concentration initial screen for all candidates and a subsequent 10-concentration dose response comparison for the top 12 candidates. The most active siRNA candidates will be selected for chemical modification optimization. ***Chemical modification optimization for lead siRNA.*** Through our research at Genevant, we have determined that 2′-OMe modifications to both sense and antisense strands yields viable and effective siRNAs without any induced toxicity, cytokine induction or off-target effects[59,62]. In this Aim, we will modify 3-6 best unmodified siRNA performers (Subaim 1-2) for each viral gene. For each parental siRNA sequence, 5-10 different modification patterns will be tested. The activity of modified siRNAs will be tested using DLR assay. The suppression effect on immune stimulatory will be verified using human whole blood assay. The siRNAs (single siRNA or siRNA cocktails) will be formulated into the lung targeting LNP and incubated with heparinised human whole blood for 24 h, followed by plasma isolation. Cytokine and/or chemokine levels will be quantitated using commercially available assays. In addition to assessments in human whole blood, modified siRNAs will also be administered to ICR mice and assessed for the production of IFN-α and IFN-β and IFN-induced protein with tetratricopeptide repeats (IFIT1) mRNA as has been done previously[51]. ***Efficacy testing of siRNA candidates against live henipavirus infection.*** Antiviral activity of the LNP-encapsulated siRNAs will be evaluated against live NiV_B, NiV_M, and HeV infection. In brief, human airway epithelial and endothelial cells or Vero cells will be infected with different strains of NiV and HeV as described previously[80,83,85,88]. One hour post-infection, cells will be treated with individual anti-NiV/HeV siRNAs. Culture fluids will be harvested at various times after challenge (e.g., 24, 48, 72, 96 hours) and assayed for the presence of infectious NiV and HeV by conventional plaque assay and by quantitative RT-PCR[73,74]. Non-targeting luciferase siRNA will be used as a control in all assays.

1.2. Identify novel LNP compositions for lung specific-siRNA delivery in naïve mice. In parallel with Subaim 1-1, we will screen and select one or more LNP lipid compositions with potent and specific delivery to the lung endothelium and/or epithelium in naïve mice. Through our previous research, we have demonstrated functional nucleic delivery (luciferase mRNA) to the lung epithelium via nebulization, with minimal expression in the liver. Our current benchmark lung formulation exhibits rapid clearance and great stability, withstanding shear forces generated during aerosolization. Furthermore, we have demonstrated the ability to design LNP compositions that specifically target different cell types in the liver following intravenous administration. We will leverage this combined experience to identify a potent LNP formulation for i.v. delivery of siRNA to lung endothelium, and/or for aerosolized delivery to the lung epithelium. Genevant has designed a library of advanced lipid components that have been engineered to clear shortly after administration. This biodegradable functionality results in improved tolerability, while maintaining high potency *in vivo*. Initial screening of these novel lipids for lung specific delivery will utilize model siRNAs (e.g., TIE-2 to target endothelial cells and CDH1 to target epithelial cells) and will take place in a naïve mouse model. ***Screen novel lipids for lung siRNA delivery in naïve mice.*** The goal is to design, screen, and select novel lipids and LNP compositions to be used for delivery of a cocktail of model siRNAs (e.g., TIE-2 and CDH1) to the lung endothelium via i.v. administration, or to the lung epithelium via aerosolized delivery. Initial screening of these novel LNP will take place in a single dose naïve mouse model and will comprise four rounds of LNP screening; each round will consist of PBS + 9 novel LNPs. Since there are two routes of administration, the same 9 LNP formulations in each round of screening (encapsulating both TIE-2 and CDH1) will be administered i.v. (in one study) and aerosolized (in a separate study). In total eight mouse studies conducted in this phase. LNP specificity will be evaluated using model siRNA specific to endothelial cells (e.g., TIE-2) or epithelial cells (e.g., CDH1). Activity of these formulations in the lung tissue (versus other tissues) will be determined by measuring mRNA knockdown using the QuantiGene 2.0 Assay (QG 2.0) assay. After four rounds of screening, the top 5 LNP compositions will advance to a dose response study (at 3 dose levels) to rank potency and assess tolerability. Tolerability of these formulations will be assessed by cytokine (e.g., MCP-1, IL-6) ELISA assays and clinical pathology analysis. The top three formulations will advance to the next phase based on their activity and tolerability profiles. ***Dose response/tolerability studies.*** The three lead LNP candidates selected from the initial LNP screens will be evaluated for dose responsiveness and tolerability at three dose levels. Activity will be measured by mRNA knockdown and tolerability will be assessed by clinical pathology, cytokine induction, and anti-PEG antibody responses. ***Duration of action/repeat dose tolerability studies.*** The three lead LNP candidates selected from the initial LNP screens will also be evaluated for duration of activity and repeat dose tolerability at an appropriate dose level selected from the dose response study above. Duration of activity (measured by mRNA knockdown over a time course) will be determined following single dose i.v. administration or aerosolization in naïve mice. Repeat dose tolerability will be assessed by clinical pathology, cytokine induction, and anti-PEG antibody responses. Rate of lipid clearance/accumulation will also be determined in this study. Frequency of siRNA LNP administration will depend on duration of activity results and will provide informative data for subsequent studies in viral challenge models where LNPs may require repeat dose administration. The best formulations (based on their activity and tolerability profiles) will advance to further assessment in naïve hamsters. ***Evaluate translation of results in naive hamster model.*** To ensure translation of results from the mouse to hamster model, we will perform a final LNP evaluation of the top three LNP candidates in naïve hamsters. Based on the activity and tolerability results in naïve hamsters, three lung targeted LNP compositions will be selected and combined with lead siRNAs (Subaim 1-1) for evaluation in the HeV and NiV hamster models at UTMB in the **Geisbert Lab** (Subaim 1-3).

1.3. Assessing anti-NiV/HeV activity of LNP-siRNA cocktail therapeutics in preclinical species. Lead siRNA sequences and LNP compositions resulting from Subaims 1 and 2 will be tested for efficacy in a series of hamster viral challenge studies against NiV and HeV. Cocktails of different siRNA candidates will be formulated to lead LNP compositions. Infected hamsters will receive treatment of LNP-siRNA cocktails via i.v. injection and/or aerosol delivery, starting at different time points post-infection to assess protective efficacy. ***In vivo* testing of anti-NiV/HeV LNP-siRNA cocktails in NiV/HeV infected hamsters.** Cocktails of chemically optimized siRNA leads from Subaim 1-1 will be formulated to LNP composition leads from Aim 1-2. The *in vivo* activity of these LNP-siRNAs will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and intranasally (i.n.) inoculated with ~ 5x10^6 PFU of NiV_B or HeV[75,89-91]. Animals will then be treated with anti-NiV/HeV LNP-siRNAs by i.v. injection (starting at 1 mg/kg) and/or aerosol delivery, beginning ~ 1 hour after virus challenge, and continuing daily for up to 6 days after exposure. The control animals will be treated in parallel with an equivalent dose of a non-targeting Luciferase LNP-siRNA. siRNA antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. siRNA candidates showing the most protection will be selected for assessment in NHPs. ***In vivo* testing of anti-NiV/HeV LNP-siRNA cocktails in NiV/HeV infected nonhuman primates.** A final proof of concept study will be performed in NHPs using the LNP-siRNA candidates providing best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated i.t. and i.n. with a uniformly lethal challenge dose (~ $2.5x10^5$ PFU per route, ~ $5x10^5$ PFU total dose) of NiV or HeV as described previously[29,35]. The treatment groups (consisting of five animals each) will be treated with an anti-NiV/HeV LNP-siRNA candidate (1 mg/kg) by bolus i.v. infusion up to 5 days after viral challenge (initiation time informed by hamster studies) while a control animal will receive an equivalent dose of non-targeting Luciferase LNP-siRNA. Animals will receive six additional daily treatments of the anti-NiV/HeV LNP-siRNAs. The siRNA antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

Aim 2. Develop and optimize replication complex inhibitors against Hendra and Nipah viruses. Toward this Aim we will 1) further develop remdesivir in NHPs; 2) perform large scale screening of small molecule libraries (up to 100,000 compounds) using an optimized HTS platform; 3) confirm, analyze, and validate hit compounds with infectious HeV and NiV *in vitro*, and rank according to their antiviral potency and cytotoxicity; 4) chemically optimize the lead compounds and construct useful Structure-Activity Relationships (SAR); 5) evaluate the most potent lead compounds with infectious HeV and NiV both *in vitro* (5-10) and *in vivo* (2-5); 6) perform mechanism of action (MOA) studies to determine the targets of these lead compounds using an integral approach of biochemical, biophysical, biological, and structural techniques; and 7) identify the best lead compounds with good oral bioavailability as candidates for an IND study. In addition, antivirals from Arbutus and Gilead funneled in from the HTS Core will be assessed *in vitro* and *in vivo* against infectious HeV and NiV.

2.1. Optimization of remdesivir in AGMs. A previous study showed that administration of remdesivir beginning one day after exposure of AGMs to NiV_B completely protected the animals against lethal disease[32]. While the results of this work are encouraging the treatment was initiated very shortly after infection before any animals showed clinical signs of illness. The goal of this Subaim is to better define the therapeutic window of remdesivir in AGMs, i.e., can remdesivir still protect AGMs against henipavirus disease if administered at or after the onset of clinical illness? A group of six AGMs will be challenged by combined i.t. and i.n. routes with a lethal challenge dose (~ $2.5x10^5$ PFU per route, ~ $5x10^5$ PFU total dose) of a low passage (p2) NiV_B isolate as previously described[29,35]. At day 4 after NiV_B infection (when AGMs begin to show signs of clinical disease) five of the animals will be given a 10 mg/kg i.v. loading dose of remdesivir, followed by 5 mg/kg i.v. daily maintenance doses 5-15 dpi, for a total of 12 consecutive days of treatment, as previously described[32] while a control AGM will be treated in parallel with sterile saline. Based on the results, the study will be repeated to further define the therapeutic window, e.g., if all five animals treated with remdesivir survive the follow up study will begin treatment at day 5 after NiV_B infection. Conversely, if any of the remdesivir treated AGMs succumb the follow up study will begin treatment at day 3 after NiV_B infection. A third study will be done to assess the protective efficacy of remdesivir for treating HeV-infected AGMs; test conditions for the HeV study will be the same as the test conditions showing the best protection against NiV_B. Defining the therapeutic window is not only important in terms of translating preclinical animal data to humans but also in regard to combination treatment studies where it is important to establish breakthrough for each individual drug to be used in combination approaches in order to be able to show a benefit of combining drugs.

2.2. HTS assay. We will employ our recently published optimized HTS protocol utilizing the recombinant CedV system[71]. Cells preseeded in a 96-well plate at a density of 2.5 x 10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at predetermined nontoxic concentrations for 1 hour at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation (PerkinElmer, Waltham, MA) as per the manufacturer's instructions. This plate reader is integrated directly with the robotic deck so that readings can be made unattended. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in HEK293T cells and Vero cells in 96-well plates. Cells will be incubated with compounds at a 3-fold serial dilution ranging from 30 nM to 200 μM followed by the addition of rCedV-Luc (MOI: 0.01). After incubation at 37 °C for 48 h, luciferase activity will be examined by reading the luminescent signal as described above. Sample signals will be normalized by signals from the DMSO control wells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with Graphpad prism. These assays will be conducted in **the Rong Lab.**

Screening Libraries. These libraries will be provided by the UIC Research Resource Center (RRC). Multiple ready-to-use chemical libraries to facilitate drug discovery and drug target identification are curated at the RRC. They are available in 96- or 384-well plate formats suitable for HTS.

AI-Aided Screens for Anti-Henipaviral (Nipah/Hendra) Drug Discovery In collaboration with the MCC at Southern Research, artificial intelligence (AI)-aided screens will be utilized for the efficient discovery of novel anti-henipaviral agents (**Figure 8**). Cheminformatics analysis will be performed on the UIC HTS library to remove the pan-assay interference compounds (PAINS) based on an in-house developed PAINS structure filter. A machine learning (ML) model will be used to perform AI-aided predictions of the phenotypical anti-henipaviral activity of non-PAINS compounds. Taking NiV as an example, an ML model (*via* BIOVIA Pipeline Pilot platform) will be constructed and trained with the already-available phenotypical anti-NiV data of 10K compounds from Southern Research database[92] as well as other anti-henipaviral compounds previously identified in PIs' labs[71]. Based on our experience of the successful development of a SARS-CoV-2 ML model using similar algorithm and data size (**Core Approach Section C1**), we expect a NiV ML model of at least 80% prediction accuracy to be developed. Subsequently, protein-structure-based virtual screens (VS) will be performed on the AI-predicted active compounds to evaluate their target specificity. For example, two of our top interests are the NiV G glycoprotein (G-gp) and polymerase. The G-gp VS will utilize a crystal structure of NiV G-gp[93] and a validated VS protocol that we previously applied in other antiviral projects[94]. The VS site will be defined as a pocket at the Ephrin-B3 (entry receptor) recognition region on G-gp that is suitable for small molecule binding. To tackle the lack of NiV and HeV polymerase crystal structures, the viral polymerase VS will utilize homology models built through an AI-aided protein structure prediction algorithm[95,96]. Both the RNA binding cleft and allosteric binding regions will be defined as VS sites. Finally, the library for actual HTS will be tailored down to 10K−100K according to both the ML and VS predictions. Overall, the AI-aided screens would significantly increase the HTS hit rate of novel antiviral chemical matters that are both phenotypically potent and target-specific.

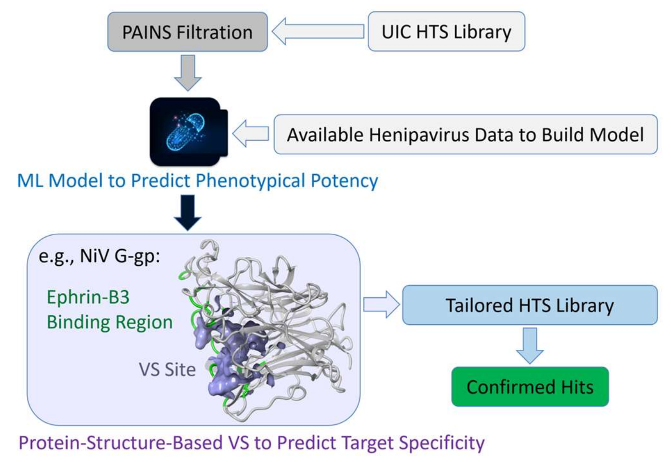

Figure 8. Workflow of AI-aided screens

There are several possible outcomes from the proposed HTS: 1) the majority of the compounds do not exert any inhibition on rCedPV infection. That is, the target cells infected with the virions in the presence of these compounds give the same levels of luciferase activity as the no compound control (DMSO). These compounds will not be further considered; 2) some compounds may enhance entry and infection (Higher Luc). These compounds will be noted but will not be characterized further since they are not the focus of this project. Nevertheless, we realize that these compounds may have added value in elucidating further details of the entry and replication of henipaviruses; 3) some compounds can "inhibit" and these compounds could be active during replication (post-entry), on the membrane fusion step during viral entry, or may be toxic to cells. These compounds will be the focus of this application, and their effects will be further evaluated.

Hit Selection Algorithm. A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used again as a specificity control. We expect that the majority of the "hit" compounds will not inhibit the VSVG-mediated viral entry. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (non-potent) will not be actively pursued, while the more potent compounds (potent inhibitor, EC_{50} less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. **Hit Validation, Cytotoxicity Assessment and Ranking.** We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" (Promega, Madison, WI) as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). The results from the screening will be analyzed and the compounds ranked according to antiviral potency and cytotoxicity. **Hit Quality Control and Identity Assurance.** The most potent and selective compounds will be analyzed for chemical purity (HPLC) to confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds found to be <80% pure will be purified and retested; compounds found to have incorrect structures assigned will be corrected. We will eliminate compounds that are known PAINS[98] (e.g., rhodanines aralkyl pyrroles, hydroxyphenylhydrazones), or that have reactive functional groups (e.g., Michael acceptors, alkylating agents).

2.3. Evaluation of protective properties of the advanced candidates in the henipavirus infectious assays will be done as previously described[71]. Vero cells will be seeded in a 96-well plate at a density of 2 × 10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (concentrations ranging from 100 μM to 0.01 μM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 hpi, viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to that from parallel cultures with virus and DMSO vehicle only. This work will be performed in the BSL-4 facility at UTMB by the **Geisbert Lab**.

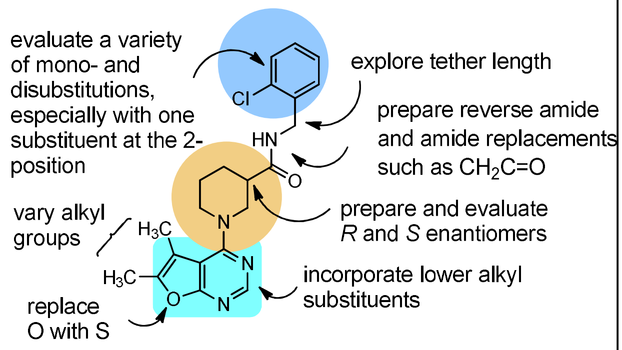

Figure 9. SAR development plan for furopyrimidine **Z2**.

2.4. Chemical optimization and SAR studies. In the initial stages, we will keep most of the molecule of interest constant while making well-defined changes in substituents. We will initially probe steric and electronic factors of the substituents, but more substantial changes in the scaffold will be investigated as the structure is optimized. By an iterative process of design, synthesis, and assay, we will improve the structure, and ultimately produce a fully optimized structure. We will also assess the cytotoxicity and construct Structure-Toxicity Relationships (STR). For potent, specific inhibitors, the SAR and STR will diverge at critical points, and we will synthesize novel inhibitors with maximized activity and minimized cytotoxicity. The SAR plan for optimization of the HTS hit Z2 is exemplified in **Figure 9**. Substituent changes on the core fused scaffold will involve variation of the alkyl groups on the furan ring, as well as adding alkyl groups at the 2-position of the pyrimidine ring, to explore the optimum overall size for the core. Note that we will be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. We will also replace the oxygen atom in the furan with a sulfur atom to compare the effect of changing the furan ring to the larger

Scheme 1. Preparation of analogs of furopyrimidine **Z2** with optimized amide *N*-substituent.

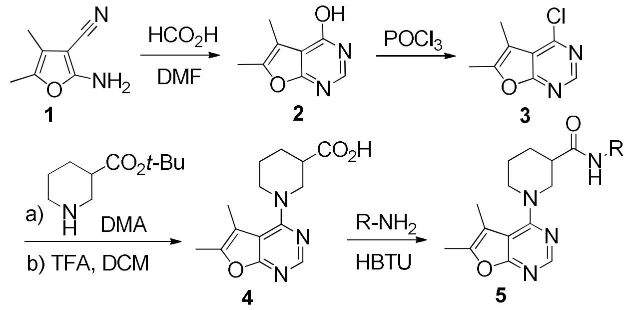

Table 2. Actelion OSIRIS calculated parameters for **Z2** (compound A) and proposed analogs.

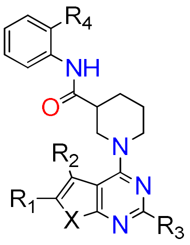

ID	R_1	R_2	R_3	R_4	R_5	cLogP	Sol	MW	Druglike-ness	Drug Score
A	Me	Me	H	Cl	O	4.0	-6.7	384	-0.95	0.23
B	Me	Me	H	F	O	3.5	-6.3	368	-2.53	0.27
C	Me	Me	H	Cl	S	4.4	-6.8	400	2.01	0.32
D	Me	Me	H	F	S	3.9	-6.3	384	0.46	0.39

H	H	H	H	F	S	3.1	-5.5	356	2.14	0.54
I	H	H	Me	F	O	3.0	-5.2	354	2.82	0.61
J	H	H	Me	F	S	3.3	-5.2	370	3.48	0.60

thiophene ring. Importantly, we will explore the biological activities of the *R*- and *S*-stereoisomers of this racemic molecule to determine whether there is differential recognition of these antipodes at the site of interaction in the inhibition assays. In addition to evaluating a variety of mono- and disubstituted aromatic rings, we will also explore length of the tether connecting these aromatic units to the amide nitrogen atom, knowing that both benzyl groups and phenyl groups give rise to active compounds.

The synthetic route that we envision for the preparation of the furopyrimidines is shown in Scheme 1, as illustrated for the optimization of the amide *N*-substituent for furopyrimidine analogs of compound **1**. Starting with the commercially available 2-amino-4,5-dimethyl-3-furancarbonitrile (**1**), treatment with formic acid in dimethylformamide will produce the 5,6-dimethylfuro[2,3-*d*]pyrimidine (**2**). Conversion of **2** to the corresponding chloro compound **3** is accomplished by treatment with phosphoryl chloride. Displacement of the chloro group with piperidine-3-carboxylic acid *t*-butyl ester, followed by removal of the *t*-butyl ester with trifluoroacetic acid, gives key intermediate **4**, which can then be elaborated to amides **5**[99]. In Table 2 is shown a set of proposed compounds related to **Z2** (compound **A**) for which we show parameters calculated using Actelion OSIRIS software[100]. All of the proposed compounds (**B** through **J**) show improved druglikeness and drug scores with respect to **Z2**, and therefore represent promising new targets for synthesis and evaluation.

2.5. *In vivo* testing of lead compounds NiV/HeV infected hamsters. The *in vivo* activity of the most potent compounds from 2.5 will be tested in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) inoculated i.n. with ~ 5x10^6 PFU of NiV_B or HeV[75,89-91]. Animals will then be treated by i.v. injection ~ 1 hour after virus challenge. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. Antiviral candidates showing the most protection will be selected for assessment in NHPs.

2.6. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates. A final proof of concept study will be performed in NHPs using the lead candidates providing best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated i.t. and i.n. with a uniformly lethal challenge dose (~ $2.5\text{x}10^5$ PFU per route, ~ $5\text{x}10^5$ PFU total dose) of NiV or HeV as described previously[29,35]. The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion up to 5 days after viral challenge (initiation time informed by hamster studies) while a control animal will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by several methods, including respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival.

2.7. Mechanism of action (MOA) studies. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed: 1) **Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells.** Confluent HEK293T cells in a 6-well plate will be treated in duplicate with cell growth medium containing either DMSO or selected furopyrimidines at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 h post infection (hpi) cells will be collected to determine viral protein expression by standard western blot techniques or viral RNA levels by quantitative real time polymerase chain reaction assays (q-RT-PCR). Subsequent immunoblot with CedV specific antibodies against the attachment (G) and fusion (F) that were generated in the **Broder Lab**. In addition, antibodies to CedV-N and CedV-P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the P gene. The one-step reaction will be performed using the Applied Biosystems (ABI) 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time; 2) **Determine the stage(s) of inhibition of furopyrimidines (and quinazolines) in the viral lifecycle.** For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 hour at 37 °C, at which time the viral inoculum will be removed and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay[37,38]. Results from this data will indicate at which stage of the viral life cycle the compounds are affecting; 3) **Analyze escape mutants against the advanced lead compounds with Cedar virus.** Escape mutants provide information on potential targets of small molecule inhibitors as well as the potential for development of drug resistance in the field. We will generate escape mutant rCedV viruses that are resistant to the identified lead compounds and determine the rate at which resistance is developed to our inhibitors. In so doing, we will also identify protein coding as well as regulatory sequences that are altered. HEK293T cells will be infected with rCedV virus at MOI of 1 in the presence of the lead compounds at 10 times the EC_{50} values of each of the compounds. At 72 hpi, viral supernatant will be passaged in Vero cells at MOI of 0.01 in the presence of increasing concentrations of compound for >5 passages to obtain the escape mutants. The escape mutants will be plaque purified and subjected to whole-genome sequencing. The identified mutation(s) will be introduced into the rCedV anti-genome cDNA and upon successful incorporation of the mutation, the mutant rCedV will be rescued and sequenced to ensure retention of the introduced mutation. The rescued mutant rCedV will be fully characterized as described.

Aim 3. Develop combination therapy of broad spectrum siRNA-conjugate therapeutics and/or replication complex inhibitors against Hendra and Nipah viruses. Different combinations of broad spectrum siRNA therapeutics and small molecule therapeutics will be evaluated in hamsters infected with HeV and NiV_B. The objectives of these studies will be to determine if the combinatorial approach will confer 1) improved antiviral efficacy over that seen with each therapeutic alone; and 2) improved efficacy when treatment is initiated either at, or even after, the prodromal phase. A combinatorial therapy approach to treat henipaviral infection has several advantages. The application of multiple modalities ensures against the development of viral escape mutants, as each of the therapeutics target different aspects of viral infection biology. In addition, therapeutic activities may synergize and offer greater efficacy in treating henipavirus infection when compared to a therapeutic used alone.

3.1. Define breakthrough conditions for anti-henipavirus inhibitors in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 that are shown to completely protect hamsters against lethal henipavirus infection. Aims 1 and 2 assess protective efficacy at times shortly after henipavirus exposure. The goal of this Subaim is to determine the time points of treatment initiation when the antivirals fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^6 PFU of NiV or HeV[75,89-91]. Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

3.2. Combination therapy of anti-henipavirus inhibitors in hamsters. This Subaim will employ the most promising antivirals from Aims 1 and 2 where breakthrough conditions have been defined in 3.1. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5x10^5 PFU of NiV or HeV[75,89-91]. Treatment with at least two different antivirals will be administered beginning at a time point where substantial breakthrough was shown in 3.1 for each individual antiviral in 3.1 to determine if combining at least two different antivirals improves survival. Groups may be repeated or group sizes increased as needed to obtain appropriate statistical power to show the survival benefit of combination therapy.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues, i.e., antiviral drugs will be coded so that researchers will not know which compounds were given to which animals until experiments and analysis are completed. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

Pitfalls and Alternative approaches: A theoretical (although unlikely) pitfall for siRNA design In Aim 1 would be the inability to identify a potent siRNA against one or more of the four viral gene targets. However, we have previously shown that LNP bearing siRNA against just one or two viral genes constitute effective antiviral therapeutics in the context of Marburg virus[50], and Sudan virus[52]. Another possible pitfall would the inability to identify a LNP formulation that provided sufficient siRNA delivery to the lung. Here, we would switch to an alternate siRNA delivery strategy, using a ligand-siRNA conjugate approach. Other groups have shown gene silencing in the airway using this type of delivery system[101]. For Aim 2, the proposed synthetic derivatives will be synthesized, under the guidance of Dr. Gaisina, by **MedChem Core.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy based on a different reaction sequence. Should we encounter a scaffold-related problem with our furopyrimidines, we will switch to the additional HTS hits[71] shown in **Figure 10** and use them as our backup scaffolds for defining lead compounds for advancement.

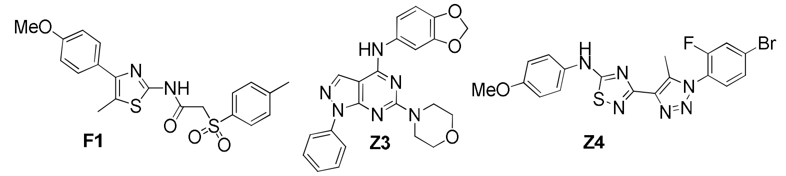

Figure 10. Additional HTS hits.

SPECIFIC AIMS

The Administrative Core of the Antiviral Drug Discovery and Development Center-2 (AD3C-2) has a history of providing organizational leadership for the current Antiviral Drug Discovery and Development Center (AD3C), a NIAID Center of Excellence for Translational Research (CETR). The Administrative Core of AD3C-2 will continue to play a key role in leadership, communication, coordination and oversight of the proposed projects and cores in this application. Importantly, it will promote collaboration and synergy between the projects. Operationally, it is responsible for the fiscal and contractual management of the Center. Further, it organizes such activities as meetings among the Scientific Advisory Board (SAB), members composed of at least 5 non-conflicted external advisors, the Executive Committee (EC, lead PIs) and, and an annual meeting of all Projects and Cores. In addition, it will manage the inter-institutional consortium/contractual agreements. The broad objectives of the Core are as follows:

1. **Providing programmatic and administrative leadership**
   a. Make decisions, specifically “go versus no-go” per discussions with the Executive Committee (EC).
   b. Track and encourage research productivity
   c. Promote interactions and collaboration between Projects and Cores, in particular facilitate overarching synergy to pursue orally bioavailable broad-spectrum antivirals as well as sharing of reagents
   d. Monitor the direction and overall priorities of the Center
   e. Directly interface with NIH staff, consultants, and the Scientific Advisory Board (SAB)
2. **Fiscal and administrative management of the center**
   a. Oversee expenditures, budget information, fiscal reports
   b. Manage contracts and the consortium agreement
   c. Establish and monitor compliance with federal and NIH regulations
3. **Develop, support and monitor progress of projects**
   a. Manage projects through regular virtual and in-person meetings
   b. Organize quarterly project reviews (face-to-face or virtual) by the EC
   c. Monitor overall Center research quality and progress annually with the SAB
   d. Solicit additional regulatory guidance on an as-needed basis
   e. Assist with identification and management of intellectual property developed by projects
   f. Manage the ‘Developmental Research’ and ‘Mentored Projects.’ The later will train young investigators in antiviral drug discovery.
4. **Stimulate collaboration and synergy**
   a. Identify potential areas or topics of collaboration between Projects and Cores
   b. Provide and facilitate access to resources needed in the Projects
   c. Ensure that all active compounds are cross-evaluated in other Projects
   d. Manage a data sharing and project tracking web-based system
   e. Encourage public/private partnerships and alternative sources of funding to expedite project development and translation to INDs
5. **Facilitate meetings**
   a. Host monthly virtual meetings among project teams
   b. Organize virtual and in-person meetings of the Project and Core PIs (EC)
   c. Organize and implement an annual face-to-face meeting with all involved personnel, including the SAB
   d. Facilitate consulting and other scientific and professional meetings
   e. Attend and assist with coordination of the NIH reverse site visit
6. **Outreach to the public**
   a. Maintain a website
   b. Manage press releases
   c. Assist with scientific publications and ensure grant acknowledgement

We firmly believe that a strong Administrative Core will be crucial to the success of the AD3C-2. We have brought together leading virologists, chemists, scientific advisors, and projects and cores from around the country and are confident that the Administrative Core will facilitate communication and collaboration among the PIs. Accomplishing the objectives set out above will ensure focus and synergy among the projects, accelerating the development of new, and potentially broad-spectrum therapeutics for emerging infections caused by coronaviruses, henipaviruses, flaviviruses, bunyaviruses and alphaviruses. With the new Developmental and Mentored projects to expand the scope and flexibility of the overall center, we will have new and exciting paths to follow.

I ADMINISTRATIVE CORE STRATEGY:

I.1 RELATIONSHIP OF THE ADMINISTRATIVE CORE TO THE PROGRAM'S GOALS

The first iteration of AD3C was established as a CETR in 2014 and is driven toward product development of broad-spectrum antivirals. Over the years of its existence, we have explored novel targets and defined their role in viral biology. Furthermore, we have utilized state-of-the-art screening mechanisms and first-rate medicinal chemistry resources to develop novel hit and lead molecules for unmet medical needs. Essential to this process has been the involvement of individuals with basic, translational, clinical and regulatory experience, and bringing them together in a structured way to ensure progress down the drug discovery and development.

AD3C and now this iteration, AD3C-2, was modeled after the Alabama Drug Discovery Alliance (ADDA), a collaboration initiated in 2008 between the University of Alabama at Birmingham (UAB) and Southern Research (SR), and directed by Dr. Richard Whitley – the proposed Program Director/Principal Investigator for this AD3C-2 application and also Lead of this Administrative Core. Similar to the AD3C-2, the ADDA aims to support the discovery and development of therapeutic molecules that address unmet medical needs. It has built on the expertise present at both UAB and SR, with several in preclinical lead development and one compound in phase I clinical trials. The ADDA has succeeded by emphasizing the use of interdisciplinary teams to achieve the project goals. These teams consist of investigators with a wide variety of expertise from both UAB and SR and contribute to the program's success. In addition, individuals from the respective technology transfer offices are an integral part of the team in order to guide intellectual property development and any commercial opportunities that may arise. Another key member of this Administrative Core is Dr. Stephanie Moore who plays a critical role in orchestrating the ADDA. She will be an important go-to for the AD3C-2 teams to facilitate communication among teams and directly work with each member of the team for communications, meetings, and progress. She has assisted the current AD3C by managing progress and communication among projects and cores as well as the NIH. The Core's Project Oversight Director, Dr. Shi from University of Texas Medical Branch (UTMB), is the proposed Co-Program Director/Principal Investigator for this AD3C-2 application. He is an expert in virology, drug discovery, and vaccine development with both translational and basic research expertise from academia, a public health laboratory, and the pharmaceutical industry. He has extensive experience in leadership, mentoring, and has played a major role in the response to the SARS-CoV-2 by quickly developing critical assays that enabled Pfizer's COVID-19 vaccine development. With the experience of these core members, and those introduced below, the administrative core will be in a position to support all of the program's Core and Project teams.

For this new iteration, Antiviral Drug Discovery and Development Center-2, we have structured our program in a similar manner as AD3C; however, we have added important new members. The focus of our drug discovery screening is biochemical in nature. Briefly, we will continue to use the structure of an interdisciplinary model to manage the five proposed research projects and their interactions with the Screening, Medicinal Chemistry, and Structural Biology Core. The Administrative Core will organize regular team meetings in which the projects' progress will be discussed, along with the identification of logical next steps. These meetings will provide an opportunity to identify potential solutions to encountered obstacles, whether those are resource or expertise related. In addition, closely monitoring projects will ensure clarity about when assays are completed and compounds of interest have emerged, particularly those of potential interest to all the projects. The expectations of each of the cores will be ensured by the Administrative Core. The Screening Core will provide the expertise and platform to develop high-through put screening and assay development for each Project. Further, the Medicinal Chemistry Core is one of the most critical aspects of this application. Chemistry from SR, University of Southern California, and UTMB with consultation and collaboration of industry partners, Arbutus, Genevant and Gilead, through iterative design and AI-assisted modeling, will design compounds optimized to inhibit viral replication among all project viral families and also decrease non-specific interactions with host-targets. Compounds must have drug-like properties for oral delivery. Since multiple medical chemistry resources are involved, efforts will be co-ordinated by Corinne Augelli-Szafran at SR and monitored by the Administrative Core. A critical asset of this program is the new Structural Biology Core, consisting of structural biologists who are also virologists. The Administrative Core ensures that each project utilizes the resources within the cores by holding monthly meetings among project and Core members.

Together, our Project PIs and Core leaders have an impressive track record in research productivity, collaboration and expertise in drug discovery and development. With our Administrative Core, we plan on maximizing utilization of these groups by providing a structured framework in which projects and advanced compounds with *in vivo* antiviral activity can progress as expeditiously and efficiently as possible.

I.2 ADMINISTRATIVE CORE STRUCTURE

There are three components to the planned Administrative Core: 1) the Core Personnel who manage day to day operations of the Center; 2) the Executive Committee (EC), which is responsible for monitoring progress of the Center's research projects as well as functionality of the Center's Cores and consists of all project PIs and core directors and 3) the Scientific Advisory Board (SAB) consisting of external advisors who will provide additional expertise and a high level review of the Center's productivity and direction on, at minimum, an annual basis; they will also be responsible for oversight and selection of the Developmental and Mentored Research Projects. Importantly, the SAB will provide 'go-no-go' insight on all projects. Regularly scheduled communications between these three components ensure timely dissemination of materials, information, data and advice – a detailed management plan can be found below under section I.3.

A key role of the Administrative Core is to support the project teams to guide the planning and progress of each individual research Project. In general, the Project teams include the project PI and listed co-investigators, but also key individuals from other projects with appropriate expertise, as well as personnel situated in the Screening Core, the Medicinal Chemistry Core, and Structural Biology Core. Involving individuals and expertise throughout the process help facilitate transferring compounds in and out of the Cores as well as between Projects, since personal relationships have been developed over time and individuals will be intimately familiar with the goals and details of the respective project. A diagram detailing the relationship of the Administrative Core with the Projects and Cores can be found in Figure 1.

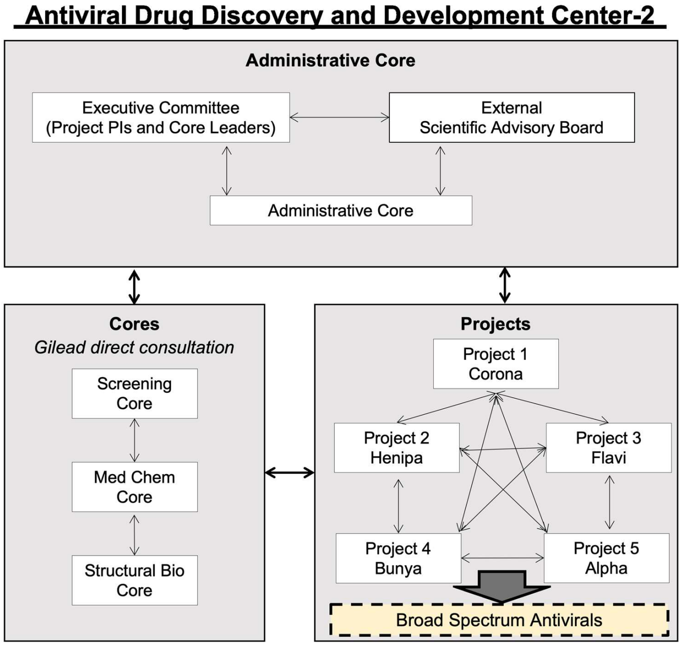

Figure 1 Structure of AD3C-2. Overall oversight will be provided by Drs. Richard Whitley and Pei-Yong Shi.

I.2.1 Role of Administrative Core Personnel

Richard J. Whitley, MD – Core Lead (2.4 calendar months)

Dr. Whitley is currently Distinguished Professor, Professor of Pediatrics, Microbiology, Medicine and Neurosurgery, and holds the Loeb Chair in Pediatrics in the Heersink School of Medicine at the University of Alabama at Birmingham (UAB). He has performed translational research for more than 40 years at UAB and has focused on antiviral drug development ranging from molecule selection, preclinical toxicology, ADME, animal models, resistance assessment, to human studies. Through his contracts from the National Institute of Allergy and Infectious Diseases' (NIAID) Collaborative Antiviral Study Group (CASG), he has directed multi-institutional Phase I-III trials in both adults and children that have led to seven NDAs. In addition, his team has performed detailed pharmacokinetic and pharmacodynamic studies on drugs advancing toward licensure for pediatric indications (acyclovir for the neonatal HSV and herpes simplex encephalitis, valganciclovir for congenital cytomegalovirus infection and oseltamivir for influenza in babies < 2 years of life. As the PI of AD3C-2, Dr. Whitley is also the Administrative Core Lead, and will utilize his expertise in managing consortia with multiple institutions to ensure appropriate communications between projects and cores and will aid in conflict resolution, should any conflicts arise.

Pei-Yong Shi, PhD – Core Project Oversight Director (1.8 calendar months effort)

Dr. Shi is the Director for the Institute for Drug Discovery, Vice President for Research Innovation, and Associate Chief Research Officer at UTMB. He is an expert in virology, drug discovery, and vaccine development with both translational and basic research expertise from academia, public health laboratory, and pharmaceutical industry. He served as Executive Director at Novartis Institute for Tropical Diseases from 2008 to 2015 and has a track record in leading multifunctional teams to develop therapeutic and vaccine products. Dr. Shi's team developed the first infectious cDNA clone and replicon systems for Zika virus and the epidemic strain of West Nile virus. His team also developed the first peer-reviewed infectious cDNA clone for SARS-CoV-2. Together with Dr. Richard Whitley (PI of the AD3C-2 Center), Dr. Shi will be responsible for the overall operation of the AD3C-2 Center as well as the oversight of the projects at UTMB.

Stephanie Moore, PhD – Associate Administrative Core Director (3.6 calendar months effort)

Dr. Moore is Instructor in the Department of Pediatrics, Heersink School of Medicine at the University of Alabama at Birmingham. She is also the Associate Director with the Alabama Drug Discovery Alliance (ADDA). In that capacity, she interfaces with a wide range of scientists involved in the drug discovery and development process, with a focus on projects in oncology, infectious diseases and neurodegenerative disorders. She is trained in biochemistry and protein biology and has a broad range of publications in protein post-translational modifications and translational studies regarding oxidative lung injury. For both collaborative efforts of the ADDA and AD3C, she aids in building Project teams for funded drug discovery grants, facilitates regular meetings and helps with communications between UAB and SR. Importantly, she will organize the necessary project teams, ensuring the appropriate expertise is represented and will organize and chair the various project team meetings. In addition, she will work with AD3C-2's PIs and Core Lead (Rich Whitley and Pei-Yong Shi – see above) and Business Officer (Sarah Dowdy – see below) to achieve the Administrative Core's objectives. These include the organization of all in-person meetings, communication with the EC and SAB, communication with NIAID, preparation of relevant documents such as annual progress reports, solicitation and organization of scientific review of supplemental research projects.

Sarah Dowdy – Administrative Core Business Officer (2.4 calendar months effort)

Ms. Dowdy has 15 years of experience in research administration managing research grants and contracts. She is the current AD3C program manager and will oversee the financial and contractual administration of the proposed AD3C-2. She has extensive experience with coordination of subcontracts, institutional invoicing, federal guidelines related to both grants and contracts and large meeting planning. She will be responsible for all budgetary issues including institutional consortium/cooperative agreements, subawards, amendments to the budget, invoicing, monitoring spending, and keeping the PI and Executive Committee informed about the status of the annual budget. She will be responsible for grants management issues and will aid Dr. Moore (see above) with meeting organization, the annual noncompetitive progress report preparation, and all other proposals related to AD3C funding. She will oversee all compliance and federal regulatory requirements of AD3C.

Other Administrative Staff

Other Administrative Staff includes Ms. Sara Davis (4.2 calendar months) who is the administrative coordinator for Dr. Rich Whitley. Ms. Davis will assist Drs. Whitley and Moore with logistical aspects of meeting scheduling, travel arrangements, and organization as well as maintenance of the AD3C-2 website. An additional administrative support person (4.2 calendar months) will be on-boarded to assist with the complex program management logistics involved in this large program. Support person would be selected for basic skills in note taking, time management, communication, and assisting with online submissions.

I.2.2 Executive Committee

The Executive Committee will be composed of all Project PIs and Core Leaders and will be responsible for monitoring the progress and direction of each project, as well as AD3C-2 as a whole. The EC will meet quarterly: one meeting will be held at the time of the annual AD3C-2 meeting in Birmingham, AL, and a second, six months following the annual meeting, at a rotating project site or in conjunction with related national scientific meetings such as International Conference on Antiviral Research (ICAR). Two additional meetings will be virtual. During these meetings, the EC will review each project and core for scientific progress as measured against the proposed timelines and milestones, as well as the utilization of financial resources. Additional opportunities for collaboration between the projects will be identified.

EC members will be familiar with the Projects since each member will participate in monthly conference calls where all Projects provide a status update. This frequency of communication will ensure that EC members are well informed and can make appropriate decisions during their quarterly EC meetings.

EC members, in addition to the PI's, Drs. Whitley and Shi, include Drs. Alec Hirsch, Dan Streblow (Oregon Health & Science University), Michael Diamond and Sean Whelan (Washington University), Mark Denison (Vanderbilt University), Mark Heise (University of North Carolina, Chapel Hill), Bob Bostwick and Corinne Augelli-Szafran, (SR), Charles McKenna (University of Southern California), Vineet Menachery, Jai Zhou, Alex Freiberg, Tom Geisbert, and Shinji Makino (UTMB), Jamil Saad, and Stephanie Moore (UAB). Our pharmaceutical partners will be invited to attend.

I.2.3 Scientific Advisory Board (SAB)

We will recruit a Scientific Advisory Board of at minimum 5 non-conflicted advisors with experience in molecular virology and biochemistry as well as, importantly, drug discovery and development. Since our Center is engaged ultimately in product development, we will have at least two advisors with industry-level expertise in antiviral therapeutics and especially those with experience at all levels of drug development. Considering the multiple contacts that the various Project and Core Leaders have had with industry throughout their respective careers, we do not anticipate any hurdles in identifying appropriate individuals. All proposed members will be vetted by NIAID staff. The SAB will complement the EC by providing a high-level evaluation of AD3C-2's progress and successes and will help refine and focus the Center's activities and direction, particularly as to those projects that should be discontinued. The SAB will perform this evaluation annually and will be invited to the EC meeting in conjunction with the annual AD3C-2 meeting, in Birmingham, AL. Additionally, their advice will be sought at quarterly intervals for appropriate projects. Of note, appropriate NIAID staff will also be invited to join this meeting, should they be able to attend. Prior to these meetings, Projects and Cores will prepare annual reports that will be submitted to the SAB for evaluation. Scheduling the SAB meeting at the end of the annual AD3C-2 meeting will allow the SAB members to attend scientific presentations of the projects that will complement the written reports, thus fully informing these individuals about the Projects' status and direction.

Annually, NIAID requires a reverse site visit at which time the progress of each Project is presented. Such meetings will be organized by the Administrative Core. Importantly, in addition to Project PIs, at least one member of the SAB will be in attendance in order to present an external, objective evaluation of the projects to NIH Program Officers and staff.

The SAB will also be engaged on an ad-hoc basis if the EC deems this appropriate. EC members participate in updates about each Project on a monthly basis via teleconference in addition to a more thorough review during the semi-annual meeting, providing important touch points to evaluate the need to engage the SAB. Should this need be identified, the Administrative Core will mediate a virtual meeting to discuss the matter.

Finally, we expect that several SAB members to have extensive regulatory expertise and will help guide the projects to an appropriate preclinical development plan in collaboration with the EC.

I.2.4 Regulatory Expertise with Respect to the Challenges Facing Infectious Diseases

The Center will draw upon the regulatory knowledge and experience of the PI, Project and Core Leaders and SAB to meet the regulatory requirements related to research in emerging infection diseases. As past president of the Infectious Diseases Society of America (IDSA) and a member of the Working Group on Influenza for the Presidential Council of Advisors on Science and Technology during the 2009 influenza pandemic and the vaccine advisory board for the current COVID-19 pandemic, Dr. Whitley is intimately familiar with challenges of conducting research in infectious diseases in the existing regulatory environment. He has led numerous UAB research projects that included both *in vitro* and *in vivo* work related to orthopox drug discovery in BSL3 certified labs. In addition, he was instrumental in the preparation and successful submission of the funding application for the BSL3 facility, SEBLAB, which opened at UAB in 2009 and is aware of strict oversight, certifications, and regulations required for select agent research lab including CDC, IACUC and Occupational and Safety review and approval for projects. Preclinical toxicology studies have been overseen by him in preparation for human Phase I studies. He has been the PI for the NIAID Collaborative Study Group that was responsible for all phases of clinical trial development from protocol design, IRB approval, including the establishment of a universal IRB, biostatistical coordination, investigator recruitment, clinical trial monitoring (by FDA standards), addressing FDA audits, and data analysis and reporting. Data tapes were provided to the NIH, FDA and pharmaceutical sponsors for registrational purposes. His studies have led to the definition of the standard of care for herpes encephalitis, neonatal herpes, congenital cytomegalovirus infections, and influenza in children, among others.

Dr. Shi also has vast experience related to navigating the challenges of regulatory requirements for research in emerging infectious diseases. As discussed above, he has unique expertise within the context of academia and industry, but he also has worked in the realm of public health too. As a key leader at Novartis institute for Tropical Diseases, he has been responsible for developing antiviral strategies and has executed drug discovery and development for this purpose. A recent example is his team at UTMB that delivered Phase I and II neutralization data for Pfizer/BioNTech’s COVID-19 vaccine, which led to the first FDA EUA and final approval.

In addition to regulatory challenges pertinent to infectious diseases, several individuals on the EC have extensive experiences in regulatory expertise appropriate for lead development activities in general, including patent issues and IND submissions.

I.3 MANAGEMENT PLAN

It is imperative that AD3C-2 is appropriately managed to ensure that projects can flourish and be supported by high-functioning cores. Timely and clear communication will be critical to achieve the objectives listed under the Specific Aims (above), and further elaborated on below. The Administrative Core will oversee and manage the Center activities by implementing the following:

1. **Providing programmatic and administrative leadership**
    a. Make decisions, specifically “go versus no-go” decisions per discussions with the EC and SAB.

        Quarterly in person meetings will provide an opportunity for the EC to be updated in-depth on progress made in each project, and provide feedback to adjust Projects’ direction and focus, as needed. At key points, more frequent meetings may be required and organized. Of note, EC members will also attend monthly conference calls.

    b. Track and encourage research productivity

        Project teams have conference calls at least monthly in which an update of the projects will be presented. This is summarized by the Administrative Director, Stephanie Moore. Meeting minutes, including action items, will be distributed to the Project teams using a ShareFile site managed at SR. Minutes will include a list of metrics, including Intellectual Property disclosures filed with respective technology transfer offices, (provisional) patents filed, patents awarded, presentations at meetings (oral or poster), and those publications submitted and accepted. These metrics will be used to assist in preparing annual progress reports to the EAB and NIAID staff.

    c. Promote interactions and collaboration between Projects and Cores

        The evaluation of active compounds in multiple projects to identify broad-spectrum antivirals will promote interactions and collaboration between Projects. In addition, the EC will meet quarterly and have a discrete agenda item for identification of additional opportunities for collaboration. Finally, the monthly conference calls for the Project teams regularly inform team members about status of all projects. Along with promoting interactions, the core will utilize the structure to identify and manage the resolution of problems in a timely fashion.

   d. Monitor the direction and overall priorities of the Center

      This will occur during the EC and SAB meetings immediately following the annual AD3C-2 meeting. We will invite NIAID staff to attend these meetings as well, who can provide feedback on how the Institute sees AD3C-2 evolving.

   e. Directly interface with NIH staff and consultants

      As mentioned above under 1.d, NIAID staff will be formally invited to attend the annual AD3C-2 meeting. In addition, the Administrative Core will regularly communicate with NIAID to answer questions that may arise and provide informal updates about AD3C-2's progress. Further, this Core will facilitate the reverse site visit at the NIH.

2. **Fiscal and administrative management of AD3C**
   a. Finances: oversee expenditures, budget information, fiscal reports

      Project leaders and administrators at each institution will be provided with quarterly financial reports, which will provide current balances and projected balances based on rate of expenditures, to ensure that projects are not over/under budget for the year. Project leaders will be notified should it appear that funds are not being expended as outlined, or if it appears re-budgeting is needed.

   b. Manage contracts and the consortium agreement

      Our team has navigated the implementation of an institutional consortium/contractual agreement among many of the members of this current proposal. Under this proposal, the Administrative Core will facilitate the development of a new consortium agreement with all members and with requirements specific to this application. We have provided the consortium agreement plan to the PIs for this application and they are committed to ensure the development of this agreement (see letters of support). The core also facilitates preparation and processing of other agreements or forms such as confidential disclosures (CDAs), material transfer agreements (MTAs) or invention statements that may be needed by investigators.

   c. Establish and monitor compliance with federal and NIH regulations

      The Administrative Core will ensure compliance with the financial and administrative aspects of the award. AD3C-2's Business Officer, Ms. Dowdy, will work closely with UAB's Office of Sponsored Programs as well as with similar offices at the participating institutions and will create and maintain necessary documentation, such as technical and administrative reports, preparing justifications, appropriately acknowledging NIAID support of research findings in publications, announcements, news programs, and other media, and ensuring compliance with other federal and organizational requirements.

3. **Develop, support and monitor progress of Projects**
   a. Manage Projects by having regular conference calls and in-person meetings

      As noted above, Project teams will have monthly conference calls with progress being tracked and to-do-items clearly delineated by preparing and distributing minutes by the Administrative Director. Quarterly EC meetings will provide regular feedback to the Projects, allowing rapid realignment, should Projects veer off course.

   b. Organize quarterly Project reviews (face-to-face) by the EC

      As elaborated above, the EC will meet quarterly, in addition to attending the monthly conference calls. This will provide the opportunity to review the Projects in greater depth.

   c. Monitor overall Center research quality and progress annually by the SAB

      Annual SAB meetings will provide feedback and advice on a high, project portfolio level. Preparation of progress reports in advance of these meetings will also help in preparing documents to be submitted NIAID.

   d. Solicit additional regulatory guidance on an as-needed basis

      As noted in above in section II.2.4, several investigators in AD3C-2 have regulatory expertise that can be brought to bear on the individual research projects. These individuals include the

PI, Drs. Whitley, Shi, and Geisbert, who have direct experience and track records in antiviral and vaccine product development.

e. Assist with identification and management of Intellectual Property developed by projects

As mentioned under Point 2.b, AD3C-2 will establish an umbrella inter-institutional consortium agreement, part of which describes how Intellectual Property (IP) is managed. Existing IP will not be affected by the agreement completed under this proposal, allowing collaborators to contribute exciting compounds to the consortium, but all inventions, developments and discoveries resulting from AD3C-2 efforts will be promptly disclosed to the employer of the associated scientists. Most likely, there will be joint inventions, as, for example, novel chemical scaffolds may be identified that have potent antiviral activity. In these cases, the Administrative Core will aid in the formation of appropriate inter-institutional agreements regarding this specific invention, which will describe aspects such as patent filing, prosecuting, patent maintenance, marketing and revenue sharing, among others, taking into account the relative contributions of the inventors.

f. Manage the Developmental Research and Mentored Project Programs

Developmental Research Projects – The Administrative Core will at the end of years 1 and 3 release a RFA to each Project and Core for Developmental Research Projects. The purpose will be to expand the scope of the current platform - develop inhibitors of viral replication – as well as to increase the range of research, investigators, and institutions involved in the program. Applicants will be directed to submit a 6-page description regarding the scope of the proposed studies and must describe how the work supports the platform, the innovation, and significance of the project, along with a biosketch and a budget and justification. The EC and SAB will be responsible for selection of applications that are potentially most scientifically fruitful and fit the Center platform. The selection committee, consisting of senior scientists in the program (TBD), will select applications to initiate studies in years 2 and 4 of the project period and must be completed by the end of year 5. The selection committee will be instructed to focus on expanding the scope of the current platform. Progress for the selected projects will be tracked by the Administrative Core and will be assisted as needed or ended with oversight from the SAB and EC. The awardees will be invited to attend monthly meetings (with appropriate agreements added as needed). The budgets will be limited for one or two years, with a range of $200,000 to $250,000 per project per year, direct costs. The Developmental Project Leader must commit at least 1.2 (CY) person months effort per year. Budgets for Developmental Research Projects can be requested in years 2-5 of the project period and must be completed by the award end date.

Mentored Projects – The Administrative Core will release, on a rolling basis during years 2-5, an RFA for mentored projects. The goal of this program will be to develop junior scientists on a career path of drug discovery. The application and the materials requested (2-page application, biosketch, and budget/justification) will be accepted via an online application form. The applicant will be required to define the scope and career goals. Once received, the Administrative Core will determine the potential fit and utilize the EC and SAB as the selection committee. Applicants must be postdoctoral fellows, early career investigators or senior investigators new to the field. The intention will be to increase the availability of qualified researchers and other personnel for antiviral discovery and to offer opportunities to advance the applicant's professional career. Furthermore, selection will focus on promoting diversity in the biomedical research workforce by making efforts to welcome underrepresented racial and ethnic groups, persons with disabilities and women. Once selected the awardee will be assigned a mentor and progress reports will be requested annually. No more than $600,000 (total) would be awarded per year; awardee(s) must devote 9.6 (CY) to the project. In addition to the financial support, the trainee would be offered the opportunity to travel to our core sites including SC, MCC, and SBC to get specialized support and training experience in drug discovery and development.

Commented [MS(1]: Cores please comment on whether this is feasible or if you have opinion on this.

4. **Stimulate collaboration and synergy**
    a. Identify potential areas of collaboration between Projects and Cores

As noted, monthly conference calls will allow Project teams to benefit from the expertise of all other scientists and will lead to additional collaborations. The quarterly EC meeting will specifically evaluate this topic during each of its get-togethers.

b. Provide and facilitate access to resources needed in the projects

   Although we have mapped out a reasonable timetable and order in which Projects will be queued up for assay support and medicinal chemistry, adjustments will undoubtedly have to be made as Projects progress and unexpected delays occur. The EC will evaluate adjustments and change resource allocation accordingly.

c. Ensure that active hits in one Project with potential against other viruses are evaluated in other Projects

   The SR Screening Core will perform a targeted evaluation of a novel 1000 compound library of nucleoside analogues against all viruses in the program. The goal is to identify hits with broad-spectrum activity. Further, all Project leads will be tested across the spectrum of virus families. These hits will be prioritized for further evaluation and optimization. The Administrative Core, in collaboration with the Medicinal Chemistry and Lead Development Core, will continue to manage a data sharing and project tracking website at SR.

   To avoid sending data files back and forth as email attachments, we will continue to utilize a password protected, web-based software system, Citrix ShareFile, to share data and track projects. All screening data on compounds will be available to all the Project team members. The data will be organized according to viral target; the database will be maintained by the SR Cores. SR has extensive experience in data management of large cooperative projects, including ones funded by NIAID. All the AD3C-2 and SAB members will have access to this secured and encrypted site.

d. Encourage public/private partnerships and alternative sources of funding to expedite project development and translation to INDs

   From the previous iteration, AD3C, we successfully competed for a complementary Partnerships for Countermeasures against Select Pathogens (R01) grant (R01AI132178). This grant has been awarded to Vanderbilt University, the University of North Carolina at Chapel Hill and Gilead Sciences, to facilitate (pre-) clinical development of an antiviral against coronavirus infections. Within, this new proposal, AD3C-2, we will encourage our projects to look for such opportunities to further support IND-enabling studies for our newly discovered direct acting antivirals.

5. Facilitate meetings

a. Host meetings among project and core teams

   Monthly virtual meetings will be held for the Project and Core teams.

b. Organize in-person meetings of the Project and Core PIs (EC)

   The EC will meet during the annual AD3C-2 meeting in Birmingham AL, and 6 months thereafter in person, at rotating project sites. Any additional meetings will be held virtually.

c. Organize and implement Annual face-to-face meeting with all involved personnel, including the SAB

   AD3C-2 will host an annual scientific meeting, in which all involved personnel will be invited to get together in Birmingham, AL, if the pandemic abates. The goal of this meeting is to learn about the status of each of the Projects. The SAB will convene at this time as well, to review the science and progress of each project. This will not only provide an opportunity to present an in-depth update of all Projects to the EC, SAB and NIAID staff, but will also provide an educational opportunity for involved trainees.

d. Facilitate consulting and other scientific and professional meetings

   As described under Point 3.d, we will solicit additional regulatory expertise on an ad-hoc basis, should this be necessary to move projects forward down the development pathway. The Administrative Core will make the necessary arrangements to orchestrate such consulting meetings and will invite the appropriate personnel to attend. Furthermore, if it is deemed appropriate to have Project teams meet face-to-face in addition to the annual meeting, the Administrative Core will facilitate such travel. This might occur for example when the chemists need to meet with the virologists to focus on the most attractive chemical series. A conference call may not allow a comprehensive interrogation of the data.

e. Attend the reverse site visit

The Administrative Core will help organize the attendance of Dr. Whitley along with selected key Project leaders and one SAB member at the annual NIAID reverse site visit. We have included funds in our travel budget for these meetings.

6. **Outreach to the public**
   a. Maintain a website

      The Administrative Core will develop a website for the AD3C-2. The website will list the Projects and the Cores, key personnel and publications, among others. This website will be updated regularly.

   b. Manage press releases

      UAB has an active and well-staffed Media Relations Office in place which includes science writers. It also maintains a web address exclusively for research related news (http://www.uab.edu/news/research). The Administrative Core will utilize the expertise of the staff to ensure that Center research findings and related news is disseminated in a timely and appropriate manner.

   c. Assist with scientific publications and ensure grant acknowledgement

      The Center will follow all current guidelines related to the NIH Public Access Policies for NIH funded research. It will assist project investigators with final review of publications resulting from research and ensure that it is submitted to PubMed Central and a PMCID number obtained. In addition, the Administrative Core staff will assist investigators with obtaining My NCBI lists of publications as part of the annual progress reports.

I.4 BSL3/4 ACTIVITIES AND ACCESS

Several Projects and Cores require access to BSL3/4 biocontainment facilities. The table below lists the various activities within AD3C that require such access, and which facilities will likely be used. Detailed descriptions of the BSL3/4 facilities can be found in the Resources sections of the respective projects.

Table I

Activity	Facility
Assay activity of compounds against SARS-Urbani Coronavirus with a nanoluc reporter (Screening Core)	Testing of antiviral activity of compounds against this virus will be performed at **Southern Research's** HTS BLS3 biocontainment facility. The Freiberg, Menachery, and Shi labs (**UTMB**) will be able to perform SARS-CoV, MERS-CoV, SARS-CoV-2, Nipah virus, and/or other BSL3/4 viruses for antiviral spectrum study.
Determine mechanism of action of compounds with activity against SARS-Coronavirus and in vivo evaluation of compounds' activity against SARS-Coronavirus (Project 1)	Both the Denison (**Vanderbilt University**) and Menachery and Shi (**UTMB**) labs have SA-registered BSL3 suites capable of working with SARS-CoV, and the Baric lab is well equipped to perform in vivo pathogenesis studies at SA-BSL3 conditions.
Compounds against Henipavirus replication (Project 2)	Both Geisbert and Freiberg labs (**UTMB**) will be able to perform Hendra virus and Nipah virus.
In vitro and in vivo evaluation of compounds' activity against West Nile Virus (Project 3)	Both the Hirsh (**OHSU)** and the Diamond (**Wash U**) labs have access to BSL3 facilities for cell culture and animal work at their respective institutions. Mice used in the in vivo evaluation will be housed either at Washington University or at OHSU in an A-BSL3 animal facility that has been approved by the USDA.
In vitro and in vivo evaluation of compounds' activity against Bunyavirus (Project 4)	The BSL-3 laboratory at SR will be utilized for testing of lead compounds against HPAI both in vitro and in vivo.

In vitro and in vivo evaluation of compounds' activity against VEEV and/or Chikungunya (CHIKV) (Project 5)	Dr. Streblow (**OHSU**) has access to the Vaccine and Gene Therapy Institute **(VGTI**) at Oregon Health and Science University, which contains 2 BSL-3 suites comprising 4 BSL-3 tissue culture laboratories of 800 sq. ft. each. One suite is registered with the Federal Select Agent Program. In addition, Dr. Streblow has access to the Oregon National Primate Research Center (ONPRC), one of eight national primate centers supported by the National Institutes of Health, located on the West Campus of the OHSU with the VGTI. Animals are housed in ABSL-2, 2+ or 3 containment housing as appropriate for the agent under study. Dr. Heise (**UNC-Chapel Hill**) supervises a secure BSL-3+ facility (approximately 1500 square feet), registered with the CDC for select agent use, with dedicated animal housing where animals will be housed in negative pressure caging.

I.5 ***<u>TRAVEL BUDGET</u>***

The Administrative Core has a travel budget that will allow for the following meetings:

- Reverse site visit to NIAID – Dr. Whitley along with 5 other Project and/or Core Leaders and 1 SAB member - Years 1-4
- In-person semi-annual EC meeting not associated with AD3C-2's annual meeting – all Years
- Annual AD3C-2 scientific meeting for all AD3C-2 personnel, in conjunction with the EC and SAB meeting – all Years
- Ad-hoc travel, such as project personnel traveling in between project sites, meeting with external consultants, etcetera.

In order to manage AD3C-2 travel budgets, the Administrative Core will utilize procedures developed as part of the meeting management and planning practices for the multi-institutional clinical trials group meetings organized by staff at UAB. As part of the meeting planning process, a budget will be set and expenses estimated for all costs including a "per traveler" estimate. Prior to any Center meetings, travelers will be provided with information related to both UAB and NIH travel guidelines, including federal rates for mileage, lodging and per diem to ensure that policies are followed. As required by UAB, travelers will be required to provide original receipts for all travel related expenses and reimbursement requests will be reviewed by Core staff prior to submission for processing. We are planning to host the annual AD3C meeting in Birmingham, AL, to keep meeting costs as low as possible. Personnel from UAB and SR would not need to travel, and Birmingham is only a few hours' drive from Nashville, TN, thus making travel for Vanderbilt personnel easy as well. Both UAB and SR have conference rooms available and have negotiated favorable rates with hotels in the vicinity. In addition, Birmingham is an airport serviced by Southwest Airlines, an airline with very favorable airfares which also services cities where the additional project sites are located (Portland, OR; Galveston (Houston), TX; Raleigh/Durham, NC).

The Screening Core (SC) will support Antiviral Drug Discovery & Development Consortium-2 (AD3C-3) for identification of novel antiviral drug-leads. SC will employ the unique set of Antiviral Assays based on rational selection of druggable viral targets and functional integration of these therapeutic targets into the molecular network of interrelated biological pathways that are linked to unique viral transcriptional machinery and associated functions. The integrated cellular models that we will construct will monitor the functions of molecular networks that are linked to viral transcription and proliferation. Before initiation of High Throughput Screening (HTS) campaigns, the SC will work with individual projects **(Figure 1)** to assess the candidate target across a common set of selection criteria such as genetic evidence, druggability, assay viability, availability of crystal structures, and availability of known ligands and essential role of the target in viral transcription and proliferation.

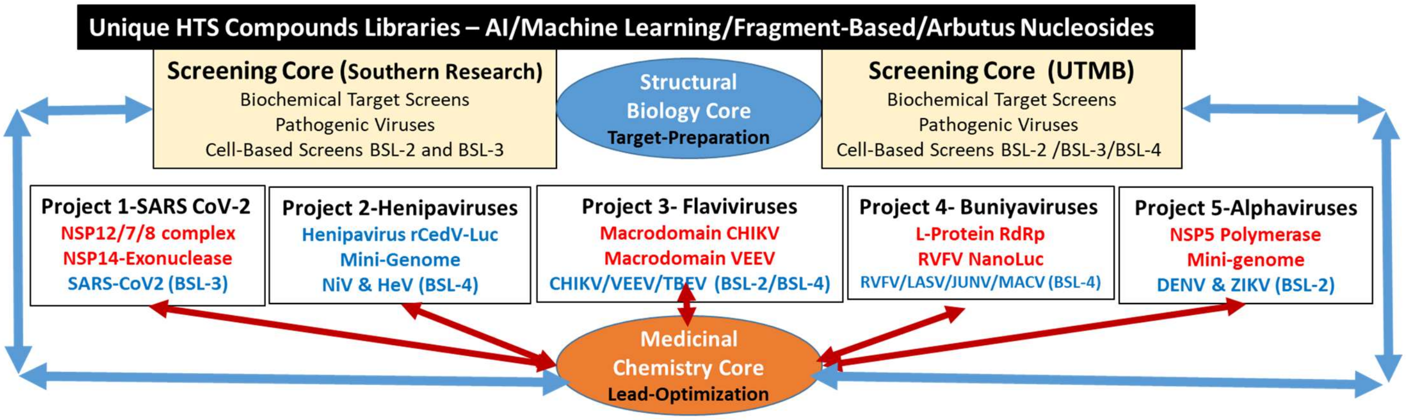

Figure 1- Overview of Antiviral Screening Core and Relationship with Other Cores and Individual Projects. The target screens shown in **Red** have been selected for HTS campaigns and will also be used in SAR analysis and reiterative screening for lead optimization. The target screens shown in **Blue** will be employed to supplement SAR, lead optimization and target identification **The target screens have been selected based on objectives of the individual research projects. The Screening and SAR Assays may be tailored based on dynamic project needs.**

The SC shall capitalize on state-of-the-art infrastructures and a highly qualified team of researchers at Southern Research (SR) and the University of Texas Medical Branch (UTMB) with complimentary experience on the development and validation of antiviral assays and a thorough understanding of pathogenesis, biology and pharmacology of antiviral drugs. This also includes experience in the constructions of transgenic cellular models. The SC will be responsible for achieving the following **Specific Aims**:

Aim 1. Develop, optimize and miniaturize assays for use in HTS to identify hit compounds and in secondary screening to support the Medicinal Chemistry Core and individual projects. Unique reagents will be required to enable development and performance of assays for RdRp and associated targets functions identified by the individual projects. The SC will work with the Structural Biology Core and Project Leaders to develop these unique reagents. Several BSL2/3/4/antiviral assays with multiple variants have already been established and optimized by the SC. Biochemical, molecular and cell-based assays will be established based on the functionality and selectivity of the antiviral targets identified by individual projects.

Aim 2. Identify novel-hit compounds for each unique viral targets by executing HTS campaign. A diverse collection of ~212K novel compounds, selected through a Machine-Learning Process from non-proprietary libraries assembled from various commercial vendors, targeted fragments library at SR and a focused set of nucleosides, will be screened to identify novel-compounds engaging each viral target. Hit compounds will be validated by determining potency and efficacy for on-target activity and antiviral functions in cell-based assays.

Aim 3. Support hit development, structure-activity relationship studies (SAR) and lead optimization for advancing the leads to preclinical & clinical development. Newly synthesized compounds originating in the Medicinal Chemistry Core will be tested in dose-response assays to provide biological data for the development of SAR for the discovery of chemical probes. Testing will be performed in an iterative fashion to help drive the design-make-test cycle in medicinal chemistry. Lead compounds will also be profiled for activity against multiple-variants, more virulent viral species as well as in secondary assays for early cytotoxicity, organ-specific toxicity and other adverse-reactions.

A comprehensive IT infrastructure with secure Oracle database will be used for screening data storage, analysis, retrieval and follow-up analyses performed by the SC. A Laboratory Management Information System (LIMS) will be used to track and manage reagent and resource consumption.

Introduction

The Screening Core (SC) will develop, optimize, and conduct biochemical and cell-based assays for High & Medium Throughput Screening (HTS) and subsequent testing of compounds synthesized to support hit identification and hit-to-lead efforts for the multiple viral-targets identified by the individual projects in the Antiviral Drug Discovery & Development Center-2 (AD3C-2) (**Figure 1**). The SC will optimize the research reagents needed for functional cell-based and target-based antiviral bioassays for use in HTS campaigns with the goal to identify the leads for target-engagement and to complement medicinal chemistry efforts for lead-optimization for enhanced activity and individual projects to investigate molecular pharmacology of novel-antiviral drug leads. The SC has worked with the individual research projects and identified the targets and assays for initial HTS campaigns. The SC will work with Structural Biology Core (SBC) to produce functionally active recombinant target proteins and also acquire engineered reporter cell-lines for the target viruses. SC will develop and validate assays for HTS and will subsequently conduct all of the HTS campaigns as well as provide data management and analysis of the hits. The SC will also perform the assays needed by the Medicinal Chemistry Core (MCC) to develop the structure-activity relationships (SAR) for each project to ensure a timely turnaround of the biological data necessary to the chemists. By screening a unique, common compound collection against multiple targets across the Projects, the program will seek to identify selective as well as broad-based inhibitors of the targets-linked to viral replication in accordance with the theme of the program. This will require an integrated approach and information sharing between the project centers the SC, SBC and MCC (**Figure 1-Specific Aims**). The SC will also provide resources to assist with specific assays that may be needed by the individual investigators and tailor these assays to support specific viral targets identified by individual projects. This core group has extensive experience in the development and miniaturization of cell based and biochemical assays as well as automation, compound management and bioinformatics experience across a wide variety of assay types. The combined SC at Southern Research (SR) and the University of Texas Medical Branch (UTMB) has the ability to conduct assays and HTS at all levels of biosafety containment (BSL1-4). Several of the key assays needed, such as SARS-CoV-2 cell-based assays using multiple strains of live virus, are already established, validated and are routinely run under BSL2/BSL3 condition at SR[1-6] and BSL2-4 conditions at UTMB[7-10].

Screening Core (SC) Overview The SC shall capitalize on state-of-the-art infrastructure for HTS as well as highly experienced team of researchers at SR and UTMB with complimentary experience on antiviral drug discovery including HTS, transgenic cell-lines, pharmacology, bioassays, target-identification, target-engagement, target-validation and HTS data analysis & management.

The HTS Center at Southern Research has advanced robotic equipment and a well-trained staff to ensure the highest quality of screening for research projects. The Center maintains a collection of over 750,000 compounds and has IT capabilities to enable large scale data analysis and management. Since 2006 the HTS Center at SR has tested over 30 million compound samples in more than 100 screening campaigns which included over 200 assays to obtain quantitative results for hit identification, confirmation, and validation. During this time the HTS Center has supported dozens of grants and contracts originating from both private organizations, academic research institutions and government agencies. Historically, the HTS Center has performed HTS campaigns for several viruses including an *in vitro* antiviral screening program for SARS-CoV[1-6], highly pathogenic (H5N1) avian influenza, and other respiratory viruses (NIAID, N01-AI-30047)[11-14], has served as the Specialized Biocontainment Screening Center for the Molecular Libraries Program during its pilot program (U54 HG003917) and further production phase (U54 HG005034). In addition, the HTS Center has performed ten HTS campaigns as assigned Task Orders under an NIAID/DAIDS contract (N01-AI-1400010I) "In Vitro Testing Resources for HIV Therapeutics and Topical Microbicides", and seven HTS campaigns for various viruses (SARS-CoV, DENV-2, WNV, ZIKV, CHIKV, VEEV, and H1N1/H3N2) as the Screening Core for the Antiviral Drug Discovery and Development (AD3C) program funded under an NIAID supported multi-institute CETR program titled "Identification of New Antiviral Therapies" (1U19AI109680). Currently, the SR HTS Center functions as the Assay Core for the AD3C funded under NIAID CETR grant (U19AI142759).

The Screening Core at University of Texas Medical Branch (UTMB), an internationally recognized institution with strong expertise and resources in the global fight against infectious diseases, is part of the Keiller Building-Galveston National Laboratory (GNL) research complex. GNL is a sophisticated high containment select agent research facility that houses approximately 36,000 sqft of BSL3/ABSL3 and 14,500 sqft of BSL4/ABSL4 space. The latter is split up between the Robert E. Shope BSL4 and the GNL BSL4 laboratories. The GNL is located on the campus of the UTMB and operates under the umbrella of UTMB's Institute for Human Infections and Immunity. Since 2011, UTMB has performed antiviral screens as part of the NIH/NIAID B task order focusing on Ebola, Marburg, Lassa, and Nipah viruses (HHSN2722010000401, B07; HHSN272201100019I, B09, B12, B16, B20, B22, B24, B27, B28, B05, and B07). Several compounds identified through these screening efforts have been further characterized in rodent models for Filoviruses through the NIH/NIAID A task orders

(HHSN272201000040I, A64, HHSN272201700040I A07, A35). In addition, UTMB is home to the World Reference Center for Emerging Viruses and Arboviruses (WRCEAV)[15,16], a collection of over >8,000 arbovirus strains, encompassing 21 viral families. These viruses, along with associated antigens and antibodies, represent a critical resource that the WRCEVA distributes to the research and surveillance community free of charge to facilitate the response to new and continuing outbreaks.

Innovation

The SC will engage novel research reagents (functionally active target recombinant proteins and uniquely engineered reporter cell lines e.g., RVFV NLuc Reporter virus) and employ innovative complex bioassays [e.g., Fluorescence Resonance Energy Transfer(FRET) SARS CoV-2 RdRp complex assay; AlphaScreen assay for CHIV/VEEV macrodomain function; Nipah Virus RdRp mini-genome bioluminescence assay) to screen a new and unique compound library assembled through machine learning algorithm, target-based fragment analysis and unique set of nucleosides for the discovery of new therapeutic approaches for antiviral drug discovery against pathogens with pandemic potential. Novel therapeutic targets have been selected based on evidence of functional integration into the molecular network of interrelated biological pathways linked to unique viral transcriptional machinery of individual viral pathogens. The HTS centers at SR and UTMB have several unique screening platforms, an unparalleled battery of BSL3/BSL4 antiviral screens, streamlined HTS data analysis and management systems as well as exceptionally experienced team of researchers & technicians that have developed and validated multiple types of antiviral assays for use in HTS, SAR and lead optimizations.

Research Strategy

The SC will follow an industry accepted hit-to-lead strategy in early phase drug discovery. Assays suitable for HTS will be developed and employed to identify active compounds which can be used as starting points for medicinal chemistry efforts to develop structure activity relationships for synthesis of new compounds and discovery of leads for further development. The overall research strategy of SC has been outlined in **Figure 2**. Additional details on individual target screens are and an overview of SC are presented in **Figure 1** (Specific Aims). A new unique library composed of compounds with structures designed and synthesized within the last three years will be screened in HTS assays for each proposed target. As such, the compounds in this collection have had very little exposure to human pathogen drug discovery programs, and have a great chance of providing novel, chemically-tractable hits for lead optimization. The unique design of the library is not only based on optimizing diversity in terms of chemical composition and spatial orientation, but also on appropriate physicochemical properties (Lipinski Rules of Five, i.e. MW) to ensure hits are appropriate starting points for medicinal chemistry efforts.

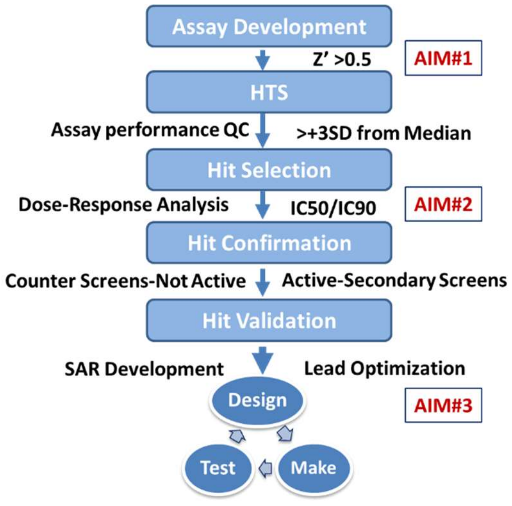

Figure 2-Overall Research Strategy of SC: Outlines

Aim 1. Develop, optimize and miniaturize assays for use in HTS to identify hit compounds and in secondary screening to support the MCC and individual projects.

Although several assays are already available for screening, others will need to be developed and optimized depending on the molecular targets (**Figure 1; Tables 1-3**). Prior to assay development it will be necessary to design and develop required reagents and tools, particularly for the RdRp target assays.

Reagent production. Unique reagents may be required to enable development and performance of an assay for new targets. The SC will work with the SBC to ensure that these reagents can be produced and that they meet the reproducibility and rigor needed to advance a discovery campaign. Also, it will be important to ensure that reagents can be produced in sufficient quantities for screening and to support SAR-driving assays. SARS-CoV-2 NSP12/8/7 RdRp complex[17-21], SARS-CoV-2 NSP14/NSP10 exonuclease function[22-26], alphaviruses macrodomain interactions[27-28], flaviviruses NSP4/NSP5 RdRp activities[29-31] and relevant proteases from target viruses have been identified as potential targets for reagent generation. Additionally, cells-based 'mini-replicon/mini-genome complex' models[32-36] may be established and tailored to investigate functions of individual components of virus replication/transcription machinery.

Development of biochemical and cell-based assays. Once the appropriate reagents are obtained the assays will be constructed and optimized. Since compound samples in the screening collection are dissolved in 100% DMSO, we will initially measure the limit of DMSO tolerance in the assay. The assay will be further developed at the DMSO concentration required for screening to determine appropriate plate type, optimized reagent concentrations, order of addition of reagents, and incubation times that give an optimal signal to background ratio and %CVs.

Assay implementation and optimization. Each assay used in HTS will be optimized to provide a positive signal above background that is of sufficient magnitude and of low enough variability to allow for reliable detection of an active compound when tested once at a single concentration. Overall assay quality will be assessed by several factors during assay implementation and validation and must meet the criteria specified below to be considered for an HTS campaign. A battery of statistical methods (***See Box- Equations 1-3)*** are used at this stage to characterize the suitability of the assay with regard to sensitivity, accuracy, precision and robustness.

Equation 1: $\boldsymbol{Coefficient\ of\ Variation\ (\%CV) = 100 \times \frac{SD}{m}}$
SD = Standard Deviation
m = mean of maximum or minimum control response values
Equation 2: $\boldsymbol{Signal\ to\ Background\ Ratio\ (SBR) = \frac{m_t}{m_b}}$
m_t = Mean of the maximum controls
m_b = Mean of the minimum controls
Equation 3: $\boldsymbol{Z' - factor\ value = 1 - \frac{3(SD_t+SD_b)}{|m_t-m_b|}}$
SD_t = Standard deviation of the maximum controls
SD_b = Standard deviation of the minimum controls

Assay sensitivity. The maximum assay signal should be sufficiently above background to allow for identification of active compounds and minimize the number of false negatives. Assays will be optimized to give SBR ≥ 5 prior to implementation in HTS.

Assay accuracy. Concentration-response assays will be performed for reference compounds, if available, on three different days and the calculated IC_{50} or EC_{50} values will be compared between runs and with those obtained in the originating investigator laboratory or as reported in the literature. The acceptance criteria is that the obtained values agree within 3-fold.

Assay precision. Inter-plate, intra-plate and inter-run reproducibility of the assay will be assessed by calculating the %CV. Acceptance criteria are %CV < 10% for Max and Min signals with SBR > 5. The assay should also exhibit plate spatial uniformity devoid of drift or edge effects. This parameter can be assessed by visual heat maps of the plate data and by calculating ratios of average signals in left/right, top/bottom, inner wells/outer wells, Quad1/Quad4, Q2/Q3, Q1/Q2, Q3/Q4, Q1/Q3 and Q2/Q4 for plates with constant signals in each. Ratios should = 1 for all comparisons of average minimum or average maximum signals.

Assay robustness. When all of the conditions are optimized, three Z-plates consisting of positive and negative controls will be run on three separate days to assess inter- and intra-day variability. For reliability under these conditions, the Z'-factor should be ≥ 0.5, indicating that the minimum and maximum signals are sufficiently separated, and that the variation of these signals do not overlap.

HTS assay validation. The final step prior to undertaking a full screening campaign is to validate the performance of the assay under screening conditions[37-40]. A subset of 10K compounds, selected to represent the chemical diversity of the full collection, will be screened at 10 μM in two independent runs on different days. The results from the two assay runs will be compared statistically to determine whether "hits" and non-hits reproduce on both days. It also provides an initial estimate of the expected hit rate for the full campaign. If the hit rate (using provisionally defined threshold of 50% effect) is very high (>2%) or very low (<0.2%), then the screening concentration can be adjusted for the full campaign. These validation runs must demonstrate that the assay is both robust (Z' ≥ 0.5) and reproducible (correlation P value < 0.001) when performed using the automated platform under conditions to be used in the full HTS campaign. This step is also used to evaluate parameters associated with running large batches of plates such as timing of reagent additions and reagent stability.

Quality control of biological reagents for HTS. As a quality control measure, cell lines will be tested for mycoplasma. Biological reagents amenable to freezing will be stored in frozen aliquots sufficient to supply a single screening run which will avoid repeated freeze/thaw cycles. We will also determine that the stability of all reagents used for an assay will be sufficient to allow for their use in an HTS format in which they may be exposed to suboptimal storage conditions for several hours during the processing of hundreds of assay plates

Aim 2. Identify novel-hit compounds for each target by executing HTS campaigns.

HTS campaigns will be implemented only when each assay is validated as described above. Assay runs will be scheduled in advance depending on the number of runs allowable within a work week to accommodate necessary incubation times. The primary HTS of the compound library will be performed by testing each compound once at a single concentration, typically 10 μM. Positive and negative controls used to assess assay quality will be placed in the outside columns of each plate to accommodate automation of liquid dispensing systems. The data generated during a screening campaign will be evaluated for consistency and bias as described above. Plates with non-uniform spatial patterns will also be scrutinized for possible effects due to liquid handling errors and scheduled for retesting. Raw values for positive and negative controls will be tracked by plate over the course of the screen and control CV values and Z'-values calculated for each plate. The trends observed in the controls are helpful in troubleshooting the automation process to minimize artifacts or reagent failures. Controls also serve a quality control purpose. Plates that do not demonstrate acceptable Z'-values, positive control compound response inconsistent with historical values or spatial-non-uniformity will be rejected and scheduled for retesting.

Upon completion of a screen, a statistical analysis of the HTS data will be performed to determine overall distribution and variability of data and to set the activity threshold or “hit” criteria at 3xSD above the average value for all of the compound wells. This is accepted as the value which is statistically outside the population of no effect data. The database will be queried to correlate the selected hits with the specified source plate and well locations for each compound. The “hit” compounds will be cherry picked from the source plates and retested in a 10-point concentration response series from 0.2 -100 µM to confirm activity and determine the potency of the compound to inhibit or enhance the assay signal. A counter-screen will be performed to exclude false positives resulting from off-target effects. In biochemical assays compounds will be tested in assays omitting the molecular target in order to exclude compounds causing interference with the assay signal. In cell-based assays compounds will be tested for cytotoxic effect on uninfected host cells. Concentration-response assays are set up as serial two-fold dilutions in an inter-plate rather than intra-plate dilution scheme to enable more efficient and cost-effective use of liquid handling systems. This method also allows for many more compounds to be selected and tested in a concentration-response assay, thus maximizing potency and efficacy data available to chemists for selecting scaffolds to advance through the hit-to-lead process.

The biological single concentration and concentration response data will be uploaded into an ActivityBase database. The technical lead scientist who conducted the screen will review the data and accept or reject the assay plates based on defined assay criteria. Once verified in ActivityBase, the data is then accessible to the chemistry team through Dotmatics and available for additional analysis such as a cluster analysis, analysis of structure–activity relationship (SAR) trends and property predictions using sophisticated software such as Pipeline Pilot, ScaffoldHunter, Star Drop, Dotmatics-Vortex, StarVision, Sybyl and Schrödinger-QikProp. The ActivityBase administrator will prepare a report describing overall assay statistics for the HTS campaign as well as a report containing concentration-response data and graphs for each individual hit compound.

The medicinal-computational chemistry team will perform cluster analysis of the hits to organize the small molecules into groups based on common core structural features referred to as clusters containing a common substructure or scaffold. In some cases, a compound may have structural features in the molecule that permits the molecule to be grouped into more than one clustered group of molecules. The hits will be analyzed and clustered based on Tanimoto distances using the predefined FCFP_4 fingerprint property of Pipeline Pilot software (Accelrys, San Diego, CA). The cluster analysis and scaffold enrichment analysis that compares the distribution of members of each scaffold within the hit set versus their distribution in the entire screening set provides knowledge regarding privileged scaffolds and structural features present in the hits. The chemists will also utilize property predictions such as solubility and metabolic liabilities of compound clusters of interest to permit prioritization of the active compounds/scaffolds based on lead-like characteristics.

Unique HTS Compounds Collections. To address the need for novel, drug-like, and target-specific antiviral chemicals, a new HTS library of 200K compounds has been assembled from recent drug-like commercial collections (**Figure 3**). A major part of this new library is a 150K diversity set from ChemDiv. This customized selection aided by our cheminformatics approaches processes multiple merits. Specifically, it only contains new chemical structures that have been synthesized within the last three years thus making this a less explored and more novel collection. It does not contain duplicates to our current HTS collection for pan-assay interference structures (PAINS)[41-45]. The library has high structural diversity (~7,500 clusters with average size of 20 compounds per cluster) but no singletons (thus every hit will have initial structure-activity-relationship information without testing additional analogs). The compounds are also pre-rated by ChemDiv to ensure synthetic feasibility. The molecular property distribution analysis indicates that the compounds in the new library are drug-like (molecular weight ≤ 500; heteroatom count ≤ 10; rotatable bonds ≤ 8; aromatic rings ≤ 4; predicted log P ≤ 5; polar surface area ≤ 125; H-bond acceptors ≤ 7; H-bond donors ≤ 3). Moreover, according to our in-house developed machine learning prediction model for SARS-CoV-2, 20K of the 150K diversity set are likely to show phenotypical anti-SARS-CoV-2 activity, which makes it suitable to meet the special need for SARS-CoV-2 drug discovery. An additional 25K compounds have been selected

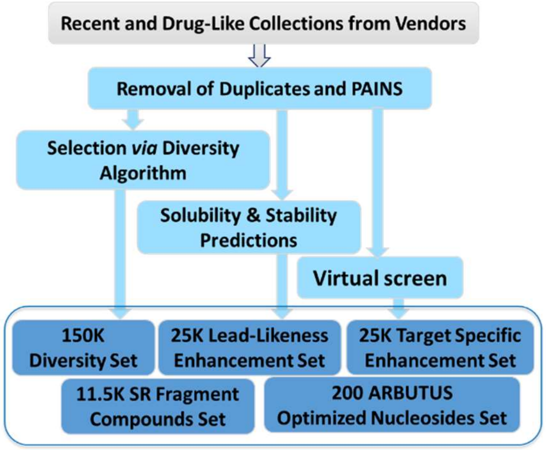

Figure 3- Unique HTS Compounds Library Sets

according to solubility and metabolic stability predictions (*via* cheminformatics software BIOVIA Pipeline Pilot) to increase the chance of finding hits with good pharmacological properties and facilitate the hit-to-lead pipeline. A 25K target specificity set selected by in-house virtual screens against viral targets nsP2 and nsP3 and virtual screens performed by vendors (e.g. viral RdRP inhibitor collections from OTAVA Chemicals and TargetMol) has been added to enhance target focus. Since the SBC will be able to crystalize several targets we will also include a library of 11,350 fragment compounds existing at SR and a library of 200 nucleotides provided by Arbutus. As a whole, these collections comprise a 211,550 HTS compound library suitable to discover novel, drug-like, and target-specific antiviral matters (**Figure 3**).

Compound Storage, Replication and Distribution: The compound library dissolved at 10 mM in 100% DMSO will be stored in deep well polypropylene 384-well plates containing 200 µL samples. This plate set is called a “mother” set. The “mother” set is then used to create copies of 384-well “daughter” plates in 384-well polypropylene Echo-qualified flat-bottom plates to allow for creation of assay ready plates (ARPs). All plates are barcoded and the compound IDs with plate and well locations are loaded to IDBS ActivityBase where they are tracked during all processes including compound plate replications, production of ARPs for single concentration and concentration response screening campaigns, distribution of ARPs to the screening labs at SR and UTMB as well as recording compound storage locations and maintaining inventory information.

HTS Assays. The HTS assays to identify compounds for each virus target are presented in Table 1. The HTS targets have been selected based on individual project objectives.

Project #	Virus	Target	Assay Type	Assay Technology	Assay Signal
1	SARS CoV-2	Nsp12/7/8 RdRp	biochemical	FRET	fluorescence
1	SARS CoV-2	Nsp14 ExoN	biochemical	Quanti-it RiboGreen	fluorescence
2	NIPAV	Mini-genome	cell-based	NLuc Reporter	luminescence
3	CHIKV	Macrodomain	biochemical	AlphaScreen	luminescence
3	VEEV	Macrodomain	biochemical	AlphaScreen	luminescence
4	RVFV	Phenotype	cell-based	NLuc Reporter Virus	luminescence
4	Bunya V	L Protein RdRp	biochemical	FP	fluorescence
5	DENV	NS5 polymerase	biochemical	AttoPhos	fluorescence

<u>SARS-CoV-2</u>: A FRET-based assay identifies RdRp inhibitors in which SARS-CoV-2 RdRp (NSP12/7/8) synthesizes RNA on a primer strand labeled with Cy3 and displaces a quencher strand resulting in an increase in Cy3 fluorescent signal[17]. SARS CoV-2 NSP14 protein is a bi-functional enzyme with an N-terminal 3-5-exoribonuclease (ExoN) domain and a C-terminal SAM-dependent N7-Methyltransferase[23],[46]. NSP14/NSP10 Exo-N function may be measured with intercalating Quant-it TM RiboGreen RNA reagent, which shows specific binding with dsRNA and generates strong fluorescent signal[47].

<u>DENV</u>: RdRp (NS5): Fluorescence-based alkaline phosphatase–coupled polymerase assay utilizes a modified nucleotide analogue (2′-[2-benzothiazoyl]-6′-hydroxy- benzothiazole) conjugated adenosine triphosphate (BBT-ATP) and 3′UTR-U30 RNA as substrates. After the polymerase reaction, treatment with alkaline phosphatase liberates the BBT fluorophore from the polymerase reaction byproduct[48, 49]. The assay can be performed with recombinant NS5 from DENV, WNV and ZIKV [50-53]

<u>NiV-</u> Small molecules inhibiting the NiV RNA synthesis machinery[54]. We will develop and optimize a HTS assay based on a NiV minigenome (MG) system. Synthesis of NiV RNA is dependent on the complex of several viral proteins, including the nucleoprotein (N), the phosphoprotein (P), and the viral RdRP[55]. Reconstitution of a functional NiV RdRp complex can be achieved by transfection of these three proteins into mammalian cells[56,57].

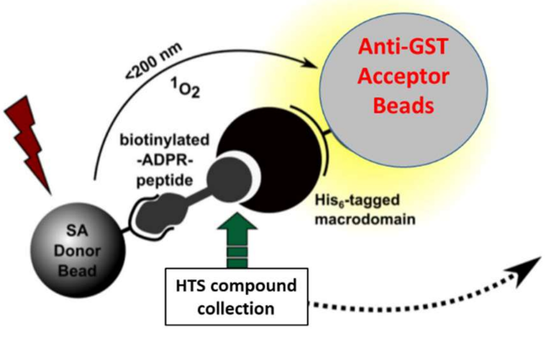

Figure 4. CHIKV Macrodomain AlphaScreen- Employs GST-tagged CHIKV NSP3, Biotinylated ADP-ribose attached peptide, Biotinylated-GST (Counter Screen) and GST Detection kit

<u>CHIKV and VEEV</u>: An AlphaScreen binding displacement assay to screen for compounds that inhibit the interaction of an ADP-ribose attached peptide to the nsP3 macrodomain[58-60] has been modified and validated for HTS at SR **(Figure 4**)

<u>RVFV:</u> A cell based nanoluciferase reporter virus assay measuring inhibition of virus replication[61,62]. We have already employed a similar assay for screening against SARS CoV-2[2,3].

Additional target assays will be included to enable dynamic individual project needs.

Aim 3. Support hit development, structure-activity relationship studies (SAR) and lead optimization for advancing the leads to preclinical & clinical development. The biochemical assays measuring target engagement of compounds will be used to drive hit-to-lead SAR. In most cases, these will be the same assays employed for HTS. However, it will be necessary to demonstrate that compounds showing target engagement in biochemical assays also exhibit antiviral activity against the live virus in a secondary cell-based assay. Also, the cell-based assays can be used to assess if compounds have pan-virus effects. These assays already exist in the SC and have been used to the support ongoing medicinal chemistry efforts of the current AD3C program. **The assays available for each virus are shown in Table 2** The MOA of compounds identified in the cell-based HTS for RVFV will be determined by the project team and the relevant target based assay will be subsequently established in the SC to drive SAR.

Virus	Assay type	Host cell
SARS CoV-2	Cytopathic Effect Reduction	VeroE6
SARS CoV-2	Virus linked nanoluciferase reporter	Calu-3 and A549 expressing ACE-2
SARS CoV-1	Cytopathic Effect Reduction	Vero E6
SARS CoV-1	Virus linked nanoluciferase reporter	Calu-3 and A549 expressing ACE-2
MERS	Cytopathic Effect Reduction	Vero CCL81
CHIKV	Virus linked nanoluciferase reporter	THF
VEEV	Cytopathic Effect Reduction	THF
DENV-2	Immunofluorescence assay	HEK293
DENV-4	Virus linked nanoluciferase reporter	HEK293
ZIKV	Immunofluorescence assay	Vero CCL81

The SC at UTMB will primarily focus on performing antiviral screens utilizing infectious viruses at BSL4 to identify small molecules that target viral replication. Previous efforts between SR and UTMB have established an automated HST platform, which was capable of testing up to 10,000 compounds per day within the BSL4 laboratory[63,64]. Using a cell-based HTS screen, compounds were identified for their ability to inhibit virus-induced cytopathic effect. However, since successfully establishing this HTS capability under BSL4 conditions, the platform has not been utilized since then. We propose to re-establish the screening capabilities at both BSL3 and BSL4 and then utilize to perform the screens through this project. Assays at BSL4 will focus on NiV[63,64], but will also be established for tick-borne flaviviruses (such as Central European Encephalitis virus) and *Nairoviridae* (Crimean-Congo hemorrhagic fever virus) to evaluate leads identified in Projects 2 and 4. At BSL3, assays will also be established for the viruses relevant to this application (SARS-CoV-1, SARS-CoV-2, MERS, CHIKV, VEEV) using cytopathic effect reduction and virus linked nanoluciferase reporter assays, as described in **Table 2**. Furthermore, antiviral screens may be employed expanding the screening of lead compounds based on individual projects. This could for example cover antiviral compounds identified in Project 4 for members of the *Bunyavirales* order and could be tested against additional human pathogenic members (such as Severe Fever with Thrombocytopenia Syndrome virus and Oropouche virus). In addition to wild-type viruses, certain recombinant viruses expressing fluorescent or luminescent reporter genes are available. **Table 3: Screening Core UTMB- Antiviral assays for BSL-4 viruses available for this program** and may be employed for expanding the screening of leads based on individual Project needs.

Virus	Assay type	Cell system
Filovirus		
Ebola Zaire (EBOV)	Cytopathic Effect Reduction	Vero CCL81, HeLa
Sudan virus (SUDV)	Cytopathic Effect Reduction	Vero CCL81
Marburg virus Angola (MARV)	Cytopathic Effect Reduction	Vero CCL81
Henipavirus		
Nipah virus (NiV)	Cytopathic Effect Reduction	Vero CCL81
rNiV-Gluc-eGFP	Luciferase Assay	Vero CCL81
Hendra virus (HeV)	Cytopathic Effect Reduction	Vero CCL81
Bunyavirales		
Rift Valley Fever virus ZH501 (RVFV)	Cytopathic Effect Reduction	Vero CCL81, A549
Crimean-Congo Hemorrhagic fever virus (CCHFV)	Cytopathic Effect Reduction	SW-13
Lassa virus (LASV)	Cytopathic Effect Reduction	Vero CCL81, Vero 76
Machupo virus (MACV)	Cytopathic Effect Reduction	Vero CCL81
Junin virus (JUNV)	Cytopathic Effect Reduction	Vero CCL81

Additional viruses that can be screened for at BSL-4 include tick-borne flaviviruses, as well as additional ebolavirus strains and arenaviruses.

Initial efforts will focus on assay implementation, optimization (as needed), and validation as described above. During this phase, the UTMB SC will work closely with colleagues at SR utilizing their HTS expertise, compound libraries, and bioinformatic support. For actual screens at UTMB and to simplify the assay performance, assay plates will be prepared at SR, sealed, and frozen plates send to UTMB. Screening will be performed against selected viruses listed in **Table 3**. Compounds that demonstrate antiviral activity in the primary screen, will then be confirmed in concentration dose-response, cell toxicity, viral yield reduction, and/or time-of-addition assays. Characterization of the MOA of identified small molecules will be further characterized by the individual Research Projects.

---

Hello all,

I'm sending drafts for Project 1: coronavirus and Project 2: Henipavirus. As well as the screening core (SC) and admin core for your input. I will send drafts from Overall and Med Chem Core, once they can incorporate the remaining two project. If you can get comments back by Tuesday, Oct. 12 at the latest, that would be helpful.

Also, just to make sure we are consistent with our core titles:
Administrative Core (Admin Core)
Screening Core (SC)
Medicinal Chemistry Core (MCC)
Structural Biology Core (SBC)

Thank you,

Stephanie

Hello all,

Please find the current draft of the Structural Biology Core from Dr. Jamil Saad and team. The file is quite large - please find the file here.

Please let me know if you have questions or need help sending edits back to him.

Thank you,

Stephanie

Subject: Project Order, PDP, and Project drafts

Hello all project and core leaders,

Thank you for your continued progress. We have a few immediate items to bring to your attention.

While working on the overall specific aims, it became necessary to reorder the projects. Therefore, here is the new project order:

1. Coronavirus
2. Henipavirus
3. Flavivirus
4. Bunyavirus
5. Alphavirus

Stephanie can help address the change of numbers on the documents and will change the component order in ASSIST to reflect the new project order.

Another point we want to address is that we would like to use a product development profile (PDP) within the "overall" section to apply to all projects. **We would like the attached paragraph that references the PDP to be added to all projects and for you to include a timeline for your project please refer to Bunya write up for an example timeline**.

Finally, please see the attached current versions of Alpha and Bunya projects. We would appreciate any comments or edits by **Thursday, Oct. 7** that we can share with them. The other project drafts will be sent as they are received.

Thank you,

Stephanie, Rich, and Pei-Yong

CEPI Task Force on Nipah Standards, Assays & Animal Models

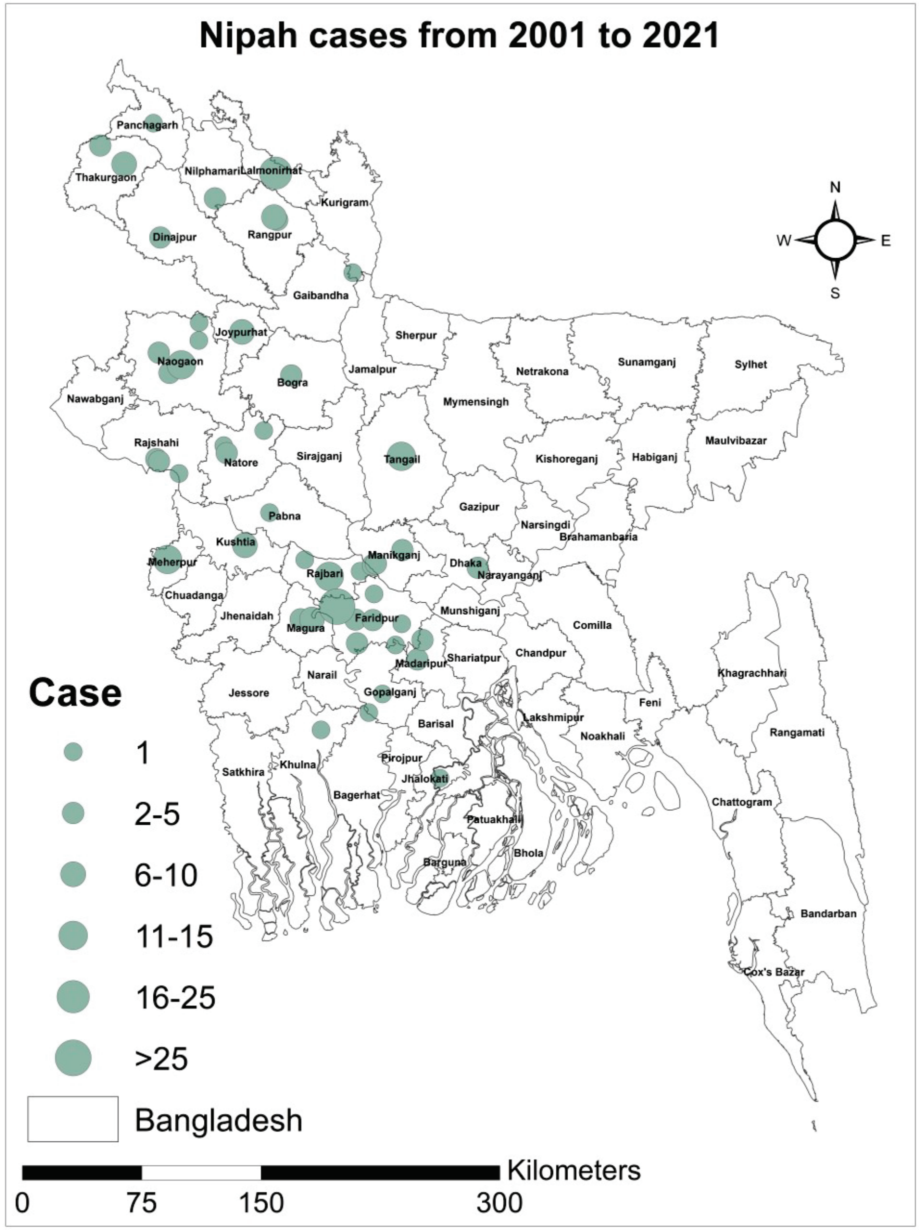
Nipah virus in Bangladesh: 2001 to 2021

Dr. Syed Moinuddin Satter
Assistant Scientist and Deputy Project Coordinator
Principal Investigator, National Nipah Surveillance
Programme for Emerging Infections, icddr,b

Professor Dr. Mahmudur Rahman
MBBS(Bangladesh), MPHM (Thailand), PhD (Cambridge, UK)
Senior Technical GHSA Consultant
Global Health Development/EMPHNET
(Support to the US CDC, Bangladesh Country Team)
Former Director, IEDCR, Bangladesh

Nipah virus transmission in Bangladesh

- First identified as the cause of an outbreak of encephalitis in 2001 in Meherpur district
- Nipah Surveillance and laboratory established in 2006
- Till July, 2021, a total of 322 cases of Nipah infection were recognized; 228 (71 %) died, indicating a very high mortality
- Spillover identified 135 times
- Secondary cases identified 46%
- Current Nipah survivor 79
- Till date, 38 outbreaks have been identified, involving 32 districts out of 64 districts



Nipah cases from 2001 to 2021

Nipah surveillance activity in Bangladesh

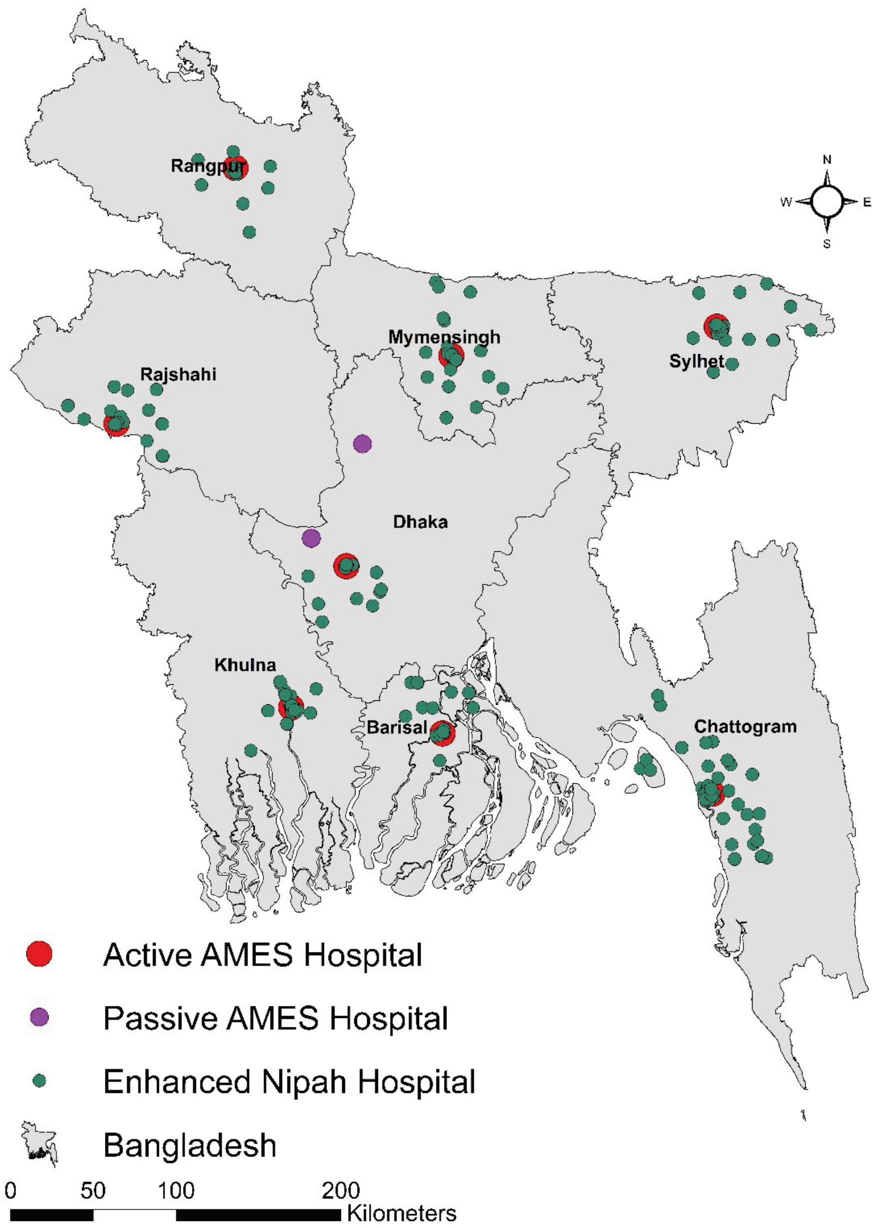
1. Hospital based sentinel surveillance (icddr,b)

- Active surveillance at eight medical collage hospitals (Three additional sites in non-Nipah belt)
- Passive surveillance at two district health care facilities
- Enhanced surveillance activity during Nipah season (Dec’2020-Apl’2021) at 355 health care facilities (HCF)
  - District and sub district public HCF: 99
  - Public HCF: 256
- Year-round Nipah testing

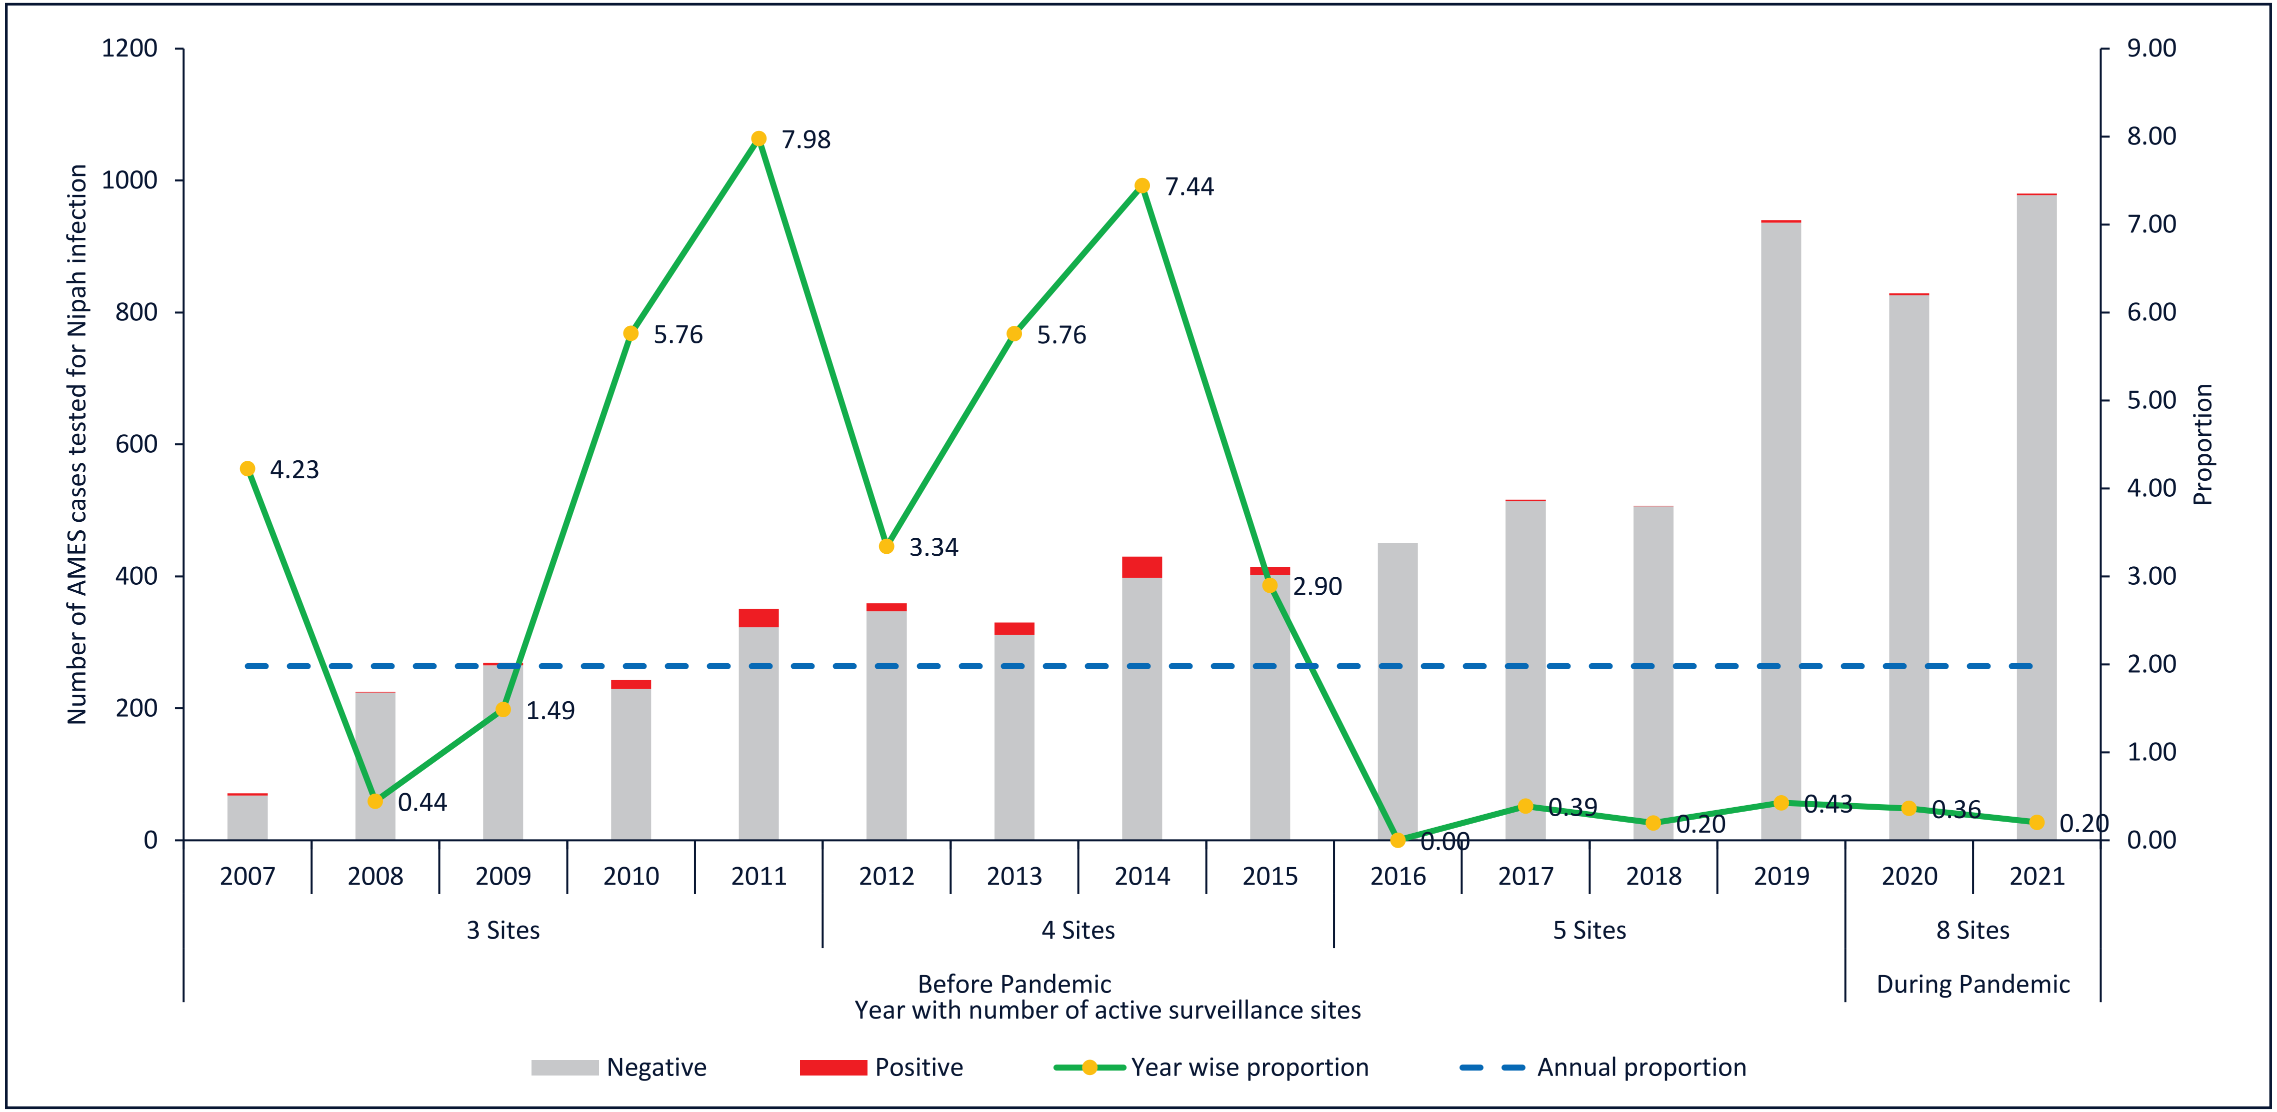
2. Event Based Surveillance at IEDCR

- 24/7 hotline (2)
- Media Monitoring
  - –All national daily newspapers
  - –All TV channels
- Any informal reporting

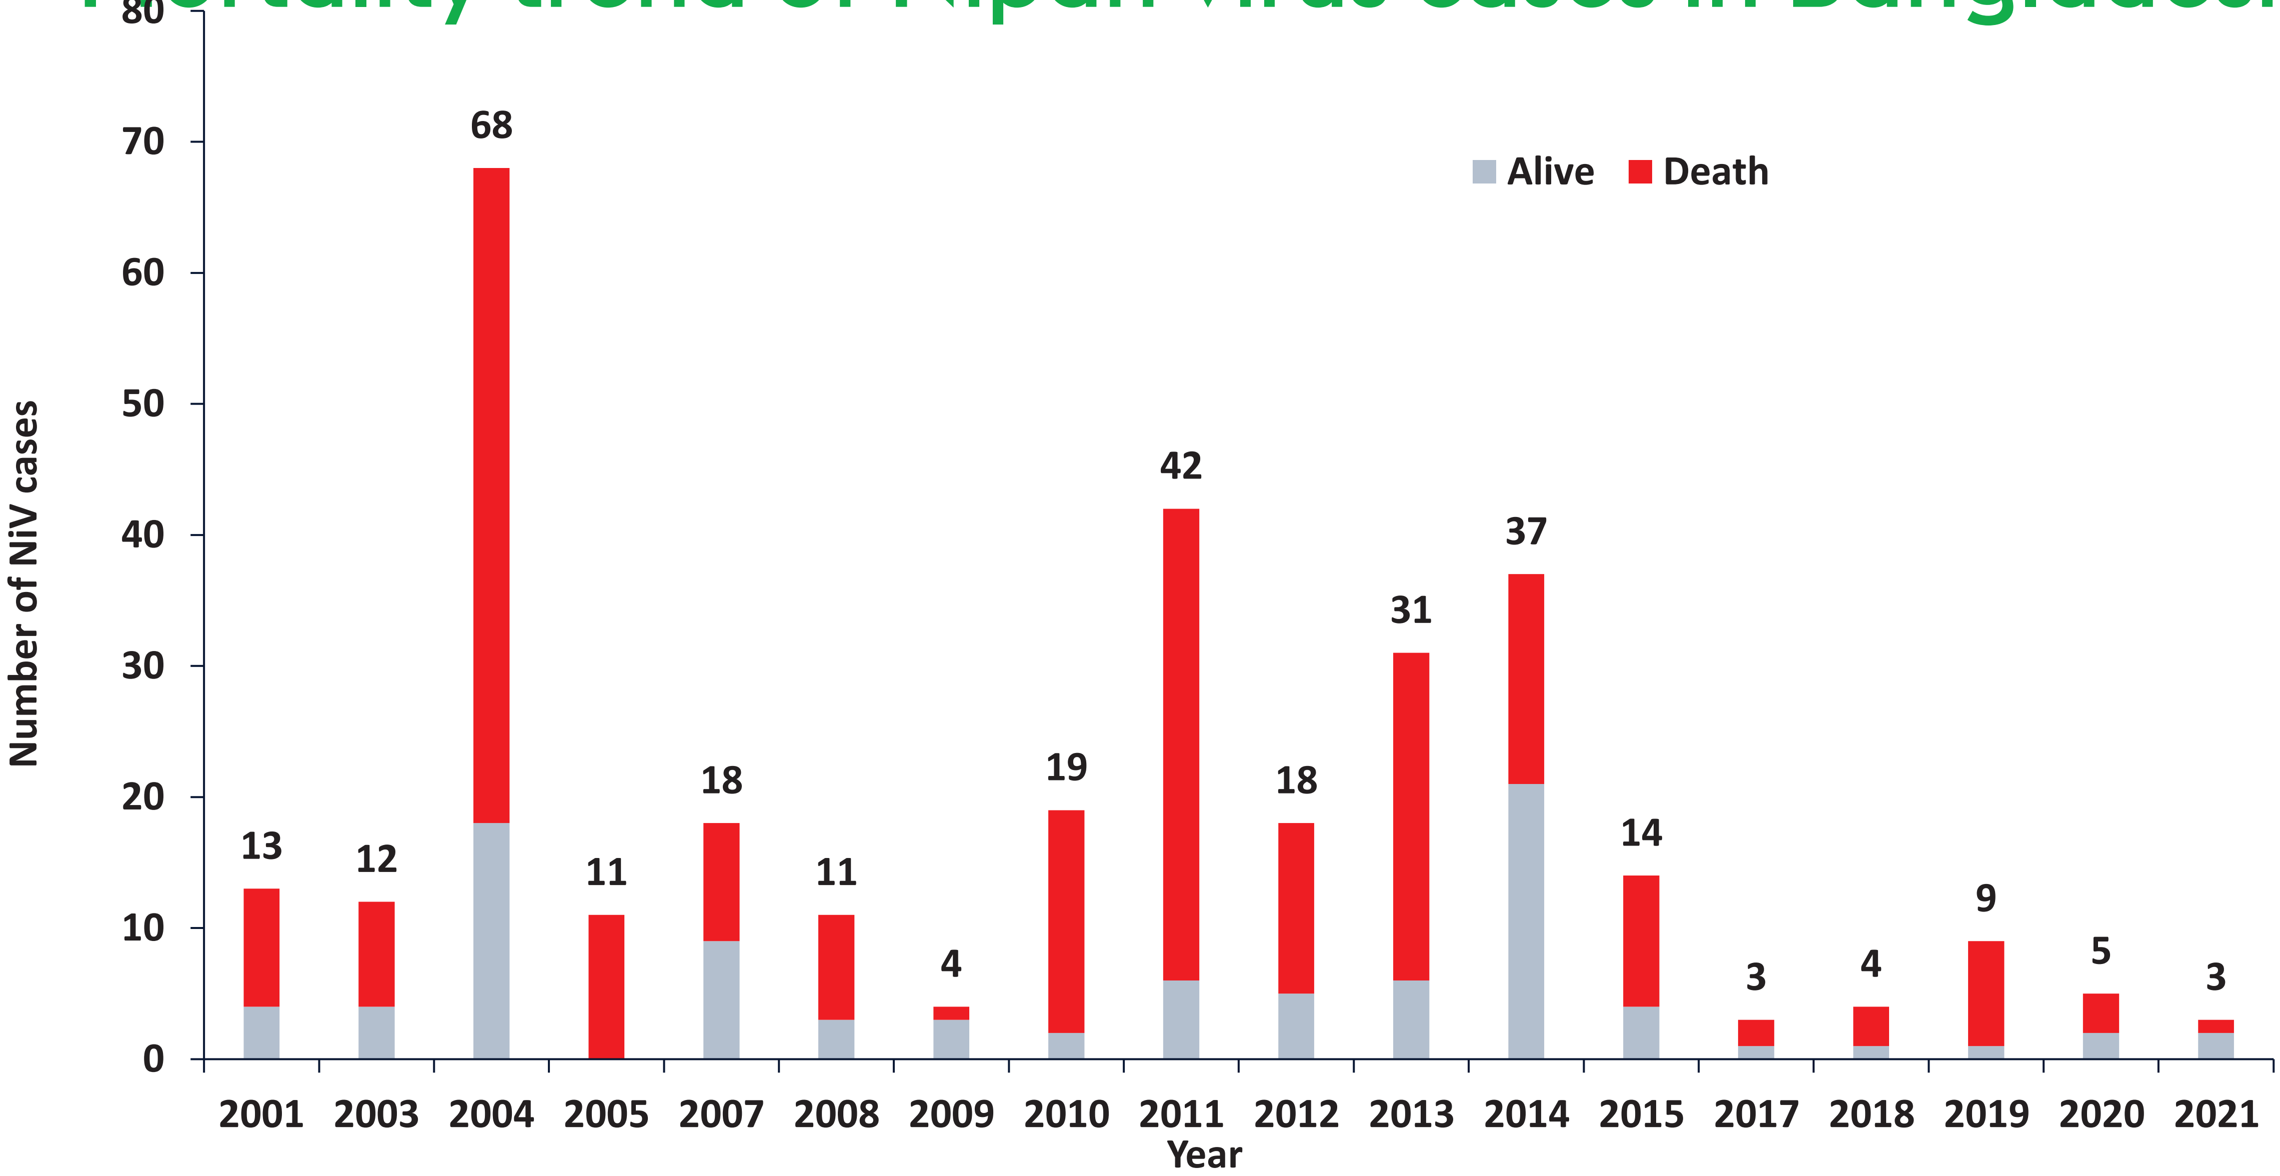
3. Other encephalitis surveillance (JE, WHO and IEDCR)



Trend of Nipah virus cases in Bangladesh



Mortality trend of Nipah virus cases in Bangladesh



Gap in Nipah surveillance

- Population based active surveillance system
- Sequelae of Nipah survivor
- Immunology status of date palm sap harvester (gachi)

Uk = Unknown

Evolution of detection and diagnosis capacity in India

2001

Siliguri Ox: 30 days; 66 cases; CFR = 74%

- Diagnosis not established.
- No BSL4/BSL3 labs.
- Misdiagnosed: Measles.
- CDC, US confirmed as NiV.

2007

Nadia Ox: 19 days; 6 cases; CFR = 100%

- Diagnosis established.
- Diagnostics provided by CDC (serology & molecular).
- BSL3 labs +.
- Early detection failed.

2015:

- BSL4 Lab operational &
- Capacity for bat surveillance established.
- Bat samples from WB & Assam screened for NiV.
- 8% positivity

2018

Kozhikode Ox: 27 days; 23 cases; CFR = 89%

- Diagnosis in index case not established.
- Early diagnosis & Ox containment.
- Bat survey positivity ~23%.
- Virus isolated
- m102.4 monoclonal imported from UQ for treating Nipah infected patients

2019

Ernakulum Ox: 1 case; No fatality.

- Quick diagnosis.
- Early Ox containment.
- Onsite diagnosis: PoC; Serology & molecular.
- Bat positivity ~12.7%.
- Validated in house diagnosis
- Clinical trial protocol developed (m102.4)

INDIAN COUNCIL OF MEDICAL RESEARCH
Serving the nation since 1911

Core capacity required for surveillance and research for Nipah virus disease

1. Surveillance for early detection of circulation of the virus
    - Human surveillance
    - Bat surveillance
2. Laboratory detection capacity
3. Capacity to conduct systematic epidemiological studies.
4. Clinical trial capacity for newer drugs, monoclonal and vaccines.
5. Clinical Research for appropriate treatment and management of patients
6. Risk communication and community mobilization strategies.

ICMR
INDIAN COUNCIL OF MEDICAL RESEARCH
Serving the nation since 1911

Human & Bat surveillance

- India has an Integrated Disease Surveillance Program (IDSP) under aegis of Ministry of Health & Family Welfare.
- IDSP picks up clusters of cases and collects outbreak samples.
- Samples are referred to Deptt. of Health Research (DHR) / Indian Council of Medical Research (ICMR) network of Virus Research & Diagnostic Laboratories (VRDLs).
- VRDLs are equipped to detect viruses of public health importance.
- Selected VRDLs with BSL-3 labs are trained to detect high risk pathogens.
- ICMR-NIV, Pune has specialized teams for bat surveillance
- Relevant recent publications:
  - *Emerg Infect Dis. 2019 May;25(5):1003-1006.*
  - *Clin Infect Dis. 2019 Jul 2;69(2):378-379.*

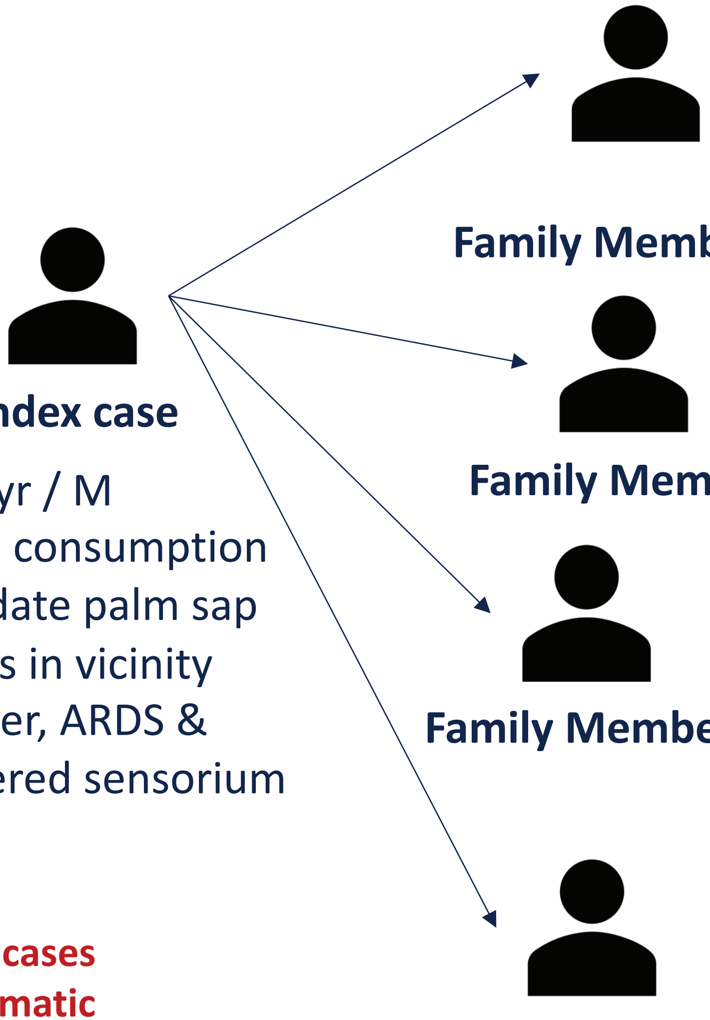
Serving the nation since 1911

Nipah Virus Outbreaks in India

Month/ Year	Location	No. of cases	No. of deaths	Case Fatality Rate
Feb. 2001	Siliguri	66	45	68%
April 2007	Nadia	05	05	100%
May 2018	Kozhikode	19	17	89.5%
June 2019	Ernakulum	01	01	0%

Siliguri Outbreak: April 9-28, 2007



Index case

- 35 yr / M
- h/o consumption of date palm sap
- Bats in vicinity
- Fever, ARDS & altered sensorium

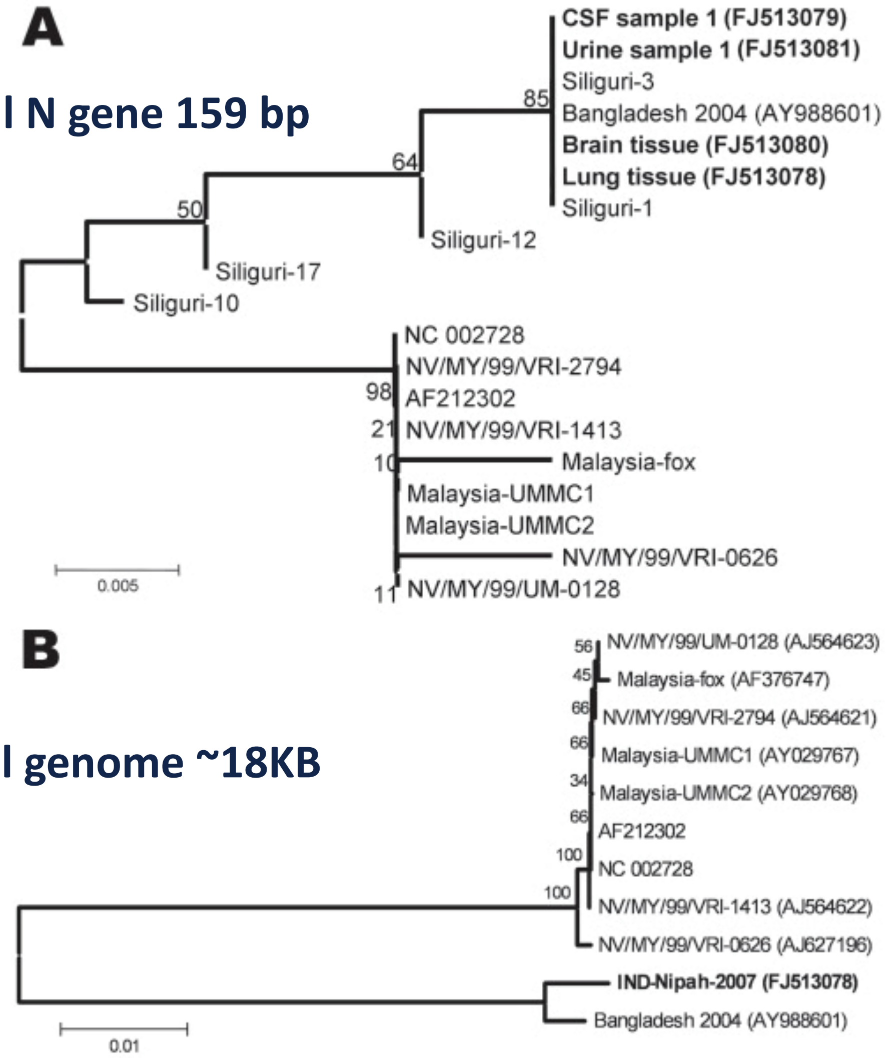
Family Member

Family Member

Family Member

Paramedical Staff

All secondary cases became symptomatic within 12-14 days of contact with index case



Partial N gene 159 bp

Full genome ~18KB

Full-genome NiV sequence from lung tissue: 99.2% nt and 99.8% aa identity with the Bangladesh-2004 isolate.

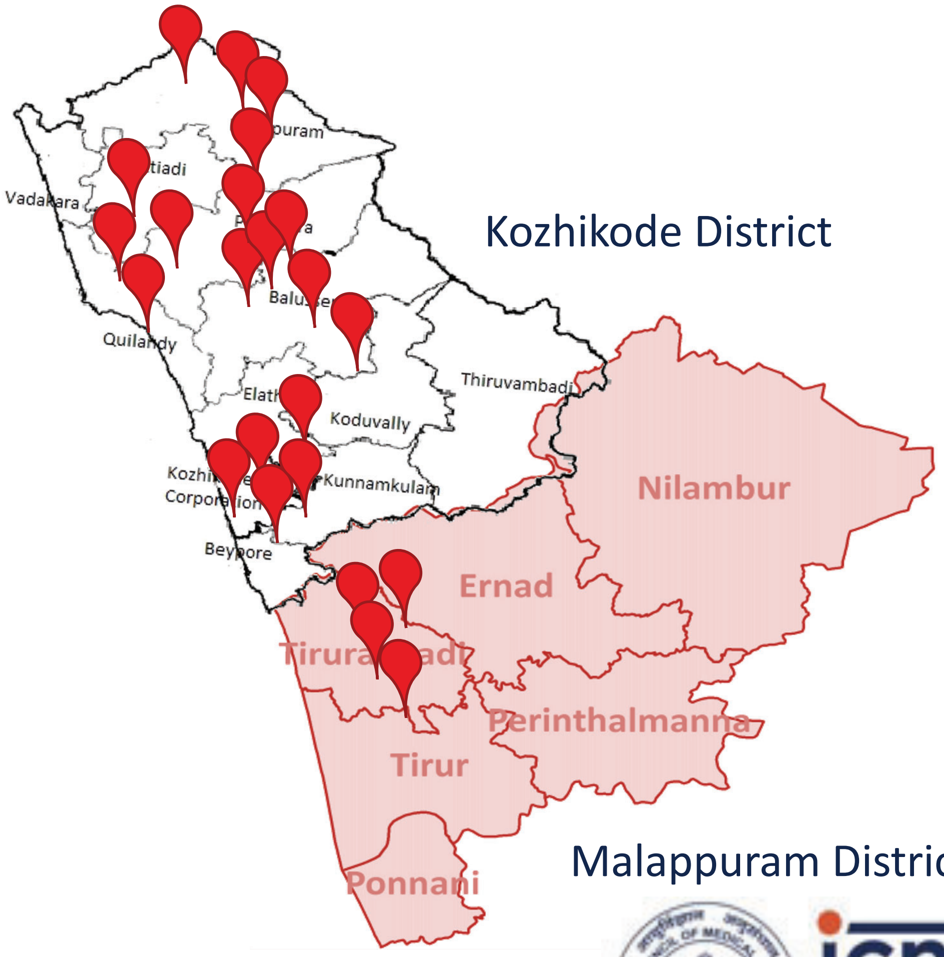
Nipah outbreak in Kozhikode and Malappuram districts (2-29 May 2018), Kerala 2018

23 cases reported

- 18 lab confirmed (NiV RNA +ve); 5 probable (including index case)
- 22 had acute neurological and/or respiratory symptoms
- 16 of the 18 lab confirmed cases died (CFR=89%)

Source of infection of primary case remained unknown

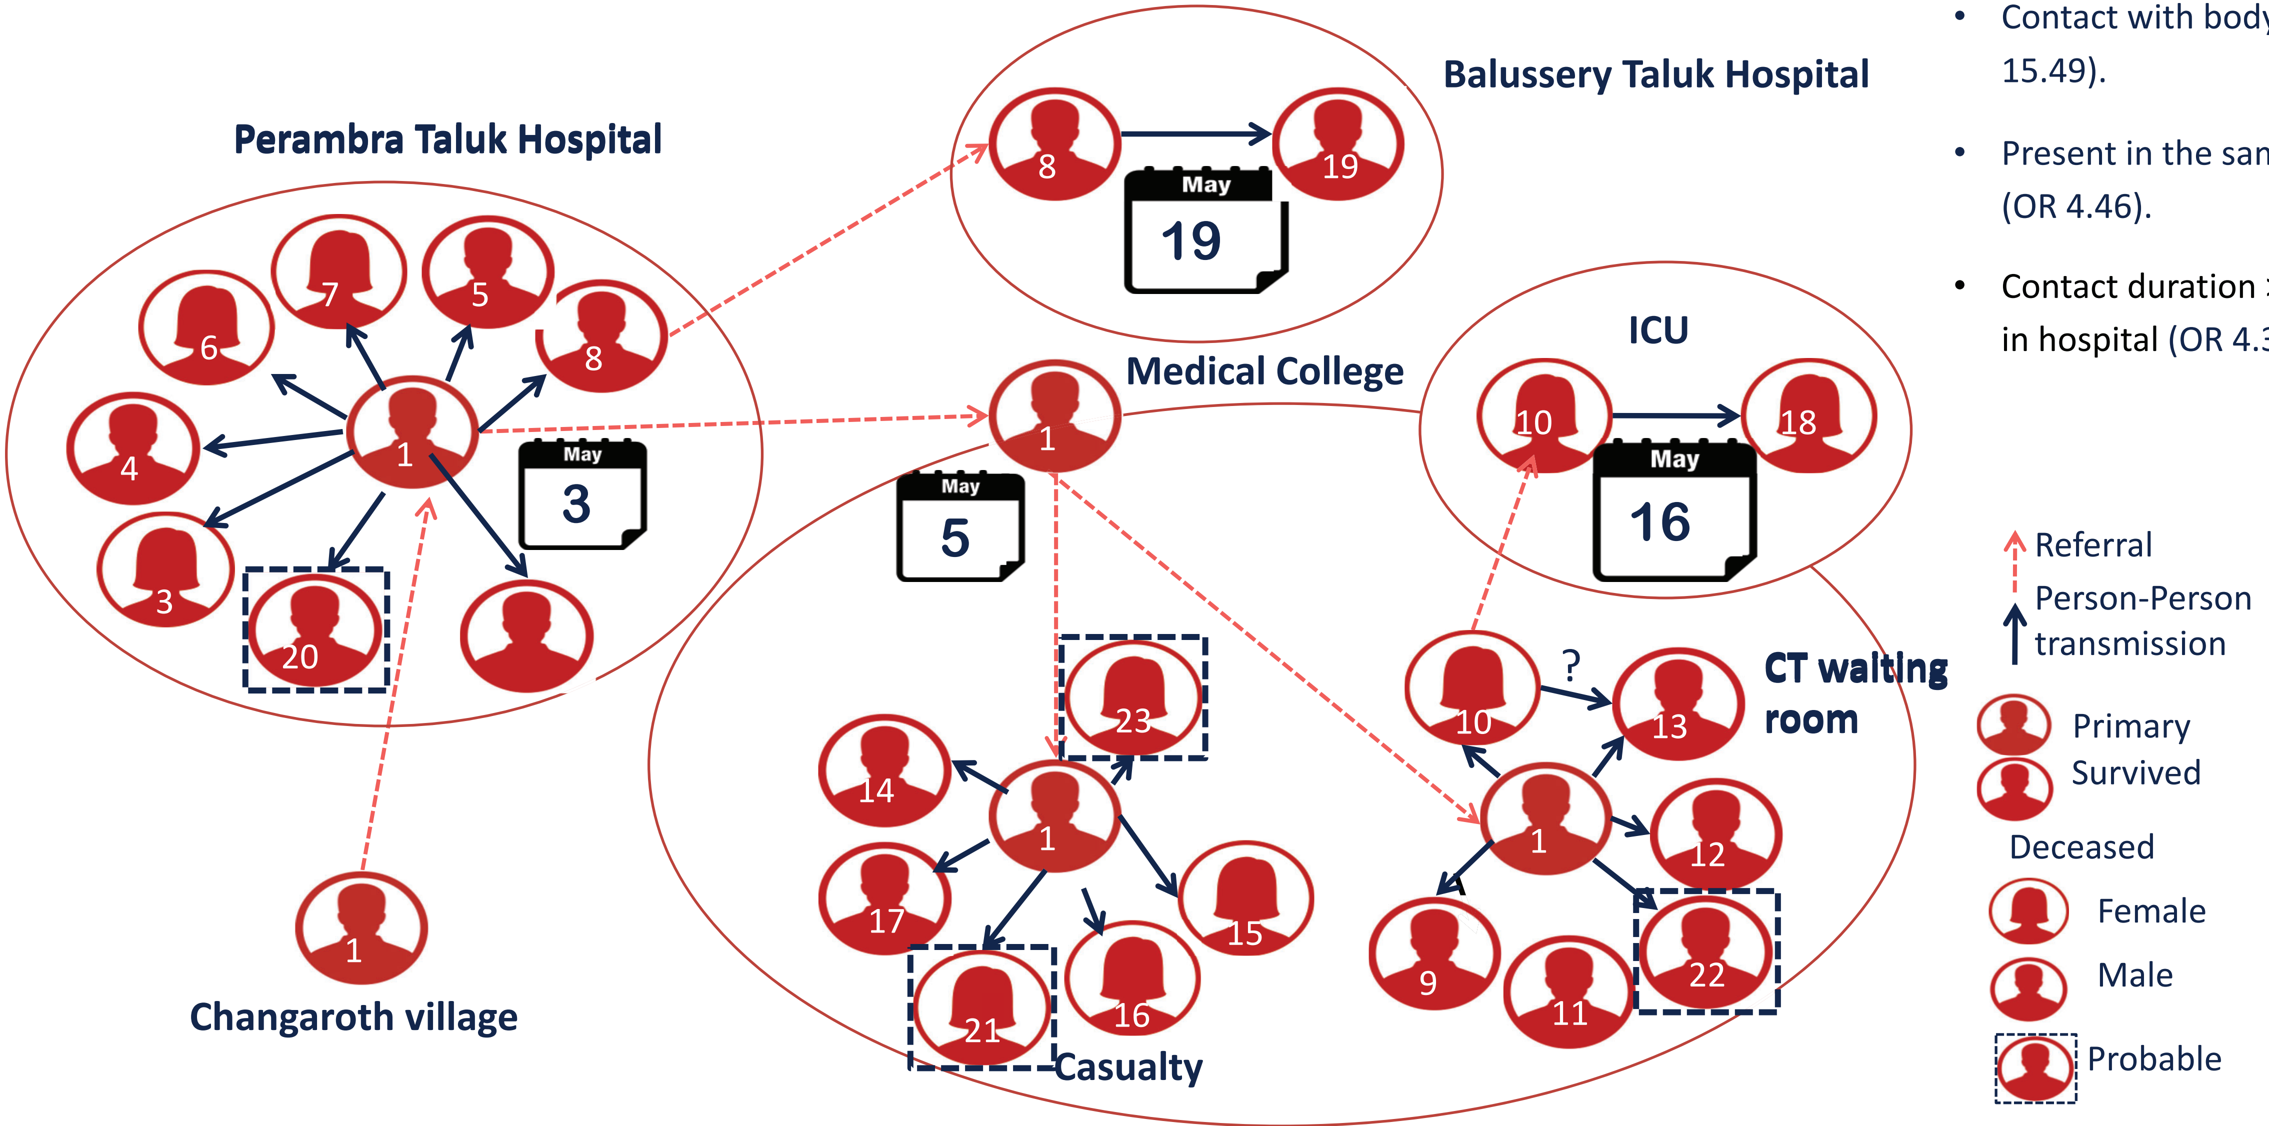
- 21 had history of contact with confirmed/probable cases



Distribution of Nipah cases (n=23) by residence

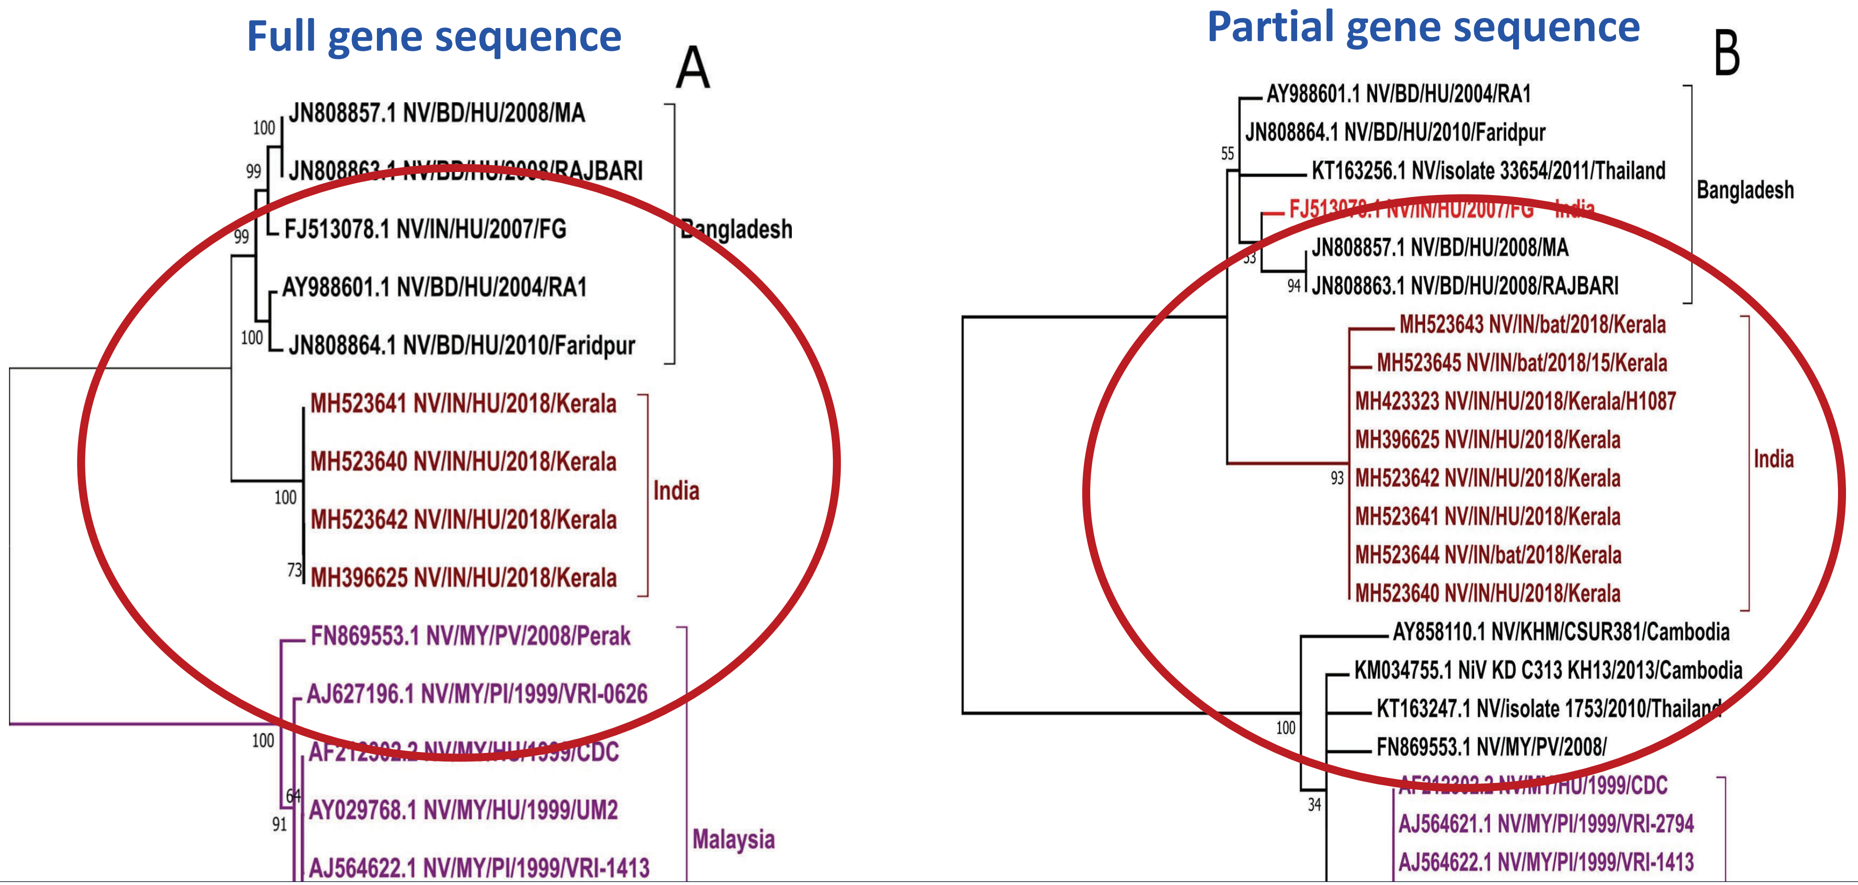
icmr
INDIAN COUNCIL OF MEDICAL RESEARCH
Serving the nation since 1911

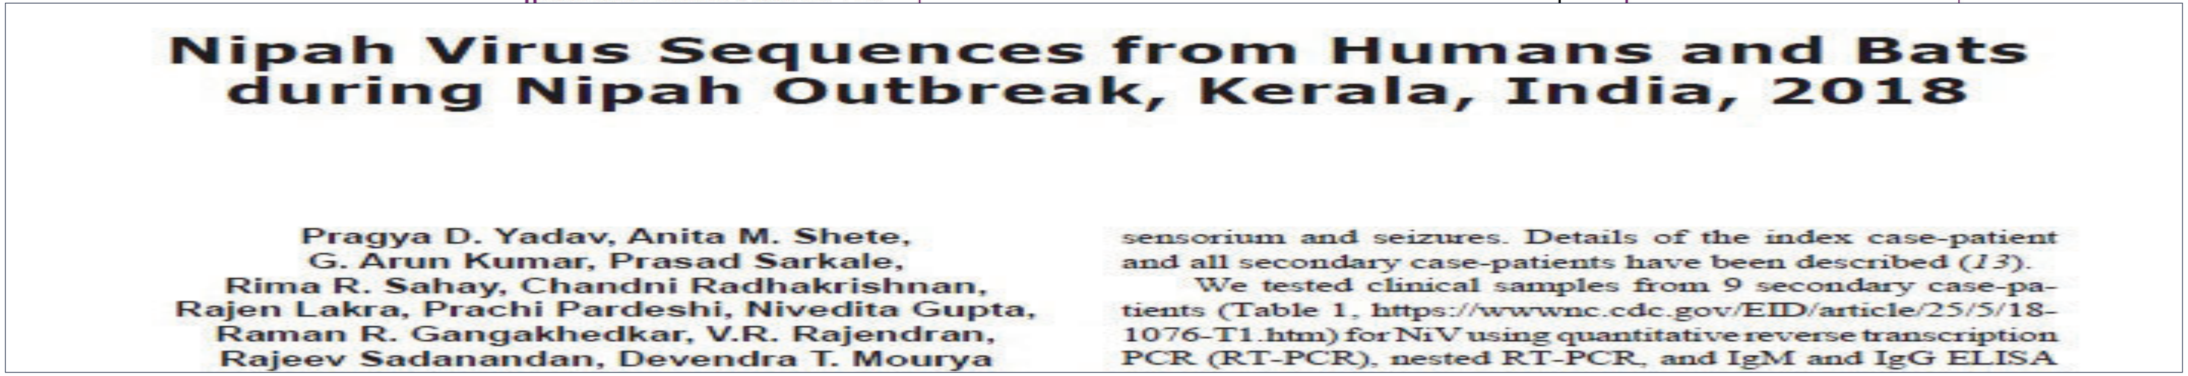
Transmission of Nipah from primary case by date of exposure and location



- **Significant risk factors**
- Contact with body fluids (OR 15.49).
- Present in the same room (OR 4.46).
- Contact duration >24 hours in hospital (OR 4.39).

Bats: Source of Infection in Kozhikode 2018 outbreak





Nipah Virus Sequences from Humans and Bats during Nipah Outbreak, Kerala, India, 2018

Pragya D. Yadav, Anita M. Shete,
G. Arun Kumar, Prasad Sarkale,
Rima R. Sahay, Chandni Radhakrishnan,
Rajen Lakra, Prachi Pardeshi, Nivedita Gupta,
Raman R. Gangakhedkar, V.R. Rajendran,
Rajeev Sadanandan, Devendra T. Mourya

sensorium and seizures. Details of the index case-patient and all secondary case-patients have been described (*13*).

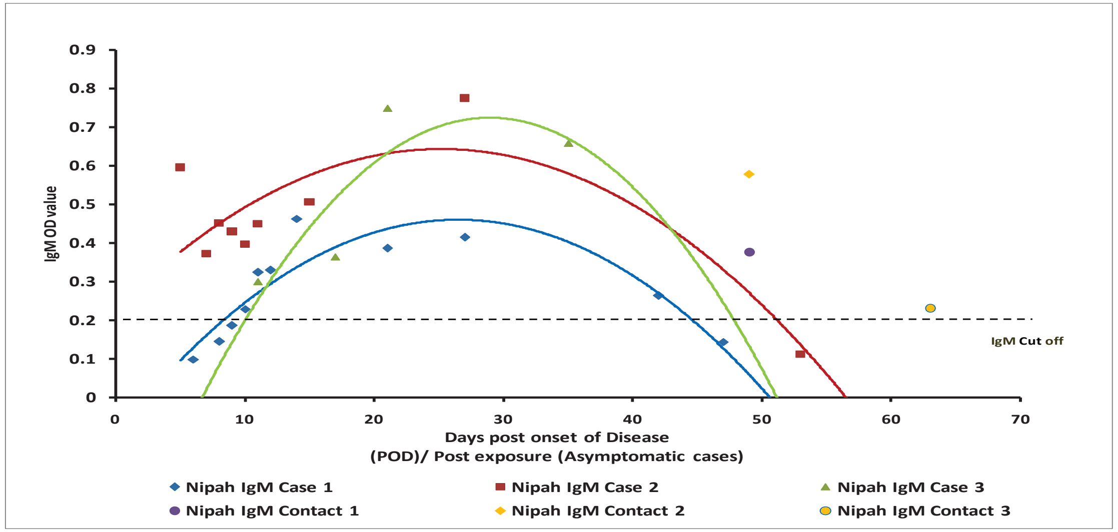
We tested clinical samples from 9 secondary case-patients (Table 1, https://wwwnc.cdc.gov/EID/article/25/5/18-1076-T1.htm) for NiV using quantitative reverse transcription PCR (RT-PCR), nested RT-PCR, and IgM and IgG ELISA

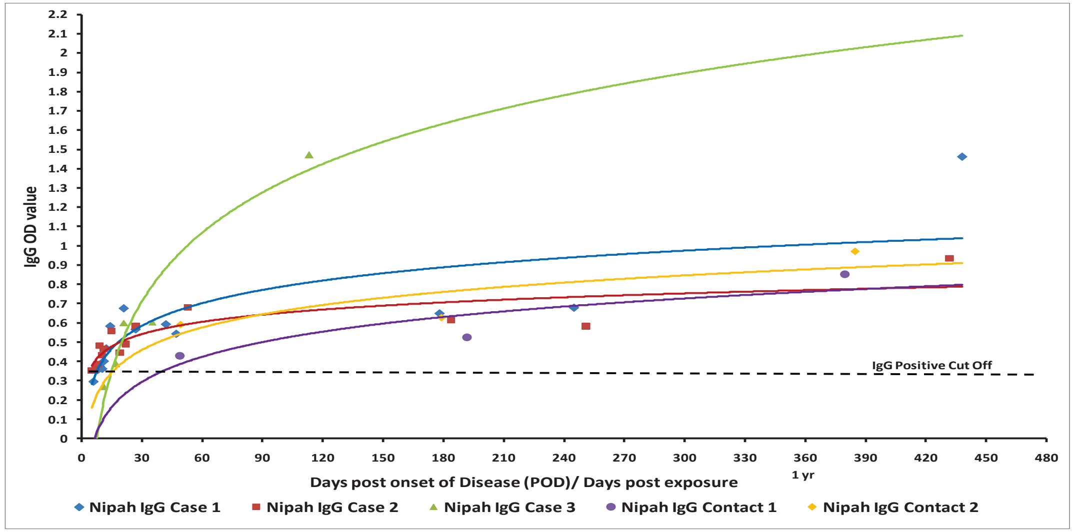
Specialized capacity for bat surveillance & sample processing

Bat Survey Team of ICMR-NIV, Pune
Trapping *pteropus* bat from Kerala

BSL-3 & BSL-4 Laboratory Complex
ICMR-National Institute of Virology, Pune

Persistence of anti-Nipah IgM and IgG antibody
(3 survivors, 3 close contacts)





Total positivity	No. positive samples/total no. of samples tested (%)	
	Anti Nipah human IgG	Anti Nipah human IgM
3/279	2/279(0.716%)	3/279(1.075%)

☐ Evidence for human to human transmission through body fluids of NiV case-patients

☐ • Low prevalence of sub-clinical NiV infection among contacts

Anti-Nipah Human IgM antibodies were detected from POD 5 to POD 42 (O.D ≥0.2)

Anti-Nipah Human IgG antibodies were detected from POD 5 to until 438 POD in survivors and 385 Days Post Exposure in close

Nipah Outbreak of 2019: Ernakulum, Kerala

Epidemiological Assessments

- ICMR team designed a risk categorization algorithm, implemented during contact tracing activities by the district teams
- 330 contacts of the index case were traced/ risk categorized
  - High-risk category included either history of direct contact with body fluids of the index case or having spent >12 hours in close proximity of index case
  - **52 contacts (35 hospital staff, 11 community members, 6 family members) were categorized into high-risk category**
  - None of these were found to be positive for Nipah virus infection
- ICMR team also aided the state to revise the Nipah surveillance and contact tracing guidelines that were finalized

Laboratory capacity for detection of Nipah virus

- ICMR-NIV, Pune team had set up the testing facilities at GMC Ernakulam within 24 hours:

- Light weight
- Portable
- Rugged (No A/C)
- Battery powered
- Ready to use, stabilized consumables

Components:

1. Sample Prep kit
2. Autoprep RNA extraction kit
3. POC Nipah Real Time machine

ICMR’s contribution in understanding NiV prevalence & further support to public health system

- Conducted surveys for Nipah virus and anti-NiV IgG antibodies in bats, pigs and human population from North-East region.
- Deputed experts to support the state government towards investigation, prevention, and control of Nipah virus outbreak in Kerala during 2018-2019
- Training on PPE donning/doffing, sample collection & triple packaging for Medical officers, HCWs ASHA and ANMs.
- Training for safe burial of human remains in cemetery.
- Un-folding the mystery- Source of outbreak in Kerala with positivity in *Pteropus* bats.
- Laboratory capacity building by training 12 VRDL laboratory for Nipah and other high risk pathogens.
- Capacity building for NiV testing at ICMR-NIV, Kerala unit
- Nationwide surveillance of for NiV in bat population revealed presence of virus in Kerala, West Bengal and Maharashtra.

Key partners

- Indian Council of Medical Research (ICMR) Headquarter (Implementing agency)
- ICMR Institutes:
  - National Institute of Virology, Pune (virus detection, in-house diagnostics, bat survey)
  - National Institute of Epidemiology, Chennai (epidemiological studies)
  - National AIDS Research Institute, Pune (clinical trial and clinical pharmacy)
- Department of Health Research (DHR) /ICMR Virus Research & Diagnostic Laboratory (VRDL) network (virus detection & surveillance)
- National Institute of Health/National Institute of Allergy & Infectious Diseases, USA (clinical trials with newer MCMs)
- Coalition for Epidemic Preparedness & Innovation, Norway (vaccine trials)
- World Health Organization –SEARO & Hq (sharing WHO blueprint implementation plan and connecting with other affected countries)
- IEDCR, Bangladesh (intercountry Nipah clinical trial)

Containment of NiV in Kerala

OVER 1,000 PEOPLE IN CONTACT LIST

- As of now, there 1,407 people in the list of people who could have been in contact with Nipah-infected persons
- The health department has also issued guidelines regarding how to deal with a person who shows Nipah symptoms
- Human Monoclonal 102.4, the medicine for Nipah, is likely to arrive from Australia on Friday
- Certain protocol needed to be followed before administering the medicine
- It is a phase-two trial drug that was found effective in patients who were infected with similar types of virus

Medical team visiting the house where the mother of Muhammad Sabith and V K Salih, victims of Nipah infection, resides at Panthirikkara on Thursday

Training for safe burial of dead body in cemetery

Training on sample collection & triple packaging for Medical officers, ASHA and ANMs

Intensive field work for case contact tracing

External Validation of Nipah virus Point of Care assay and ELISA

Assays developed for Nipah detection

1. TruenatTM Nipah Point of Care Test (POCT), developed by Molbio Diagnostics and optimized by ICMR-NIV, Pune.
2. Nipah Human IgG ELISA
3. Nipah Human IgM ELISA

❑ Indigenous assays developed by ICMR NIV, Pune

❑ CDCSO (DCGI) approved the clinical protocol of PoC for NiV detection

❑Nipah Human IgM and IgG ELISA reagents from CDC, USA were used as a gold standard.

❑99.26% specificity and 100% sensitivity was found for both the assays.

Nipah POCT Validation in collaboration with Institute of epidemiology disease control and research, Dhaka

- MoU was signed between ICMR-NIV , Pune and IEDCR, Dhaka , November 2020
- NIV team visited IEDCR during period of 3-7 November and performed the validation
- Used the clinical samples of IEDCR for validation of Nipah assays .

Anti-Nipah Human IgM and IgG ELISA onsite validation in Kerala and Bangladesh
IEDCR, Dhaka and Kerala indicated 100% concordant results in comparison of CDC reagents

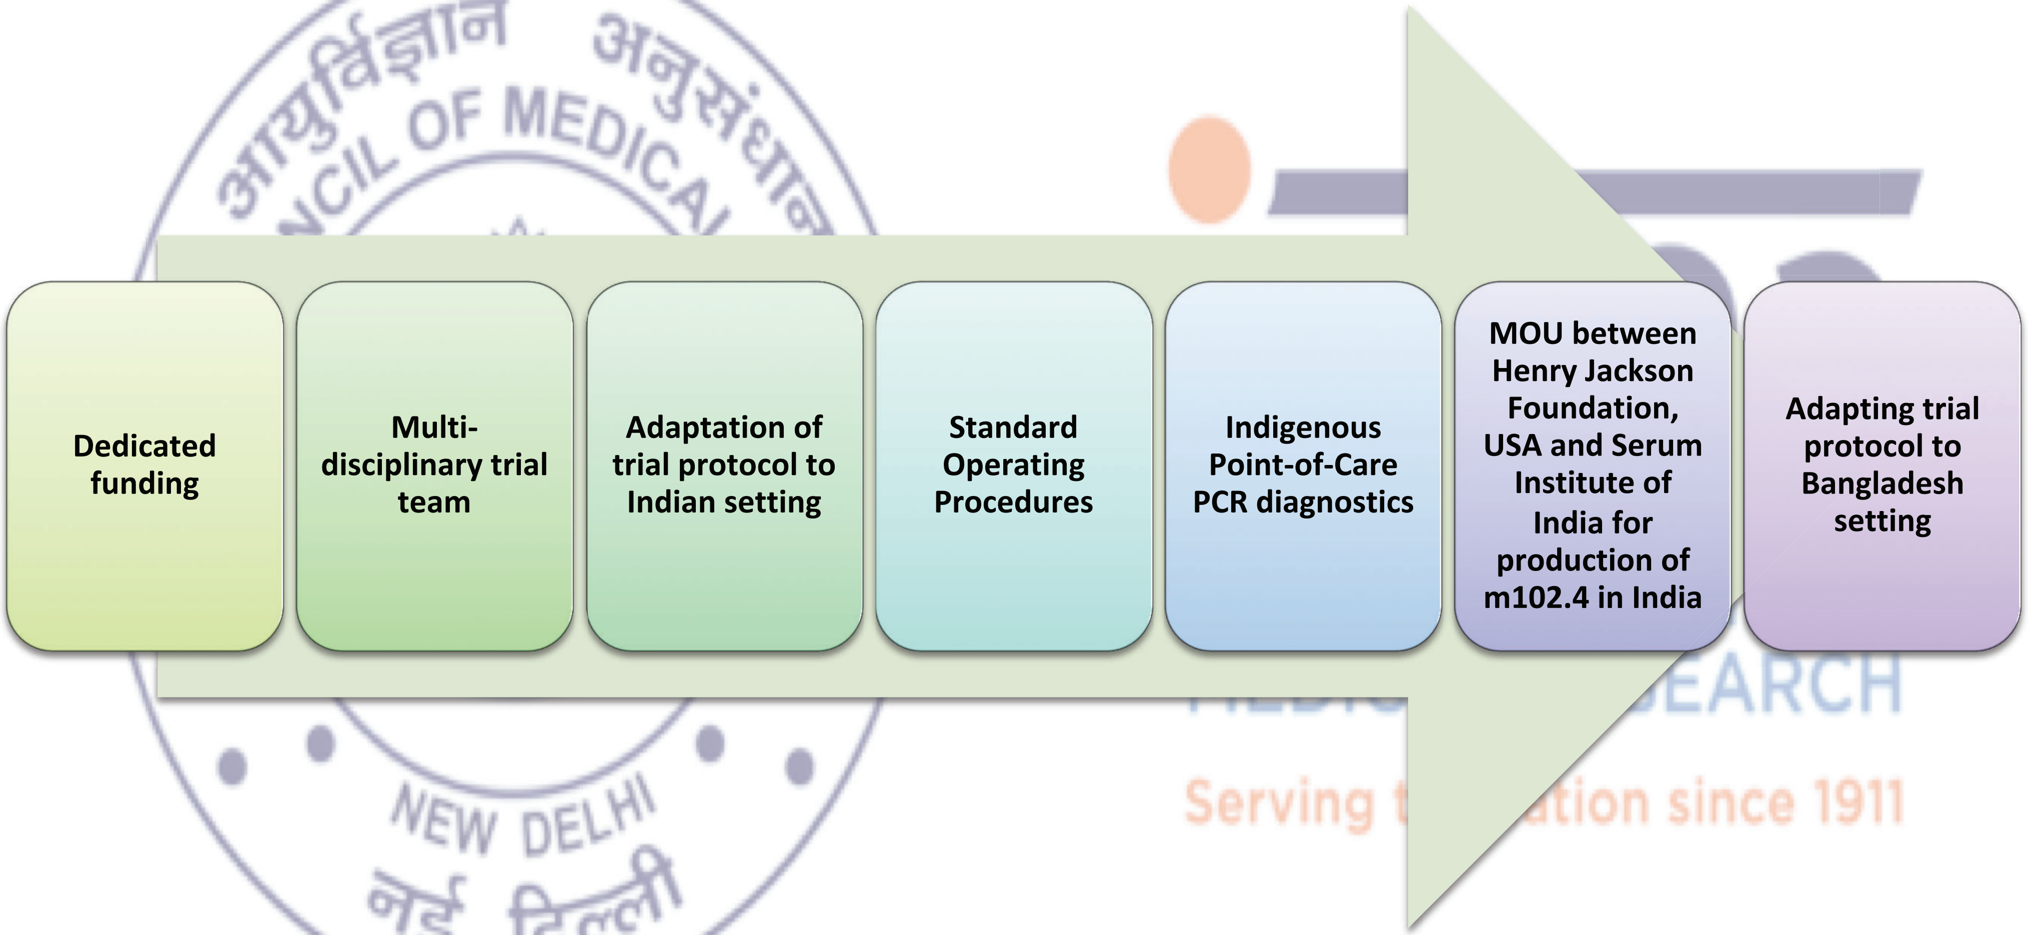
ICMR’s commitment to Nipah virus infection therapeutic clinical trial



- Dedicated funding
- Multi-disciplinary trial team
- Adaptation of trial protocol to Indian setting
- Standard Operating Procedures
- Indigenous Point-of-Care PCR diagnostics
- MOU between Henry Jackson Foundation, USA and Serum Institute of India for production of m102.4 in India
- Adapting trial protocol to Bangladesh setting

ICMR-WHO collaborative International Consultation for R&D on Nipah Virus and Nipah road map [2018-19]

- ☐ Monoclonal antibody trials
- ☐ Vaccine possibilities
- ☐ Diagnostic issues
- ☐ Preparedness for next outbreak
- ☐ R& D for Nipah

Nipah task force Expert meeting for Team members from NIH, Bangladesh , Malaysia , WHO and ICMR and Non-ICMR other institutes of India

Followed by consultation meeting for the implementation of Nipah Clinical Trial in Dhaka Bangladesh from 24th to 26th September 2019

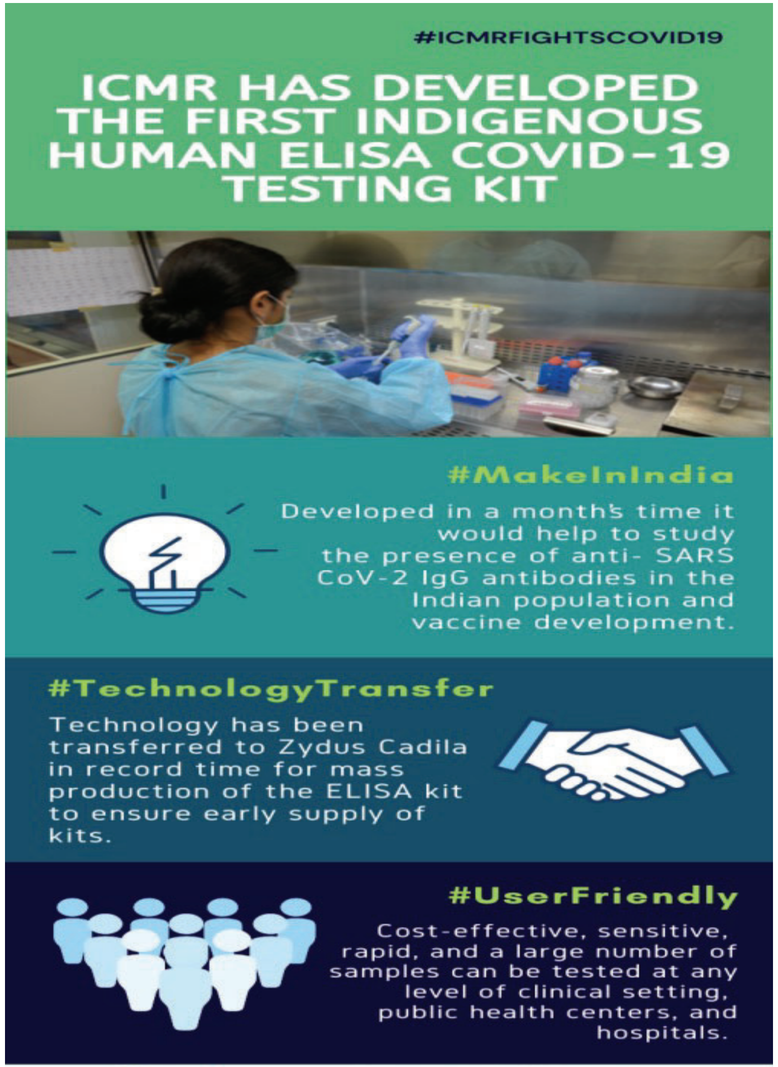
3. Impact of COVID-19 on henipavirus projects

- *Please describe the impact COVID-19 has had on henipavirus-related work. This could include impact on staff, resources, laboratories, etc.*
- *Please include projections of how you anticipate projects will be delayed.*
- *In very few cases, COVID-19 research may accelerate R&D for other viruses. Please describe if this is the case for your working group(s).*

Contribution in Pandemic

- First Genome sequencing and virus isolation
- Variant of concern and its studies
- Validation of Real time PCR, RNA extraction, ELISA , Antigen kits
- Development of assays eg. ELISA, IFA, PRNT, MNT etc
- Development of animals model for SARS CoV-2
- Screening of Anti-viral protocol and compounds
- Development of Monoclonal and Polyclonal Antibody
- Indigenous Vaccine development with Bharat Biotech International Limited
- Preparing antigen bulk for raising equine sera for therapy
- Preclinical study for vaccine in collaboration with Serum Institute and Zydus Cadilla

Indigenous Development COVID 'KAWACH' ELISA



#ICMRFIGHTSCOVID19

ICMR HAS DEVELOPED THE FIRST INDIGENOUS HUMAN ELISA COVID-19 TESTING KIT

#MakeInIndia

Developed in a month's time it would help to study the presence of anti- SARS CoV-2 IgG antibodies in the Indian population and vaccine development.

#TechnologyTransfer

Technology has been transferred to Zydus Cadila in record time for mass production of the ELISA kit to ensure early supply of kits.

#UserFriendly

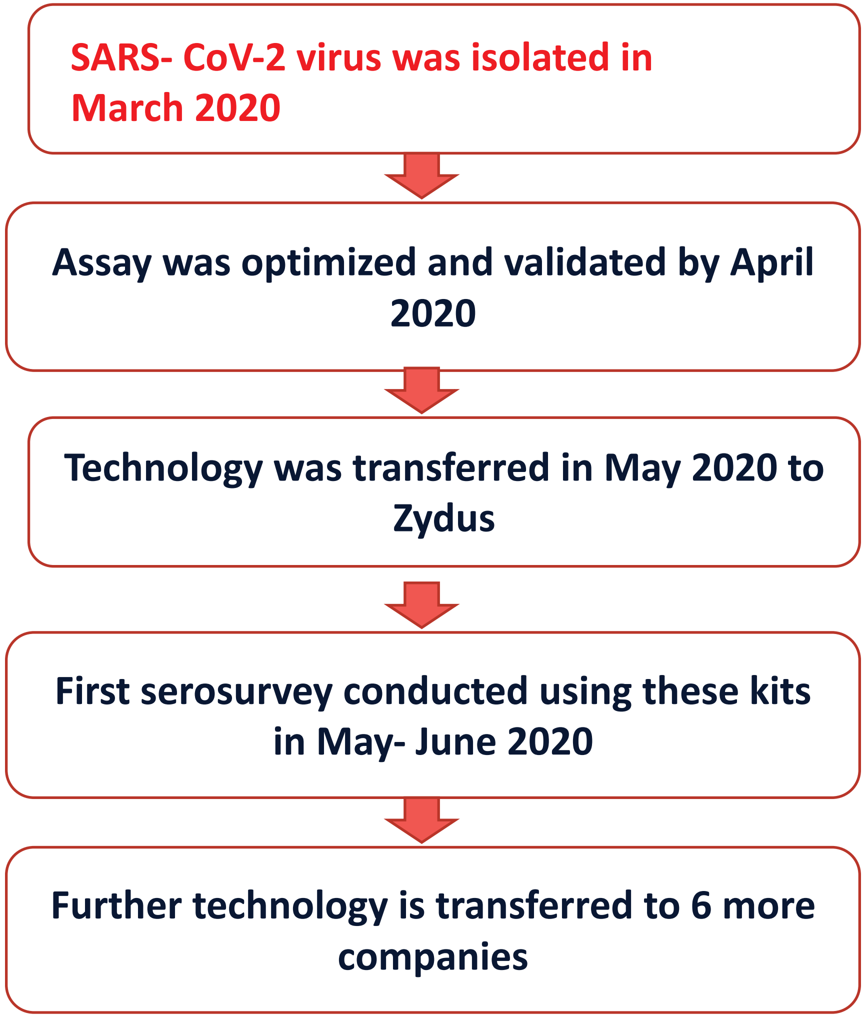
Cost-effective, sensitive, rapid, and a large number of samples can be tested at any level of clinical setting, public health centers, and hospitals.

Technology transferred to Zydus Cadila & seven other companies

To check presence of IgG (determine exposure COVID-19 in past)

#ICMRFightsCovid19

ICMR's technology has been transferred to Zydus Cadila in record time for mass production of the ELISA kit to ensure early supply of COVID-19 testing kits



SARS- CoV-2 virus was isolated in March 2020

Assay was optimized and validated by April 2020

Technology was transferred in May 2020 to Zydus

First serosurvey conducted using these kits in May- June 2020

Further technology is transferred to 6 more companies

Impact of COVID-19 on Nipah virus R&D in India

Impact	Lesson learned and advantages gained
With all the challenges of natural disaster happening and two severe waves of pandemic in 2020 and 2021 and emerge of VOC has impacted the Nipah virus bat survey in different states due to intermittent lockdown in different states .	➢ Enhanced strengthening, testing of the laboratories in the country including mobile laboratory and containment facility ➢ Laboratory capacity for preclinical studies of vaccine and clinical trial sites improved and enhanced in country ➢ Ready for Nipah vaccine and drugs trials and preclinical study
Both the waves of the pandemic had led the public health system to completely driven for the SARS-CoV-2 surveillance and control. This had led to reduce surveillance of other diseases including Nipah and other high-risk pathogens .	➢ Self reliance for the development of PPEs, Vaccine, along with conducting pre-clinical study in animal models and multi-centric trials on different products. ➢ Excellent private and Government collaborations
This has also impacted the further strengthening of the RESEARCH platform and Nipah clinical trial work	➢ Bio-risk mitigation practices improved, creation of isolation facility and PPE donning and doffing training all over the country and its importance is now inculcated amongst the health care and frontline workers
All efforts and research are diverted to SARS-CoV-2 pandemic.	➢ Working in extreme diversity and showing the humungous efforts at each level
No cases referred so we don't know the immediate status	➢ Establishment of robust validation of kits including PCR, RNA, Serological assay
R& D research focused complete as per need of country for COVID 19	➢ Fast track approval from different sectors to enhance studies

4. Major obstacles and how Task Force can facilitate moving forward

Major obstacles for Nipah	Way out
➢ Diagnosis and scaling up ➢ [Molecular and serological assays and its quality] ➢ Containment facility ➢ Augment clinical research capacity.	✓ Strengthen AES/SARI network including Nipah as one of screening agent ✓ Validation at different facility to make robust testing including standard diagnostic is needed ✓ External validation of the diagnostic assays
➢ Risk communication and community mobilization strategies during Nipah virus outbreak as well as during implementation of clinical trials during outbreak.	✓ Enhancing number of such facilities and work culture
➢ **Cutting edge technology for development of vaccine candidates**	✓ Development of the vaccine and therapeutic products and its clinical trial at fast speed ✓ Need help of CEPI and other organization
➢ Augment clinical trial capacity with newer medical countermeasures (drugs, vaccines and monoclonals)	✓ Safety and efficacy studies and Immunogenicity studies in multiple-partners network
➢ Epidemiological studies to enable early detection of Nipah virus (including modelling).	✓ Need multicentre approach and smooth process
➢ As the cases of Nipah outbreaks are mostly sporadic, its difficult to initiate any such study. ➢ Dedicated team should plan and ready for such outbreaks to act immediately in clinical trail mode. ➢ Preparedness	✓ Need for the trained manpower for field, laboratory and clinical trail related work

“COVID-19 has taught that diseases have no borders, pathogens treat humans equally. Remember the strength which we have gained , lessons which we have learnt to fight unending war of infectious disease but lets do it together”

ORIGINAL ARTICLE

The critical region for viral RNA encapsidation in leader promoter of Nipah virus

Lian Yih Pong[1,2] · **Amir Rabu**[1] · **Nazlina Ibrahim**[1]

Received: 23 December 2019 / Accepted: 25 July 2020

Abstract

Encapsidation by nucleocapsid (N) protein is crucial for viral RNA to serve as a functional template for virus replication. However, the potential region that is vital for RNA encapsidation of Nipah virus (NiV) is still unknown. Thus, this study was aimed to identify these regions using a NiV minireplicon system. A series of broad range internal deletion mutations was generated in the 5′ non-translated region (NTR) of the N gene mRNA region of NiV leader promoter via site-directed overlapping PCR-mediated mutagenesis. The mutation effects on synthesis and encapsidation of antigenome RNA, transcription, and RNA binding affinity of N protein were evaluated. The deletions of nucleotides 73–108, 79–108, and 85–108 from NiV leader promoter inhibited the encapsidation of antigenome RNA, while the deletion of nucleotides 103–108 suppressed the synthesis and encapsidation of antigenome RNA, implying that these regions are required for genome replication. Surprisingly, none of the mutations had detrimental effect on viral transcription. Using isothermal titration calorimetry, the binding of NiV N protein to genome or antigenome RNA transcript lacking of nucleotides 73–108 was found to be suppressed. Additionally, in silico analysis on secondary structure of genome RNA further supported the plausible cause of inefficient encapsidation of antigenome RNA by the loss of encapsidation signal in genome template. In conclusion, this study suggests that the nucleotides 73–90 within 5′ NTR of the N gene mRNA region in NiV leader promoter contain *cis*-acting RNA element that is important for efficient encapsidation of antigenome RNA.

Keywords Paramyxovirus · Reverse genetics · Minigenome system · Site-directed mutagenesis · Non-translated region · *Cis*-acting element

Seroprevalence of Nipah Virus Infection in Peninsular Malaysia

Ming-Yen Yong,[1] Soo-Ching Lee,[2] Romano Ngui,[2] Yvonne Ai-Lian Lim,[2,3] Maude E Phipps,[4] and Li-Yen Chang[1]

[1]Department of Medical Microbiology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [2]Department of Parasitology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [3]Center for Malaysian Indigenous Studies, University of Malaya, Kuala Lumpur, [4]Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Sunway, Malaysia

Nipah virus (NiV) outbreak occurred in Malaysia in 1998. The natural host reservoir for NiV is *Pteropus* bats, which are commonly found throughout Malaysia. Humans become infected when NiV spills over from the reservoir species. In this study, NiV serosurveillance in Peninsular Malaysia, particularly among the indigenous population, was performed. The collected samples were tested for presence of NiV antibodies using a comparative indirect enzyme-linked immunosorbent assay based on the recombinant NiV nucleocapsid (rNiV-N) protein. We found that 10.73% of the participants recruited in this study had antibodies against rNiV-N, suggesting possible exposure to NiV.

Keywords. Nipah virus; serosurveillance; Malaysia; indigenous population; comparative indirect ELISA; nucleocapsid protein.

doi: 10.14202/vetworld.2017.1297-1300 **How to cite this article:** Mikail M, Putra TATR, Suri AS, Hezmee MNM, Marina MT (2017) Preliminary study of Malaysian fruit bats species diversity in Lenggong Livestock Breeding Center, Perak: Potential risk of spill over infection, *Veterinary World*, 10(11): 1297-1300.

Abstract

Aim: Farms that are neighboring wildlife sanctuaries are at risk of spillover infection from wildlife, and the objective of this research is to examine the species diversity of Malaysian fruit bats in livestock farm in determining the possible risk of spill over infection to livestock.

Materials and Methods: Fifty individual fruit bats were captured using six mists net, from May to July 2017. The nets were set at dusk (1830 h) as bats emerge for foraging and monitored at every 30-min intervals throughout the night until dawn when they returned to the roost. The nets were closed for the day until next night, and captured bats were identified to species levels.

Results: All the captured bats were mega chiropterans, and *Cynopterus brachyotis* was the highest captured species, representing 40% of the total capture. Shannon–Weiner index is 2.80, and Simpson index is 0.2. Our result suggests that there is a degree of species dominance with low diversity in Lenggong Livestock Breeding Center.

Conclusion: We concluded that fruit bats are indeed, encroaching livestock areas and the species identified could be a potential source of infection to susceptible livestock. Hence, an active surveillance should be embarked on farms that border wildlife sanctuaries.

Keywords: Fruit bats, Lyssaviruses, Nipah virus, Wildlife sanctuaries, Zoonotic diseases.

Knowledge, attitude and health seeking practice on bats-borne diseases among residents of Tioman Island, Malaysia

Mohamed, N.A.[1*], Said, M.H.[1], Mohd Rani, M.D.[1], Ramli, S.[1] and Isahak, I.[1]
[1]Faculty of Medicine & Health Sciences, Universiti Sains Islam Malaysia, Menara B, Persiaran MPAJ, Jalan Pandan Utama, Pandan Indah, 55100 Kuala Lumpur, Malaysia
[*]Corresponding author e-mail: Email: drnurul@usim.edu.my

Received 16 April 2018; received in revised form 6 March 2019; accepted 7 March 2019

CONCLUSION

We found that human exposures to bats were high and there were gaps in residents' knowledge on bats-borne infections. Therefore, health education and promotion are highly necessary for the residents. Education, particularly, should include balancing bats conservation and prevention of bats-borne infection among residents. This is where the importance of the role the mass media play in promoting health education and prevention strategies to the mass.

Impact of Covid-19 on henipavirus projects

Item	Impact
Proposal submission and new project funding	No impact in general, but less prioritized now
Staffing, resources, laboratories	Not applicable, except for project requiring resources and infrastructure from hospitals
Progress of funded projects	Delayed due to WFH, no inter-state and inter-district travel
Acceleration of research due to COVID-19	Not applicable

Major obstacles and how Task Force can facilitate

1. Project funding and support
2. Link and connect with potential partners

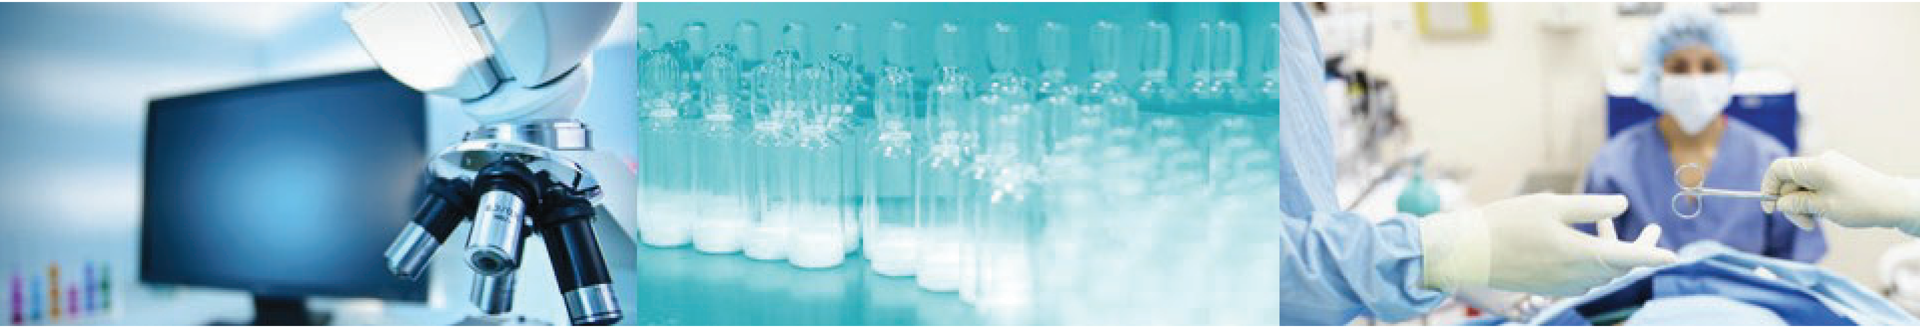
Nipah antibody standard development - NIBSC

Mark Hassall

7th September 2021



Why do we need biological standards in assays

The potency of biological products can differ between different tests and laboratories and this needs to be controlled for

Without any physical measure of activity they can be measured by referencing against a standard

Serology testing in bioassays can be harmonised by comparison to the performance of a reference standard

For clinical testing this allows comparison of vaccine responses from different assays or labs

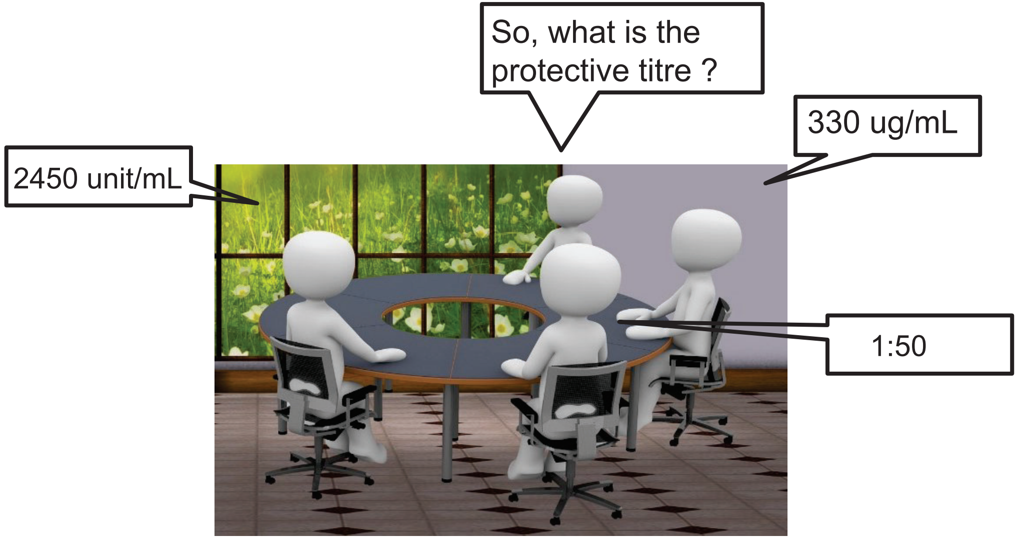
Hierarchy of standards:

- Primary calibrant – WHO IS
- External control/secondary standards
- Assay standards
  - Internal calibrator/standard
  - run control
  - working reagent
  - Secondary or tertiary reagent

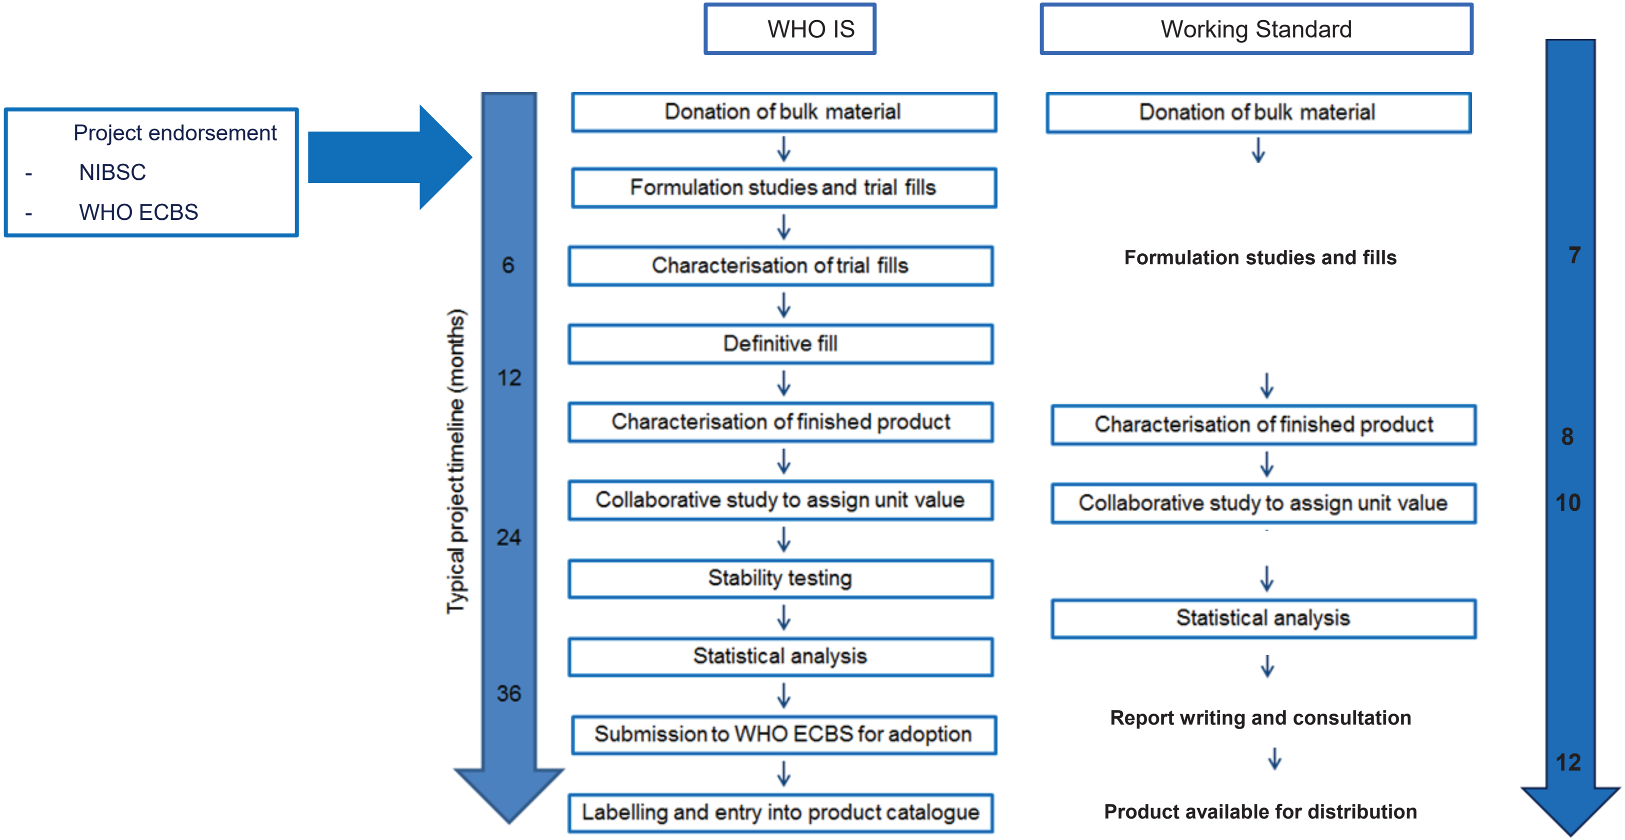
Primary calibrant

WHO International Standard – established by the WHO ECBS

Define the common language to express potency of the samples



Standards projects



Project endorsement
- NIBSC
- WHO ECBS

Product available for distribution

Sample collection and preparation

- UM will collect samples from convalescent patient and ship to PHE
- NIBSC will provide PHE with any blood virology report & previous PCR test results associated with samples
- Samples tested for Nipah virus and If sample is negative ship to NIBSC
- Samples received at NIBSC CL3 lab
- Samples treated by solvent detergent
- Samples tested by ELISA and PV assay
- Samples prepared for final formulation

Nipah antibody standard timelines

Cepi Working standard

- Endorsement by the WHO Expert committee on Biological standardization (Jan 2019)
- Sample collection from source country/partner – MTA signed with UM (Aug-Sept 2021)
- Sample testing by PHE then transfer to NIBSC (Sept 2021)
- Characterisation of antibody at NIBSC by ELISA, neutralisation assay (Sept-Oct 2021)
- Data reporting to partner and recommendation for larger donation (Oct 2021)
- Sample testing by PHE then transfer to NIBSC (Dec 2021)
- Formulation of working standard candidate and reference panel (Jan 2022)
- Feasibility study (Feb-Mar 2022)
- Analysis and reporting of study (Mar-Apr 2022)
- Establishment of working standard and reference panel (Apr 2022)

Nipah antibody standard timelines

International standard

- Stability study for candidate International Standard (Feb 2022-Feb 2023)
- Organisation of the WHO Collaborative study (Apr-May 2022)
- WHO Collaborative study (Jun-Sep 2022)
- Statistical analysis (Sep-Oct 2022)
- Collaborative study report and submission to WHO (Oct-Nov 2022)
- Establishment of International Standard by WHO ECBS (Mar or Oct 2023)
- Deliverable: WHO International Standard made available for distribution (May or Dec 2023)

What is the purpose of a collaborative study?

- It is to gather a set of data to confirm that an antibody reference candidate is fit for purpose
    - It should work in a range of assays (ELISA, neutralisation)
    - It allows harmonisation of results from different labs/assays
    - It works across a titration range (limit of detection)
- To assign an (international)unitage to the standard and a consensus on the panel levels (high, medium, low)
- It is <u>not</u> for validating or for testing assays

Collaborative study

Ahead of receiving the study samples you will be sent

- A study protocol
  - Introduction to the study - aims
  - Description of the study samples (numbers, volume, origin, treatments, etc.)
  - How many independent assays and possible dilutions suggestion
  - How to report the results - timelines
  - Contact details
- A result reporting Excel file
  - Assay reporting tables already setup
  - Data reporting tabs for each assay method
  - Comments box

When the samples are shipped participants will be notified of shipment and arrival dates, and

- Information for use – including MSDS

After the collaborative study is completed the data will be analysed at NIBSC and a report with the results issued (labs are anonymised). All participants will have the opportunity to comment

NIBSC

Antibody standard
Q&A

CEPI

Natural History Studies

Sept 1, 2021

Concept and Assumptions

- CEPI and NIAID will design an animal modeling approach that will serve CEPI and NIAID (maybe also other USG entities) with robust Nipah animal models that will suit regulatory applications for product approval using the Animal Rule approval pathway
    - Studies will be executed to high data quality standards (GLP or well-documented)
    - Assumption: 2 animal species will be used, Syrian golden hamsters and African Green monkeys (SGH and AGM)
- Studies will be protocol driven, reviewed by stakeholders
- Using a pre-IND submission package for formal FDA interaction through CEPI regulatory support, Study Protocols will be presented to FDA for review and approval, feedback to be shared with stakeholders
- Work to be performed by CEPI Animal Model Network Partner lab

Progress on design of natural history studies

- July 20, CEPI circulated design plans for hamster and AGM studies to experts and stakeholders:
  - CEPI internal, NIAID team (NI-V PO, CREID, Preclinical services)
  - RML, IRF, UTMB
  - CEPI statistical support
  - CEPI laboratory network partner engaged to carry out this work

- Ongoing work, planned through Q3 2021:
  - Designing studies (complete with statistical rationale), endpoints and scoresheet design to support euthanasia criteria
  - Compiling, reviewing study protocols, obtaining regulatory support from CEPI and other stakeholders
  - Submission of pre-IND package for model building
  - NIAID/BEI production of NIV-B stock (characterized, with CofA) expected in Fall 2021

Summary of proposed activities, circulated for feedback 7/20

1. Virus stock

Strain at hand: NiV Bangladesh

BEI Inventory: 35 vials, supported with CofA

NIAID stock generation effort

2. Confirmation of virulence studies

Use new stock

Hamster first

Then AGM

3. Dose titration studies

Bracket confirmation of virulence doses

Determine adequate dose for reproducible modelling

Hamster and AGM

4. Natural History studies

Detailed study at chosen dose level

Serial sac design was favored for certain aspects

Hamster and AGM

Results will provide a complete package describing model

Comments and issues raised by reviewers

“Design as written is repetitive, and experiments may be combined for collection of enough data and statistical power.”

“Desirable to define an LD50, LD99 if possible.” Plan is to actually use the LD99 dose or something close to it in our models studies testing the NiV-B stock.

CEPI statistical consultant proposes: **Adaptive dose finding study** can be informed by using a starting dose of virus expected to cause severe disease/lethality in hamster (e.g. 10^7 pfu/mL or TCID50 for hamsters); a similar design can be evaluated for AGM (different dose)

Choose 3 doses, ideally equally spaced and logarithmic (eg. **10^6**, **10^7**, and **10^8**), n=5 or 6 animals per group

Collect data, refine curve with second block design, calculate LD50 and LD99

Benefit: spares use of many animals in large groups to define LD50 in a large blind study; two experiments’ data can be compiled if data are independent blocks

“Should we consider a study that is designed to rule out any role that sedation/manipulation might play in NiV disease progression?”

Suggestion that NIAID’s PCS could do this in parallel. Maybe also evaluate alternative routes of inoculation (IP vs IN)

“Are we using more than one site for data collection/model establishment?”

Probably, and especially if NIAID chips in for parallel studies. Raises questions of how endpoints collected at various sites will be standardized to allow comparison. E.g. Need consistent euthanasia criteria and health scoring sheets to perform consistent work, as well as consistent animal species ages, weights, feeding and handling methods, etc.

“Use TCID50 or PFU/mL, and be consistent.” Perhaps early studies could present data in both formats, enabling comparisons.

If we are evaluating hematology and clinical chemistry parameters, we should make sure normal values for these in the animals under test are established at the site.

Model characterization studies, serial-sac design

- Well-designed serial sac studies could enable collection of model characterization over infection time period, yet also collect timepoints
- Animals would be randomized to sac days (eg. 2, 4, 6, 8, 10 etc, out as far as day 28 or 35 (if any survivors in those groups).
- The collection of longitudinal data from this study will be useful in designing challenge and other studies:
    - The serial sacrifice and natural mortality will produce a survival curve that can be estimated using the Kaplan Meier method. Parameters such as average and median survival time can be estimated.
    - The logitudinal nature of the data allows for a more sophisticated analyses of data using mixed models to estimate characteristics of the infected animals. This may allow us to define additional target parameters for assessing vaccines or other treatments.

Study Elements

- Telemetry for temperature, activity levels, RR, BP, SPO_2, etc
  - Also EEG?, CVC was not favored.
- Frequency of clinical monitoring (at least 2x per day, 3 or 4 times during disease timeframe)
- Clinical signs expected: depression, lethargy, fever, loss of appetite – Draft clinical score sheet TBD
- Observations on labored breathing, nasal (bloody) discharge
- Observations for neurological signs, seizures, muscle twitch tremors, paralysis (may not be consistent)
- Blood sampling to evaluate: viral load (infectious virus and RT-PCR), IgM and IgG, wbc and serum clinical chemistry (what analytes? CRP, etc)
- Euthanasia criteria plan should be based on clinical scoring (what are driving attributes of clinical scoring?)
  - Febrile response (loss thereof?)
  - Observed changes in posture and activity levels
  - Changes in breathing patterns, labored breathing
- Necropsy and tissue histology. Can discuss full tissue list.

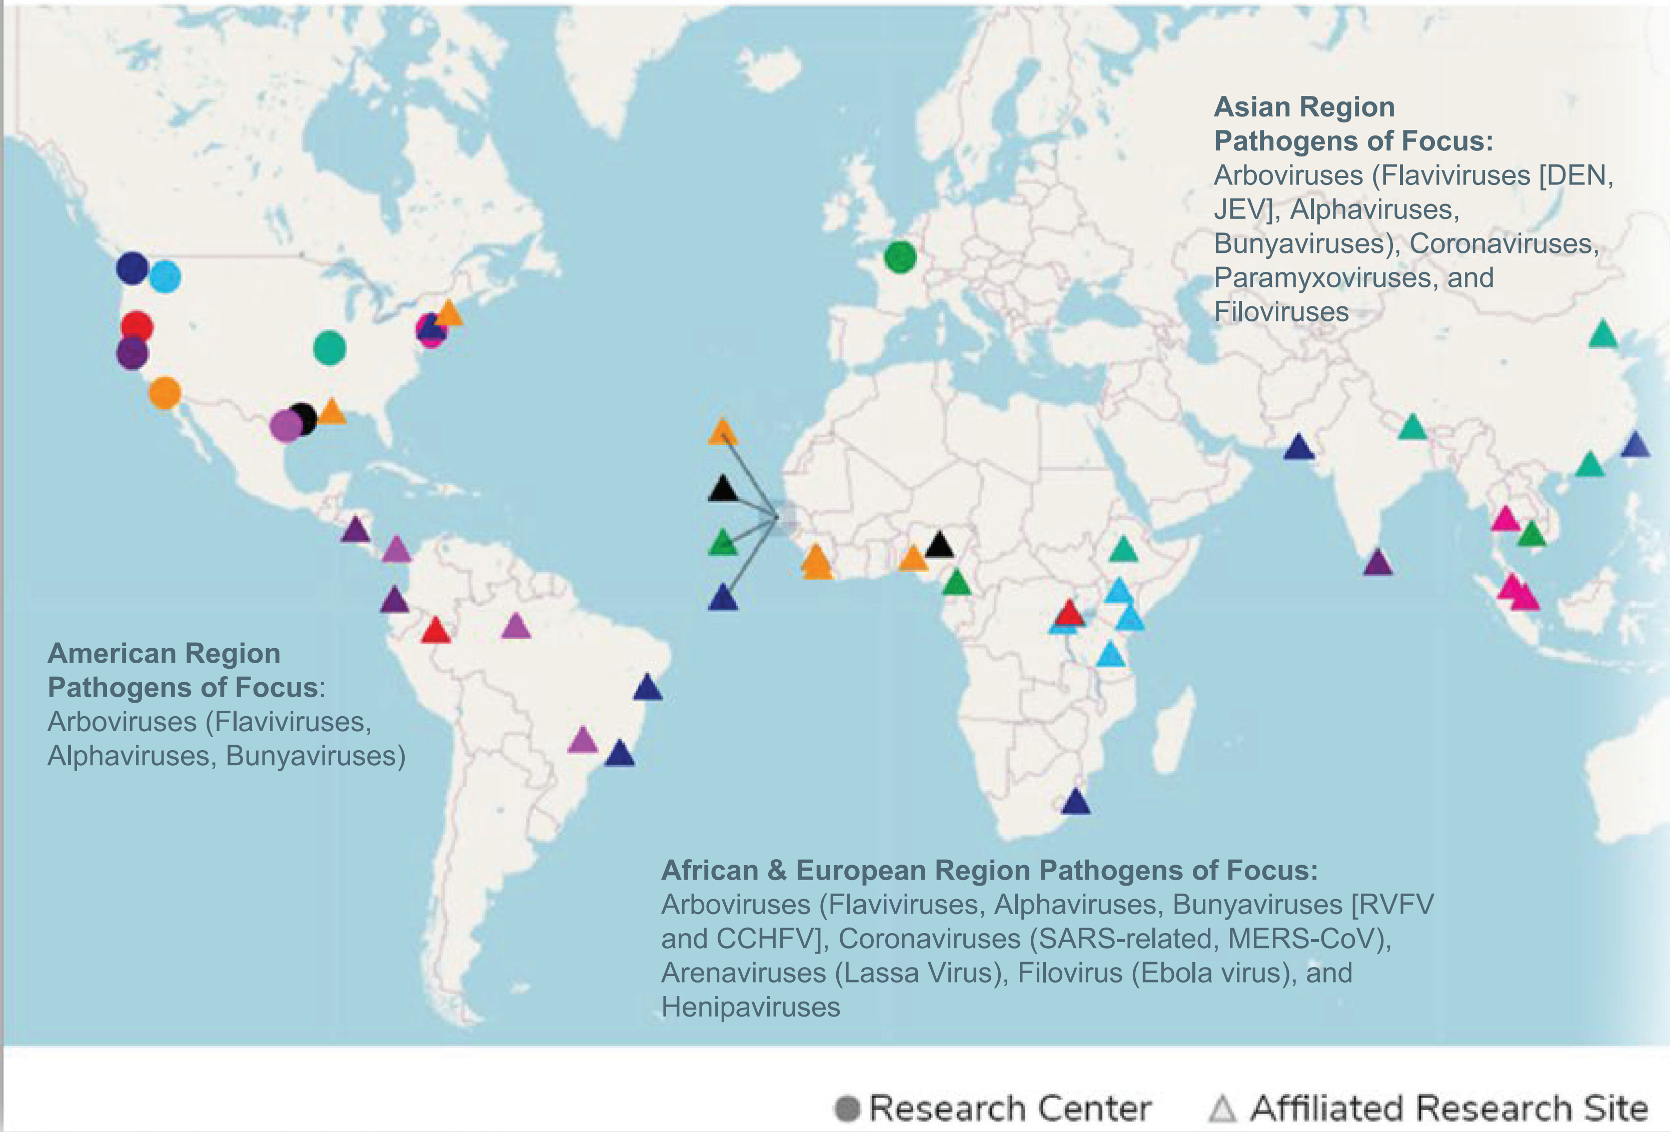
CREID Program Goals & Objectives

- Improve knowledge of emerging and re-emerging infectious diseases
    - Conducting pathogen/host surveillance and clinical research studies
    - Studying pathogen transmission
    - Developing reagents and diagnostic tests for detection of emerging pathogens and vectors
- Increase outbreak research response flexibility and capacity
- Contribute to training the next generation of EID investigators & leaders

Where is CREID?



Asian Region Pathogens of Focus:
Arboviruses (Flaviviruses [DEN, JEV], Alphaviruses, Bunyaviruses), Coronaviruses, Paramyxoviruses, and Filoviruses

RfP: Characterizing the epidemiological diversity of Nipah strains

An epidemiological investigation

PL: Maïna L'Azou Jackson

PM: Roice Fulton

RfP available at:

https://cepi.net/get_involved/cfps/?learn-more-7099=5

https://cepi.net/wp-content/uploads/2021/08/CEPI-Nipah-RfP-Call-Text.pdf

Background

- The vast majority of experimental Nipah virus research in the past 20 years has been performed with a single isolate obtained from a patient during the Nipah virus outbreak in Malaysia (Nipah Virus, 1999 Malaysia).
- More recent work has expanded to include an isolate from a patient in Bangladesh (Nipah virus, 2004 Bangladesh). However, this still means that all experimental knowledge on Nipah virus has been derived from work with only 2 virus strains, limiting inferences and interpretations about the impact of strain variation on pathogenicity, virus shedding, transmission, and efficacy of countermeasures.
  - With a regulatory approach based on animal experiments, there will be a need to characterize the challenge strains and compare them with the circulating strains.
- Difficult-to-obtain samples
  - Disease progression is rapid, and delays in seeking care coupled with lack of rapid diagnostics means that only rarely are patients diagnosed with Nipah virus infection before death, severely limiting opportunities to collect biological samples.
  - Furthermore, outbreaks have occurred in areas where diagnostic autopsy is not the standard of care, due to religious and cultural concerns or to limited capacity, further limiting samples available for analysis.
- The true geographical spread of Nipah is unknown and cases likely to pass undetected in certain countries (communications with US CDC)

Emily S. Gurley Christina F. Spiropoulou and Emmie de Wit. Twenty Years of Nipah Virus Research: Where Do We Go From Here? The Journal of Infectious Diseases® 2020;221(S4):S359–62

Goal and needs

- **Goal**: To fundamentally expand our phylogenetic understanding of Nipah virus in all affected countries and any associated epidemiology in humans to ensure vaccine development efforts *are suitably addressing any strain variation.*
- 607 reported cases of Nipah
  - of which 110 patients have been sampled
  - A recent paper (Whitmer et al., 2021) reported 55 full length genomes. There were initially only 20 full length genomes but this paper has identified and sequenced an additional 35 full length genomes (22 directly from Bangladeshi clinical specimens and 13 viral isolates - 6 Malaysian and 7 Bangladeshi)
    - Research concluded that additional genotyping is needed in and beyond the Nipah 'belt'
- There is a need to revisit the meta and epi data - as new evidence is emerging from sequencing activities - to characterize the diversity of NIV and understand if for example the different NiV B clades 1 and 2 genotypes translate into different phenotypes, such as differences in human-to-human transmission rates, pathology, morbidity, and mortality.

Deliverables

- This RfP is open to any organization or consortium of organizations with the requisite expertise, experience and resources to complete the following tasks, grouped into workstreams (proposed outputs are included per workstream below, but may be adapted by applicants to the specifics of their proposed implementation):
- **Workstream 1**: Retrospectively explore whether there are additional "historical" human NIV samples that could be sequenced from known affected geographical areas
  - Output 1: Map and describe extant samples and isolates from human Nipah cases

    Explore the possibilities for additional analyses on these samples to produce new biologic data and, with assistance from qualified biocontainment labs made available through CEPI or via applicant partnerships, investigate whether virus can be isolated and cultured for use as a future research strain
  - Output 2: Complement the existing genome sequences by sequencing any extant NIV samples which have not yet been sequenced
  - Output 3: Ensure sequences are made available in public genome database(s)
- **Workstream 2**: Retrospectively analyze the metadata associated with extant human NIV sequences
  - Output 1: Build out database on existing genomes with associated metadata
  - Output 2: Retrospective analysis of the existing metadata associated with NIV sequences, including assessment of differences between countries and strains over time
  - Output 3: Peer-reviewed publication(s) of results of the above analyses (WS1 & WS2)
- **Workstream 3:** Prospectively provide additional support to existing surveillance systems to: - sequence Nipah samples from human clinical cases, - report them in public genomic databases in a timely manner, and collect epi data and prospectively analyse metadata associated with these sequences in known affected geographical areas

Sensitivity: CEPI Internal

Solving Opportunities for Spillover (SOS): Frequency and Mechanisms of Cross-species Transmission of Nipah Virus in Bangladesh

SPECIFIC AIMS

Nipah virus has characteristics that suggest it could pose a meaningful pandemic threat: human infections are highly fatal [1], there are currently no therapies or vaccines, and it can spread person-to-person through the respiratory route [1]. Nipah virus is not currently transmitted efficiently between people [1], but this characteristic is mutable and could change in the future – other viruses have accomplished this through infections in intermediate hosts (e.g., SARS coronavirus). Due to the risk of pandemic emergence of Nipah virus, it is prudent to learn more about the frequency, geographic distribution, and nature of spillover events so that we can prevent them. Since the first recognized outbreak in Bangladesh in 2001 [2], human Nipah infections have been detected nearly every year [1]. Human spillovers primarily occur through consumption of date palm sap contaminated with bat saliva or urine [3]. Human spillovers through date palm sap occur primarily during winter, when the sap is consumed fresh, but more spillovers occur in colder winters [4,5]. **Temperature variations explain well the inter-annual variation in human spillover events, but the mechanisms driving these differences remain unexplored** [5]. Moreover, Nipah outbreaks in humans are uncommon events and may not represent the true number of spillovers occurring from bats. Antibodies against Nipah virus have been found in several domesticated animal species in Bangladesh [6], indicating additional spillover events from bats. However, little is known about the role of these animals in Nipah virus ecology. In particular, **the timing, frequency, and transmission routes of spillovers into other animals in Bangladesh have not been investigated**. If we are to meaningfully mitigate our risk for Nipah virus pandemics, we must solve the remaining questions about spillovers. Specifically, **we must understand how many spillovers are occurring, which animal species are involved, and what ecological forces drive variation in spillovers**.

This multidisciplinary study, integrating epidemiology, ecology, and anthropology, will solve these most pressing questions related to Nipah virus spillover. This work ~~is centered on the~~ establishes~~ment of~~ longitudinal animal cohorts for measuring Nipah seroincidence and household surveys to capture variation in human date palm sap consumption at two sites in Bangladesh.

Specific Aim 1: Characterize the frequency, nature, and timing of contact between bats, humans, and potential intermediate hosts. We hypothesize that humans and domesticated animals have numerous interactions with each other and bats that could lead to Nipah virus spillover. In areas near bat roosts in Faridpur and Chittagong, we will use surveys, social mapping, and camera traps to describe the ecological interactions between human and domesticated animal populations at a fine geographic scale.

Specific Aim 2: Measure seroincidence of Nipah virus spillovers in mammals. We hypothesize that several domesticated animal species have non-zero incidence of Nipah virus exposure due to contact with bats. We will sample cohorts of cattle, pigs, goats, dogs, and cats living near bat roosts to measure seroprevalence at baseline and seroconversion over time.

Specific Aim 3: Identify drivers of variation in human sap consumption behavior. We hypothesize that date palm physiology and human date palm sap consumption vary with weather patterns. Household cohorts will report their sap consumption weekly during winter to track intra-annual and inter-annual patterns of sap consumption while we monitor weather patterns, volume of sap production, and sap quality to identify drivers of human consumption.

The **expected products** of this study include: **1)** descriptions of interactions between bats, humans, and domesticated animals that could facilitate Nipah spillover; **2)** quantification of spillover events occurring from bats into domesticated animals; and **3)** identification of sources of variation in date palm sap production and human consumption.

Commented [spl1]: Clearly, this is a proposal about Nipah virus, but it is also a remarkable opportunity to study the little understood phenomena of spillover. You may consider embedding this as part of the rationale.

Commented [spl2]: Likely to change during the time the grant is funded. Would be careful not to buttress the rationale too centrally on this point.

Commented [3]: Make sure that we are emphasizing:
- why this matters and the context it is in
- the primary objective
- the primary hypothesis/question

Commented [spl4]: We do not solve questions. We answer them.

Commented [spl5]: There are two different notions of spillover here. First, is spillover from bats into domestic animals. The second notion of spillover is how this bat virus gets into people. The phrasing of the sentence is ambiguous regarding which notion of spillover is being referred to. I was assuming the first notion, and from that perspective the phrasing is not technically correct. I recommend defining terms so that these two different notions are designated separately so that your meaning is clearly communicated.

Commented [spl6]: Since domestic animals are fairly short-lived and prior studies demonstrate antibodies against Nipah, don't we already have sufficient evidence to embrace this hypothesis?

Commented [spl7]: Useful to know, but not as closely tied to the animal spillover ideas that I see is core to this proposal.

Commented [spl8]: Couldn't we already do this without even implementing the study? What does the study add?

Commented [spl9]: How does this help us?

Commented [10]: Add one more sentence that expresses the main outcome and why it matters.

I was thinking our outcome was new, highly impactful knowledge about Nipah ecology in Bangladesh, but will also provide an important model for studying Nipah in other locations/cultural contexts.

But I'm not sure what will be the best way to frame it...

RESEARCH STRATEGY – SIGNIFICANCE

Nipah virus is an emerging zoonotic pathogen that has caused outbreaks of human illness with high case fatality in Malaysia, Bangladesh, India, and likely the Philippines (Arunkumar et al., 2019; Chadha et al., 2006; Ching et al., 2015; Kaw Bing Chua, 2003; Nikolay et al., 2019). Systematic surveillance of human Nipah cases only occurs in a limited region within Bangladesh (Naser et al., 2015), so the known cases outside of Bangladesh have exclusively been detected as part of outbreaks. Since Bangladesh represents a small portion of the geographic range that *Pteropus* fruit bat hosts of Nipah virus occupy in South and Southeast Asia (**Figure**), many human Nipah infections in this region are not captured with current surveillance efforts. Furthermore, Nipah virus poses some risk for pandemic spread (Luby, 2013). Observed outbreaks with person-to-person transmission have not been sustained for more than five generations, but its elevated mutation rate as an RNA virus, and its geographic niche in a densely populated and interconnected region of Asia highlight the need for continued study of this virus. Each new spillover event from bats represents an opportunity for a new Nipah virus strain to emerge with greater transmissibility in humans and thus greater pandemic potential.

Commented [11]: Roughly 1-2 pages, with maybe one figure (map of Pteropus range and surveillance hospital locations)

Commented [12]: Some draft text from our previous document.

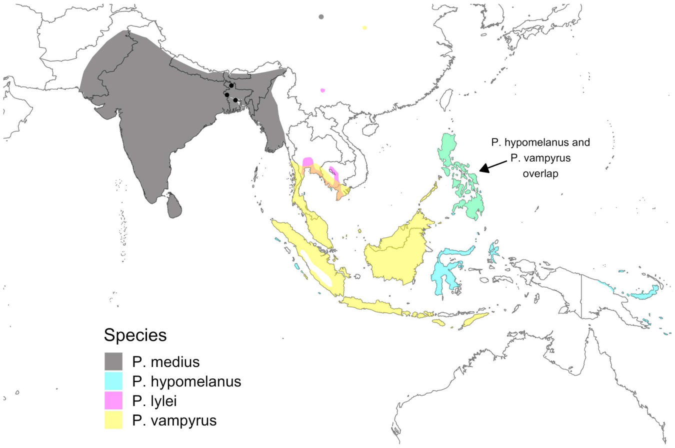

Figure. The overlapping geographic ranges of *Pteropus* fruit bat species with evidence of Nipah virus infection via sequencing or virus isolation. Black points show the location of hospitals with systematic surveillance of human Nipah cases in Bangladesh.

Beyond the aims outlined above for understanding the ecology of Nipah virus at the human-animal interface in Bangladesh, there are opportunities to expand the impact of this work. For example, the study framework and samples collected from bats and other animals could be used to study infections with other viruses shed by *Pteropus* bats, including novel paramyxoviruses recently identified from these roosts. Multiple studies have found evidence of human and animal exposure to other bat paramyxoviruses (Albariño et al., 2014; Baker et al., 2013; Philbey et al., 1998; Yaiw et al., 2007). Since paramyxoviruses unrelated to Nipah virus have been detected in *P. medius* in Bangladesh (Anthony et al., 2013) and other *Pteropus* species in Asia and Australia (K B Chua et al., 2001; Marsh et al., 2012; Sasaki et al., 2012), it is possible that these viruses may share some pathways to animal and human spillover with Nipah virus. Furthermore, the study framework devised for this project could easily be scaled and adapted for use in understanding Nipah virus ecology in other regions within the range of *Pteropus* spp. reservoir hosts (**Figure 1**). Projects such as these could explore some of the ecological and cultural dimensions that may explain why some regions of Asia with documented Nipah virus circulation in bat populations have yet to experience documented outbreaks of human disease.

Commented [spl13]: This seems too early to present these ideas. I recommend focusing on the exciting learning/understanding the can come from this work. You can include them later, in terms of closing comments, other work that this might lead to. Stated differently, I anticipate the review committee will be much more interested in what can be learned during this five years, then in setting up a productive infrastructure.

- However, during two outbreaks in 2001 and 2003, epidemiologic studies showed that cases were more likely to have had contact with livestock than controls (Hsu et al. 2004).
- In addition, one child with NiV reported exposure to goats who had died from apparent neurological illness, but these animals were not available for exam during the investigation (Luby et al. 2009).

RESEARCH STRATEGY – INNOVATION

The primary aim of surveillance for spillovers has focused on human infections, yet many of these likely go undetected nonetheless. In Bangladesh, where active surveillance for acute cases has been ongoing at hospitals since 2007, an estimated half of all human cases in the catchment area of hospitals still go undetected (Hegde et al. 2019). When surveillance for acute cases of emerging pathogens is limited, serological surveys are frequently used to detect pathogen spillover into human populations outside of documented outbreaks (Cappelle et al., 2020; Yong et al., 2020). However, this approach would be inefficient for Nipah virus due to the rarity of spillover in a given year and the high case fatality of Nipah virus infection in humans, often exceeding 70% for primary cases in Bangladesh (Nikolay et al., 2019).

Looking for infections exclusively in humans is also an overly narrow approach for detecting Nipah virus spillover events, especially given the importance of intermediate hosts in past outbreaks. The human outbreak of Nipah virus in Malaysia in 1998-1999 was driven by transmission from pigs following spillover from bats (Kaw Bing Chua et al., 2002; Kaw Bing Chua, 2003). A similar outbreak occurred in the Philippines in 2014 with horses as the likely intermediate hosts (Ching et al., 2015). Although there has been no clear involvement of intermediate hosts in human outbreaks in Bangladesh, there is evidence of Nipah virus exposure in domestic animals. Studies of animals living around *Pteropus* bat roosts in areas of Bangladesh with past Nipah virus outbreaks have found antibodies against Nipah virus in cattle, goats, and pigs (Chowdhury et al., 2014) as well as in dogs and cats (Islam et al., unpublished data). These data suggest that transmission of Nipah virus to humans through domestic animals is possible and may contribute to spillover risk in regions where outbreaks involving intermediate hosts have not yet been observed.

The advantage of animal serological surveys is that they are easier and less costly to perform than human surveys, so greater sample sizes can be obtained. Domesticated animals may also have more frequent interactions with bats or bat excreta than humans and lower case fatality following exposure, thereby increasing the probability of spillover events. Thus, serological surveys of animals are likely to yield better information on the zoonotic force of infection of Nipah virus than records of human outbreaks or human serological surveys alone. Animal serosurveys could also be expanded to regions outside of the small catchment area for human Nipah surveillance in Bangladesh and into other countries with *Pteropus* bat populations (**Figure**). Data from such animal serosurveys would increase our understanding of the frequency of Nipah virus spillover events occurring from bats. Knowledge of these animal spillover events would aid in evaluating risks for subsequent human spillover and the opportunities for viral adaptation in different hosts.

Commented [14]: Roughly 1-2 pages, with the conceptual figure that Raina suggested

Commented [15]: Some draft text from our previous document.

Commented [spl16]: This would seem a good location to include the two ideas in the bullet points above the research strategy.

Commented [spl17]: I recommend leading with scientific rather than logistical advantages.

Commented [spl18]: Yes, but this is not the strategy that is proposed for this study.

In addition to more accurate estimates of Nipah virus spillover, there is a need to understand the ecological drivers of spillover in the cultural context of Bangladesh. Consumption of date palm sap contaminated with Nipah virus from fruit bat excreta or saliva is the primary spillover route in this country and variation in sap consumption rates partially explain the geographic localization of documented human cases (Gurley et al., 2017). Nevertheless, there is substantial annual variation in the number of Nipah virus spillover events that is not matched with longitudinal data on date palm sap production and consumption in Bangladesh. Moreover, more spillover events appear to happen in years with cooler winters (McKee et al., 2021), suggesting that climate may affect bat behavior, Nipah virus shedding from bats or survival in sap, date palm biology, human consumption behavior, or a combination of these factors. Thus, there is a need to collect concurrent longitudinal data on Nipah virus shedding in bat populations, date palm sap physiology, and date palm sap production and consumption to understand how these factors interact to explain yearly variation in spillover events.

RESEARCH STRATEGY – APPROACH

Preliminary data

Ecological interactions with bats: Previous studies have identified ecological interactions between humans, bats, and domesticated animals, although the role these interactions play in Nipah virus ecology are unclear. As mentioned above, the primary route for human exposure to Nipah virus is through consumption of raw or fermented date palm sap [3,7]. *Pteropus medius* fruit bats frequently visit date palm trees to feed on sap during collection and can contaminate sap with their saliva, urine, or feces [8,9]. Some households also report feeding raw date palm sap to their livestock [7]. *P. medius* bats also feed frequently on cultivated fruit trees in populated areas [7], dropping partially eaten fruits that are sometimes consumed by humans or fed to domesticated animals [6,7]. While consumption of bat-bitten fruit is not a significant risk factor for human infection [3], it may contribute to exposure in domesticated animals, as was hypothesized to occur~~red~~ with pigs in the 1998-1999 Nipah outbreak in Malaysia [10]. A study of Nipah seroprevalence in domesticated animals found that seropositive cattle and goats were more likely to have been fed fruits partially eaten by bird and/or bats and palmyra palm fruit juice than seronegative animals [6]. Bat hunting is a direct interaction with bats practiced in Bangladesh for consumption or medicinal use [11], although no outbreaks have been associated with hunters [7]. Finally, dogs, cats, and pigs may be exposed when hunting or scavenging [12–14], including possible consumption of dead bats or bat placenta.

Commented [spl19]: A2.

Commented [spl20]: E2. I would make clear that this is our group's work.

Nipah virus exposure in domesticated animals: There is existing evidence that domesticated animals are exposed to Nipah virus in Bangladesh outside of the context of human outbreaks, but systematic surveillance is missing. A serological survey of cattle, goats, and pigs sampled between 2009 and 2011 from seven districts of central and western Bangladesh (the region where most human outbreaks have been reported) found 6.5% of cattle, 4.3% of goats, and 44.2% of pigs were positive for antibodies against Nipah virus glycoprotein using a Luminex-based multiplexed microsphere assay [6]. A second study of animals sampled between 2013 and 2015 from five districts in the same region of Bangladesh using an enzyme-linked immunosorbent assay for Nipah immunoglobulin G found 1.1% of cattle, 1.2% of goats, 3.2% of dogs, and 4.7% of cats were seropositive (Islam et al., unpublished data). Pigs and cats are highly susceptible to Nipah virus infection in experimental settings and shed virus from the nasopharynx [15,16]. Other studies outside of Bangladesh have reported exposure to Nipah virus or other related henipaviruses. Infected or seropositive goats, dogs, and cats were detected during the 1998-1999 outbreak among pigs and humans in Malaysia [17–19]. During a henipavirus outbreak among humans and horses in the Philippines in 2014, four cats and one dog died after consuming horse meat, and four dogs were found with neutralizing antibodies against Nipah virus [13]. Sheep and goats in Ghana [20] and pigs and horses in Nigeria [21] have also been reported seropositive for henipavirus exposure.

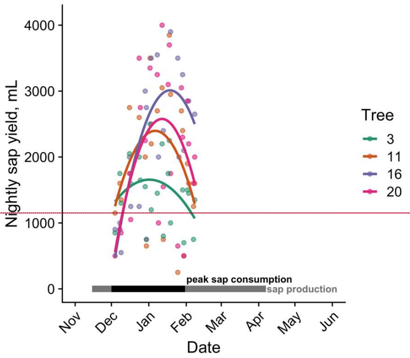
Commented [spl21]: E2.

Commented [spl22]: I recommend noting that Nipah virus is a generalist, that is it can in fact nearly any animal because the cellular receptor it leverages for infection is the highly filer genetically conserved ephrin B2/B3 receptor. Indeed, this is part of what makes mammal surveillance so efficient.

Date palm physiology and sap consumption patterns: The limited data available suggest that sap production and consumption vary seasonally (**Figure 1**) and that annual temperature fluctuations in winter may explain changes in sap consumption and the resulting risk of human spillovers. Fresh date

Figure 1.

Seasonal date palm sap production and consumption.



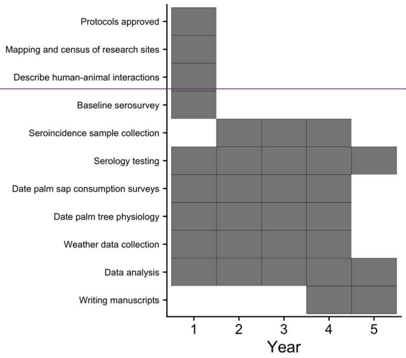
palm sap is usually harvested fresh in winter between mid-November and early March [22]; peak months for household consumption of fresh sap are in January and February (Shanta et al., unpublished data). In some areas of Bangladesh where fermented date palm sap (*tari*) is consumed, *tari* production occurs year-round, although production peaks during winter to meet higher customer demand for *tari* [23]. Sap yield also appears to peak during January during the coolest weather, although these data come from only one study of four trees in the winter of 1911-1912 [22] (**Figure 1**). Information from sap collectors also indicates that sap flows more freely and is higher quality during clear, cool nights while warm or cloudy weather diminish sap yield and quality [9,22]. However, no longitudinal data on date palm sap yield and quality over multiple years are available to determine the effects of weather. Nearly all human Nipah outbreaks have occurred in winter, with the highest proportion of spillover events occurring in January [4]. Additionally, more spillovers occur in winter weeks following a previous week with cooler temperatures [4] and more spillover events have been observed in years with colder winters [5]. Human sap consumption also varies annually. The proportion of households consuming date palm sap declined across Bangladesh during the winters of 2014 through 2016 (Shanta et al., unpublished data). Coincidentally, the winters became progressively warmer during those years and the number of reported human Nipah spillover events declined [5]. It is possible that warmer temperatures during those winters decreased the availability or quality of date palm sap, resulting in reduced consumption and the associated risk of Nipah virus exposure.

Commented [spl23]: Can you strengthen the case on why this knowledge is scientifically important? If

Overall strategy

Figure 2.

Project timeline.



The three specific aims of this study will be pursued in stages over five years (**Figure 2**). In Year 1, we will map the study sites, census animal populations, and interview households about their interactions with animals and typical date palm sap consumption behavior (Aim 1). Cohorts of censused domesticated animals and human households will be enrolled in Year 1 and an initial serological survey will establish baseline levels of Nipah virus exposure. Collection of sera from domesticated animal cohorts will follow every six months in Years 2–4 to measure Nipah seroincidence (Aim 2). A cohort of date palm trees will also be identified at each site in Year 1 for weekly measurements of sap yield and quality in winter through Year 4, along with temperature and other weather variables. Records of date palm sap consumption during winters of Year 1–4 will be collected weekly from household cohorts (Aim 3). Data analysis and testing of sera will occur continuously through Year 5.

Commented [24]: Talk about how work will be partitioned among teams and how they will collaborate.

Might consider moving this towards the end of the document.

Commented [25]: Add in preliminary work by USU to design and validate beads.

Study Sites

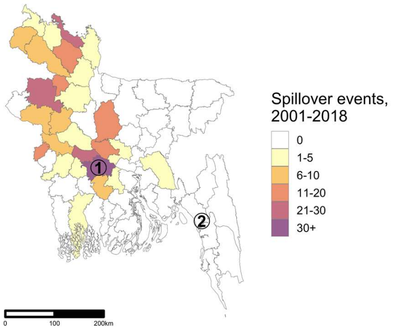
Research will be conducted at two study sites in Bangladesh that differ in the number of reported Nipah spillovers despite similarities in their ecology. A goal of this study is to understand how spillover events in domesticated animals relate to observed human risk at these sites, if at all. *Pteropus medius* bat populations roosting in Faridpur and Chittagong do not have overlapping home ranges and are genetically distinct [24,25]. Nipah virus shedding in urine has been detected repeatedly in longitudinal surveys of bats at both sites (Gurley et al., unpublished data). Humans and animals live in close

Commented [spl26]: I do not see this goal mentioned anywhere in the specific aims. It seems odd that it pops up here in the methods section.

proximity to bats in each area, but Faridpur has reported the highest number of Nipah spillover events into humans in Bangladesh while spillovers have never been detected in Chittagong (**Figure 3**). Communities in Faridpur also report higher rates of drinking fresh date palm sap than those in Chittagong [7]. Furthermore, seropositive cattle and goats [6] and dogs and cats (Islam et al., unpublished data) have also been reported from studies in Faridpur. It is likely that Nipah virus spillover events are occurring undetected in animals and humans in Chittagong ~~due to lack of surveillance effort~~. However, there may be other important biological and cultural factors explaining variation in spillover risk between these two areas that will be explored in this study, including the frequency of interactions between bats, humans, and other animals and different patterns of date palm sap production and consumption.

Figure 3.

Proposed study sites in 1) Faridpur and 2) Chittagong.



Commented [spl27]: Also, D7.

Commented [spl28]: But with an N=2, we are not powered to assess whether any differences we observe are due to unmeasured characteristics that are different between the two sites.

Aim 1 Strategy

Commented [29]: Reiterate the main goal, the hypotheses that will be tested.

Make sure we make super clear everything we are going to measure, how we are going to evaluate it, and what the implications are.

Community enrollment: Previously identified roosts of *Pteropus medius* fruit bats in Faridpur (~2000 bats) and Chittagong (~8000 bats) will serve as central points for enrolling communities into the study. Based on a survey of Bangladeshi communities on household size [7], we conservatively estimate that there are 200 households in a given suburban community. Survey estimates of the average numbers of domesticated animals owned per household indicate that at least three communities will need to be enrolled at each site to capture enough individual cattle, goats, pigs, dogs, and cats for the serological assessments in Aim 2 and for the required number of households for assessing trends in date palm sap consumption in Aim 3. Communities nearest to the focal bat roosts will be enrolled first, with a maximum radius of 15 km for community enrollment based on the observed home range size of *P. medius* [25].

Mapping and census: Teams dispatched to each community within the Faridpur and Chittagong sites will first speak with local leaders to delineate the boundaries of the community. Once boundaries are established, teams will then map the location of households and other structures, populations of livestock and peri-domestic animals (cattle, goats, pigs, dogs, and cats), fruit bat roosts, cultivated fruit trees (e.g, mango, lychee), date palm trees, and any other natural resources that are shared between host groups (**Figure 4**). GPS locations for each point will be recorded and then used to develop preliminary maps of each community and the estimated populations of humans, bats, and domesticated animal species.

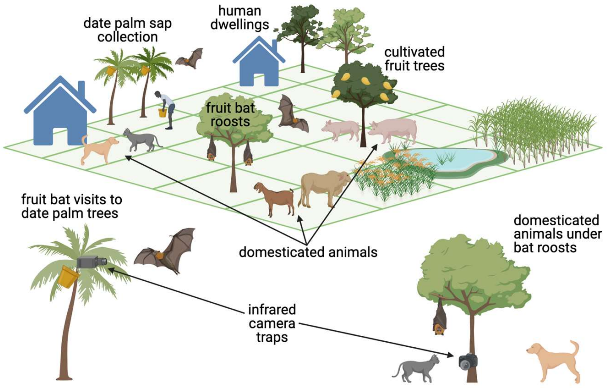


Figure 4. Mapping and recording interactions between bats, humans and domesticated animals.

Describing human-animal and animal-animal interactions: This portion of the work will occur in three parts. First, teams will enroll members of each community for a social mapping exercise. In this exercise, members will collaborate in focus groups to identify where domesticated animal populations or bat roosts are located in the community and the known forms of interactions. Human-domesticated animal interactions may include owning and caring for livestock, dogs, or cats. Human-bat interactions could include bat hunting or observing bats visiting a residential fruit tree or eating bat-bitten fruit. Domesticated animal-bat interactions might involve livestock, cats, or dogs grazing or scavenging underneath bat roosts or popular bat feeding sites; domesticated animals being fed bat-bitten fruits or date palm sap; or observations of carnivores scavenging dead bats or bat placenta.

Second, qualitative information on ecological interactions gathered from the social mapping will be used to design surveys to quantify the types and intensity of human-animal and animal-animal interactions. In addition to the example interactions given above, the survey will ask households about their typical consumption of date palm sap, either fresh or fermented. Questions about the number of household members that drink sap during winter, how frequently household members drink sap, and the typical volume consumed. These data will provide a baseline for the longitudinal assessments of sap consumption in Aim 3. Two hundred randomly selected households across enrolled communities at each site will be administered the survey in Year 1 to evaluate a difference in the proportion of households consuming sap between study sites.

> *Power calculation:* With 200 households interviewed at each site, this sample size will be sufficient to identify a moderate effect size (d = 0.4) for a difference in the proportion of households consuming sap between sites with 0.8 power and a significance level of 0.05. As discussed in the strategy for Aim 3, this number of households will be sufficient for assessing differences in sap consumption between study sites or years.

Commented [spl30]: I concede that you have the power to do this, but I'm less clear on what scientific inference of general interest it allows.

Third, nighttime space use and food resource consumption will be described using camera traps in Year 1. Based on the social mapping exercise and household interviews, teams will identify *Pteropus medius* bat roosts (beyond the focal roost at each study site), fruit trees that are popular feeding sites for bats and other animals, and date palm trees that are harvested for fresh sap. A motion-sensor tripped infrared camera will be mounted at the base of each bat roost tree (Figure 4) for three consecutive nights each month to record any visitations by livestock, dogs, cats, or other wild animals at night and any interactions they may have with bats (e.g., scavenging dead bats). Cameras will be installed at the base of fruit trees that are known popular feeding sites for bats in each community; recordings will be performed over three consecutive nights during the tree species' peak fruiting time. Finally, if date palm trees are found within the community and are harvested for fresh sap in winter, cameras will record visits by bats or other animals (e.g., rodents). Cameras will be mounted at the top of the tree near the collection pot to observe animals touching or licking sap [9] (Figure 4). A target of five date palm sap trees per community will be recorded for three consecutive nights in winter (between December and February). All cameras will be set at dusk and record animal visits until cameras are retrieved at dawn. A hired guard will protect the cameras during each night they are mounted.

Limitations:

Commented [31]: Add in section for anticipated challenges and their solutions.

Aim 2 Strategy

Commented [32]: Reiterate the main goal, the hypotheses that will be tested.

Make sure we make super clear everything we are going to measure, how we are going to evaluate it, and what the implications are.

Need some information about design of serological assay

Baseline seroprevalence survey and force of infection: Between the surveyed communities from Aim 1, teams will aim to capture 150 animals each of cattle, goats, pigs, dogs, and cats in Year 1 from the Faridpur and Chittagong study sites (**Figure 5**). Teams will capture animals and take a sample of whole blood. Blood samples will be placed in a vacutainer, centrifuged to separate the serum, and immediately preserved in liquid nitrogen in the field. Samples will then be stored in a -20 °C freezer until testing. Serum samples will be tested for the presence of Nipah virus antibodies using a bead-based assay.

Commented [33]: Henrik: Any lab challenge studies showing the feasibility for these animals to become infected? Do they die/get sick?

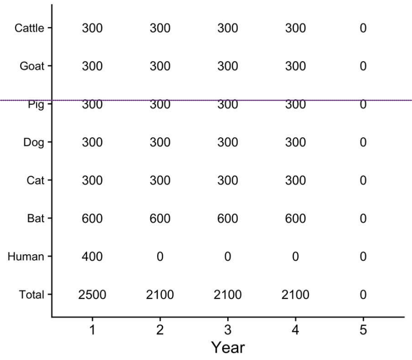
Zia: Can we also consider shrew and rodents?

Commented [34]: Henrik, lab studies were done on cats and pigs, as referenced in the preliminary data section above. Cats develop clinical disease, pigs do not. Its unclear of disease would have been fatal in cats, as they were euthanized prior to that endpoint.

Zia, we could, and I think it would be interesting to see those results. However, given that there is no prior information on NiV infection in these animals and the fact that we have a limited budget, I think we might have to keep our target animal species limited to the five already mentioned. I would be willing to include them as long as the budget allows.

Figure 5.

Animal serum sampling schedule.



Year	1	2	3	4	5
Cattle	300	300	300	300	0
Goat	300	300	300	300	0
Pig	300	300	300	300	0
Dog	300	300	300	300	0
Cat	300	300	300	300	0
Bat	600	600	600	600	0
Human	400	0	0	0	0
Total	2500	2100	2100	2100	0

> *Power calculation:* Based on a survey showing Nipah seroprevalence 1.1% in cattle, 1.2% in goats, 3.2% in dogs, and 4.7% in cats, a sample size of 150 animals

is more than sufficient to measure a seroprevalence greater than zero in the baseline survey, with a power of 0.8 and a significance level of 0.05.

During capture, teams will record the age in months of each animal if known from the owner. Otherwise, teams will estimate the age of animals or classify animals into juvenile or adult age groups. The serology data will then be used to calculate baseline seroprevalence by animal species, and using the age information, seroprevalence by age classes. The latter data will then be used to fit catalytic models to estimate the average annual force of infection from NiV in the region for each animal species [26]. These will be used as a baseline estimate of annual incidence that will be compared to the prospective study.

Commented [spl35]: Consider with some veterinary support if a finer grained estimate could be generated.

Estimating seroincidence prospectively: During animal captures in Year 1, teams will identify the number of juvenile cattle, goats, pigs, dogs, and cats that are Nipah seronegative at baseline. In Year 2, additional juvenile animals of each species will be captured to reach a cohort of 150 seronegative individuals. This same cohort will be sampled again six months later in Year 2 to measure the change in serostatus. If any members of the cohort seroconvert or cannot be captured due to disappearance or death, a new seronegative animal will be identified and added to the cohort. The same procedure of serological testing on 150 cohort animals per site of all five species every six months will continue through Years 3 and 4 (**Figure 5**). Juveniles will be targeted for two primary reasons: 1) juvenile animals are more likely to be immunologically naïve to Nipah virus than adults, so seroconversion will be easy to interpret; and 2) young animals are more likely to remain alive throughout the duration of the study. The latter is especially true for livestock animals, which are typically slaughtered for meat after about a year. The same serological assay as was used in the baseline survey will be used. Seroincidence during Years 2–4 will be measured for each animal species as the number of individuals seroconverting in a six month period and over the entire year.

Commented [36]: Rajib, how do you think we should mark captured animals in order to identify individuals upon recapture? Would microchips work? Or do we need some external marking, like an ear tag or paint?

Commented [spl37]: Will be important to know how long animals live.

Commented [spl38]: May not want to have animals that are too young, because they may have Nipah IgG from their mothers.

Bat serology: In addition to domesticated animals, we will measure changes in seroprevalence in the fruit bat populations living in the focal roosts in Faridpur and Chittagong. A target of 50 bats per site will be captured for blood serum sampling every other month in Years 1–4 (**Figure 5**) and tested for Nipah antibodies using the same bead-based assay as the domesticated animals. Changes in the proportion of juvenile and adult bats in the roosts will be monitored over time to compare with any observed changes in seroprevalence. All captured bats will be marked with microchips so that any change in serostatus (conversion or reversion) can be recorded for recaptured individuals.

Commented [39]: Emphasize this part a little more, because without force of infection from bats, no spillovers to humans and domesticated animals.

Human seroprevalence: In Year 1, during the interviews on household consumption of date palm sap and animal interactions as part of Aim 1, blood samples will be taken from household members that report drinking the most fresh sap to test for Nipah antibodies, with a target of 200 tests per site (**Figure 5**). Responses to quantitative survey questions will be used to analyze if any ecological interactions (e.g., consuming date palm sap) or history of contact with a human Nipah cases can explain seropositivity.

Limitations:

Commented [40]: Add in section for anticipated challenges and their solutions.

Aim 3 Strategy

Commented [41]: Reiterate the main goal, the hypotheses that will be tested.

Make sure we make super clear everything we are going to measure, how we are going to evaluate it, and what the implications are.

Date palm tree physiology: To understand how date palm sap production relates to patterns of human consumption, we will enroll a cohort of 20 date palm trees per site to measure sap yield and quality over the winter production period in Years 1–4. For two nights each week over the 22 weeks of the typical sap production season (mid-November to mid-April), we will measure nightly sap yield, sap pH, sap sugar content (using a Brix refractometer), and sap clarity from each tree (**Figure 6**). In addition to sap measurements, each

Commented [spl42]: How will these be selected?

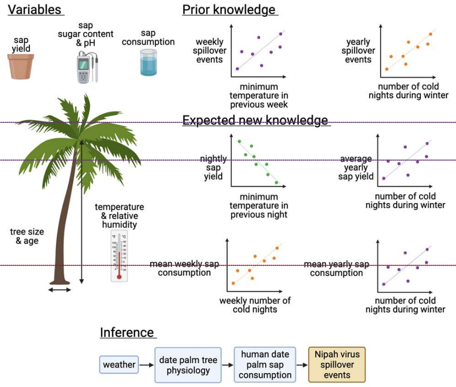


Figure 6. Inferential framework for understanding date palm sap production and consumption.

tree's height, trunk diameter, age, sex, amount of foliage, flowering status, and health status based on appearance will be recorded to explain individual variation in sap flow or quality.

Power calculation: With 20 date palm trees per site followed for two nights over 22 weeks, this sample size (880 observations) will be more than sufficient to detect a small effect size (d = 0.2) for the difference in mean sap yields between years or between sites with a power of 0.8 and a significance level of 0.05.

Commented [spl43]: Again, not clear to me what breakthrough knowledge this would generate.

Household surveys on sap consumption: Households reporting date palm sap consumption during the baseline survey of 200 households at each site in Year 1 as part of Aim 1 will be enrolled into a cohort whose fresh sap consumption behavior will be enumerated throughout winter over Years 2–4. Households will be given a paper log sheet to tally the daily volume of date palm sap consumed by each household member and the price that was paid per volume. Teams will then return to each household monthly to switch out paper logs and to perform a short survey on household sap consumption behavior. The survey will ask household members about the factors influencing their choice to buy sap that month, including sap availability, price, and quality (e.g., sweetness, flavor).

Power calculations: Assuming that 60% of households consume sap in Faridpur and 30% consume sap in Chittagong [7], 120 households in Faridpur and 60 households in Chittagong will be enrolled in the longitudinal assessments of sap consumption behavior. When daily sap consumption records from households at each site are combined over the 22 weeks of winter (mid-November to mid-April, covering the typical sap production period), this will produce sample sizes (15400 observations in Faridpur, 9240 in Chittagong) that are more than sufficient to identify a small effect size (d = 0.2) for the difference between the average number of household members consuming sap in a given year with 0.8 power at a significance level of 0.05.

Commented [spl44]: We anticipate that there will be zero incident human Nipah infections during this observation. Not sure what we will learn here. Are you trying to make the point that these two single sites, one in the high incidence area and one in a low incidence area are representative of high incidence and low incidence areas across all of Bangladesh? If so, then this should be stated explicitly and defended.

Weather patterns: Weather variables that could influence sap production and quality will be measured concurrently with tree physiology measurements. Based on anecdotal reports of their effects on sap yield or quality [22], measured variables will include ambient temperature, relative humidity, solar illuminance, and precipitation (**Figure 6**). All variables from throughout the sap production season will be downloaded from the nearest weather station; cloud cover and solar illuminance will be recorded during daytime prior to tree observations using a handheld light meter.

Inferential models: These data will build on existing knowledge within the system, including increased nightly *Pteropus* fruit bat visits to taller date palm trees and more visits during winter months (Islam et al., in review), more Nipah virus spillover events during cooler weeks [4], more Nipah spillover events in cooler years [5], and anecdotal reports from sap producers that date palm sap is sweeter and flows more freely during cooler weather [8,22,23]. These data on sap production and consumption, along with weather variables, will then be used to develop inferential models to disentangle the interactions between weather and date palm sap consumption patterns, including weekly variation within winter months and inter-annual variation between winters, and then relate these patterns with what has been previously observed in Nipah virus spillover risk in humans (**Figure 6**).

Commented [45]: Need to edit this section

Limitations:

Commented [46]: Add in section for anticipated challenges and their solutions.

Study Team

Commented [47]: This section should include:
- data management/cross-site communication
- project leadership/management
- justification/feasibility/background

Conclusion

Commented [48]: Include statements about the implications of the study and the potential benefits to human health.

MEMORANDUM FOR BRIAN K AGAN, MD , P and R - Uniformed Services University of the Health

Sciences (USUHS) SUBJECT: USUHS IRB (FWA 00001628; DoD Assurance P60001) Approval

Modification of Protocol 409136 (IDCRP-085) for Human Subjects Participation

The modification to your Minimal Risk 32 CFR 219 / 21 CFR 56 human subjects research protocol 409136 (IDCRP-085) (ref # 931762) titled “***Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)”*** was reviewed and approved for execution on October 15, 2020 by Dr. Edmund G. Howe, M.D., J.D., chair USUHS IRB under the provision of 32 CFR 219.110(b)(2). This approval will be reported to the USUHS IRB scheduled to meet on October 22, 2020.

The protocol outlines a systematic approach to collection of clinical specimens and data by adapting standard procedures for conducting clinical characterizations of severe emerging infections as published by the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) network (ISARIC/WHO Clinical Characterization Protocol for Severe Emerging Infections, version 3.1). .

This action approves the modification to update Appendix A of the protocol. This will reflect recent changes approved in the ICD/HIPAA document and set forth in the recent partial HIPAA waiver authorization indicating what information may be obtained from MDR or J6.

Authorization to conduct protocol 409136 (IDCRP-085) will automatically expire on July 25, 2021. If you plan to continue data collection or analysis beyond this date, IRB approval for continuation is required. Please submit a Continuing Review Form via EIRB to the IRB Office 60 days prior to your expiration date.

You are required to submit amendments to this protocol, changes to the informed consent document (if applicable), adverse event reports, and other information pertinent to human research for this project. No changes to this protocol may be implemented prior to IRB approval. If you have questions regarding this IRB action or questions of a more general nature concerning human participation in research, please contact Chris Murphy at christopher.murphy.ctr@usuhs.edu or (301) 319-0444.

Nevo, Lev N/A, M.D.
Rozman, Julia Sofia
Sanchez Edwards, Margaret Anne, MS

The Protocol Contact(s) will receive all important system notifications along with the Principal Investigator. (i.e. The protocol contact(s) are typically either the Protocol Coordinator or the Principal Investigator themselves).

3.4 If applicable, please select the Designated Site Approval(s):

Add the name of the individual authorized to approve and sign off on this protocol from your Site (e.g. the Site Chair).

4.0
Project Information

4.1 Is this a research study?

● Yes ○ No

4.2 What type of research is this?

☑ Biomedical Research

☐ Clinical trial (FDA regulated)
☐ Behavioral Research
☐ Educational Research
☐ Psychosocial Research
☐ Oral History
☐ Other

4.4 Is this human subjects research (Activities that include both a systematic investigation designed to develop or contribute to generalizable knowledge AND involve a living individual about whom an investigator conducting research obtains data through intervention or interaction with the individual or identifiable private information. Activities covered by 32 CFR 219.101(a) (including exempt research involving human subjects) and DoDI 3216.02)?

● Yes ○ No

4.5 Do you believe this human subjects research is exempt from IRB review?

○ Yes ● No

5.0 Personnel Details

5.1 Will you have a Research Monitor for this study?

○ Yes
● No
○ N/A

Research Monitor Role:

If applicable, you may nominate an individual to serve as the Research Monitor:

No Users have been selected.

6.0 Data/Specimens

6.1 Does the study involve the use of existing data or specimens only (no interaction with human subjects)?

○ Yes ● No

7.0 Funding and Disclosures

7.1 Source of Funding:

Funding Source	Funding Type	Amount

NIAID IAA	:Other	56632

Total amount of funding:

56632

7.2 Do you or any other Investigator(s) have a disclosure of a personal interest or financial nature significant with sponsor(s), product(s), instrument(s) and/or company(ies) involved in this study?

○ Yes ● No

8.0 Study Locations

8.1 List any Research Team members without EIRB access that are not previously entered in the protocol:

9.0 Study Details

9.1 Abstract/ Summary:

Summarize the proposed study in 500 words or less, to include the purpose, the subject population, the study's design type, and procedures

The overarching objective of the Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC) protocol is to provide the Military Health System (MHS) with a contingency protocol intended for activation at Military Treatment Facilities (MTFs) during outbreaks to allow clinical investigation of severe or potentially severe acute infections with pathogens of concern to public health and U.S. military medical readiness. The protocol outlines a systematic approach to collection of clinical specimens and data by adapting standard procedures for conducting clinical characterizations of severe emerging infections as published by the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) network (ISARIC/WHO Clinical Characterisation Protocol for Severe Emerging Infections, version 3.1).
The EPICC protocol can be conducted as a multi-site study at participating MTFs, and overall protocol oversight will be coordinated centrally by the Uniformed Services University's Infectious Disease Clinical Research Program (IDCRP). MHS-wide enrollment for online participation will be coordinated by the IDCRP Program Coordinating Center (PCC).
EPICC activities will be executed by clinical study teams comprising existing IDCRP clinical research investigators and staff located at each MTF and protocol investigators from relevant hospital departments. The protocol is designed to be modified to accommodate longitudinal observational study of specific emerging or re-emerging pathogens. Protocol modifications will describe methods for serial collection and clinical characterization of specimens and associated demographic, laboratory, clinical, and other data specific for the pathogen of interest and associated study population(s).

9.2 Key Words:

Provide up to 5 key words that identify the broad topic(s) of your study

Epidemiology, Immunology, Emerging Infectious Diseases

9.3 Background and Significance:

Include a literature review that describes in detail the rationale for conducting the study. Include descriptions of any preliminary studies and findings that led to the development of the protocol. The background section should clearly support the choice of study variables and explain the basis for the research questions and/or study hypotheses. This section establishes the relevance of the study and explains the applicability of its findings

The EPICC protocol is intended to serve as a foundation for modification to allow the observational, longitudinal study of specific emerging or re-emerging pathogens causing disease with pandemic potential within the MHS. Modifications responsive to specific diseases will be described to include a schedule for serial collection of clinical specimens and data and methods for recruiting, enrolling, and observational study within the desired MHS study population(s). In general, enrolled participants (eligible adults or children) who are known or suspected cases at MTFs as inpatients or in isolation settings will undergo serial collections of biological specimens and clinical and laboratory data at day of enrollment and during the duration of hospitalization or isolation, with follow-up specimen and data collection convalescent and long-term follow-up timepoints. The study design can also include clinical observational investigation in outpatients. The major focus of this protocol is to conduct clinical observational study in symptomatic individuals; however, there is also the opportunity to enroll and follow (potentially at a reduced specimen and data collection frequency relative to symptomatic participants) individuals who are asymptomatic but who are at high/some risk for exposure. Inclusion of an asymptomatic comparator cohort could provide insight on risk factors or biomarkers associated with symptomatic versus asymptomatic presentations. The protocol supports observational, longitudinal collection of clinical specimens and data with a goal of identifying host biomarkers that predict severity of illness, resistance to infection, treatment failure, etc. If volunteers receive an experimental treatment product under eIND, the data collected through the EPICC protocol may help inform about the safety and efficacy of that product.

In subsequent sections, relevant background information on acute respiratory infections (ARI) of pandemic potential is provided, followed by specific schedule of events and other details to allow observational study of an ongoing outbreak of the 2019 novel coronavirus (COVID-19).

Acute Respiratory Infections of Pandemic Potential: Epidemiology, Immunology and Clinical Characteristics

ARI Case Definitions

To characterize the epidemiology, immunology and clinical features of novel pathogens associated with severe ARI, case definitions appropriate to emerging infection scenarios will be utilized. These definitions will vary by the availability and result of laboratory-based diagnostic tests.

I. *For laboratory-confirmed cases*, the case definition includes the presence of laboratory-confirmed infection with an agent of severe ARI (e.g., SARS-CoV-2, influenza A/H7N9, MERS-CoV, SARS, etc.).

OR

II. For persons under investigation (PUI), the case definition includes:

1. The current CDC case definition for a PUI for a respiratory pathogen under study.
2. An unknown or pending laboratory confirmation of an agent of severe ARI.

III. For individuals who are asymptomatic and have had recent high-risk exposure to the pathogen of interest such that they have increased their risk for infection, 1 or more of the following criteria must be met:

1. Unprotected exposure (for e.g., < 14 days of illness onset, modified commensurate with evolving epidemiologic information) with confirmed or suspected cases of human infection with a novel respiratory pathogen. Close contact is typically defined as coming within about 6 feet (2 meters) of a confirmed or suspected case while the case was ill (beginning 1 day prior to illness onset and continuing until resolution of illness).
2. Unprotected exposure to infectious pathogens in a laboratory setting.
3. If exigencies warrant, then asymptomatic/high exposure risk individuals in isolation may be considered for enrollment.

Acute respiratory infections (ARI) are among the most common infectious diseases. Due to conditions and circumstances of military training and deployment (e.g., crowding, inadequate hygiene practices, physical stress, etc.), military personnel in congregate settings are at increased risk for outbreaks due to ARI. There are a number of emerging viral respiratory pathogens to which military forces may be exposed, that carry substantial importation risk, and that also have significant pandemic potential. Recent and current examples are described below.

1. Influenza A/H5N1 was first identified in the human population in Hong Kong in 1997. Since 2003, 16 countries have reported 668 confirmed cases and 393 deaths due to influenza A/H5N1 (as of 1 Nov 2014). The global case fatality rate for influenza A/H5N1 infection is 60%, and the estimates range widely (0% to 100%) by country. While the significant morbidity and mortality of influenza A/H5N1 infection is readily apparent, its occurrence among humans has been relatively infrequent to date. Circulation of H5N1 predominates in poultry, currently the main reservoir, in Asia and northeast Africa. Host-to-human (i.e., zoonotic transmission of A/H5N1) infections are unpredictable and “remain rare

despite frequent and widespread contact with infected poultry and contaminated environments" (1). The majority (71%) of cases of influenza A/H5N1 have had recent exposure to live birds or contaminated areas. Cases of influenza A/H5N1 to date have been relatively young (median age: 19 years) (2). Exposure to other cases of influenza A/H5N1 has not been a major risk factor to date, suggesting that the likelihood of human-to-human transmission of this particular strain remains low (R0< 1) (3). The severity of influenza A/H5N1 is dependent upon the strain associated with infection /disease. Among strains with low pathogenicity, generally mild, non-fatal illnesses have been observed, ranging from conjunctivitis to influenza-like illness (e.g., fever, cough, sore throat, muscle aches) to lower respiratory disease (pneumonia). Among strains with high pathogenicity, the disease spectrum has ranged from a milder febrile respiratory illness to severe disease (e.g., dyspnea, hypoxemia, pneumonia, acute respiratory failure) with multi-organ disease, sometimes accompanied by nausea, abdominal pain, diarrhea, vomiting and delirium. The high mortality rate (~60%) associated with pathogenic strains of influenza A/H5N1 has been reported from multiple studies (2).

2. Influenza A/H7N9 infection of humans was first identified in China in March 2013. Since then China has reported 453 confirmed cases and 175 deaths due to influenza A/H7N9 (WHO 2014). As with influenza A/H5N1, most of the cases had recent exposures to live poultry or had visited areas where live poultry was sold (75%) (3). By contrast to influenza A/H5N1, the host reservoir, main exposures, routes of transmission, and distribution and prevalence of influenza A/H7N9 among humans and animals are unknown. Influenza A/H7N9 does not appear to transmit easily from birds or the environment to humans. In addition, reported cases of Influenza A/H7N9 have not demonstrated high transmissibility between humans to date, suggesting that the risk of pandemic potential currently remains low (4). Though limited in its reach, influenza A/H7N9 infection has been associated with significant mortality: approximately 39% of cases resulted in a fatal outcome (4).
3. The coronavirus associated with the Middle Eastern Respiratory Syndrome (MERS-CoV) was first identified in Saudi Arabia in 2012 (5). Several outbreaks have since occurred, originating in Middle Eastern countries and spreading globally, albeit to a limited extent, by international travelers. Symptoms including fever, rigors, malaise, cough, myalgia, headache, shortness of breath, anorexia, diarrhea and abdominal pain were observed in MERS-CoV cases (6,7). As of October 2014, a total of 897 confirmed cases and 325 deaths (case fatality rate [CFR]: 36%) have been reported worldwide (WHO 2014). In 2013, two studies concluded that MERS-CoV did not yet exhibit pandemic potential, with an estimated basic reproduction number less than 1.0 (8, 9). Some research indicates that camels may act as the host reservoir for MERS-CoV, although evidence is inconclusive (10). Human-to-human transmission of MERS-CoV has been observed in healthcare settings, possibly due to greater infectiousness in the later stages of illness; however, evidence that may further elucidate risk factors for transmission is limited (6, 7).
4. The 2002-3 pandemic of Severe Acute Respiratory Syndrome (SARS), also due to a novel Coronavirus, originated in China's Guangdong Province and resulted in 8,422 probable cases and 916 deaths reported from 29 countries (mostly in mainland China, where 63% of cases and 38% of deaths occurred) (11). The global case fatality rate due to SARS was estimated to be 11% (11). Although the host reservoir remains unknown, some studies have found coronaviruses similar to the SARS coronavirus circulating in bat populations (12). Transmission in human populations occurs by direct contact with the infectious respiratory droplets and/or fomites via the eyes, nose, and mouth (13). The incubation period ranges from 1-14 days (mean 4-6 days) and transmissibility appears to increase with severity of illness (greatest at day 10) (14). Attack rates ranged widely by geographic region from 2.2 per 100,000 in Guangdong Province to 25.6 per 100,000 in Hong Kong (14). Risk factors for infection include occupation as a healthcare worker (21% of all probable cases), household contact with a probable case, older age, male sex and existing illnesses (14). Symptoms include fever, dry cough, dyspnea, headache and hypoxemia (14).
5. Since December 2019 through March 2020, the **2019 novel coronavirus (SARS-CoV-2) causing "coronavirus disease 2019" (COVID-19)** has spread from Wuhan, China to 64 countries and has led to more than 88,948 confirmed cases globally, including 80,174 confirmed cases in China and 8,774 confirmed cases outside of China (15). To date, there have been 2,915 deaths in China and 128 deaths outside of China. As of 03 March 2020, in the United States there are 60 confirmed cases (22 travel-related, 11 person-to-person spread, 27 under investigation) and a total of 6 deaths (16). Individuals with COVID-19 can present with fever, and cough, ground-glass opacity on chest computed tomography (CT), and lymphocytopenia (17). The case-fatality rate (CFR) appears to be highly variable with early reports of 8-15% in older adults infected in Hubei Province (CFR is increased in adults with comorbid conditions who develop respiratory symptoms) but likely no higher than 1-2% outside of Hubei (though data is limited and this will depend on accurate detection of those with mild disease) (18). Several risk factors, including age, history of smoking, maximum body temperature on hospital admission, respiratory failure, albumin, and C-reactive protein, appear associated with increased risk for progression to pneumonia among COVID-19 hospitalized patients (19). Risk factors of disease progression and magnitude of clinical severity are incompletely understood and require further study. SARS-CoV-2 is believed to be transmitted primarily via person-to-person, such as through close

contact (within about 6 feet) and exposure to respiratory droplets from an infected individual who coughs or sneezes (20). Evidence exists for transmission of SARS-CoV-2 via the oral-fecal route, as viral nucleotide was detected in rectal swabs and blood later in the course of infection when virus was not detected in oral swabs (21). On the population level, there is a poorly-defined risk of transmission via asymptomatic infection (22). The occurrence of asymptomatic infections has raised concerns about the rapid spread of transmission to vulnerable populations (21).

9.4 Objectives/Specific Aims/Research Questions:

Describe the purpose and objective(s) of the study, specific aims, and/or research questions/hypotheses

General Goals and Objectives:

1. To describe the natural history of clinical disease
2. To identify risk factors for infection and severe clinical course
3. To characterize the host immune response to infection
4. To evaluate the correlation between symptom severity, virologic/microbiologic characteristics, the host immune response and clinical course and outcome
5. To develop and/or operationally assess diagnostic and prognostic tools for the study of novel pathogens / emerging infectious diseases
6. To establish a clinical and laboratory database, and related specimen repository, for future studies of novel pathogens / emerging infectious diseases
7. To investigate efficacy of emergency Investigational New Drug (eIND) therapies that may be administered to enrolled study participants during the course of clinical care

For COVID-19 / SARS-CoV-2 infection, clinical and demographic data will be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest to include, but not limited to, the following:

- Incubation period
- Duration of illness / symptoms
- Duration of functional disability
- Duration of shedding from respiratory and gastrointestinal tract
- Incidence and duration of viremia
- Predictors of severe disease: clinical signs, symptoms, laboratory features; host factors, eg smoking, vaping, alcohol consumption, comorbid illness/conditions, occupational health factors influencing lung disease; host biomarkers; virologic (strain/virulence) attributes
- Supportive management required: O_2, HFNC, NIPPV, ventilation; hemodynamics
- Complications: e.g., bacterial pneumonia; bacteremia; AKI; liver injury; CNS involvement, etc.
- Outcomes: resolution of symptoms; return to pre-illness functional status; requirement for O_2; development / exacerbation of reactive airway disease; pulmonary function; resolution of medical complications; new Rx requirements, eg bronchodilators; other sequelae
- Development of immunity (i.e., correlates), kinetics, duration of antibody detection
- Relationship between acute illness (or pre-illness) HCoV titer and infection, outcome, virologic parameters
- Costs of care, costs of duty days lost

9.5 Study Design:

Describe study design in one to two sentences (e.g., prospective, use of existing records/data /specimens, observational, cross-sectional, interventional, randomized, placebo-controlled, cohort, etc.). Specify the phase – Phase I, II, III, or IV – for FDA-regulated investigational drug research

A prospective, longitudinal cohort study of novel pathogens / emerging infections with pandemic potential

9.6 Target Population:

Describe the population to whom the study findings will be generalized

Study findings will be generalized and applicable to all populations that travel to or reside in disease endemic areas or live within an area that has been exposed to infectious pathogens with pandemic potential; some of which include military personnel and the general public.

9.7 Benefit to the DoD:

State how this study will impact or be of benefit to the Department of Defense

Infectious diseases are a significant source of morbidity among military forces. Infectious disease outbreaks compromise force readiness and interfere with training programs. Strategies to characterize and ultimately to treat and prevent the major infectious disease threats to military personnel are urgently needed.

10.0

Study Procedures and Data management

10.1 Study Procedures:

Describe step-by-step how the study will be conducted from beginning to end

Recruitment and enrollment strategies will be dynamically responsive to the outbreak as the situation evolves. Study volunteers may be recruited from areas of the hospital where they present for care or in the inpatient and isolation settings. Informed consents and enrollments will be conducted by study staff included on the IRB approved protocol, including staff named on delegation log, and trained in study procedures. Clinical evaluations will be performed by the MTF healthcare team and may also be conducted by qualified study team members.
In addition to MTF enrollment, MHS beneficiaries who have been clinically tested for COVID-19 will be invited to participate in a limited schedule of assessments for EPICC, including completion of a series of online questionnaires and at-home capillary blood sample collection at three timepoints. See Appendix A for further details.
At the time of a participant’s initial consultation at an MTF, study activities will consist of explanation of study goals and purpose, and obtaining informed consent (may include consultation with Legally Authorized Representative). The day of enrollment will be defined as Study Day 0. The team will subsequently conduct serial collection of data (demographics, vital signs, clinical findings, diagnostics and other laboratory results, etc.) through study participant interview and from medical record review from time of disease onset throughout study duration. Specific risk factors linked to pathogen exposure (eg., travel history to disease endemic regions, contact with sick individuals or known reservoirs of disease, etc.) will also be acquired from study volunteers, mainly through interview at Day 0. Medical records collected prior to day of enrollment will also be evaluated to ascertain medical history information pertinent to understanding baseline health and analysis of underlying risk factors associated with disease progression and other outcomes. Study team members will collect for research purposes biological specimens (e.g., nasopharyngeal and oropharyngeal swabs, rectal swabs, and blood) from enrolled participants who are laboratory-confirmed or suspected cases at time of enrollment, during the duration of hospitalization and/or isolation, with follow-up specimen collection up to approximately 1 year post-enrollment.

When possible, the study team will also obtain residual volumes of specimens collected for clinical care that would otherwise be discarded. Sample types include but are not limited to bronchoalveolar lavage, blood, urine, sputum, saliva, stool, cerebrospinal fluid, semen (adults only), or vomit.As available, these residual samples will be obtained from the time of onset of the disease under study. For active duty servicemembers, the study team will also request a pre-illness (up to 2 years prior to enrollment) serum sample from the DoD Serum Repository (DoDSR).

Some subjects may undergo clinical imaging studies as part of regular patient care or as part of this protocol using clinical imaging devices. For example, point-of-care portable ultrasound may be used to image areas such as the lungs, heart, and lower extremity veins, to explore the prognostic use of ultrasound in early detection of pneumonia and cardiovascular sequelae associated with severe disease. These imaging studies, when available, will be part of the collected subject data.

Study participants recruited and enrolled at MTFs who are ambulatory may also be evaluated via serial self-collection of samples such as nasopharyngeal swabs, oropharyngeal swabs, capillary blood samples, and/or other specimens appropriate for self-collection.

Recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital as well as healthcare providers who have potentially been exposed to known or suspected cases. Enrollees who are asymptomatic high/some risk will undergo serial collections of clinical and laboratory data as well as biological specimens (e.g., nasopharyngeal, oropharyngeal, and rectal swabs and blood) at enrollment, with follow-up specimen collection up to approximately 12 months post-enrollment. The study team may consider implementing a plan for asymptomatic study volunteers to conduct self-collection of clinical specimens (e.g. nasopharyngeal swabs, oropharyngeal swabs, rectal swabs, capillary blood smaples) through the follow-up period. Demographic, clinical, and other data as described above for symptomatic volunteers may also be acquired for asymptomatic high/some risk participants.

The Flu- PRO questionnaire (24-27) may be used to record the patient-reported outcome (PRO) on severity of clinical symptoms and the impact of clinical interventions on infection. A web link to the Flu-PRO questionnaire may be provided to participants to record the severity of ILI symptoms daily for 14 days from either the day of enrollment, or the date of onset of symptoms (for subjects who were asymptomatic at enrollment). Paper versions of the Flu-PRO questionnaire may be administered as needed.

In addition, an online questionnaire will be administered at enrollment and follow-up timepoints to collect data on medical history, comorbidities, behavioral risk factors, symptoms and recovery status.

If a participant is dually enrolled in a treatment protocol and scheduled to receive investigational products under an eIND, an additional sample may be collected in the first 48 hours after test article administration. If eligible, study participants may also be considered for enrollment concurrently in an interventional clinical trial evaluating efficacy of treatment regimens. The priority of collection of clinical specimens will be as follows: 1. specimens collected for clinical care; 2. specimens collected in support of an interventional clinical trial; and 3. specimens collected for observational study (i.e., EPICC protocol).

The study team may consider discontinuation of study participants who have a negative test result for the pathogen of interest (based on current standard of care diagnostics) and/or are diagnosed with another respiratory pathogen other than the one of interest and/or the disease of interest is highly unlikely based on the primary clinical team assessment. This approach may need to be taken to conserve study staff time and resources depending upon local epidemiologic circumstances, e.g. very high incidence and subject accrual.

Results obtained from research analyses will not be entered into the participant’s medical record. However, the study team will communicate relevant findings to the participant’s primary care provider overseeing care of the indicated infection of study. The study volunteer’s primary healthcare provider is likely to be a member of the protocol study team, and as such will be directly aware of study findings. If the primary healthcare provider is not a part of the protocol team, relevant findings from the study will be communicated to the healthcare provider verbally in a private setting to protect patient confidentiality or via a secure encrypted electronic communication.

Pregnant participants will be followed monthly until delivery to collect information on pregnancy outcome and health of the child with regards to the disease under study, to the extent practicable. A cord blood sample may be collected for research purposes following childbirth.

Specimens collected through this observational study will be evaluated in various laboratory assays to characterize the epidemiology, immunology, clinical characteristics, and other important outcomes of interest. Associated clinical and demographic data will also be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest as described in Section 9.4.

Schedule of Patient Evaluation and Data Collection

The table below shows the schedule of assessments for study participants enrolled in EPICC. Given the possibility of critical illness of the patient and the potential increased risk of exposure to medical personnel, assessments that cannot be completed due to patient care considertaions, indection control measures, or other logistical challenges will not constitute protocol deviations. In addition, the frequency of specimen and data collection may be reduced to accommodate logistics of acquiring specimens and data among study volunteers who are outpatients.
Ambulatory subjects who do not have restrictions of movement for infection control purposes (i.e., not advised by their care provider/local health authority to remain home in isolation) will be invited to return to the hospital for follow-up assessment and collection of specimens.

If an asymptomatic and/or COVID-19-negative subject develops symptoms or receives a positive test result for COVID-19, they will be asked to contact study staff to report their symptoms/test result and will restart the schedule of assessments from Day 0.

Inpatient MTF-Enrolled Subjects

Specimen/ Assessment	Enrollment (Day 0)	Days 3, 7 (± 1 day)	Once Weekly until discharge (± 2 days)	Day 14 if Discharged (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Montl (± 28 day
Virology Sample: Nasal, Throat, and/or Oral specimen*	√	√	√	√			
Virology Sample: Rectal Swab	√	√	√		√		
Blood	√	√	√	√¶	√¶	√¶	√¶
Residual Clinical Samples #	√	√	√	√	√	√	√
Radiologic images **	√	√					
Flu-PRO Symptom Diary ***	√	√	√	√			
Online Questionnaire	√				√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.

¶ Blood collection after discharge may be done using a commercial at-home microsampling blood collection kit.

Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.

** Lung, cardiac, and/or venous ultrasound may be conducted on hospitalized subjects on days 0, 1, and 3 as resources and local patient care policy allows. Findings from any additional radiologic images obtained during routine clinical care will be collected for research.

*** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.

Outpatient MTF-Enrolled Subjects

Specimen/ Data	Enrollment (Day 0)	Day 7 (± 1 day)	Day 14 (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Virology Sample: Nasal, Throat, and/or Oral specimen*	√‡		√			
Blood¶	√‡	√	√	√	√	√
Flu-PRO Symptom Diary **	√	√	√			
Online Questionnaire	√			√	√	√
Residual clinical samples #	√	√	√	√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.

¶ Blood collection may be done using a commercial at-home microsampling blood collection kit.

Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.

** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.

‡ There is a +3 day window for Day 0 research sample collection to allow for distribution of self-collection kits to participants whose samples could not be collected at enrollment.

Online Cohort: See Appendix A

Specimen/ Data		Day 28		

	Enrollment (Day 0)	(± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Online Questionnaire	√	√	√	√
Self-collected blood¶		√	√	√

¶ All blood collection for this cohort will be done using a commercial at-home microsampling blood collection kit.

Considerations for Pediatric Participants

- Flu-PRO symptom diary may be completed by subjects aged **7 and older**.
- Pediatric subjects will not be asked to complete the online questionnaires.
- Self-collection of specimens is an option for subjects aged **8 and older**.
- Blood collection volume and frequency may be reduced to comply with safety limits. For these subjects, the amount drawn may not exceed the lesser of 50 ml or 3 ml per kg in an 8 week period and collection may not occur more frequently than 2 times per week.

Research Laboratory Methods

Clinical specimens collected through this observational study will be evaluated in a variety of laboratory assays developed by laboratory partners. Specific laboratory assays to study the virologic, immunologic, and other relevant aspects of infections are unlikely to be available at the time of specimen collection (i.e., during the outbreak) given the time required to establish assays specific for novel, emerging pathogens. Below is a general description of laboratory assay methods and endpoints that may be used; however, this does not represent an exhaustive list to include new methodologies that are later developed in response to assaying novel pathogens.

To characterize virologic correlates (e.g., viremia) of clinical symptoms and disease severity, serum levels of viral genomes can be assessed by real time-PCR at various time points. Serum concentration of viral antigen can be evaluated by enzyme-linked immunosorbent assay (ELISA). These same assays may be utilized in the longitudinal detection of virus in body fluids (e.g., nasal mucosa, sputum, urine, stool, etc.) throughout the course of evaluation/illness.

In addition, serum may be assayed for concentrations of virus-specific IgM and IgG in the acute and convalescent stages of evaluation/illness. Cytokine profiles can be conducted via multiplex assay to describe the pro- versus anti-inflammatory cytokine responses of study volunteers throughout the course of illness. PBMCs may be collected to investigate cell-mediated immune responses in the acute and convalescent phases of illness.

Novel biomarkers, including transcriptomic and proteomic signatures, are promising for diagnosis and prognosis. Collection of appropriate specimens from individuals with well-characterized illnesses is required to inform assay development. Immune factors have been used as biomarkers for predicting clinical course and outcome, as well as the severity of clinical symptoms. For example, higher levels of cytokines IL2, IL7, IL10, GCSF, IP10, MCP1, MIP1A, and TNFα were observed in patients with SARS-CoV-2 infection requiring ICU-level care compared to those receiving non-ICU care (21). Host specific responses may be evaluated using real-time PCR and other molecular methods to identify biomarkers, transcriptomic signatures, or other lab-based endpoints indicative of severity of clinical course of disease progression and other risk factors associated with clinical outcomes, etc. In addition, evaluation of host transcriptomic responses among symptomatic versus asymptomatic, high risk exposure individuals may identify an early warning means for identifying asymptomatic people who eventually develop disease. RNA sequencing of blood specimens may also be conducted to assess viral transcription signatures as biomarkers for clinical outcomes. Blood specimens may also be used in phosphoproteomic assessments by measuring the proportion of host immune system proteins that are phosphorylated to evaluate novel biomarkers associated with activation of protein signaling pathways in response to infection.

10.2 Data Collection:

Describe all the data variables, information to be collected, the source of the data, how the data will be operationally measured, and approvals needed for use of information from DoD databases

Diagnostic Tests and Laboratory Analysis to be Obtained:

As available, laboratory data elements, such as but not limited to hematologic, biochemical, and other clinical parameters; clinical images and associated reports; and clinical diagnosis of the pathogen of interest (SARS-CoV-2) and

/or alternate or co-infective pathogens, will be abstracted from the medical record of study volunteers on the day of enrollment (Study Day 0), throughout the period of hospitalization (inpatients) and through duration of follow-up. In addition, laboratory and diagnostic data available in medical records prior to Day 0 will be abstracted for study of baseline health, existing co-morbidities, etc.

Data Elements

Case report forms (CRFs) for this protocol have been adapted from those of the International Severe Acute Respiratory Infection Consortium (ISARIC).

There are five main components of the data collection forms, encompassing study participant information at:

1. The time of enrollment (at time of presentation at MTF, hospital admission, or being placed in isolation),
2. Period prior to Day 0, as appropriate, to assess recent medical history,
3. Medical encounter data (inpatient or outpatient),
4. The time of discharge or death
5. Follow-up period (following hospital discharge or being released from isolation setting, or otherwise as an out-patient)

Major data variable categories to be collected include, but are not limited to the following:

- Day of enrollment
    - Demographics (Residence, Occupation, Military Status)
    - Signs and Symptoms at onset of illness and presentation for care
    - Epidemiological Risk Factors and Exposures
    - Pre-admission Medications
    - Review of recent medical history via medical record review
    - Flu-PRO symptom severity questionnaire
- Hospitalization or Isolation Period
    - Daily Observations (i.e., vital signs) and Treatments (i.e., receipt of IV fluids)
    - Daily Laboratory Results
    - Medications and Blood Products
    - Microbiology Results
    - Critical Care
    - Severe Symptoms and Complications
    - Flu-PRO symptom severity questionnaire
- Outcome
    - Final Diagnosis
    - Patient Status at Outcome
    - Follow-up period

Data Collection

Study data will be copied onto electronic CRFs at the study site. These transcriptions will occur on an ongoing basis during the study in accordance with Good Clinical Practice (GCP) guidelines. Data entered on CRFs, as well as corrections made, shall be performed by authorized individuals. This study will make use of electronic case report forms (eCRFs) using tablets with the Research Electronic Data Capture (REDCap). For cases where a tablet cannot be used because of infection control concerns or logistical issues, authorized personnel will capture CRF information using a paper based version and later electronically record results into REDCap. All data transmitted to and from the application is done using a secure, encrypted transmission (SSL/HTTPS). For increased security, the application additionally verifies the SSL certificate of the REDCap server that it is communicating with in order to validate the server’s identity. The REDCap mobile application employs encryption-at-rest on the mobile device’s hard drive, so all data and information stored on the device is protected from unauthorized users. REDCap has built-in safeguards such as username and PIN, and remote lockout. When resources are available, data from clinical devices including de-identified ultrasound or radiograph images, continuous vital signs, and/or cardiac telemetry will be locally stored on password-protected devices, and if possible, transmitted wirelessly to a secure Cloud backup. Henry Jackson Foundation (HJF) headquarters IT will host deidentified study data on HJF HQ secured servers. HJF is responsible for the purchase, setup, maintenance, and service of any its servers and technology.

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as questionnaires may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

Data Management/Quality Control

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, documentation of informed consent and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves or authorized study personnel. Only designated study personnel shall record or change data on a CRF. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. PHI will be removed from clinical devices, such as those used for radiology, and associated data will be labeled with the study participant's ID. For each pivotal analysis (e.g., for a sub-study, manuscript, or presentation), the 'snapshot' (or 'data freeze') database will be made and archived in the study data repository. After the study analysis ends, the database will be locked.

10.3 At any point in the study, will you request, use, or access PII from the Military Health System (MHS)?

● Yes ○ No

10.4 Have you consulted with an MHS data expert to determine the data elements to be extracted or the information system(s) to access?

Consulting with a data expert often saves time later in the compliance process because the data expert can advise on the data available in the numerous MHS information systems, the quality of that data and the methods for encrypting and collapsing data. To schedule a consult with an MHS data expert, send an email to: (**dha.ncr.pcl.mbx.privacyboard@mail.mil**)

● Yes, then complete the questions below according to the data consult

○ No, then complete the questions below according to the best of your knowledge (NOTE: It is highly recommended that you work with an MHS data expert)

10.5 Indicate whether you plan to receive a data extract from the MHS or plan to access an information system directly to create a data set:

A data extract is when the MHS or a contractor provides the data set directly to the researcher. When receiving a data set through data extract, the researcher may indicate whether the data elements should be provided as is, encrypted or collapsed. In contrast to a data extract, access to an information system means that the researcher may directly access an MHS information system and create a data set for the research study

☐ Data Extract

☑ Access

10.6 Do you intend to use only de-identified data from the MHS in your research study?

There are different two methods for de-identifying data pursuant to HIPAA:
1) Safe Harbor Method: Removing all of the identifiers listed in Table 1 below, provided that the researcher does not have actual knowledge that the remaining data can be used alone or in combination with other information to identify the individual who is the subject of the information
2) Statistical Method: An expert, with appropriate knowledge of and experience with generally accepted statistical and scientific principles and methods for rendering information not individually identifiable, determines that the data is not individually identifiable

○ Yes ● No

10.7 If your research study requires access to an MHS information system, please indicate the system to obtain data:

If you do not know which system(s) contain the data elements you need, refer to the Guide for DoD Researchers on Using MHS Data or seek guidance from an MHS data expert:

PHI Systems:

MHS Information System	Requesting Data

: AHLTA	: Yes
: CHCS	: Yes
: ESSENTRIS	: Yes
: MDR	: Yes

PII-Only Systems:

MHS Information System	Requesting Data
No records have been added	

De-Identified Data & Other Systems:

Information System	Requesting Data
Expense Assignment System	
MHS Genesis; JLV (accessed via AHLTA or MHS Genesis)	: Yes
DMSS, DRSi	: Yes

10.8 Do you intend to merge or otherwise associate the requested data with data from any sources outside of the MHS, including other DoD systems that are not part of the MHS?

● Yes, will merge data
○ No, will not merge data

10.9 Indicate the categories of data that you will request from MHS systems or MHS health care providers about research participants or relatives, employers, or household members of the research participants.

Data Element(s)	MHS	Non-MHS Systems
1. Names	☑	☐
2. Postal address with only town, city, state and zip code	☑	☐
3. Postal address with all geographic subdivisions smaller than a state, including street address, city, county, precinct, zip code and their equivalent geocodes, except for the initial three digits of a zip code if, according to the current publicly available data from the Bureau of Census: 1) the geographic unit formed by combining all zip codes with the same three initial digits contains more than 20,000 people; and 2) the initial three digits of a zip code for all such geographic units containing	☑	☐

20,000 or fewer people is changed to 000		
4. Dates including all elements (except year) directly related to an individual, including birth date, admission date, discharge date, and date of death	☑	☐
5. Ages over 89 and all elements of dates (including year) indicative of such age, unless you will only request a single category of “age 90 or older”	☑	☐
6. Telephone numbers	☑	☐
7. Fax numbers	☑	☐
8. Electronic mail addresses	☑	☐
9. Social Security numbers (SSNs)	☑	☐
10. Medical record numbers	☑	☐
11. Health plan beneficiary numbers	☑	☐
12. Account numbers	☐	☐
13. Certificate/license numbers	☐	☐
14. Vehicle identifiers and serial numbers, including license plate numbers	☐	☐
15. Device identifiers and serial numbers	☐	☐
16. Web Universal Resource Locators (URLs)	☐	☐
17. Internet Protocol (IP) address numbers	☐	☐
18. Biometric identifiers, including finger and voice prints	☐	☐
19. Full-face photographic images and any comparable images	☐	☐

20. Any other unique identifying number, characteristic, or code (DEERs ID, EDIPN, Rank)	☑	☐

If you are obtaining SSNs, provide a justification as to why and explain why a substitute cannot be used

We request to access potential subjects' medical records in order to evaluate them for recruitment for this protocol. PHI to be screened include (name, date of birth, social security number and health beneficiary numbers). These risks are no more than minimal because they are not greater than those ordinarily encountered by the patient during a medical visit.

Study investigators and personnel will review potential subjects' medical history to assess protocol eligibility. If the person consents to participate in the research study, the PHI will be stored in accordance with the protocol.

10.10 Is it possible that the data will become identifiable because of triangulation, a small cell size, or any unique data element(s)?

Triangulation means using different data elements that are not themselves identifiable but that when combined can be used to identify an individual. For example, triangulation would be using rank and race together to determine the identity of an individual with a particular health condition
Small cell size means that there are only a small number of eligible individuals that satisfy the category description. Guidance for acceptable cell size is available from the Centers for Medicare and Medicaid Services. For example, the rank category of four star generals with a particular diagnosis may be less than 30 so the rank category may need to be expanded to include lower ranks
A unique data element includes any unique features that are not explicitly enumerated in the categories of data in rows 1 – 19 of Table 1 above, but that could be used to identify an individual. Examples of unique data elements include: 1) a unique number, such as a medical record number or EDIPN; 2) a unique code, such as a diagnosis code or a bar code on an electronic health record; and 3) any unique characteristic, such as the rank of general or admiral, or a race or gender combined with another unique characteristic

● Yes, there is a reasonable possibility the data will become identifiable
○ No, there is no reasonable possibility the data will become identifiable

10.11 HIPAA Privacy Rule and Use of Protected Health Information in Research:

○ N/A – will not use or disclose protected health information (PHI)
○ HIPAA Authorization will be obtained
○ Use of a limited data set where a data use agreement will be obtained
● Waiver/alteration of HIPAA Authorization is being requested

10.12 Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for this Study:

Include in this section the plan for acquiring data (both electronic and hard copy), access during the study, data/specimen storage and length of time stored, shipment/transmission, and the plan for storage and final disposition at the conclusion of the study. Describe any data agreements in place for accessing data within and/or outside of your institution (e.g., Data Sharing Agreement, Data Use Agreement, Business Agreements, etc.)

Human Biological Specimens

1. Intended Use of the Samples/Specimens/Data

Specimens will be processed and handled as appropriate following applicable MTF enhanced precaution and Infection Control SOPs. Methods for specimen collection, handling, and processing are described in their respective SOPs. Details of specimen storage, maintenance, and QA/QC are described in their respective SOPs.

Samples and data collected under this protocol will be analyzed to study the pathogenesis of disease and the host immune response to infection. Genetic testing on human specimens
will be conducted to evaluate the host (subject's) immune response to SARS-CoV-2 infection and its association with clinical outcomes. Additional genetic testing will examine viral genetic markers and transcription signatures as predictors of infection severity, clinical course, and outcomes. Genetic testing results will not be provided to participants.

This is a purely observational study. Any experimental treatments will be done under other protocols for which separate IRB review and approval will be obtained.

2. How Samples/Specimens/Data Will Be Stored

Access to research samples will be limited using locked facilities and monitored freezers. Samples and data will be stored using codes assigned by the investigators or their designee(s). Data will be kept in password-protected computers. Only investigators or their designee(s) will have access to the samples and data.

3. How Samples/Specimens/Data Will Be Stored & Tracked

Samples from individuals found infected with a novel pathogen / emerging infectious disease of interest will be archived and stored at an appropriate biosafety level facility.

Samples acquired as part of the protocol will be tracked using appropriate software, such as Freezer Works, a sample tracking, biorepository management and freezer inventory program.

4. What Will Happen to the Samples/Specimens/Data at the Completion of the Protocol?

In the future, other investigators may wish to study these samples and/or data. IRB approval will be sought prior to any sharing of samples/data. Any clinical information associated with the sample, with or without patient identifiers, will be shared after IRB approval has been obtained.Upon study closure, all samples and data will be de-identified in accordance with the DHA-approved Data De-Identification Plan.

5. What Circumstances Would Prompt the PI to Report to the IRB Loss or Destruction of Samples/Specimens/Data

Any loss or unanticipated destruction of samples (for example, due to freezer malfunction) or data (for example, misplacing a printout of data with identifiers) that compromises the scientific integrity of the study will be reported to the IRB.

6. Storage and Tracking of Samples/Specimens/Data

Research use of data collected through this protocol will be coded and will not contain identifiers. These data will be coded with access maintained by a custodian not affiliated with the study team per IDCRP policy. Much of the subsequent research using the coded materials collected under the auspices of this study will be accomplishable through approved exempt or non-human use sub-studies. All research using the materials collected under this protocol will be conducted in accordance with an IRB-reviewed protocol. Data and specimens released for research use will be labeled by PIN only; data will be shared without any identifiers or links to individuals. The DCC custodian, the DCC Chief, will not share identifying information with investigators without explicit IRB approval.

A Defense Health Agency (DHA) Data Sharing Agreement will be implemented as needed to access MHS data. Appropriate data sharing agreements and other legal agreements will be implemented prior to sharing of data and specimens with collaborators.

10.13 Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for Future Research:

If the study involves collecting, storing, or banking human specimens, data, or documents (either by the Investigator or through an established repository) for FUTURE research, address. How the specimens /data will be used, where and how data/specimens will be stored (including shipping procedures, storage plan, etc.), whether and how consent will be obtained, procedures that will fulfill subjects' request as stated in the consent, whether subjects may withdraw their data/specimens from storage, whether and how subjects may be recontacted for future research and given the option to decline, whether there will be genetic testing on the specimens, who will have access to the data/specimens, and the linkage, the length of time that data/specimens will be stored and conditions under which data/specimens will be destroyed

Establishment of a specimen repository for future clinical and laboratory investigation for future emerging infectious disease research:

The study aims to build a repository of biological specimens (e.g. whole blood, serum, and PBMCs, as well as nasopharyngeal fluid, sputum, bronchioalveolar lavage fluid, oropharyngeal fluid, saliva, urine, semen, and rectal swab specimens, etc.) from an observational, longitudinal study of emerging infectious diseases. Specimens may be stored in an appropriate biosafety level facility at a protocol-approved biorepository. These specimen repositories will be linked to an extensive de-identified clinical database.

In the future, this repository might be used in the identification and validation of biomarkers for severe infection, identification and molecular characterization of novel pathogens, development and evaluation of new diagnostic platforms, and/or evaluation of host factors that may be associated with susceptibility and outcome. Coupled with detailed clinical history and risk factor information gleaned through electronic medical record review, this repository will ultimately be an invaluable resource for future investigations of emerging infectious diseases in clinical as well as laboratory settings. Moreover, the infrastructure developed through these activities will serve as a broad-based platform for a diverse portfolio of relevant sub-studies into emerging infectious diseases and strategies for its control and prevention.

Study Time Line

This natural history core protocol will be open indefinitely, although sites may close once an epidemic has passed.

11.0
Statistical/Data Analysis Plan

11.1 Statistical Considerations:

List the statistical methods to be used to address the primary and secondary objectives, specific aims, and/or research hypotheses. Explain how missing data and outliers will be handled in the analysis. The analysis plan should be consistent with the study objectives. Include any sub-group analyses (e.g., gender or age group). Specify statistical methods and variables for each analysis. Describe how confounding variables will be controlled in the data analysis

Statistical Considerations

This is an enhanced surveillance protocol using clinical observations and laboratory testing, supplemented by additional lab testing for research purposes. The frequency and expansion of such outbreaks is unknown, and hence this protocol will be activated on contingencies in many cases. Data from a given outbreak will be compiled into a dataset for descriptive analyses. Risk factors will be identified retrospectively using odds ratios. Comparison between similar outbreaks may be performed if sufficient data allows. It is recognized that a proportion (i.e., not all) of eligible subjects will consent to participate in this study. As such, the limitations and generalizability of the study findings will be acknowledged in associated reports and manuscripts.

11.2 Sample Size Estimation:

As determined by exigencies of the outbreak, and resource availability. Please see Appendix A for sample size considerations for the online cohort.

11.3 Data Analysis Plan:

Data Analysis Plan

Student’s t test (or Wilcoxon rank-sum test if appropriate) on continuous variables and Pearson’s chi-square tests (or Fisher’s exact test if appropriate) for categorical variable to summarize key outcomes of interest. Multivariate regression techniques will be used to assess relationships between key variables adjusted for potential confounders.

A data analysis plan will be created to meet the following reporting requirements:

- During an outbreak, descriptive clinical and laboratory data will be summarized per patient on a regular basis as appropriate for all investigators, involved hospitals, the respective service's public health agencies, AFHSB, and DHA leadership as a part of the epidemiologic reporting requirements. It is recognized this data may not be fully cleaned. Aggregate data report will be prepared monthly.
- At conclusion of an outbreak, a summary report per outbreak will be prepared once all data is cleaned. This will take an estimated 90 days.

With respect to the analysis of the study data, the following objectives will be addressed, and more fully articulated, in a statistical analysis plan:

1) Describe natural history of clinical disease.

Data items related to disease duration include duration of fever and other predominant symptoms, and days from onset of symptoms until hospital discharge/return to normal activity. Each variable will be summarized by mean, standard deviation, median, inter-quartile range, minimum and maximum overall and also for each group within several groupings: age categories, adult vs. minor, gender, different race groups, index cases vs. secondary cases, military rank and/or nature of duties for those with active duty military duty status. We will also use symptom severity data from the Flu-PRO questionnaire to explore the extent to which ARI symptom severity scores differs across the cohort.

Adverse binary outcomes where the time to event may also be of interest: These include requirement for ICU admission, development of any super infection, development of oxygen requirement, mortality, etc. For each of these, we will first give a simple summary of the number and percent experiencing each outcome. We will also summarize by different subgroups as above.

2) Identify risk factors for infection and severe clinical course.

One set of analyses will treat laboratory-confirmed diagnosis as the outcome in logistic regression models, with the following covariates: age, sex, race, military rank, service branch, type of exposure, use of personal protective equipment, etc. Similar logistic regression models will be developed to determine predictors of severe clinical course, such as mortality.

Another set of analyses will treat illness duration as a quantitative endpoint to be used as the outcome variable in multiple linear regressions. The key endpoint will be the total symptom score considered at three different time points: at symptom onset, at 48 hours post symptom onset, and at its maximum value whenever that occurs. Other potential confounders to be included as covariates are: age, sex, race, and number of days since presumed exposure.
Complementary methods of subject recruitment and data collection within the study will address the following specific aims:

1. Among COVID-19 confirmed cases, compare risk factors (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for:
    1. Those who get hospitalized vs. those who do not get hospitalized
    2. Those who get hospitalized with a ventilator vs. those who do not get hospitalized and those hospitalized but not placed on a ventilator
    3. Those who get hospitalized in the ICU vs. those who do not get hospitalized and those hospitalized but not in the ICU
    4. Those who go on to die vs. those who do not die

1. Compare risk factors (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for infection among the total COVID-19 tested study population of COVID-19 confirmed cases (test positive) vs. confirmed non-cases (test negative).
2. Compare symptoms between various groups:
    1. Among the total COVID_19 tested study population, COVID-19 confirmed cases vs. confirmed non-cases
    2. Among COVID-19 confirmed cases for those:
        1. who get hospitalized vs. those who do not get hospitalized
        2. who get hospitalized in the ICU vs. those who are hospitalized, but not in the ICU
        3. who go on to die vs. those who do not die
3. Among the COVID-19-confirmed cases and an appropriate and hypothesis-specific randomly selected comparison group, using medical record data, identify comorbidities and medications that are associated with reduced occurrence of COVID-19 symptoms as well as with becoming infected with COVID-19.

The proposed analytic strategy will be to report crude (non-adjusted), age and sex-adjusted, and multivariable adjusted probability of hospitalization in those with and without the exposures of interest.

1. Calculate crude (non-adjusted) likelihood of hospitalization in demographic sub-populations of interest (e.g. by age strata, sex, and race/ethnicity)

2. Determine the age-specific prevalence of the major comorbidities (obesity, hypertension, asthma) separately by sex and race/ethnicity
3. The primary model will be logistic regression, calculating adjusted predicted prevalence of hospitalization for those with each comorbidity alone and comorbidity clusters (since comorbidities are correlated)
    1. A priori, evaluate whether risk associated with each comorbidity is similar for men and women and for African Americans vs others (interaction by sex; interaction by race).

Conduct separate models for the active duty population and the beneficiary populations

3) Characterize host immune response.

We will examine the relationship between factors, such as the immune response (e.g., serum antibody concentration) and pathogen infection kinetics, and disease progression, symptom severity, and clinical outcomes of interest. We will look at both cross-sectional relationships (i.e., among people) and within person relationships. For cross-sectional relationships, we will start by plotting the total symptom severity score against the immune response, separately for each of the four blood samples. We anticipate a monotonic relationship, but it is possible for a U-shaped relationship in some cases, i.e., illness severity is greater if there is a too small immune response or a too large one. We will develop regression models with the outcome of the symptom severity or clinical course on the chosen function of immune response to see if there is a statistically significant relationship. We will add covariates to control for possible confounders, such as age, race, sex, military status, etc. and others mentioned above.

4) Evaluate correlations between symptom severity, virologic/microbiologic characteristics, host immune response and clinical course/outcome.

We will consider two groups: subjects with versus without a severe clinical course, such as mortality. We will compare the proportions with a significant serum antibody 'response' between the two groups by contingency table chi-square tests. We anticipate that the categorization of immune response will be binary (i.e., proportion of individuals exceeding a given concentration of serum antibody), in which case we will be comparing a binomial probability between the two groups. These analyses will form the backbone for more elaborate multivariate analyses.

5) Develop diagnostic and prognostic tools.

Data and specimens from this protocol may be used in the development of diagnostic and prognostic assays for novel pathogens. For example, the collection of blood and other body fluids from individuals with laboratory-confirmed infection may aid in the development of novel assays with higher sensitivity and specificity. Additionally, the collection of longitudinal clinical characteristics in addition to clinical laboratory data may aid in the development of prediction models to determine risk factors for severe clinical course, such as mortality.

12.0 Participant Information

12.1 Subject Population:

As this is an observational study, subjects of all ages will be enrolled. Military Treatment Facilities see a diverse population including all genders and races, and a wide range of ages. This study will examine the epidemiology of novel pathogens / emerging infectious diseases, seek to identify risk factors for severe disease and elucidate mechanisms of host immunity to these pathogens.

Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study also allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Males and females of all ages who are symptomatic or asymptomatic individuals (at high/some risk of exposure) meeting inclusion criteria are eligible for participation.

Participation in the online-only study group is limited to adults only.

12.2 Age Range:

☑ 0-17
☑ 18-24

☑ 25-34
☑ 35-44
☑ 45-54
☑ 55-64
☑ 65-74
☑ 75+

12.3 Gender:

☑ Male
☑ Female

12.4 Special categories:

☑ Minors /Children - “You must also consider the requirements of 45 CFR 46 Subpart D and DoDI 3216.02, Enclosure 3, paragraph 7.d.”
☐ Students
☐ Employees - Civilian - “You must also consider the requirements of DoDI 3216.02, paragraph 7.e.”
☐ Employees - Contractor
☐ Resident/trainee
☐ Cadets /Midshipmen - “You must also consider the requirements of DoDI 3216.02, Enclosure 3, paragraphs 7.e. and 12.”
☑ Active Duty Military Personnel - “You must also consider the requirements of DoDI 3216.02, Enclosure 3, paragraph 7.e.”
☐ Wounded Warriors - “Depending on your intended subjects’ status, you may also need to consider the requirements of DoDI 3216.02, Enclosure 3, paragraph 7.e.”
☐ Economically Disadvantaged Persons - “You must also consider the requirements of 32 CFR 219.111 (b).”
☐ Educationally Disadvantaged Persons - “You must also consider the requirements of 32 CFR 219.111 (b).”
☐ Physically Challenged (Physical challenges include visual and/or auditory impairment)
☑ Persons with Impaired Decisional Capacity - “You must also consider the requirements of 10 USC 980.”
☐ Prisoners - “You must also consider the requirements of 45 CFR 46 Subpart C and DoDI 3216.02, Enclosure 3, paragraphs 7.b. and 7.c.”
☑ Pregnant Women, Fetuses, and Neonates
☐ Non-English Speakers
☐ International Research involving Foreign Nationals - Headquarters Review is necessary

12.5 Inclusion Criteria:

Order Number	Criteria
1	Inclusion Criteria: Individuals of any age who are eligible for care at an MTF and meet at least one of the following criteria: 1. **Laboratory-confirmed presence of the pathogen of interest** (e.g., SARS-CoV-2, influenza A /H7N9, etc.) ***OR*** 2. **Meet criteria for testing for the pathogen of interest, as identified per current CDC guidelines** at **https://www.cdc.gov/coronavirus/2019-nCoV/hcp/clinical-criteria.html**
	Additional Inclusion Criteria for **Online Enrollment:**

2	1. An MHS Beneficiary who has been clinically tested for the pathogen of interest 2. Able to receive email communications and respond to web-based questionnaires 3. ≥18 years of age

12.6 Exclusion Criteria:

Order Number	Criteria
1	Individuals who decline participation in the study
2	Individuals who the study investigators believe are unable to comply with the requirements of the study

13.0

Recruitment and Consent

13.1 Identification and Selection of Subjects:

Given the dynamic nature of novel pathogens/emerging infectious diseases, there is no pre-defined target enrollment for the protocol. The main objective of this protocol is to recruit and enroll a representative proportion of cases of emerging infectious diseases to characterize the epidemiology and clinical characteristics of disease. Site study team members will engage with relevant clinical staff to identify eligible patients in inpatient wards, intensive care units, acute care clinics, and emergency departments. Participants will be identified through screening of medical records to identify individuals with the recent exposures and clinical manifestations of interest, and will be approached following the initial medical evaluation. The study will be described to patients, and their eligibility and willingness to participate will be assessed. For those with confirmed or suspected infection, room access may be limited and consent will be performed by study staff members with patient access.

Individuals presenting for care at MTFs, such as at clinics or in the inpatient and isolation setting, will be recruited and enrolled and will participate in serial collection of biological specimens over a 12-month period, with more intensive (i.e., daily, weekly) data collection occurring during the inpatient or isolation period. Information on current and prior medical conditions and hospitalizations will be collected via medical chart review and/or MDR data extractions. Information on specific epidemiologic risk factors during or related to deployment (e.g., travel history, zoonotic exposures, etc.) will be ascertained through participant interview or review of available medical records (e.g., AHLTA-T, ALTHA, CHCS, Essentris, MHS Genesis, JLV (accessed via AHLTA or MHS Genesis), MDR, DMSS, and/or DRSi). Study participants evaluated at MTFs and who are either 1. ambulatory cases advised to return home and remain home in isolation or 2. classified as asymptomatic individuals with high/some risk for exposure may also be evaluated for follow up through a study design including serial self-collection of nasal swabs, oropharyngeal swabs, rectal swabs, or other specimens appropriate for self-collection. A similar schedule of data collection and methods used for enrolled inpatients will be applied for ambulatory cases (non-hospitalized) and asymptomatic individuals as feasible.

Details on the recruitment, consent, and enrollment of subjects participating through the MHS-wide online process are included in Appendix A.

13.2 Recruitment Process:

Recruitment of study volunteers at the MTFs will rely heavily on the direct interface of healthcare providers with potential eligible participants. The study team will develop an MTF communications plan, outlined in the protocol’s Manual of Procedures, that will be implemented by local site teams to facilitate identification of potential eligible participants. Study volunteers may be recruited from clinics and inpatient or isolation settings. In addition, recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital. Another group of individuals who may be approached for recruitment as asymptomatic high/some risk participants, are healthcare providers who are in close contact with and potentially exposed to known cases. Adults and children are eligible for participation.

The study team will use multiple means of communicating study awareness to enhance recruitment efforts, including periodic briefings delivered by the site PI's and their study teams to their critical care and infectious disease staff and inpatient nursing staff. Information notices with points of contacts will be posted in clinical sites such as inpatient units, acute care clinics, and several points in the emergency room. Research team members who are Active Duty military personnel will not wear visible signs of their rank during recruitment. Site PI's or their authorized designees will conduct daily queries of MTF electronic health heath records (including infectious disease reportables list, DRSi, and searching in CHCS for patients with coronavirus lab code) to identify individuals who tested positive for disease of interest and will review daily admissions into the ICU, general pediatric and internal medicine wards with their study personnel to identify new inpatients. Information from infection control, preventive medicine and infectious disease departments may be obtained to find patients who may be managed / followed outside of the MTF.

J6 Data: Staff at the J6 CarePoint MHS Information Portal will provide subject identifiers (including names, Active Duty status, DoD Identifier, DOB, Email addresses, Date of Initial COVID-19 Respiratory Swab PCR Test, and all available COVID-19 Respiratory Swab PCR Test results) of AD members and beneficiaries who have been tested for COVID-19 to the approved research team using DoD SAFE. These data will be used to contact subjects for potential enrollment in the study and to contact subjects while enrolled. The original data file is retained only until a QC check determines the data have been uploaded successfully to REDCap, after which the file is destroyed. At study end, all PHI and PII shall be de-identified per the De-identification Plan.

Depending on age, severity of infection, and MTF requirements, study staff will determine if a potential subject is capable and/or allowed to provide a signed consent, verbal consent, or if an LAR is required according to IRB, HIPAA, and local MTF requirements.

13.3 Compensation for Participation:

In accordance with 24 USC 30:

MTF-enrolled subjects will be provided compensation in the form of a gift card. Subjects enrolled in the online-only group will receive compensation in the form of an electronic gift code sent via email.

Subjects will receive:

- $50 for each outpatient venipuncture
- $10 for each self-collected sample completed at home
- $10 for completion of each online questionnaire
- $10 for completion of 14-day Flu-PRO symptom diary

13.4 Eligibility Assessment Process:

As part of medical record review, the team will assess the eligibility of potential subjects. Individuals identified as having known risk factors for an emerging infectious disease (e.g., recent travel to a disease-endemic region, or close contact with a known or suspected infected individual or a returning traveler) who present to a participating MTF for medical care (e.g., febrile illness) or are placed into isolation are eligible for study participation. Additionally, asymptomatic high/some risk for exposure individuals may be enrolled at MTFs. Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Eligibility will be assessed and a final determination of subject eligibility will be made during the consent process. Please refer to section 12.5 for the inclusion criteria.

13.5 Consent Process:

Are you requesting a waiver or alteration of informed consent?

● Yes ○ No

What type?

☑ Waiver of documentation of informed consent
☐ Waiver or alteration of informed consent

Please explain why you qualify for a waiver or alteration of informed consent:

Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff. The study team is requesting a waiver of documentation of informed consent to allow for verbal subject/LAR informed consent, an Alteration of Authorization of HIPAA to allow for verbal subject/LAR HIPAA authorization, as well as a partial Waiver of HIPAA Authorization to identify eligible potential subjects and make initial contact with individuals to notify them regarding the study. These will be used as appropriate based on the circumstances of the disease being studied and MTF requirements. This study falls under the following criteria noted in 32 CFR 219.117: “That the research presents no more than minimal risk of harm to subjects and involves no procedures for which written consent is normally required outside of the research context."

Please explain the consent process:

ICD and Assent Regulatory Requirements

The Informed Consent Document (ICD) and Assent Form, including a HIPAA authorization, will be reviewed and approved by the IRB prior to initiation of the study. The ICD will contain a full explanation of the possible advantages and risks of study participation. The ICD will be compliant with applicable DoD regulations, 32 CFR 219, and the Belmont Principles, and the Health Insurance Portability and Accountability Act (HIPAA) Authorization. Informed consent includes the principle that it is critical the participant be informed about the principal potential risks and benefits. This information will allow the participant to make a personal risk versus benefit decision and understand the following general principles:

- Participation is entirely voluntary,
- Participants may withdraw from participation at any time,
- Refusal to participate involves no penalty; and
- The individual is free to ask any questions that will allow him/her to understand the nature of the protocol.

An ICD or Assent Form (with parental permission) will be signed by the participant before any study-related procedures are initiated for each participant. The investigators or their designees will present the protocol in lay terms to the participants. If access is limited, an authorized member of the study team accompanied by a witness may conduct the informed consent process. Questions on the nature of the protocol, the means by which it is to be accomplished, and the risks to the participants will then be solicited. Any question that cannot be answered will be referred to the principal investigator (PI). All participants will be given the opportunity to ask questions. No participant should grant consent until questions have been answered to his/her satisfaction. Documented parental permission will be received prior to obtaining assent from a minor. If rules allow, a copy should be provided to the volunteer or their guardian.

Minors:

An assent form (with parental permission) will be used for children aged 7-17. The ICD and Assent Form (with parental permission) indicate that by signature, the participant permits access to relevant medical records by the study investigators and regulatory authorities. Documented parental permission is required prior to assent by a minor using the ICD. A Waiver of Documentation of Assent will be used for children 6 and under, documenting that the study was explained to the child in age-appropriate terms and that the child has either expressed verbal assent or does not have the capacity to do so.

For adults who are incapacitated by the illness:

Consent may be obtained by a Legally Authorized Representative (LAR). The patients should be consented themselves at such time that they are able to provide consent.

For Hospital Staff who are Active Duty Military:

Hospital staff who are active duty military, and therefore eligible for care at a military treatment facility, may be approached for consenting to the study due to their potential exposure to coronavirus. If hospital staff who are active duty military are approached for participation in the study, supervisors will not be present at any human subject recruitment sessions or during the consent process in which hospital staff who are active duty military under their supervision are afforded the opportunity to participate as human subjects. Supervisors (e.g., military and civilian supervisors or anyone in the supervisory structure) will not influence the decisions of their subordinates regarding their participation as subjects in this study.

Verbal Informed Consent:

Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff.

The study team is requesting a waiver of documentation of informed consent, an Alteration of HIPAA Authorization, as well as a partial Waiver of HIPAA Authorization to use as appropriate based on the circumstances of the disease being studied and MTF requirements. When possible, the subject will provide signed ICD and HIPAA authorization. If the subject is unable to provide signed authorizations, the Alteration of HIPAA Authorization will be utilized, allowing the subject/LAR to provide verbal, rather than written, HIPAA Authorization. If study personnel are unable to work near the potential and/or active subject for safety reasons, the study personnel will contact the patient according to the requirements of the MTF. Options may include but are not limited to speaking with the patient from a safe distance in person, contacting the patient by phone in person with a barrier in between the potential and/or active subject and the study personnel, contacting the patient by phone from a separate location, or having a study physician trained in infectious disease safety procedures meet with the potential and/or active subject in close proximity (if allowed by the MTF).

Regardless of the method of delivery, the potential and/or active subject would be thoroughly briefed on the study’s Informed Consent and HIPAA information. They would also be provided with an opportunity to ask any questions and an unsigned copy of the informed consent if permissible by the MTF. In turn, study staff will thoroughly document the informed consent process and the subject’s verbal consent in the study chart. The study personnel will sign and file the ICD. The study personnel will also include a note in the study chart summarizing the informed consent process.

13.6 DoDI 3216.02 requires an ombudsman to be present during recruitment briefings when research involves greater than minimal risk and recruitment of Service members occurs in a group setting. If applicable, you may nominate an individual to serve as the ombudsman.

● N/A
○ Propose ombudsman

13.7 Withdrawal from Study Participation:

Explain the process for withdrawal and specify whether or not the subjects will be given the opportunity to withdraw their data their data/specimens in the event they wish to withdraw from the study

A subject may voluntarily end participation in the study at any time. If a subject withdraws, the investigator will make a reasonable effort to determine the reason for the subject’s withdrawal from the study. Telephone calls, registered letters, and/or e-mail correspondence will be considered reasonable effort. Data and specimens collected up to the time of withdrawal will be retained and de-identified in accordance with IRB, HIPAA, and Safe Harbor requirements.

Subjects may be discontinued by the study team if there is a determination by the on-site physician that the volunteer may be unable to comply with the requirements of the study, or in the interest of the military mission.

The study team may consider discontinuation of study participants who have a negative test result for the pathogen of interest (based on current standard of care diagnostics) *and/or* are diagnosed with another respiratory pathogen other than the one of interest *and/or* the disease of interest is highly unlikely based on the primary clinical team assessment. This approach may need to be taken to conserve study staff time and resources depending upon local epidemiologic circumstances, e.g. very high incidence and subject accrual.

14.0
Risks and Benefits

14.1

Risks of Harm:

Identify all research-related risks of harm to which the subject will be exposed for each research procedure or intervention as a result of participation in this study. Consider the risks of breach of confidentiality, psychological, legal, social, and economic risks as well as physical risks. Do not describe risks from standard care procedures; only describe risks from procedures done for research purposes

Risks associated with obtaining specimens:

- Obtaining specimens could be associated with discomfort from a needle stick, swab, or other procedure, and occasionally associated with bleeding, bruising, local or systemic infection.
- Genetic testing may reveal sensitive information that subjects may not want disclosed, and may cause some emotional distress for the participant.

Risks associated with privacy:

- Despite meticulous precautions, breaches of confidential information (including genetic information) do occasionally occur, although the chances of such a breach are unlikely.

Expected Adverse Events from Research Risks and Reporting

a. Rare (Event Rate < 1%)
Secondary infection and syncope from vasovagal reactions occur from blood collection in rare cases. Risks of nasopharyngeal swab, rectal swab, cheek swab could include bleeding or mucous membrane irritation.

b. Less Likely (1% ≤ Event Rate < 5%)
No known risks

c. Likely (5% ≤ Event Rate < 10%)
Bruising and bleeding may occur as a result of blood collection procedures.

d. More likely (Event Rate ≥10%)
No known risks

14.2

Measures to Minimize Risks of Harm (Precautions, safeguards):

For each research procedure or intervention, describe all measures to minimize and/or eliminate risk of harms to subjects and study personnel

Participation in this protocol will impose minimal risks to the participant. As feasible, the study team will coordinate the collection of research purpose blood draws during timing of blood collection for clinical care to minimize discomfort to the patient. Blood volume collection per visit will be approximately 25 mL total. Total blood volumes collected over the 12 month duration of study will not exceed limitations for adults and children outlined in the CFR §46.110: Expedited review procedures for certain kinds of research involving no more than minimal risk, and for minor changes in approved research. Blood draw volumes will be reduced for pediatric subjects, small adults, and pregnant women in accordance with minimal risk and safety guidelines, and as needed per guidance from the primary care provider overseeing care of enrolled patients.

Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care. Specimen collection should be harmonized with the clinician’s requirements, and missed samples will not be re-drawn.

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII/PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment (PPE). PPE training will be conducted and documented for all personnel who may interact directly with patients and/or samples in order to mitigate any UPIRTSO related to accidental exposure of study staff and other individuals in the facility.

14.3
Confidentiality Protections (for research records, data and/or specimens):

Describe in detail the plan to maintain confidentiality of the research data, specimens, and records throughout the study and at its conclusion (e.g., destruction, long term storage, or banking). Explain the plan for securing the data (e.g., use of passwords, encryption, secure servers, firewalls, and other appropriate methods). If data will be shared electronically with other team members/collaborators outside the institution, describe the method of transmission and safeguards to maintain confidentiality. Explain whether this study may collect information that State or Federal law requires to be reported to other officials or ethically requires action, e.g., child or spouse abuse

A certificate of confidentiality will not be used in this protocol.

The only electronic links established between the participant name, SSN, and the Study ID number will be in the data management system managed by DCC and on a tracking spreadsheet used for scheduling purposes, which will both require a password to access and will only be accessed by authorized study personnel. During the study, source documents will be held in a secured cabinet with restricted access. Team members with access to the documents are counseled on the importance of confidentiality of participant medical records. All staff involved in this study have completed the required human subjects protection and ethics training. In all electronic records for data analysis, the participant is not referenced by name, but only Study ID number. This method is designed to protect the privacy of study participant medical information. All CRFs will be held at the individual study sites in the research spaces in secured cabinets with restricted access.

The only hard copy link between participant identifiers and Study ID will be on the Registry Form and Contact Information Form. This will be kept in a secure location separate from source document files. Any copies faxed to DCC personnel acting as a backup Registrar will be shredded after registration is complete.

In order to determine whether an individual has been enrolled previously at another study site, study staff at all active sites will have the ability to query DCC's data management system to locate an individual. The data management system is secure and can only be accessed via authorized individuals using a password.

What precautions will you take to protect the confidentiality of research source documents (Case Report Forms, questionnaires, etc.), the research data file, and the master code (if any)?

The only hard copy link established between the participant's name, SSN, and the study code number will be held in a secured cabinet with access restricted to research team members with a need to use the Registry Form or Contact Information Form. Team members with access to CRFs are counseled on the importance of confidentiality of participant medical records. In all electronic records for data analysis, the participant is not referenced by name, but only study code number.

The only electronic link will be stored on a secure password protected server. The file is only accessible directly to the DCC data custodian. The designated CRC at each site and two backups at DCC will also have access via DCC's data management system.

Will research data including Identifiable Protected Health Information be sent outside of Department of Defense facilities?

The study team may share coded data with collaborators at non-DoD facilities, and may work with participating MTFs to assist with appropriate public health data reporting requirements.

14.4
Potential Benefits:

Describe any real and potential benefits of the research to the subject and any potential benefits to a specific community or society

If the individuals in the research are considered experimental subjects (per 10 USC 980), and they cannot provide their own consent, the protocol must describe the intent to directly benefit all subjects

This is an observational study that does not test interventions that would offer direct benefit to study volunteers.

Study volunteers may indirectly benefit from enhanced clinical testing, physical examination, radiographic studies, and longitudinal follow up, or improved access to related trials of therapeutics.

14.5 Privacy for Subjects:

Describe the measures to protect subject's privacy during recruitment, the consent process, and all research activities, etc.

When possible, all means necessary will be taken to ensure participant privacy. This may entail conducting study procedures in a private area and keeping study documents coded. Non-coded study documents will be kept in a locked drawer and/or locked file in a locked room. Subjects will disclose information at their consent, if subjects choose not to disclose information, the study team will respect subject privacy and not inquire further.

14.6 Incidental or Unexpected Findings:

Describe the plan to address incidental findings and unexpected findings about individuals from screening to the end of the subject's participation in the research. In cases where the subject could possibly benefit medically or otherwise from the information, state whether or not the results of screening, research participation, research tests, etc., will be shared with subjects or their primary care provider. State whether the researcher is obligated or mandated to report results to appropriate military or civilian authorities and explain the potential impact on the subject

The study team will share relevant findings from research labs/imaging with the patient's healthcare provider(s).

Aspects of this study may include epidemiologic reporting to AFHSB and public health authorities at the respective services, state and local health departments, and CDC. That data transfer is not subject to Data Use Agreement or HIPAA requirements.

15.0 Study Monitoring

15.1 Data Monitoring Plan:

Describe the plan to monitor the data to verify that data are collected and analyzed as specified in the protocol. Include who will conduct the monitoring, what will be monitored and the frequency of monitoring

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as questionnaires may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, signed ICD and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves (questionnaires) or authorized study personnel. Only designated study personnel shall record or change data on a CRF. The data system includes password protection and internal quality checks, such as automatic range checks, to identify data that appear inconsistent, incomplete, or inaccurate. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. A Quality Management Plan (QMP) will be used for this study. The QMP will include a QC subject data review checklist, a QC Subject data review checklist, as well as automatic queries from the electronic database based on expected parameters for data entry, noting possible inconsistencies or omissions. The QC subject data review checklist will be completed at each site on 100% of subject’s study files. This will be completed by another member of the study team who did not complete the original source document or CRF. A QA subject data review checklist will also be used on a small subset of study records at each site to ensure that quality management processes are being conducted appropriately for the study. QA review will be conducted by an individual on the study who is not involved in the day-to-day activities of the study.

Responsibilities of the Data Coordination Center (DCC)

1. Provides review of protocol, CRFs, data security plan and data management SOPs
2. Complies with protocol, SOPs, and all federal and local regulations and policies
3. Develops clinical database
4. Entry and quality control of CRF based study data
5. Receipt and management of specimen tracking and laboratory data
6. Provides study database to IDCRP Program Coordination Center (PCC)
7. Locks final study database

15.2 Safety Monitoring Plan:

Describe the plan to monitor the data to ensure the safety of subjects

Participation in this protocol will impose minimal risks to the participant. Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care. Specimen collection must be harmonized with the clinician’s requirements, and missed samples will not be re-drawn. Proper safety training, following hospital Infection Control requirements, of study team members who come in contact with study participants will be implemented to mitigate disease transmission risk.

Termination of study participation will take place through 1) an expressed desire by the volunteer to terminate participation, 2) a determination by the on-site physician that the volunteer risks his/her health by further participation in the study, or 3) in the interest of the military mission.

15.3 Does your study require independent data and safety monitoring?

○ Yes ● No

16.0 Reportable Events

16.1 Reportable Events:

Consult with the research office at your institution to ensure requirements are met

• Describe plans for reporting expected adverse events. Identify what the expected adverse events will be for this study, describe the likelihood (frequency, severity, reversibility, short term management and any long term implications of each expected event)
• Describe plans for reporting unexpected adverse events and unanticipated problems. Address how unexpected adverse events will be identified, who will report, how often adverse events and unanticipated problems will be reviewed to determine if any changes to the research protocol or consent form are needed and the scale that will be used to grade the severity of the adverse event

Reporting Protocol Deviations

The PI or designee will be responsible for identifying and reporting all deviations, which are defined as isolated occurrences involving a procedure that did not follow the study protocol or study-specific procedure. Investigators will report protocol deviations to the USU IRB within 2 business days that:

- relate to participant safety
- relate to the informed consent process
- are any other protocol deviations which, in the opinion of the PI, should be promptly reported to the IRB.

A log of all deviations will be reported annually in the continuing review report to the IRB and in the Final Study Report.

Reportable events will also be submitted to reporting site's regulatory authorities as required.

Reporting Adverse Events and Serious Adverse Events

In this observational, no-greater-than-minimal risk study, the reporting of adverse events is limited to an analysis at the time of annual reporting. Prompt reporting is required for any related serious adverse event or unanticipated problems involving risk to subject or others (UPIRTSO).

An adverse event is defined as any untoward or unfavorable medical occurrence in a human subject, including any abnormal sign (e.g., abnormal physical exam or laboratory finding), symptom, or disease, temporally associated with the subject's participation in the research, whether or not considered related to the research.

AEs that meet all of the following criteria will be recorded by the study team and reported to the IRB at the annual Continuing Review:

- At least possibly related to study procedures
- Unexpected (i.e. not included in the list of known risks in section 14)
- Moderate or greater severity

Additional AEs may be reported if the determined by the study site investigator to be of sufficient significance to require reporting to the IRB.

AEs are recorded and inspected by the supervising physician investigator to determine severity and relatedness to participation (definite, probable, possible, or unlikely). The physician investigator is responsible for directly managing or coordinating management of adverse events.

Reporting unanticipated problems involving risk to subjects or others

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII /PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment. Any sample collection for research purposes (as compared to clinical care) that results in an exposure to clinical staff is considered a UPIRTSO.

All UPIRTSOs will be collected and reported to the IRB within 24 hours of the PI recognition of the problem.

17.0

Equipment/non-FDA Regulated Devices

17.1 Does the study involve the use of any unique non-medical devices/equipment?

○ Yes ● No

18.0
FDA-Regulated Products

18.1 Will any drugs , dietary supplements, biologics, or devices be utilized in this study?

☐ Drugs
☐ Dietary Supplements
☐ Biologics
☐ Devices
☑ N/A

18.5 Sponsor (organization/institution/company):

☐ N/A

If applicable, provide sponsor contact information:

Infectious Diseases Clinical Research Program
Department of Preventive Medicine and Biometrics
Uniformed Services University of the Health Sciences
11300 Rockville Pike, Suite 1211
Rockville, MD 20852

19.0
Research Registration Requirements

19.1 ClinicalTrials.gov Registration:

● Registration is not required
○ Registration pending
○ Registration complete

19.2 Defense Technical Information Center Registration (Optional):

● Registration is not required
○ Registration pending
○ Registration complete

US - United States

USU - Uniformed Services University of the Health Sciences

WHO - World Health Organization

INFORMED CONSENT DOCUMENT FOR AN OBSERVATIONAL COVID-19 RESEARCH STUDY: IDCRP-085: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)

Thank you for your interest in learning more about this study. Please read the following information to ensure that you would like to participate. The Department of Defense has sponsored this research study, led by the Infectious Disease Clinical Research Program at the Uniformed Services University of the Health Sciences (the military's medical school), to better understand risks and illness caused by the novel Coronavirus disease (**COVID-19**).The COVID-19 pandemic is a global public health emergency. We are asking you to consider volunteering for this research study because you may have COVID-19 and/or qualify for COVID-19 testing according to the Centers for Disease Control and Prevention (CDC) guidelines. We are asking you to complete questionnaires about your health history, possible exposures, symptoms and health care visits, and keep a two week daily diary of your symptoms. We also are asking to collect nose, mouth, rectum, and blood samples, as well as ultrasounds of your lungs, heart and veins. From your medical care, we would like to use any leftover samples, and review your medical records in the military health system now and in the future for information related to COVID-19 risks, treatments, and health outcomes.

Who can participate?

This study is available to DoD beneficiaries (active duty and non-active duty) of all ages who have confirmed COVID-19 or who meet current CDC criteria for testing for the virus that causes COVID-19. If you are unable to actively participate in this informed consent process, your legally authorized representative (LAR) may do that on your behalf. If your LAR consents on your behalf and you later become capable of consent, you will be asked to give your informed consent once you are able to do so.

KEY INFORMATION

- This is an observational study meaning we will look at your medical records and collect data and samples from you *but we will not give you any medicine or treatment*. Questions about your treatment should be directed to your doctor.
- Volunteering for this study does not limit your ability to participate in another study of an experimental drug or vaccine. That decision would be made in discussion with your doctor and the other study's investigators and is separate from this study. We may collect additional blood to assess the new treatment's effects.
- Your participation is voluntary, your decision will not affect your care or any other benefits to which you are entitled. Your alternative to volunteering is to not participate.
- Your participation will last about 1 year.
- You may end your participation at any time without any consequences.
- There is no cost for participating.
- All information and samples you provide will be handled securely and in confidence. Only those involved in conducting this study will know you are enrolled.
- The information collected about you is for research purposes only. This information will not be used to guide your medical care.
- Leftover samples from tests your doctor orders will be stored and may be shared for future analyses related to COVID-19 or other infections
- You may not personally benefit from this study. The information gained from this study may not be available in time to affect your care. The information we learn may help in caring for other future patients with COVID-19 or similar pandemics.
- Potential risks in participating include the following:
  - Blood draws can cause a risk of pain, bruising, bleeding, and (rarely) fainting or infection.
  - Nose, mouth, and rectal swabs may cause discomfort but are generally well tolerated.
  - There may also be unforeseen risks associated with this study.
- If you are pregnant, there are no additional known risks to you or your fetus.

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

- Once your identifying information has been removed from the collected data and specimens, additional consent will not be sought for future studies. This also applies if you withdraw from the study.

<u>What is involved in the study?</u>

<u>During your hospitalization:</u>

- ✓ We will review your medical records to collect information related to your health.
- ✓ Blood samples for research will be collected (~5 teaspoons each time from your vein) and/or you will be asked to collect a small blood sample (a few drops from your finger), using a specially designed device similar to blood glucose monitoring used by diabetic people.
- ✓ Nose, mouth and rectum samples will be collected using a swab or other simple collection method to identify and count the virus. You may also be asked to collect some samples yourself with our help. The type of sample may change during your participation in the study as we learn more about the virus.
- ✓ We may do an ultrasound to look at your lungs, heart, and veins.
- ✓ You will start a daily online symptom diary called Flu-PRO for 14 days.
- ✓ We will ask you to complete a small questionnaire about your medical history, illness, and vaccine history.

Samples will be collected following the below schedule as feasible, however it is possible that not all samples will be collected.

Procedure / Assessment	**Day 0 (today)**	**Days 3 and 7**	**If hospitalized longer than 7 days: samples obtained weekly until discharge**
Nose, mouth, and rectal samples	✓	✓	✓
Blood collection for research	✓	✓	✓
Ultrasound of your lungs, heart and veins *	✓	✓	
Flu-PRO Symptom Diary (14 days)**	✓	✓	✓
Online Questionnaire	✓		

* May be performed on or around hospital days 0 (admission), 1, and 3, based on availability.

** Does not all have to be completed while hospitalized.

<u>Follow-Up Visits:</u>

In 1 Week (If you've left the hospital)	• Continue the Flu-PRO online daily symptom diary (14-days total). • Blood collection – we will draw blood from your vein (about 25 mL or 5 teaspoons) and/or you will be asked to collect a small blood sample (a few drops from your finger), using a specially designed device similar to blood glucose monitoring used by diabetic people. • If you are at home, we will provide you with the materials and instructions to collect your own samples, including pre-paid mailing materials to return your samples.
In 2 Weeks (If you've left the hospital)	• Finish the Flu-PRO online daily symptom diary (14-day total). • To check for active virus, we will collect samples from your nose and/or mouth using a swab or other simple collection method. This method may change during your participation in the study as we learn more about the virus. • Blood collection (same as above - either at home or in clinic).
In 1 Month	• Complete an online questionnaire that takes about 10 minutes. We will send you an email reminder with the web link as it gets closer to the time. • Blood collection (same as above - either at home or in clinic). • If you return to the clinic for this visit, we will ask to collect a follow-up rectal swab sample to check for presence of the virus.
In 6 Months	The following procedures happen at each time point (6 and 12 months): • Complete an online questionnaire that takes about 10 minutes. We will send you an email reminder with the web link as it gets closer to the time. • Blood collection (same as above - either at home or in clinic).
In 12 Months	

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

Additional information

- You can choose not to provide blood samples or swabs and still participate in the study.
- The total amount of blood collected for research while hospitalized or during a return visit at the hospital at one sitting will be about 25 mL (5 teaspoons). The total number of required blood samples depends on the duration of your illness. During the 12 months that you participate in the study, no more than 550 mL (2⅓ cups) total of blood will be collected. For comparison, a typical blood drive donation is 470 mL (about 2 cups) in one day. To minimize discomfort to you, we will try to coordinate with your healthcare providers so that the collection of research blood samples happens at the same time as your standard blood draws.
- Based on your answers to the questionnaires, we may contact you to discuss your health if you have particular symptoms or any new illness that may be related to COVID-19.
- Throughout your participation in the study, we will collect leftover samples from tests your doctors order such as blood, swabs, urine, etc. We will collect these samples dating back to the time you became ill. We will study these materials for COVID-19 and related illnesses. You do not have to do anything additional for this.
- The US military regularly stores service members blood samples obtained for medical surveillance in the DoD Serum Repository. If you are Active Duty or former military (since the 1990s) we plan to obtain stored blood specimens prior to and after your COVID-19 illness. You do not have to do anything additional for this.
- If you are pregnant or become pregnant during the study participation period, we will follow up with you until your baby is born. We may collect a sample of umbilical cord blood at the time of birth, review your baby's medical records, and ask you questions about your baby's health. There are no additional known risks to you or your fetus for participating in the study.

Genetic Information

The study is focusing on risks related to COVID-19 including your genetic results as part of the analysis. The risks of studying your unique genetic code may be the identification of risk for developing certain diseases. We will not be studying general issues related to your genetic results because our research is focused on COVID-19 and related illnesses. We will not provide you with your genetic results or release any information regarding your results connected to your personal identification.
Please let us know your decision by signing your initials:

______ Yes, I give permission to use my **genetic information** for COVID-19-related research

______ No, I DO NOT give permission to use my **genetic information** for COVID-19 research

Compensation:

You will receive payment (compensation) in the form of gift cards as follows for completion of the following study procedures**:**

- Completion of each online questionnaire: $10 (if completed off-duty for service members)
- Completion of 14-day Flu-PRO Symptom Diary: $10 (if completed off-duty for service members)
- Completion of each at-home self-collected sample: $10 (if completed off-duty for service members)
- Blood draws at hospital/clinic after you leave the hospital: $50 per blood draw

Under 24 USC 30, payment to Federal Employees and Active Duty military personnel for participation in research while on duty is limited to blood donation. Military members may not receive any payment or non-monetary compensation for participation in a research study unless they are off duty or on leave during the time they are participating in the protocol. There are no restrictions on payment while off-duty.

HIPAA: AUTHORIZATION TO USE AND/OR DISCLOSE PROTECTED HEALTH INFORMATION FOR RESEARCH

PI Name and Rank: Brian Agan, MD, DrPH

Corps and Service/Organization: Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences
Title of Research Study: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential

Purpose of this Document:
An Authorization is your signed permission to use or disclose your health information. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule, as implemented by the Department of Defense (DoD), permits the Military Health System (MHS) to use or disclose your health information with a valid Authorization. The MHS is defined as all DoD health plans and DoD health care providers that are organized under the management authority of, or in the case of covered individual providers, assigned to or employed by, the Defense Health Agency (DHA), the Army, the Navy, or the Air Force. A valid Authorization must include the core elements and required statements as contained in this document.

Please read the information below and ask questions about anything you do not understand before deciding to give permission for the use and disclosure of your health information.

The Health Insurance Portability & Accountability Act of 1996, Public Law 104-109 (also known as HIPAA), establishes privacy standards to protect your health information. This law requires the researchers to obtain your authorization (by signing this form) before they use or disclose your protected health information for research purposes in the study discussed in this form. Note: Protected health information of military service members may be used or disclosed for activities deemed necessary by appropriate military command authorities to ensure the proper execution of the military mission.

By signing this authorization, you give your permission for information gained from your participation in this study to be published in medical literature, discussed for educational purposes, and used generally to further medical science. You will not be personally identified; all information will be presented as anonymous data.

A. What health information will be used or disclosed about you?

- Names
- Address
- Date of birth
- Ages over 89 (can be grouped as age 90 or older)
- DoD identification number
- Health information
- Health plan beneficiary numbers
- Phone numbers
- Fax numbers
- E-mail addresses
- Social security numbers
- Medical record numbers

B. Who will be authorized to use or disclose (release) your health information?

MTFs who have treated you over the past ten years

C. Who may receive your health information?

- The Institutional Review Board (USU IRB)
- Infectious Disease Clinical Research Program (IDCRP)
- Military Treatment Facilities who have treated you or Department of Defense representatives
- Henry M. Jackson Foundation and their representatives
- Neoteryx and their representatives
- Local, State and Federal Government representatives, when required by law
- Defense Health Agency (DHA)
- Food and Drug Administration (FDA)
- Centers for Disease Control and Prevention (CDC)
- National Institute of Allergy and Infectious Disease (NIAID) and their representatives

The researchers and those listed above agree to protect your health information by using and disclosing it only as permitted by you in this Authorization and as directed by state and federal law.

You need to be aware that some parties receiving your protected health information may not have the same obligations to protect your protected health information and may re-disclose your protected health information to parties not named here. If your protected health information is re-disclosed, it may no longer be protected by state or federal privacy laws. This authorization does not expire.

D. What if you decide not to sign this Authorization?
You do not have to sign this Authorization. If you decide not to sign the Authorization it will not affect your treatment, payment or enrollment in any health plans or affect your benefit eligibility. You will not be allowed to participate in this research study because your health information is required in order for you to take part in this study. The MHS will not condition (withhold or refuse) treatment that is not part of this study, payment, enrollment, or eligibility for benefits on whether you sign this Authorization.

E. Is your health information requested for future research studies?
Yes, your health information is requested for future research studies as specified below: Your health information will not be used for future research studies unless you give your permission by initialing your choice below:

____ YES, I give permission to use my health information for future research studies

____ NO, I do not give permission to use my health information for future research studies

F. Can you access your health information during the study?
You may have access to your health information at any time, unless your identifiers are permanently removed from the data.

G. Can you revoke this Authorization?
You may change your mind and revoke (take back) your Authorization at any time. However, if you revoke this Authorization, any person listed above may still use or disclose any already obtained health information as necessary to maintain the integrity or reliability of this research.

- If you revoke this Authorization, you may no longer be allowed to participate in this research study.
- If you want to revoke your Authorization, you must write to the Study Doctor.

H. Does this Authorization expire?
No, it does not expire

I. What else may you want to consider?
- No publication or public presentation about the research described above will reveal your identity without another signed Authorization from you.
- If all information that does or can identify you is removed from your health information, the remaining de-identified information will no longer be subject to this Authorization and may be used or disclosed for other purposes.
- In the event your health information is disclosed to an organization that is not covered by HIPAA, the privacy of your health information cannot be guaranteed.

If you have not already received a copy of the brochure entitled "Military Health System Notice of Privacy Practices," you may request one. DD Form 2005, Privacy Act Statement - Military Health Records (located on your medical records jacket), contains the Privacy Act Statement for the records. If you have any questions or concerns about your privacy rights, you should contact the Uniformed Services University of the Health Sciences (USU) Human Research Protections Program at 301-295-9534.

Who can answer my questions?
Any questions about this research study or if you believe you have received a research-related injury, you may contact the lead for the study at your hospital or the study Principal Investigator.
PRINCIPAL INVESTIGATOR: Overall director of this research study is Dr. Brian Agan at the Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences (a DoD institution).

Questions? Call Dr. Agan at 1-833-475-0881 or contact at this address: Uniformed Services University of the Health Sciences (USU), Department of Preventive Medicine and Biostatistics, 4301 Jones Bridge Road, Bethesda, MD 20814-5119

LOCAL PRINCIPAL INVESTIGATOR (Study Doctor): – [Sites will fill in]

The USU Institutional Review Board is the research ethics committee responsible for safeguarding your rights as a research participant. If you have any questions about your rights as a research participant or any other concerns that cannot be addressed by the Study Doctor, you can contact the Director of the Human Research Protections Program at (301) 295-9534.

SIGNATURE PAGE:

Your signature is voluntary consent to participate in this study. Your signature also acknowledges that you authorize personnel to use and disclose your Protected Health Information (PHI) collected about you for research purposes as described above. A copy of this form will be offered to you.

INFORMED CONSENT DOCUMENT FOR AN OBSERVATIONAL COVID-19 RESEARCH STUDY: IDCRP-085: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)

Thank you for your interest in learning more about this study. Please read the following information to ensure that you would like to participate. The Department of Defense has sponsored this research study, led by the Infectious Disease Clinical Research Program at the Uniformed Services University of the Health Sciences (the military's medical school), to better understand risks and illness caused by the novel Coronavirus disease (**COVID-19**).

The COVID-19 pandemic is a global public health emergency. We are asking you to consider volunteering for this research study because you may have COVID-19 and/or qualify for COVID-19 testing according to the Centers for Disease Control and Prevention (CDC) guidelines. If you agree to participate, we will ask you to complete online questionnaires about your health history, possible exposures, symptoms, and health care visits. We will collect swabs from your nose and/or mouth to check for the virus, and draw blood to see how your body reacts to the infection. In the future we will ask you to return for more visits and/or collect some samples at home such as a nose and/or mouth swab and a few drops of blood from your fingertip, using a simple kit that you mail in. Your medical records in the military health system will be reviewed now and in the future for information related to COVID-19 risks, treatments, and health outcomes.

Who can participate?

This study is available to DoD beneficiaries (active duty and non-active duty) of all ages who have confirmed COVID-19 or who meet current Centers for Disease Control and Prevention (CDC) criteria for testing for the virus that causes COVID-19.

KEY INFORMATION

- This is an observational study, meaning we will look at your medical records and collect data and samples from you *but we will not give you any medicine or treatment*. Questions about your treatment should be directed to your doctor.
- Volunteering for this study does not limit your ability to participate in another study of an experimental drug or vaccine. That decision would be made in discussion with your doctor and the other study’s investigators and is separate from this study. We may collect additional blood to assess the new treatment’s effects.
- Your participation is voluntary, your decision will not affect your care or any other benefits to which you are entitled. Your alternative to volunteering is to not participate.
- Your participation will last about 1 year.
- You may end your participation at any time without any consequences.
- There is no cost for participating.
- All information and samples you provide will be handled securely and in confidence. Only those involved in conducting this study will know you are enrolled.
- The information collected about you is for research purposes only. This information will not be used to guide your medical care.
- Leftover samples from tests your doctor orders will be stored and may be shared for future analyses related to COVID-19 or other infections.
- You may not personally benefit from this study. The information gained from this study may not be available in time to affect your care. The information we learn may help in caring for future patients with COVID-19 or similar pandemics.
- Potential risks in participating include the following:
  - Blood draws can cause a risk of pain, bruising, bleeding, and (rarely) fainting or infection.
  - Nose and mouth swabs may cause discomfort but are generally well tolerated.
  - There may also be unforeseen risks associated with this study.
- If you are pregnant, there are no additional known risks to you or your fetus.

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

- Once your identifying information has been removed from the collected data and specimens, additional consent will not be required for future studies. This also applies if you withdraw from the study.

What is involved in the study?
The following schedule describes the research study procedures and when they occur.

Today	• You will be given a link to a questionnaire to complete online (takes about 20 minutes). • Blood collection – we will draw blood from your vein (about 25 mL or 5 teaspoons) and/or you will be asked to collect a small blood sample (a few drops from your finger), using a specially designed device similar to blood glucose monitoring used by diabetic people. • We will collect samples from your nose and/or mouth using a swab or other simple collection method. You may also be asked to collect some samples yourself with our help. The type of sample may change during your participation in the study as we learn more about the virus. • If you are at home, we will provide you with the materials and instructions to collect your own samples, including pre-paid mailing materials to return your samples. • You will start an online daily symptom diary called Flu-PRO.
In 1 Week	• Blood collection (same as above - either at home or in clinic). • Continue to complete the Flu-PRO online daily symptom diary.
In 2 Weeks	• Finish the Flu-PRO online daily symptom diary (14 days total). • Nose and/or mouth sample (same as above, either at home or in clinic). • Blood collection (same as above - either at home or in clinic).
In 1 Month	The following procedures happen at each of the time points (1, 6, and 12 months): • Blood collection (same as above - either at home or in clinic). • Online questionnaire (takes about 10 minutes).
In 6 Months	
In 12 Months	

Additional information

- Blood collection: During the 12 months that you participate in the study, approximately 180 mL (less than a cup) total of blood will be collected. For comparison, a typical blood drive donation is 470 mL (about 2 cups) in one day.
- You can choose to not provide samples and still participate in the study.
- If you are admitted to the hospital for COVID-19 symptoms, we may ask to collect additional samples.
- Based on your answers to the questionnaires, we may contact you to discuss your health if you have particular symptoms or new illness that may be related to COVID-19.
- Throughout your participation in the study, we will collect leftover samples from tests your doctors order such as blood, swabs, urine, etc. We will collect these samples dating back to the time you became ill. We will study these materials for COVID-19 and related illnesses. You do not have to do anything additional for this.
- The US military regularly stores service members blood samples obtained for medical surveillance in the DoD Serum Repository. If you are Active Duty or former military (since the 1990s) we plan to obtain stored blood specimens prior to and after your COVID-19 illness. You do not have to do anything additional for this.
- If you are pregnant or become pregnant during the study participation period, we will follow up with you until your baby is born. We may collect a sample of umbilical cord blood at the time of birth, review your baby's medical records, and ask you questions about your baby's health.

Genetic Information
The study is focusing on understanding risks related to COVID-19 including how genetic factors impact COVID-19. The risks of studying your unique genetic code may be the identification of risk for developing certain diseases. We will not be studying general issues related to your genetic results because our research is focused on COVID-

19 and related illnesses. We will not provide you with your genetic results or release any information regarding your results connected to your personal identification.

Please let us know your decision by signing your initials:

_______Yes, I give permission to use my **genetic information** for COVID-19-related research

_______ No, I DO NOT give permission to use my **genetic information** for COVID-19 research

Compensation:

You will receive payment (compensation) in the form of gift cards as follows for completion of the following study procedures:

- Completion of each online questionnaire: $10 (if completed off duty for servicemembers)
- Completion of 14-day Flu-PRO Symptom Diary: $10 (if completed off-duty for service members)
- Completion of each at-home self-collected sample: $10 (if completed off-duty for service members)
- Blood draws at hospital/clinic: $50 per blood draw

Under 24 USC 30, payment to Federal Employees and Active Duty military personnel for participation in research while on duty is limited to blood donation. Military personnel may not receive any payment or non-monetary compensation for participation in a research study unless they are off duty or on leave during the time they are participating in the protocol. There are no restrictions on payment while off-duty.

HIPAA: AUTHORIZATION TO USE AND/OR DISCLOSE PROTECTED HEALTH INFORMATION FOR RESEARCH

PI Name and Rank: Brian Agan, MD, DrPH

Corps and Service/Organization: Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences

Title of Research Study: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential

Purpose of this Document:

An Authorization is your signed permission to use or disclose your health information. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule, as implemented by the Department of Defense (DoD), permits the Military Health System (MHS) to use or disclose your health information with a valid Authorization. The MHS is defined as all DoD health plans and DoD health care providers that are organized under the management authority of, or in the case of covered individual providers, assigned to or employed by, the Defense Health Agency (DHA), the Army, the Navy, or the Air Force. A valid Authorization must include the core elements and required statements as contained in this document.

Please read the information below and ask questions about anything you do not understand before deciding to give permission for the use and disclosure of your health information.

The Health Insurance Portability & Accountability Act of 1996, Public Law 104-109 (also known as HIPAA), establishes privacy standards to protect your health information. This law requires the researchers to obtain your authorization (by signing this form) before they use or disclose your protected health information for research purposes in the study discussed in this form. Note: Protected health information of military service members may be used or disclosed for activities deemed necessary by appropriate military command authorities to ensure the proper execution of the military mission.

By signing this authorization, you give your permission for information gained from your participation in this study to be published in medical literature, discussed for educational purposes, and used generally to further medical science. You will not be personally identified; all information will be presented as anonymous data.

A. What health information will be used or disclosed about you?

- Names
- Address
- Date of birth
- Health plan beneficiary numbers
- Phone numbers
- Fax numbers

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

- Ages over 89 (can be grouped as age 90 or older)
- DoD identification number
- Health information
- E-mail addresses
- Social security numbers
- Medical record numbers

B. Who will be authorized to use or disclose (release) your health information?
MTFs who have treated you over the past ten years

C. Who may receive your health information?

- The Institutional Review Board (USU IRB)
- Infectious Disease Clinical Research Program (IDCRP)
- Other Military Treatment Facilities or Department of Defense representatives
- Henry M. Jackson Foundation and their representatives
- Neoteryx and their representatives
- Local, State and Federal Government representatives, when required by law
- Defense Health Agency (DHA)
- Food and Drug Administration (FDA)
- Centers for Disease Control and Prevention (CDC)
- National Institute of Allergy and Infectious Disease (NIAID) and their representatives

The researchers and those listed above agree to protect your health information by using and disclosing it only as permitted by you in this Authorization and as directed by state and federal law.
You need to be aware that some parties receiving your protected health information may not have the same obligations to protect your protected health information and may re-disclose your protected health information to parties not named here. If your protected health information is re-disclosed, it may no longer be protected by state or federal privacy laws. This authorization does not expire.

D. What if you decide not to sign this Authorization?
You do not have to sign this Authorization. If you decide not to sign the Authorization it will not affect your treatment, payment or enrollment in any health plans or affect your benefit eligibility. You will not be allowed to participate in this research study because your health information is required in order for you to take part in this study. The MHS will not condition (withhold or refuse) treatment that is not part of this study, payment, enrollment, or eligibility for benefits on whether you sign this Authorization.

E. Is your health information requested for future research studies?
Yes, your health information is requested for future research studies as specified below: Your health information will not be used for future research studies unless you give your permission by initialing your choice below:

____ YES, I give permission to use my health information for future research studies

____ NO, I do not give permission to use my health information for future research studies

F. Can you access your health information during the study?
You may have access to your health information at any time, unless your identifiers are permanently removed from the data.

G. Can you revoke this Authorization?
You may change your mind and revoke (take back) your Authorization at any time. However, if you revoke this Authorization, any person listed above may still use or disclose any already obtained health information as necessary to maintain the integrity or reliability of this research.

- If you revoke this Authorization, you may no longer be allowed to participate in this research study.
- If you want to revoke your Authorization, you must write to the Study Doctor.

H. Does this Authorization expire?
No, it does not expire

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

I. What else may you want to consider?

- No publication or public presentation about the research described above will reveal your identity without another signed Authorization from you.
- If all information that does or can identify you is removed from your health information, the remaining de-identified information will no longer be subject to this Authorization and may be used or disclosed for other purposes.
- In the event your health information is disclosed to an organization that is not covered by HIPAA, the privacy of your health information cannot be guaranteed.

If you have not already received a copy of the brochure entitled "Military Health System Notice of Privacy Practices," you may request one. DD Form 2005, Privacy Act Statement - Military Health Records (located on your medical records jacket), contains the Privacy Act Statement for the records. If you have any questions or concerns about your privacy rights, you should contact the Uniformed Services University of the Health Sciences (USU) Human Research Protections Program at 301-295-9534.

Who can answer my questions?

Any questions about this research study or if you believe you have received a research-related injury, you may contact the lead for the study at your hospital or the study Principal Investigator.

PRINCIPAL INVESTIGATOR: Overall director of this research study is Dr. Brian Agan at the Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences (a DoD institution).

Questions? Call Dr. Agan at 1-833-475-0881 or contact at this address: Uniformed Services University of the Health Sciences (USU), Department of Preventive Medicine and Biostatistics, 4301 Jones Bridge Road, Bethesda, MD 20814-5119

LOCAL PRINCIPAL INVESTIGATOR (Study Doctor): – [Sites will fill in]

The USU Institutional Review Board is the research ethics committee responsible for safeguarding your rights as a research participant. If you have any questions about your rights as a research participant or any other concerns that cannot be addressed by the Study Doctor, you can contact the Director of the Human Research Protections Program at (301) 295-9534.

INFORMED CONSENT DOCUMENT FOR AN OBSERVATIONAL COVID-19 RESEARCH STUDY: IDCRP-085: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)

Thank you for your interest in learning more about this study. Please read the following information to ensure that you would like to participate. The Department of Defense has sponsored this research study, led by the Infectious Disease Clinical Research Program at the Uniformed Services University of the Health Sciences (the military's medical school), to better understand risks and illness caused by the novel Coronavirus disease (**COVID-19**).

The COVID-19 pandemic is a global public health emergency. We are asking you to consider volunteering for this research study because you may have been tested for COVID-19. If you agree to participate, we are asking you to complete online questionnaires about your health history, possible exposures, symptoms and health care visits and to collect small blood samples using a simple in-home kit to look for immunity (antibodies against the virus). Your medical records in the military health system will be reviewed now and in the future for information related to COVID-19 risks, treatments, and health outcomes.

Who can participate?

The EPICC study is available to DoD beneficiaries of all ages who have confirmed COVID-19 or who meet current Centers for Disease Control and Prevention (CDC) criteria for testing for the virus that causes COVID-19.

This online-only section of the study is available to adult DoD beneficiaries who have been tested for COVID-19 and are able to send/receive email and complete online questionnaires. You do not have to know the result of your COVID-19 test to volunteer, nor does the test have to be positive.

KEY INFORMATION

- This is an observational study meaning we will look at your medical records and collect data and samples from you *but we will not give you any medicine or treatment*. Questions about your treatment should be directed to your doctor.
- Your participation is voluntary, your decision will not affect your care or any other benefits to which you are entitled. Your alternative to volunteering is to not participate.
- Your participation will last about 1 year.
- You may end your participation at any time without any consequences.
- There is no cost for participating.
- All information and samples you provide will be handled securely and in confidence. Only those involved in conducting this study will know you are enrolled.
- The information collected about you is for research purposes only. This information will not be used to guide your medical care.
- You may not personally benefit from this study. The information gained from this study may not be available in time to affect your care. The information we learn may help in caring for other future patients with COVID-19 or similar illnesses.
- Potential risks in participating include the following:
  - Blood draws can cause a risk of pain, bruising, bleeding, and rarely fainting or infection.
  - There may also be unforeseen risks associated with this study.
- If you are pregnant, there are no additional risks to you or your fetus.
- Once your identifying information has been removed from the collected data and specimens, additional consent will not be sought for future studies. This also applies if you withdraw from the study. Leftover samples will be stored and may be shared for future analyses related to COVID-19 or other infections.
- Volunteering for this study does not limit your ability to participate in another study of an experimental drug or vaccine. That decision would be made in discussion with your doctor and the other study’s investigators and is separate from this study. We may ask to collect additional blood to assess the new treatment’s effects.

What is involved in the study?
The following schedule describes the research study procedures and when they occur.

Today	• You will be asked to sign this informed consent form online that also includes HIPAA authorization (related to your privacy protections). • After consenting you will be provided a link to an online questionnaire that takes about 20 minutes to complete.
In 1 Month	The following procedures happen at each of the time points (1, 6 and 12 months): • Complete an online questionnaire that takes about 10 minutes to complete. We will send you an email reminder with the web link as it gets closer to the time. • Collect a small blood sample at home consisting of a few drops of blood from your finger, similar to blood glucose monitoring used by diabetic people. You will use a simple kit that we provide. You will then mail the kit into our lab using a pre-paid mailer.
In 6 Months	
In 12 Months	

You can choose to not provide these blood samples and still participate in the study. If you agree to participate in this portion of the study, we will inform you if you will be asked to provide the samples. Due to availability of study resources, not all participants who agree to provide a blood sample will be invited.
Please let us know your decision by signing your initials:

______ Yes, I DO want to participate in the at-home blood collection part of the study.

______ No, I DO NOT want to participate in the at-home blood collection part of the study.

Additional information

- Based on your answers to the questionnaires, we may contact you to discuss your health if you have particular symptoms or new illness that may be related to COVID-19.
- The US military regularly stores servicemembers blood samples obtained for medical surveillance in the DoD Serum Repository. If you are Active Duty or former military (since the 1990s) we plan to obtain stored blood specimens prior to and after your COVID-19 illness. You do not have to do anything additional for this.
- If you are pregnant or become pregnant during the study participation period, we will follow up with you until your baby is born. We may review your baby's medical records, and ask you questions about your baby's health.

Genetic Information
The study will be evaluating how a person's genes are associated with risk and outcomes related to COVID-19. The risks of studying your unique genetic code may be the identification of risk for developing certain diseases. We will not be studying general issues related to your genetic results because our research is focused on COVID-19 and related illnesses. We will not provide you with your genetic results or release any information regarding your results connected to your personal identification.
Please let us know your decision by signing your initials:

______Yes, I give permission to use my **genetic information** for COVID-19-related research.

______ No, I DO NOT give permission to use my **genetic information** for COVID-19 research.

Compensation:
You will receive payment (compensation) in the form of Amazon gift codes as follows for completion of the following study procedures:

- Completion of each online questionnaire: $10 (if completed off duty for servicemembers)
- Completion of each self-collected blood sample: $10

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

Under 24 USC 30, payment to Federal Employees and Active Duty military personnel for participation in research while on duty is limited to blood donation. They may not receive any payment or non-monetary compensation for participation in a research study unless they are off duty or on leave during the time they are participating in the protocol. There are no restrictions on payment while off-duty.

- Fax numbers
- E-mail addresses
- Social security numbers
- Medical record numbers

B. Who will be authorized to use or disclose (release) your health information?

MTFs who have treated you over the past ten years.

C. Who may receive your health information?

- The Institutional Review Board (USU IRB)
- Infectious Disease Clinical Research Program (IDCRP)
- Other Military Treatment Facilities or Department of Defense representatives
- Henry M. Jackson Foundation and their representatives
- Neoteryx and their representatives
- Local, State and Federal Government representatives, when required by law
- Defense Health Agency (DHA)

- Food and Drug Administration (FDA)
- Centers for Disease Control and Prevention (CDC)
- National Institute of Allergy and Infectious Disease (NIAID) and their representatives

The researchers and those listed above agree to protect your health information by using and disclosing it only as permitted by you in this Authorization and as directed by state and federal law.

You need to be aware that some parties receiving your protected health information may not have the same obligations to protect your protected health information and may re-disclose your protected health information to parties not named here. If your protected health information is re-disclosed, it may no longer be protected by state or federal privacy laws. This authorization does not expire.

D. What if you decide not to sign this Authorization?

You do not have to sign this Authorization. If you decide not to sign the Authorization it will not affect your treatment, payment or enrollment in any health plans or affect your benefit eligibility. You will not be allowed to participate in this research study because your health information is required in order for you to take part in this study. The MHS will not condition (withhold or refuse) treatment that is not part of this study, payment, enrollment, or eligibility for benefits on whether you sign this Authorization.

E. Is your health information requested for future research studies?

Yes, your health information is requested for future research studies as specified below: Your health information will not be used for future research studies unless you give your permission by initialing your choice below:

____ YES, I give permission to use my health information for future research studies

____ NO, I do not give permission to use my health information for future research studies

F. Can you access your health information during the study?

You may have access to your health information at any time, unless your identifiers are permanently removed from the data.

G. Can you revoke this Authorization?

You may change your mind and revoke (take back) your Authorization at any time. However, if you revoke this Authorization, any person listed above may still use or disclose any already obtained health information as necessary to maintain the integrity or reliability of this research.

- If you revoke this Authorization, you may no longer be allowed to participate in this research study.
- If you want to revoke your Authorization, you must write to the Study Doctor.

H. Does this Authorization expire?

No, it does not expire

I. What else may you want to consider?

- No publication or public presentation about the research described above will reveal your identity without another signed Authorization from you.
- If all information that does or can identify you is removed from your health information, the remaining de-identified information will no longer be subject to this Authorization and may be used or disclosed for other purposes.
- In the event your health information is disclosed to an organization that is not covered by HIPAA, the privacy of your health information cannot be guaranteed.

If you have not already received a copy of the brochure entitled “Military Health System Notice of Privacy Practices,” you may request one. DD Form 2005, Privacy Act Statement - Military Health Records (located on your medical records jacket), contains the Privacy Act Statement for the records. If you have any questions or concerns about your privacy rights, you should contact the Uniformed Services University of the Health Sciences (USU) Human Research Protectio at 301-295-9534.

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

Who can answer my questions?

Any questions about this research study or if you believe you have received a research-related injury, you may contact the study Principal Investigator (overall director based at USU).

PRINCIPAL INVESTIGATOR (Study Doctor): Overall director of this research study is Dr. Brian Agan at the Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences (a DoD institution).

Questions? Call Dr. Agan at 1-833-475-0881 or contact at this address: Uniformed Services University of the Health Sciences (USU), Department of Preventive Medicine and Biostatistics, 4301 Jones Bridge Road, Bethesda, MD 20814-5119

The USU Institutional Review Board is the research ethics committee responsible for safeguarding your rights as a research participant. If you have any questions about your rights as a research participant or any other concerns that cannot be addressed by the Study Doctor, you can contact the Director of the Human Research Protections Program at (301) 295-9534.

Your digital signature (signed using your mouse or finger) is voluntary consent to participate in this study. Your signature also acknowledges that you authorize personnel to use and disclose your Protected Health Information (PHI) collected about you for research purposes as described above.

A copy of this form will be sent to you by email.

ASSENT FORM FOR PARTICIPANTS AGED 7-17 YEARS

IDCRP-085: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)

We are doing a research study about people who are sick with a new illness called COVID-19. A research study is a way to find out about something. We are talking to you today because you may have had COVID-19, or you may have been close to people who are sick with COVID-19. We want to ask you to help us find out more about this illness.

You can decide if you want to be in this research study or not. We have discussed this research with your parent(s)/guardian, and they know that we are also asking you if you want to join. **If you want to participate in the study, your parent(s)/guardians need to give permission. If you do not want to be in the study, you do not have to, even if your parents have given permission.**

If you do want to be in the study, this is what will happen:

- We will ask you and your parent or guardian to sign a form letting us know that you want to be in the study.
- A staff member may rub the inside of your nose and mouth with a swab. This may be uncomfortable and may cause you to cough, sneeze, or bleed a little bit.
- A staff member may draw a small amount of blood from you. When the blood is drawn, it will be done using a clean needle that is stuck into your arm or a tube that is already connected to you. When your blood is drawn, it may hurt, but the hurt will go away before very long. You may bleed a little bit or get a bruise. Sometimes getting blood drawn can make some people faint, but this doesn't happen very often.
    - We will try our best to draw blood at the same time as your doctor so you don't have to be stuck with a needle as often.
- If there are any leftover samples from other tests that your doctors do, we will keep them so the leftovers can be tested.
- We will ask you to answer some questions about how you're feeling every day for the next 2 weeks using an online diary called Flu-PRO.
- ***If you are 8 or older***, we may ask you to use a simple kit to collect a sample from your nose and/or mouth, and take a small blood sample from your finger using a different simple kit. Your parent/guardian can help.
- ***If you are in the hospital***:
    - We may use ultrasound to look at your lungs, heart, arms and legs using a wand and gel.
    - We may ask to swab the inside of your bottom/butt. You can do this yourself, or your parent/guardian or a staff member can help. This may be uncomfortable.

Some of these procedures will be done while you are in a hospital or clinic. We may ask you to return there after you have left to do more tests and ask you more questions about how you are feeling. If you can't come back, we may ask you to collect your own samples with help from your parent/guardian.

Being in the study may not benefit you or help you. What we learn about the sickness from you may help other people not get sick in the future or help them get better faster. If we learn anything that will help you, we will let your doctors know right away.

For your participation in this research, you will receive $50 for each sample of blood that is collected from your arm after you leave the hospital, $10 for each sample you collect at home, and $10 for completing the 14-day Flu-PRO diary.

(USUHS) IRB 1
IRB NUMBER: 409136 (IDCRP-085)
IRB APPROVAL DATE: 07/28/2020
IRB EXPIRATION DATE: 07/25/2021

We will not tell other people that you are in this study. The only people that will know you are in the study are those people that work on the research study. Any information about you will have a number on it instead of your name. Only the researchers will know what your number is, and we will lock up that information. It will not be shared with or given to anyone except the hospital and people who make sure that research is done in a way that is safe.

You can ask questions if you don’t understand something about the study. You don’t have to be in this study. **The choice is yours**. You will still be taken care of even if you decide that you don’t want to be in the study. If you say okay now, but change your mind later, that’s okay too. Just tell one of the study doctors.

To be in this study, both you and your parent must agree.

If you want to be in this study, please sign and print your name. You will be offered a copy of this form to keep.

☐ **Yes, I will be in this research study.**

☐ **No, I do not want to be in this research study.**

INFORMED CONSENT DOCUMENT FOR AN OBSERVATIONAL COVID-19 RESEARCH STUDY: IDCRP-085: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)

Thank you for your interest in learning more about this study. Please read the following information to ensure your child would like to participate. The Department of Defense has sponsored this research study, led by the Infectious Disease Clinical Research Program at the Uniformed Services University of the Health Sciences (the military's medical school), to better understand risks and illness caused by the novel Coronavirus disease (COVID-19).

The COVID-19 pandemic is a global public health emergency. We are asking you to consider allowing your child to participate in this research study because your child may have COVID-19 and/or qualify for COVID-19 testing according to the Centers for Disease Control and Prevention (CDC) guidelines.

Who can participate?

This study is available to DoD beneficiaries of all ages (active duty and non-active duty) who have confirmed COVID-19 or who meet current Centers for Disease Control and Prevention (CDC) criteria for testing for the virus that causes COVID-19.

KEY INFORMATION

- This is an observational study, meaning we will look at your child's medical records and collect data and samples from your child, *but we will not give your child any medicine or treatment*. Questions about your child's treatment should be directed to your child's doctor.
- Your child's participation is voluntary, you and your child's decision will not affect your child's care or any other benefits to which he or she is entitled. Your child's alternative to volunteering is to not participate.
- Your child's participation will last about 1 year. If your child is not sick now but later develops symptoms, we will follow up with them for 1 year from the time they became ill.
- If your child is unable to actively participate in the assent process, for example if they are incapacitated due to illness, you may do that on their behalf. If they later become capable of assent, they will be approached to give their assent.
- You or your child may end his or her participation at any time without any consequences.
- There is no cost for participating.
- All information and samples your child provides will be handled securely and in confidence. Only those involved in conducting this study will know your child is enrolled.
- The information collected about your child is for research purposes only. This information will not be used to guide your child's medical care.
- Your child may not personally benefit from this study. The information gained from this study may not be available in time to affect your child's care. The information we learn may help in caring for other future patients with COVID-19 or similar pandemics.
- Leftover samples from tests ordered by your child's doctor will be stored and may be shared for future analyses related to COVID-19 or other infections.
- Potential risks in participating include the following:
    - Blood draws can cause a risk of pain, bruising, bleeding, and rarely fainting or infection.
    - Nose, mouth, and rectal swabs may cause discomfort but are generally well tolerated.
    - There may also be unforeseen risks associated with this study.
- If your child is pregnant, we will ask to follow your child until your grandchild is born. There are no known additional risks to your child or her fetus.
- Once your child's identifying information has been removed from the collected data and specimens, additional consent will not be required for future studies. This also applies if your child withdraws from the study.
- Volunteering for this study does not limit your child's ability to participate in another study of an experimental drug or vaccine. That decision would be made in discussion with your child's doctor and the other study's investigators and is separate from this study. If your child receives an experimental drug or vaccine, we may collect an additional blood sample to study the new treatment's effects.

IF YOUR CHILD IS CURRENTLY HOSPITALIZED:

During your child's hospitalization:

- ✓ We will review your child's medical records now and in the future for information related to your child's health.
- ✓ Blood samples for research will be collected.
- ✓ Nose, mouth and rectum sample will be collected for identifying and counting the virus.
  If your child is 8 years old or older, we may ask your child to collect some of their own samples with your help.
- ✓ We may do an ultrasound to look at your child's lungs, heart, and veins.
- ✓ If your child is 7 or older, we will ask them to complete a daily symptom diary for 14 days.

Samples will be collected following the below schedule as feasible, however it is possible that not all samples will be collected.

Procedure / Assessment	**Day 0 (Today)**	**Days 3 and 7**	**If hospitalized longer than 7 days: samples obtained weekly until discharge**
Nose, mouth, and rectal samples	✓	✓	✓
Blood collection for research	✓	✓	✓
Ultrasound of lungs, heart and veins *	✓	✓	
Flu-PRO Symptom Diary (14 days)**	✓	✓	✓

* May be performed on or around hospital days 0 (admission), 1, and 3, based on availability.
** For participants 7 years of age and older. Does not all have to be completed while hospitalized.

IF YOUR CHILD IS NOT HOSPITALIZED:

If your child is 8 years old or older, we may request self-collection of a nose and/or mouth sample to check for the virus, as well as self-collection of blood using a sample kit to perform blood collection to look for immunity (antibodies against the virus). Your child may collect the nose and/or mouth samples and blood (few droplets from fingerstick) by themselves, or you may assist them with sample collection. *For at-home collections you will be given instructions and pre-addressed mailing materials to return the specimens.* Your child's medical records in the military health system will be reviewed now and in the future for information related to COVID-19. If your child is admitted to the hospital for COVID-19 symptoms, we may ask to collect additional samples.

Today	• Blood collection – we will draw your child's blood, from a vein (about 25 mL or 5 teaspoons; total blood collected may be less based on body weight, age, and other factors). We may also collect another blood sample (a few drops from finger/heel prick) using a simple device similar to blood glucose monitoring used by diabetic people. • We will collect samples from your child's nose and/or mouth using a swab or other simple collection method. The type of sample may change during your participation in the study as we learn more about the virus. • *For children 8 years of age and older*: your child may be asked to collect their own samples with your help. • *For children age 7 and older*: you will assist your child with starting a daily online symptom diary called Flu-PRO.
In 1 Week	• Blood collection (same as above - either at home or in clinic). • *For children age 7 and older:* Continue to assist your child with the Flu-PRO symptom diary.

FOLLOW-UP VISITS FOR ALL PARTICIPANTS

In 2 Weeks	• *For children age 7 and older:* Finish the Flu-PRO daily online symptom diary (14 days total). • Nose and/or mouth sample (same as above, either at home or in clinic). • Blood collection (same as above - either at home or in clinic).
In 1 Month	• Blood collection (same as above - either at home or in clinic). • *If your child was hospitalized,* we will ask to collect a follow-up rectal swab sample to check for presence of the virus, if you return to the hospital/clinic for this visit.
In 6 Months	• Blood collection (same as above - either at home or in clinic).
In 12 Months	

Additional information

- The total amount of blood collected for research while hospitalized or during a return visit at the hospital at one sitting will be up to 25 mL (5 teaspoons). Blood collection volume and frequency may be reduced to comply with safety limits. The amount of blood drawn for research will not exceed the lesser of 50 mL or 3 mL per kg in any 8 week period, and collection will not occur more frequently than 2 times per week. For comparison, a typical blood drive donation is 470 mL (about 2 cups) in one day. To minimize discomfort to your child, we will try to coordinate with your healthcare providers so that the collection of research blood samples happens at the same time as standard blood draws.
- Your child can choose not to provide samples at the time points listed above and still participate in the study.
- You will be asked to read, sign, and date this consent form after the study has been verbally explained to you by one of the research staff members and all your questions have been answered. Your child will be asked to read and sign an assent form if he or she is between the ages of 7 and 17 years old.
- Throughout your child's participation in the study, we will collect leftover samples from tests their doctors order such as blood, swabs, urine, etc. We will collect samples dating back to the time your child became ill. We will study these materials for COVID-19 and related illnesses. You do not have to do anything additional for this.

Genetic Information

The study is focusing on understanding risks related to COVID-19, including how genetic factors impact COVID-19. The risks of studying your child's unique genetic code may be the identification of risk for developing certain diseases. We will not be studying general issues related to your child's genetic results, our research is focused on COVID-19 and related illnesses. We will not provide you or your child with your child's genetic results or release any information regarding your child's results connected to his or her personal identification.
Please let us know your decision by signing your initials:

_______ Yes, I give permission to use my child's **genetic information** for COVID-19-related research

_______ No, I DO NOT give permission to use my child's **genetic information** for COVID-19 research

Compensation:

Your child will not receive any compensation while hospitalized. Your child will receive payment (compensation) in the form of gift cards as follows for completion of the following study procedures:

- Completion of each at-home self-collected sample: $10
- Completion of 14-day Flu-PRO Symptom Diary: $10 total *(for participants 7 years of age and older)*
- Blood draws at hospital/clinic after your child leaves the hospital: $50 per blood draw

HIPAA: AUTHORIZATION TO USE AND/OR DISCLOSE PROTECTED HEALTH INFORMATION FOR RESEARCH

PI Name and Rank: Brian Agan, MD, DrPH

Corps and Service/Organization: Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences
Title of Research Study: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential

Purpose of this Document:
An Authorization is your signed permission to use or disclose your child's health information. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule, as implemented by the Department of Defense (DoD), permits the Military Health System (MHS) to use or disclose your child's health information with a valid Authorization. The MHS is defined as all DoD health plans and DoD health care providers that are organized under the management authority of, or in the case of covered individual providers, assigned to or employed by, the Defense Health Agency (DHA), the Army, the Navy, or the Air Force. A valid Authorization must include the core elements and required statements as contained in this document.
Please read the information below and ask questions about anything you do not understand before deciding to give permission for the use and disclosure of your child's health information.
The Health Insurance Portability & Accountability Act of 1996, Public Law 104-109 (also known as HIPAA), establishes privacy standards to protect your child's health information. This law requires the researchers to obtain your authorization (by signing this form) before they use or disclose your child's protected health information for research purposes in the study discussed in this form. Note: Protected health information of military service members may be used or disclosed for activities deemed necessary by appropriate military command authorities to ensure the proper execution of the military mission.
By signing this authorization, you give your permission for information gained from your child's participation in this study to be published in medical literature, discussed for educational purposes, and used generally to further medical science. Your child will not be personally identified; all information will be presented as anonymous data.

A. What health information will be used or disclosed about your child?

- Names
- Address
- Date of birth
- DoD identification number
- Health information
- Health plan beneficiary numbers
- Phone numbers
- Fax numbers
- E-mail addresses
- Social security numbers
- Medical record numbers

B. Who will be authorized to use or disclose (release) your child's health information?
MTFs who have treated your child over the past ten years

C. Who will be authorized to use or disclose (release) your child's health information and who may receive your child's health information?

- The Institutional Review Board (USU IRB)
- Infectious Disease Clinical Research Program (IDCRP)
- Other Military Treatment Facilities or Department of Defense representatives
- Henry M. Jackson Foundation and their representatives
- Neoteryx and their representatives
- Local, State and Federal Government representatives, when required by law
- Defense Health Agency (DHA)
- Food and Drug Administration (FDA)
- Centers for Disease Control and Prevention (CDC)
- National Institute of Allergy and Infectious Disease (NIAID) and their representatives

The researchers and those listed above agree to protect your child's health information by using and disclosing it only as permitted by you in this Authorization and as directed by state and federal law.
You need to be aware that some parties receiving your child's protected health information may not have the same obligations to protect your child's protected health information and may re-disclose your child's protected health information to parties not named here. If your child's protected health information is re-disclosed, it may no longer be protected by state or federal privacy laws.

D. What if you decide not to sign this Authorization?

You do not have to sign this Authorization. If you decide not to sign the Authorization it will not affect your child's treatment, payment or enrollment in any health plans or affect your child's benefit eligibility. Your child will not be allowed to participate in this research study because your child's health information is required in order for them to take part in this study. The MHS will not condition (withhold or refuse) treatment that is not part of this study, payment, enrollment, or eligibility for benefits on whether you sign this Authorization.

E. Is your child's health information requested for future research studies?

Yes, your child's health information is requested for future research studies as specified below: Your child's health information will not be used for future research studies unless you give your permission by initialing your choice below:

____ YES, I give permission to use my child's health information for future research studies

____ NO, I do not give permission to use my child's health information for future research studies

F. Can you access your child's health information during the study?

You may have access to your child's health information at any time, unless their identifiers are permanently removed from the data.

G. Can you revoke this Authorization?

You may change your mind and revoke (take back) your Authorization at any time. However, if you revoke this Authorization, any person listed above may still use or disclose any already obtained health information as necessary to maintain the integrity or reliability of this research.

- If you revoke this Authorization, your child may no longer be allowed to participate in this research study.
- If you want to revoke your Authorization, you must write to the Study Doctor.

H. Does this Authorization expire?

No, it does not expire

I. What else may you want to consider?

- No publication or public presentation about the research described above will reveal your child's identity without another signed Authorization from you.
- If all information that does or can identify your child is removed from your health information, the remaining de-identified information will no longer be subject to this Authorization and may be used or disclosed for other purposes.
- In the event your child's health information is disclosed to an organization that is not covered by HIPAA, the privacy of your child's health information cannot be guaranteed.

If you have not already received a copy of the brochure entitled "Military Health System Notice of Privacy Practices," you may request one. DD Form 2005, Privacy Act Statement - Military Health Records (located on your child's medical records jacket), contains the Privacy Act Statement for the records. If you have any questions or concerns about your child's privacy rights, you should contact the USU Human Research Protections Program at 301-295-9534.

<u>Who can answer my questions?</u>

Any questions about this research study or if you believe your child's child has received a research-related injury, you may contact the lead for the study at your child's hospital (overall director based at USU) or the study Principal Investigator.

PRINCIPAL INVESTIGATOR: Overall director of this research study is Dr. Brian Agan at the Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences (a DoD institution).

Questions? Call Dr. Agan at 1-833-475-0881 or contact at this address: Uniformed Services University of the Health Sciences (USU), Department of Preventive Medicine and Biostatistics, 4301 Jones Bridge Road, Bethesda, MD 20814-5119

LOCAL PRINCIPAL INVESTIGATOR (Study Doctor): – [Sites will fill in]

The USU Institutional Review Board is the research ethics committee responsible for safeguarding your child's rights as a research participant. If you have any questions about your child's rights as a research participant or any other concerns that cannot be addressed by the <u>Study Doctor</u>, you can contact the Director of the Human Research Protections Program at (301) 295-9534.

SIGNATURE PAGE:

You have been asked to provide permission for your child, for whom you are either the parent or legal representative, to participate in this research study. Your signature indicates that you have had this information presented to you and your child, have had the opportunity to ask questions about the research and your child's participation, and agree to permit them to participate in the study. Your signature also acknowledges that you authorize personnel to use and disclose your child's Protected Health Information (PHI) collected about your child for research purposes as described above. Further, your signature indicates that you have been offered a copy of this consent document. You will also be offered a copy of your child's assent document.

Printed Name of Parent/Guardian	Relationship to Participant
Parent/Guardian Signature	Today's Date
Printed Name of Study Representative	
Study Representative Signature	Today's Date

Verbal/physical limitation section: use the section below only if applicable

The subject's parent/guardian, ____ (name), has verbally consented for their child to participate in the study as described and also authorizes the use and disclosure their child's health information as described. The subject's parent/guardian is coherent and has understood the nature and consequences of participation in the study, but the subject's parent/guardian is physically disabled or in isolation and is unable to sign.

The consent and authorization information were accurately explained. The subject's parent/guardian was given the opportunity to ask questions. All questions were answered before giving verbal consent. The subject's parent/guardian apparently understood the information. The informed consent and authorization were given freely by the subject's parent/guardian.

Dr Munster and all,

We are enthused to start this collaboration on the EPICC project. See below for the next two steps:

1. Below is a description of the proposed scope of this work so we can get the agreements in place to send specimens and data to the Munster Lab. Is the below accurate?
    a. IDCRP/USU sends up to 500 uL of sera from 50 subjects and associated metadata from the EPICC study.
    b. Munster Lab perform wild type MERS, SARS-CoV-1 and SARS-COV2 neutralization on up to 50 SARS-CoV-2 positive sera with and without cross binding to MERS and SARS-1 (as determined by the Broder lab) with an objective to examine how cross-binding correlates with wildtype cross-neutralization.
2. For your NIH NHSR determination, please find the protocol, CV, and ICF attached.

Thanks, let me know if you have any questions

Simon

Subject: RE: nhps and CoV-2 question

Hi all

Following up on the below:

1/ See current protocol and IRB approval to inform NIAID NHSR determination

2/ CCing in Stephanie Cammarata for agreements

3/ Eric and Chris: to confirm, is the proposed project synopsis essentially wt VNT of n = ?25 SARS-CoV-2 positive sera with and without cross binding to MERS and SARS-1 with an aim to examine how cross-binding correlates with wildtype cross-neutralization?

Thanks

Simon

Subject: RE: nhps and CoV-2 question

Dr Munster,

I am one of the AIs on the EPICC study and the director of the COVID19 research area at IDCRP. Pleased to meet you and looking forward to this EPICC subproject. Dr Brian Again is the EPICC PI and deputy science director of IDCRP and Caroline English the CRM of EPICC. Stephanie Cammarata is our IDCRP Agreements Officer (among other roles). Below are the relatively simple next logistic steps required to execute this really interesting serology subproject.

1. Ethics review (NIAID NHSR determination) - Attached is the EPICC protocol v 9 for your preliminary review. I will send ICF and protocol for version 10. Caroline are you able to send the relevant DoD determination?

2. I discussed with Stephanie Cammarata and this should just require a SLA between USU and NIAID. We can initiate this on our side.

3. Study synopsis – for the purposes of #2, we'd need a brief synopsis. Eric and Chris, this sounds like wt VNT of n = ?25 SARS-CoV-2 positive sera with and without cross binding to MERS and

> SARS-1 with an aim to examine how cross-binding correlates with wildtype cross-neutralization?

Happy to assist on all the above as needed

Simon

Subject: [EXTERNAL] RE: nhps and CoV-2 question

Thanks Eric,

Sounds good, would be easy to determine any neutralizing cross-reactivity with MERS, SARS-2/2

Cheers,

Vincent Munster, PhD

Subject: Re: nhps and CoV-2 question

Hi Vincent,

Looping back to this topic regarding MERS/SARS-CoV VNs/PRNTs and bringing in the IDCRP leadership that can begin an approval process for non-human research determination.

We have a handful of SARS-CoV-2 IgG positive serum samples (~15 - 20) with fairly high cross-reactivity to SARS-CoV-1 and MERS-CoV. Some of these serum samples are longitudinal collections from the same subject; over time, the cross-reactivity decreases as the IgG response matures and becomes monotypic for SARS-CoV-2. It would be interesting to write a short letter about cross-reactivity and cross-neutralization between SARS-CoV-2 IgG antibodies and high priority zoonotic bCoVs.

Subject: Re: nhps and CoV-2 question

Hi Vincent and Emmie,

Any interest or bandwidth for testing SARS-CoV-2 patient serum samples that are highly cross-reactive with MERS-CoV and SARS-CoV-1 spike proteins to assess cross-neutralization potential? We have a handful of SARS-CoV-2 seroconverts that have a strong polyclonal response to SARS-CoV-1 and MERS-CoV, could be an interesting short translational letter if the antisera retains neutralizing antibodies.

MEMORANDUM FOR BRIAN K AGAN, MD , P and R - Uniformed Services University of the Health

Sciences (USUHS) SUBJECT: USUHS IRB (FWA 00001628; DoD Assurance P60001) Approval

Modification of Protocol 409136 (IDCRP-085) for Human Subjects Participation

The modification to your Minimal Risk 32 CFR 219 / 21 CFR 56 human subjects research protocol 409136 (IDCRP-085) (ref # 931762) titled "***Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)"*** was reviewed and approved for execution on October 15, 2020 by Dr. Edmund G. Howe, M.D., J.D., chair USUHS IRB under the provision of 32 CFR 219.110(b)(2). This approval will be reported to the USUHS IRB scheduled to meet on October 22, 2020.

The protocol outlines a systematic approach to collection of clinical specimens and data by adapting standard procedures for conducting clinical characterizations of severe emerging infections as published by the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) network (ISARIC/WHO Clinical Characterization Protocol for Severe Emerging Infections, version 3.1). .

This action approves the modification to update Appendix A of the protocol. This will reflect recent changes approved in the ICD/HIPAA document and set forth in the recent partial HIPAA waiver authorization indicating what information may be obtained from MDR or J6.

Authorization to conduct protocol 409136 (IDCRP-085) will automatically expire on July 25, 2021. If you plan to continue data collection or analysis beyond this date, IRB approval for continuation is required. Please submit a Continuing Review Form via EIRB to the IRB Office 60 days prior to your expiration date.

You are required to submit amendments to this protocol, changes to the informed consent document (if applicable), adverse event reports, and other information pertinent to human research for this project. No changes to this protocol may be implemented prior to IRB approval. If you have questions regarding this IRB action or questions of a more general nature concerning human participation in research, please contact Chris Murphy at christopher.murphy.ctr@usuhs.edu or (301) 319-0444.

The Protocol Contact(s) will receive all important system notifications along with the Principal Investigator. (i.e. The protocol contact(s) are typically either the Protocol Coordinator or the Principal Investigator themselves).

3.4 If applicable, please select the Designated Site Approval(s):

Add the name of the individual authorized to approve and sign off on this protocol from your Site (e.g. the Site Chair).

4.0 Project Information

4.1 Is this a research study?

● Yes ○ No

4.2 What type of research is this?

☑ Biomedical Research

☐ Clinical trial (FDA regulated)
☐ Behavioral Research
☐ Educational Research
☐ Psychosocial Research
☐ Oral History
☐ Other

4.4 Is this human subjects research (Activities that include both a systematic investigation designed to develop or contribute to generalizable knowledge AND involve a living individual about whom an investigator conducting research obtains data through intervention or interaction with the individual or identifiable private information. Activities covered by 32 CFR 219.101(a) (including exempt research involving human subjects) and DoDI 3216.02)?

● Yes ○ No

4.5 Do you believe this human subjects research is exempt from IRB review?

○ Yes ● No

5.0 Personnel Details

5.1 Will you have a Research Monitor for this study?

○ Yes
● No
○ N/A

Research Monitor Role:

If applicable, you may nominate an individual to serve as the Research Monitor:

No Users have been selected.

6.0 Data/Specimens

6.1 Does the study involve the use of existing data or specimens only (no interaction with human subjects)?

○ Yes ● No

7.0 Funding and Disclosures

7.1 Source of Funding:

Funding Source	Funding Type	Amount

NIAID IAA	: Other	56632

Total amount of funding:

56632

7.2 Do you or any other Investigator(s) have a disclosure of a personal interest or financial nature significant with sponsor(s), product(s), instrument(s) and/or company(ies) involved in this study?

○ Yes ● No

9.0 Study Details

9.1 Abstract/ Summary:

Summarize the proposed study in 500 words or less, to include the purpose, the subject population, the study's design type, and procedures

The overarching objective of the Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC) protocol is to provide the Military Health System (MHS) with a contingency protocol intended for activation at Military Treatment Facilities (MTFs) during outbreaks to allow clinical investigation of severe or potentially severe acute infections with pathogens of concern to public health and U.S. military medical readiness. The protocol outlines a systematic approach to collection of clinical specimens and data by adapting standard procedures for conducting clinical characterizations of severe emerging infections as published by the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) network (ISARIC/WHO Clinical Characterisation Protocol for Severe Emerging Infections, version 3.1).
The EPICC protocol can be conducted as a multi-site study at participating MTFs, and overall protocol oversight will be coordinated centrally by the Uniformed Services University's Infectious Disease Clinical Research Program (IDCRP). MHS-wide enrollment for online participation will be coordinated by the IDCRP Program Coordinating Center (PCC).
EPICC activities will be executed by clinical study teams comprising existing IDCRP clinical research investigators and staff located at each MTF and protocol investigators from relevant hospital departments. The protocol is designed to be modified to accommodate longitudinal observational study of specific emerging or re-emerging pathogens. Protocol modifications will describe methods for serial collection and clinical characterization of specimens and associated demographic, laboratory, clinical, and other data specific for the pathogen of interest and associated study population(s).

9.2 Key Words:

Provide up to 5 key words that identify the broad topic(s) of your study

Epidemiology, Immunology, Emerging Infectious Diseases

9.3 Background and Significance:

Include a literature review that describes in detail the rationale for conducting the study. Include descriptions of any preliminary studies and findings that led to the development of the protocol. The background section should clearly support the choice of study variables and explain the basis for the research questions and/or study hypotheses. This section establishes the relevance of the study and explains the applicability of its findings

The EPICC protocol is intended to serve as a foundation for modification to allow the observational, longitudinal study of specific emerging or re-emerging pathogens causing disease with pandemic potential within the MHS. Modifications responsive to specific diseases will be described to include a schedule for serial collection of clinical specimens and data and methods for recruiting, enrolling, and observational study within the desired MHS study population(s). In general, enrolled participants (eligible adults or children) who are known or suspected cases at MTFs as inpatients or in isolation settings will undergo serial collections of biological specimens and clinical and laboratory data at day of enrollment and during the duration of hospitalization or isolation, with follow-up specimen and data collection convalescent and long-term follow-up timepoints. The study design can also include clinical observational investigation in outpatients. The major focus of this protocol is to conduct clinical observational study in symptomatic individuals; however, there is also the opportunity to enroll and follow (potentially at a reduced specimen and data collection frequency relative to symptomatic participants) individuals who are asymptomatic but who are at high/some risk for exposure. Inclusion of an asymptomatic comparator cohort could provide insight on risk factors or biomarkers associated with symptomatic versus asymptomatic presentations. The protocol supports observational, longitudinal collection of clinical specimens and data with a goal of identifying host biomarkers that predict severity of illness, resistance to infection, treatment failure, etc. If volunteers receive an experimental treatment product under eIND, the data collected through the EPICC protocol may help inform about the safety and efficacy of that product.

In subsequent sections, relevant background information on acute respiratory infections (ARI) of pandemic potential is provided, followed by specific schedule of events and other details to allow observational study of an ongoing outbreak of the 2019 novel coronavirus (COVID-19).

Acute Respiratory Infections of Pandemic Potential: Epidemiology, Immunology and Clinical Characteristics

ARI Case Definitions

To characterize the epidemiology, immunology and clinical features of novel pathogens associated with severe ARI, case definitions appropriate to emerging infection scenarios will be utilized. These definitions will vary by the availability and result of laboratory-based diagnostic tests.

I. *For laboratory-confirmed cases*, the case definition includes the presence of laboratory-confirmed infection with an agent of severe ARI (e.g., SARS-CoV-2, influenza A/H7N9, MERS-CoV, SARS, etc.).

OR

II. For persons under investigation (PUI), the case definition includes:

1. The current CDC case definition for a PUI for a respiratory pathogen under study.
2. An unknown or pending laboratory confirmation of an agent of severe ARI.

III. For individuals who are asymptomatic and have had recent high-risk exposure to the pathogen of interest such that they have increased their risk for infection, 1 or more of the following criteria must be met:

1. Unprotected exposure (for e.g., < 14 days of illness onset, modified commensurate with evolving epidemiologic information) with confirmed or suspected cases of human infection with a novel respiratory pathogen. Close contact is typically defined as coming within about 6 feet (2 meters) of a confirmed or suspected case while the case was ill (beginning 1 day prior to illness onset and continuing until resolution of illness).
2. Unprotected exposure to infectious pathogens in a laboratory setting.
3. If exigencies warrant, then asymptomatic/high exposure risk individuals in isolation may be considered for enrollment.

Acute respiratory infections (ARI) are among the most common infectious diseases. Due to conditions and circumstances of military training and deployment (e.g., crowding, inadequate hygiene practices, physical stress, etc.), military personnel in congregate settings are at increased risk for outbreaks due to ARI. There are a number of emerging viral respiratory pathogens to which military forces may be exposed, that carry substantial importation risk, and that also have significant pandemic potential. Recent and current examples are described below.

1. Influenza A/H5N1 was first identified in the human population in Hong Kong in 1997. Since 2003, 16 countries have reported 668 confirmed cases and 393 deaths due to influenza A/H5N1 (as of 1 Nov 2014). The global case fatality rate for influenza A/H5N1 infection is 60%, and the estimates range widely (0% to 100%) by country. While the significant morbidity and mortality of influenza A/H5N1 infection is readily apparent, its occurrence among humans has been relatively infrequent to date. Circulation of H5N1 predominates in poultry, currently the main reservoir, in Asia and northeast Africa. Host-to-human (i.e., zoonotic transmission of A/H5N1) infections are unpredictable and “remain rare

despite frequent and widespread contact with infected poultry and contaminated environments" (1). The majority (71%) of cases of influenza A/H5N1 have had recent exposure to live birds or contaminated areas. Cases of influenza A/H5N1 to date have been relatively young (median age: 19 years) (2). Exposure to other cases of influenza A/H5N1 has not been a major risk factor to date, suggesting that the likelihood of human-to-human transmission of this particular strain remains low (R0< 1) (3). The severity of influenza A/H5N1 is dependent upon the strain associated with infection /disease. Among strains with low pathogenicity, generally mild, non-fatal illnesses have been observed, ranging from conjunctivitis to influenza-like illness (e.g., fever, cough, sore throat, muscle aches) to lower respiratory disease (pneumonia). Among strains with high pathogenicity, the disease spectrum has ranged from a milder febrile respiratory illness to severe disease (e.g., dyspnea, hypoxemia, pneumonia, acute respiratory failure) with multi-organ disease, sometimes accompanied by nausea, abdominal pain, diarrhea, vomiting and delirium. The high mortality rate (~60%) associated with pathogenic strains of influenza A/H5N1 has been reported from multiple studies (2).

2. Influenza A/H7N9 infection of humans was first identified in China in March 2013. Since then China has reported 453 confirmed cases and 175 deaths due to influenza A/H7N9 (WHO 2014). As with influenza A/H5N1, most of the cases had recent exposures to live poultry or had visited areas where live poultry was sold (75%) (3). By contrast to influenza A/H5N1, the host reservoir, main exposures, routes of transmission, and distribution and prevalence of influenza A/H7N9 among humans and animals are unknown. Influenza A/H7N9 does not appear to transmit easily from birds or the environment to humans. In addition, reported cases of Influenza A/H7N9 have not demonstrated high transmissibility between humans to date, suggesting that the risk of pandemic potential currently remains low (4). Though limited in its reach, influenza A/H7N9 infection has been associated with significant mortality: approximately 39% of cases resulted in a fatal outcome (4).
3. The coronavirus associated with the Middle Eastern Respiratory Syndrome (MERS-CoV) was first identified in Saudi Arabia in 2012 (5). Several outbreaks have since occurred, originating in Middle Eastern countries and spreading globally, albeit to a limited extent, by international travelers. Symptoms including fever, rigors, malaise, cough, myalgia, headache, shortness of breath, anorexia, diarrhea and abdominal pain were observed in MERS-CoV cases (6,7). As of October 2014, a total of 897 confirmed cases and 325 deaths (case fatality rate [CFR]: 36%) have been reported worldwide (WHO 2014). In 2013, two studies concluded that MERS-CoV did not yet exhibit pandemic potential, with an estimated basic reproduction number less than 1.0 (8, 9). Some research indicates that camels may act as the host reservoir for MERS-CoV, although evidence is inconclusive (10). Human-to-human transmission of MERS-CoV has been observed in healthcare settings, possibly due to greater infectiousness in the later stages of illness; however, evidence that may further elucidate risk factors for transmission is limited (6, 7).
4. The 2002-3 pandemic of Severe Acute Respiratory Syndrome (SARS), also due to a novel Coronavirus, originated in China's Guangdong Province and resulted in 8,422 probable cases and 916 deaths reported from 29 countries (mostly in mainland China, where 63% of cases and 38% of deaths occurred) (11). The global case fatality rate due to SARS was estimated to be 11% (11). Although the host reservoir remains unknown, some studies have found coronaviruses similar to the SARS coronavirus circulating in bat populations (12). Transmission in human populations occurs by direct contact with the infectious respiratory droplets and/or fomites via the eyes, nose, and mouth (13). The incubation period ranges from 1-14 days (mean 4-6 days) and transmissibility appears to increase with severity of illness (greatest at day 10) (14). Attack rates ranged widely by geographic region from 2.2 per 100,000 in Guangdong Province to 25.6 per 100,000 in Hong Kong (14). Risk factors for infection include occupation as a healthcare worker (21% of all probable cases), household contact with a probable case, older age, male sex and existing illnesses (14). Symptoms include fever, dry cough, dyspnea, headache and hypoxemia (14).
5. Since December 2019 through March 2020, the **2019 novel coronavirus (SARS-CoV-2) causing "coronavirus disease 2019" (COVID-19)** has spread from Wuhan, China to 64 countries and has led to more than 88,948 confirmed cases globally, including 80,174 confirmed cases in China and 8,774 confirmed cases outside of China (15). To date, there have been 2,915 deaths in China and 128 deaths outside of China. As of 03 March 2020, in the United States there are 60 confirmed cases (22 travel-related, 11 person-to-person spread, 27 under investigation) and a total of 6 deaths (16). Individuals with COVID-19 can present with fever, and cough, ground-glass opacity on chest computed tomography (CT), and lymphocytopenia (17). The case-fatality rate (CFR) appears to be highly variable with early reports of 8-15% in older adults infected in Hubei Province (CFR is increased in adults with comorbid conditions who develop respiratory symptoms) but likely no higher than 1-2% outside of Hubei (though data is limited and this will depend on accurate detection of those with mild disease) (18). Several risk factors, including age, history of smoking, maximum body temperature on hospital admission, respiratory failure, albumin, and C-reactive protein, appear associated with increased risk for progression to pneumonia among COVID-19 hospitalized patients (19). Risk factors of disease progression and magnitude of clinical severity are incompletely understood and require further study. SARS-CoV-2 is believed to be transmitted primarily via person-to-person, such as through close

contact (within about 6 feet) and exposure to respiratory droplets from an infected individual who coughs or sneezes (20). Evidence exists for transmission of SARS-CoV-2 via the oral-fecal route, as viral nucleotide was detected in rectal swabs and blood later in the course of infection when virus was not detected in oral swabs (21). On the population level, there is a poorly-defined risk of transmission via asymptomatic infection (22). The occurrence of asymptomatic infections has raised concerns about the rapid spread of transmission to vulnerable populations (21).

9.4 Objectives/Specific Aims/Research Questions:

Describe the purpose and objective(s) of the study, specific aims, and/or research questions/hypotheses

General Goals and Objectives:

1. To describe the natural history of clinical disease
2. To identify risk factors for infection and severe clinical course
3. To characterize the host immune response to infection
4. To evaluate the correlation between symptom severity, virologic/microbiologic characteristics, the host immune response and clinical course and outcome
5. To develop and/or operationally assess diagnostic and prognostic tools for the study of novel pathogens / emerging infectious diseases
6. To establish a clinical and laboratory database, and related specimen repository, for future studies of novel pathogens / emerging infectious diseases
7. To investigate efficacy of emergency Investigational New Drug (eIND) therapies that may be administered to enrolled study participants during the course of clinical care

For COVID-19 / SARS-CoV-2 infection, clinical and demographic data will be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest to include, but not limited to, the following:

- Incubation period
- Duration of illness / symptoms
- Duration of functional disability
- Duration of shedding from respiratory and gastrointestinal tract
- Incidence and duration of viremia
- Predictors of severe disease: clinical signs, symptoms, laboratory features; host factors, eg smoking, vaping, alcohol consumption, comorbid illness/conditions, occupational health factors influencing lung disease; host biomarkers; virologic (strain/virulence) attributes
- Supportive management required: O_2, HFNC, NIPPV, ventilation; hemodynamics
- Complications: e.g., bacterial pneumonia; bacteremia; AKI; liver injury; CNS involvement, etc.
- Outcomes: resolution of symptoms; return to pre-illness functional status; requirement for O_2; development / exacerbation of reactive airway disease; pulmonary function; resolution of medical complications; new Rx requirements, eg bronchodilators; other sequelae
- Development of immunity (i.e., correlates), kinetics, duration of antibody detection
- Relationship between acute illness (or pre-illness) HCoV titer and infection, outcome, virologic parameters
- Costs of care, costs of duty days lost

9.5 Study Design:

Describe study design in one to two sentences (e.g., prospective, use of existing records/data /specimens, observational, cross-sectional, interventional, randomized, placebo-controlled, cohort, etc.). Specify the phase – Phase I, II, III, or IV – for FDA-regulated investigational drug research

A prospective, longitudinal cohort study of novel pathogens / emerging infections with pandemic potential

9.6 Target Population:

Describe the population to whom the study findings will be generalized

Study findings will be generalized and applicable to all populations that travel to or reside in disease endemic areas or live within an area that has been exposed to infectious pathogens with pandemic potential; some of which include military personnel and the general public.

9.7 Benefit to the DoD:

State how this study will impact or be of benefit to the Department of Defense

Infectious diseases are a significant source of morbidity among military forces. Infectious disease outbreaks compromise force readiness and interfere with training programs. Strategies to characterize and ultimately to treat and prevent the major infectious disease threats to military personnel are urgently needed.

10.0

Study Procedures and Data management

10.1 Study Procedures:

Describe step-by-step how the study will be conducted from beginning to end

Recruitment and enrollment strategies will be dynamically responsive to the outbreak as the situation evolves. Study volunteers may be recruited from areas of the hospital where they present for care or in the inpatient and isolation settings. Informed consents and enrollments will be conducted by study staff included on the IRB approved protocol, including staff named on delegation log, and trained in study procedures. Clinical evaluations will be performed by the MTF healthcare team and may also be conducted by qualified study team members.
In addition to MTF enrollment, MHS beneficiaries who have been clinically tested for COVID-19 will be invited to participate in a limited schedule of assessments for EPICC, including completion of a series of online questionnaires and at-home capillary blood sample collection at three timepoints. See Appendix A for further details.
At the time of a participant's initial consultation at an MTF, study activities will consist of explanation of study goals and purpose, and obtaining informed consent (may include consultation with Legally Authorized Representative). The day of enrollment will be defined as Study Day 0. The team will subsequently conduct serial collection of data (demographics, vital signs, clinical findings, diagnostics and other laboratory results, etc.) through study participant interview and from medical record review from time of disease onset throughout study duration. Specific risk factors linked to pathogen exposure (eg., travel history to disease endemic regions, contact with sick individuals or known reservoirs of disease, etc.) will also be acquired from study volunteers, mainly through interview at Day 0. Medical records collected prior to day of enrollment will also be evaluated to ascertain medical history information pertinent to understanding baseline health and analysis of underlying risk factors associated with disease progression and other outcomes. Study team members will collect for research purposes biological specimens (e.g., nasopharyngeal and oropharyngeal swabs, rectal swabs, and blood) from enrolled participants who are laboratory-confirmed or suspected cases at time of enrollment, during the duration of hospitalization and/or isolation, with follow-up specimen collection up to approximately 1 year post-enrollment.

When possible, the study team will also obtain residual volumes of specimens collected for clinical care that would otherwise be discarded. Sample types include but are not limited to bronchoalveolar lavage, blood, urine, sputum, saliva, stool, cerebrospinal fluid, semen (adults only), or vomit.As available, these residual samples will be obtained from the time of onset of the disease under study. For active duty servicemembers, the study team will also request a pre-illness (up to 2 years prior to enrollment) serum sample from the DoD Serum Repository (DoDSR).

Some subjects may undergo clinical imaging studies as part of regular patient care or as part of this protocol using clinical imaging devices. For example, point-of-care portable ultrasound may be used to image areas such as the lungs, heart, and lower extremity veins, to explore the prognostic use of ultrasound in early detection of pneumonia and cardiovascular sequelae associated with severe disease. These imaging studies, when available, will be part of the collected subject data.

Study participants recruited and enrolled at MTFs who are ambulatory may also be evaluated via serial self-collection of samples such as nasopharyngeal swabs, oropharyngeal swabs, capillary blood samples, and/or other specimens appropriate for self-collection.

Recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital as well as healthcare providers who have potentially been exposed to known or suspected cases. Enrollees who are asymptomatic high/some risk will undergo serial collections of clinical and laboratory data as well as biological specimens (e.g., nasopharyngeal, oropharyngeal, and rectal swabs and blood) at enrollment, with follow-up specimen collection up to approximately 12 months post-enrollment. The study team may consider implementing a plan for asymptomatic study volunteers to conduct self-collection of clinical specimens (e.g. nasopharyngeal swabs, oropharyngeal swabs, rectal swabs, capillary blood smaples) through the follow-up period. Demographic, clinical, and other data as described above for symptomatic volunteers may also be acquired for asymptomatic high/some risk participants.

The Flu- PRO questionnaire (24-27) may be used to record the patient-reported outcome (PRO) on severity of clinical symptoms and the impact of clinical interventions on infection. A web link to the Flu-PRO questionnaire may be provided to participants to record the severity of ILI symptoms daily for 14 days from either the day of enrollment, or the date of onset of symptoms (for subjects who were asymptomatic at enrollment). Paper versions of the Flu-PRO questionnaire may be administered as needed.

In addition, an online questionnaire will be administered at enrollment and follow-up timepoints to collect data on medical history, comorbidities, behavioral risk factors, symptoms and recovery status.

If a participant is dually enrolled in a treatment protocol and scheduled to receive investigational products under an eIND, an additional sample may be collected in the first 48 hours after test article administration. If eligible, study participants may also be considered for enrollment concurrently in an interventional clinical trial evaluating efficacy of treatment regimens. The priority of collection of clinical specimens will be as follows: 1. specimens collected for clinical care; 2. specimens collected in support of an interventional clinical trial; and 3. specimens collected for observational study (i.e., EPICC protocol).

The study team may consider discontinuation of study participants who have a negative test result for the pathogen of interest (based on current standard of care diagnostics) and/or are diagnosed with another respiratory pathogen other than the one of interest and/or the disease of interest is highly unlikely based on the primary clinical team assessment. This approach may need to be taken to conserve study staff time and resources depending upon local epidemiologic circumstances, e.g. very high incidence and subject accrual.

Results obtained from research analyses will not be entered into the participant’s medical record. However, the study team will communicate relevant findings to the participant’s primary care provider overseeing care of the indicated infection of study. The study volunteer’s primary healthcare provider is likely to be a member of the protocol study team, and as such will be directly aware of study findings. If the primary healthcare provider is not a part of the protocol team, relevant findings from the study will be communicated to the healthcare provider verbally in a private setting to protect patient confidentiality or via a secure encrypted electronic communication.

Pregnant participants will be followed monthly until delivery to collect information on pregnancy outcome and health of the child with regards to the disease under study, to the extent practicable. A cord blood sample may be collected for research purposes following childbirth.

Specimens collected through this observational study will be evaluated in various laboratory assays to characterize the epidemiology, immunology, clinical characteristics, and other important outcomes of interest. Associated clinical and demographic data will also be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest as described in Section 9.4.

Schedule of Patient Evaluation and Data Collection

The table below shows the schedule of assessments for study participants enrolled in EPICC. Given the possibility of critical illness of the patient and the potential increased risk of exposure to medical personnel, assessments that cannot be completed due to patient care considertaions, indection control measures, or other logistical challenges will not constitute protocol deviations. In addition, the frequency of specimen and data collection may be reduced to accommodate logistics of acquiring specimens and data among study volunteers who are outpatients.
Ambulatory subjects who do not have restrictions of movement for infection control purposes (i.e., not advised by their care provider/local health authority to remain home in isolation) will be invited to return to the hospital for follow-up assessment and collection of specimens.

If an asymptomatic and/or COVID-19-negative subject develops symptoms or receives a positive test result for COVID-19, they will be asked to contact study staff to report their symptoms/test result and will restart the schedule of assessments from Day 0.

Inpatient MTF-Enrolled Subjects

Specimen/ Assessment	Enrollment (Day 0)	Days 3, 7 (± 1 day)	Once Weekly until discharge (± 2 days)	Day 14 if Discharged (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Montl (± 28 day
Virology Sample: Nasal, Throat, and/or Oral specimen*	√	√	√	√			
Virology Sample: Rectal Swab	√	√	√		√		
Blood	√	√	√	√¶	√¶	√¶	√¶
Residual Clinical Samples #	√	√	√	√	√	√	√
Radiologic images **	√	√					
Flu-PRO Symptom Diary ***	√	√	√	√			
Online Questionnaire	√				√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.
¶ Blood collection after discharge may be done using a commercial at-home microsampling blood collection kit.
# Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.
** Lung, cardiac, and/or venous ultrasound may be conducted on hospitalized subjects on days 0, 1, and 3 as resources and local patient care policy allows. Findings from any additional radiologic images obtained during routine clinical care will be collected for research.
*** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.

Outpatient MTF-Enrolled Subjects

Specimen/ Data	Enrollment (Day 0)	Day 7 (± 1 day)	Day 14 (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Virology Sample: Nasal, Throat, and/or Oral specimen*	√‡		√			
Blood¶	√‡	√	√	√	√	√
Flu-PRO Symptom Diary **	√	√	√			
Online Questionnaire	√			√	√	√
Residual clinical samples #	√	√	√	√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.
¶ Blood collection may be done using a commercial at-home microsampling blood collection kit.
# Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.
** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.
‡ There is a +3 day window for Day 0 research sample collection to allow for distribution of self-collection kits to participants whose samples could not be collected at enrollment.

Online Cohort: See Appendix A

Specimen/ Data		Day 28		

	Enrollment (Day 0)	(± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Online Questionnaire	√	√	√	√
Self-collected blood¶		√	√	√

¶ All blood collection for this cohort will be done using a commercial at-home microsampling blood collection kit.

Considerations for Pediatric Participants

- Flu-PRO symptom diary may be completed by subjects aged **7 and older**.
- Pediatric subjects will not be asked to complete the online questionnaires.
- Self-collection of specimens is an option for subjects aged **8 and older**.
- Blood collection volume and frequency may be reduced to comply with safety limits. For these subjects, the amount drawn may not exceed the lesser of 50 ml or 3 ml per kg in an 8 week period and collection may not occur more frequently than 2 times per week.

Research Laboratory Methods

Clinical specimens collected through this observational study will be evaluated in a variety of laboratory assays developed by laboratory partners. Specific laboratory assays to study the virologic, immunologic, and other relevant aspects of infections are unlikely to be available at the time of specimen collection (i.e., during the outbreak) given the time required to establish assays specific for novel, emerging pathogens. Below is a general description of laboratory assay methods and endpoints that may be used; however, this does not represent an exhaustive list to include new methodologies that are later developed in response to assaying novel pathogens.

To characterize virologic correlates (e.g., viremia) of clinical symptoms and disease severity, serum levels of viral genomes can be assessed by real time-PCR at various time points. Serum concentration of viral antigen can be evaluated by enzyme-linked immunosorbent assay (ELISA). These same assays may be utilized in the longitudinal detection of virus in body fluids (e.g., nasal mucosa, sputum, urine, stool, etc.) throughout the course of evaluation/illness.

In addition, serum may be assayed for concentrations of virus-specific IgM and IgG in the acute and convalescent stages of evaluation/illness. Cytokine profiles can be conducted via multiplex assay to describe the pro- versus anti-inflammatory cytokine responses of study volunteers throughout the course of illness. PBMCs may be collected to investigate cell-mediated immune responses in the acute and convalescent phases of illness.

Novel biomarkers, including transcriptomic and proteomic signatures, are promising for diagnosis and prognosis. Collection of appropriate specimens from individuals with well-characterized illnesses is required to inform assay development. Immune factors have been used as biomarkers for predicting clinical course and outcome, as well as the severity of clinical symptoms. For example, higher levels of cytokines IL2, IL7, IL10, GCSF, IP10, MCP1, MIP1A, and TNFα were observed in patients with SARS-CoV-2 infection requiring ICU-level care compared to those receiving non-ICU care (21). Host specific responses may be evaluated using real-time PCR and other molecular methods to identify biomarkers, transcriptomic signatures, or other lab-based endpoints indicative of severity of clinical course of disease progression and other risk factors associated with clinical outcomes, etc. In addition, evaluation of host transcriptomic responses among symptomatic versus asymptomatic, high risk exposure individuals may identify an early warning means for identifying asymptomatic people who eventually develop disease. RNA sequencing of blood specimens may also be conducted to assess viral transcription signatures as biomarkers for clinical outcomes. Blood specimens may also be used in phosphoproteomic assessments by measuring the proportion of host immune system proteins that are phosphorylated to evaluate novel biomarkers associated with activation of protein signaling pathways in response to infection.

10.2 Data Collection:

Describe all the data variables, information to be collected, the source of the data, how the data will be operationally measured, and approvals needed for use of information from DoD databases

Diagnostic Tests and Laboratory Analysis to be Obtained:

As available, laboratory data elements, such as but not limited to hematologic, biochemical, and other clinical parameters; clinical images and associated reports; and clinical diagnosis of the pathogen of interest (SARS-CoV-2) and

/or alternate or co-infective pathogens, will be abstracted from the medical record of study volunteers on the day of enrollment (Study Day 0), throughout the period of hospitalization (inpatients) and through duration of follow-up. In addition, laboratory and diagnostic data available in medical records prior to Day 0 will be abstracted for study of baseline health, existing co-morbidities, etc.

Data Elements

Case report forms (CRFs) for this protocol have been adapted from those of the International Severe Acute Respiratory Infection Consortium (ISARIC).

There are five main components of the data collection forms, encompassing study participant information at:

1. The time of enrollment (at time of presentation at MTF, hospital admission, or being placed in isolation),
2. Period prior to Day 0, as appropriate, to assess recent medical history,
3. Medical encounter data (inpatient or outpatient),
4. The time of discharge or death
5. Follow-up period (following hospital discharge or being released from isolation setting, or otherwise as an out-patient)

Major data variable categories to be collected include, but are not limited to the following:

- Day of enrollment
    - Demographics (Residence, Occupation, Military Status)
    - Signs and Symptoms at onset of illness and presentation for care
    - Epidemiological Risk Factors and Exposures
    - Pre-admission Medications
    - Review of recent medical history via medical record review
    - Flu-PRO symptom severity questionnaire
- Hospitalization or Isolation Period
    - Daily Observations (i.e., vital signs) and Treatments (i.e., receipt of IV fluids)
    - Daily Laboratory Results
    - Medications and Blood Products
    - Microbiology Results
    - Critical Care
    - Severe Symptoms and Complications
    - Flu-PRO symptom severity questionnaire
- Outcome
    - Final Diagnosis
    - Patient Status at Outcome
    - Follow-up period

Data Collection

Study data will be copied onto electronic CRFs at the study site. These transcriptions will occur on an ongoing basis during the study in accordance with Good Clinical Practice (GCP) guidelines. Data entered on CRFs, as well as corrections made, shall be performed by authorized individuals. This study will make use of electronic case report forms (eCRFs) using tablets with the Research Electronic Data Capture (REDCap). For cases where a tablet cannot be used because of infection control concerns or logistical issues, authorized personnel will capture CRF information using a paper based version and later electronically record results into REDCap. All data transmitted to and from the application is done using a secure, encrypted transmission (SSL/HTTPS). For increased security, the application additionally verifies the SSL certificate of the REDCap server that it is communicating with in order to validate the server’s identity. The REDCap mobile application employs encryption-at-rest on the mobile device’s hard drive, so all data and information stored on the device is protected from unauthorized users. REDCap has built-in safeguards such as username and PIN, and remote lockout. When resources are available, data from clinical devices including de-identified ultrasound or radiograph images, continuous vital signs, and/or cardiac telemetry will be locally stored on password-protected devices, and if possible, transmitted wirelessly to a secure Cloud backup. Henry Jackson Foundation (HJF) headquarters IT will host deidentified study data on HJF HQ secured servers. HJF is responsible for the purchase, setup, maintenance, and service of any its servers and technology.

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as questionnaires may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

Data Management/Quality Control

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, documentation of informed consent and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves or authorized study personnel. Only designated study personnel shall record or change data on a CRF. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. PHI will be removed from clinical devices, such as those used for radiology, and associated data will be labeled with the study participant's ID. For each pivotal analysis (e.g., for a sub-study, manuscript, or presentation), the 'snapshot' (or 'data freeze') database will be made and archived in the study data repository. After the study analysis ends, the database will be locked.

10.3 At any point in the study, will you request, use, or access PII from the Military Health System (MHS)?

● Yes ○ No

10.4 Have you consulted with an MHS data expert to determine the data elements to be extracted or the information system(s) to access?

Consulting with a data expert often saves time later in the compliance process because the data expert can advise on the data available in the numerous MHS information systems, the quality of that data and the methods for encrypting and collapsing data. To schedule a consult with an MHS data expert, send an email to: (**dha.ncr.pcl.mbx.privacyboard@mail.mil**)

● Yes, then complete the questions below according to the data consult

○ No, then complete the questions below according to the best of your knowledge (NOTE: It is highly recommended that you work with an MHS data expert)

10.5 Indicate whether you plan to receive a data extract from the MHS or plan to access an information system directly to create a data set:

A data extract is when the MHS or a contractor provides the data set directly to the researcher. When receiving a data set through data extract, the researcher may indicate whether the data elements should be provided as is, encrypted or collapsed. In contrast to a data extract, access to an information system means that the researcher may directly access an MHS information system and create a data set for the research study

☐ Data Extract

☑ Access

10.6 Do you intend to use only de-identified data from the MHS in your research study?

There are different two methods for de-identifying data pursuant to HIPAA:
1) Safe Harbor Method: Removing all of the identifiers listed in Table 1 below, provided that the researcher does not have actual knowledge that the remaining data can be used alone or in combination with other information to identify the individual who is the subject of the information
2) Statistical Method: An expert, with appropriate knowledge of and experience with generally accepted statistical and scientific principles and methods for rendering information not individually identifiable, determines that the data is not individually identifiable

○ Yes ● No

10.7 If your research study requires access to an MHS information system, please indicate the system to obtain data:

If you do not know which system(s) contain the data elements you need, refer to the Guide for DoD Researchers on Using MHS Data or seek guidance from an MHS data expert:

PHI Systems:

MHS Information System	Requesting Data

:AHLTA	:Yes
:CHCS	:Yes
:ESSENTRIS	:Yes
:MDR	:Yes

PII-Only Systems:

MHS Information System	Requesting Data	
No records have been added		

De-Identified Data & Other Systems:

Information System	Requesting Data
Expense Assignment System	
MHS Genesis; JLV (accessed via AHLTA or MHS Genesis)	:Yes
DMSS, DRSi	:Yes

10.8 Do you intend to merge or otherwise associate the requested data with data from any sources outside of the MHS, including other DoD systems that are not part of the MHS?

● Yes, will merge data
○ No, will not merge data

10.9 Indicate the categories of data that you will request from MHS systems or MHS health care providers about research participants or relatives, employers, or household members of the research participants.

Data Element(s)	MHS	Non-MHS Systems
1. Names	☑	☐
2. Postal address with only town, city, state and zip code	☑	☐
3. Postal address with all geographic subdivisions smaller than a state, including street address, city, county, precinct, zip code and their equivalent geocodes, except for the initial three digits of a zip code if, according to the current publicly available data from the Bureau of Census: 1) the geographic unit formed by combining all zip codes with the same three initial digits contains more than 20,000 people; and 2) the initial three digits of a zip code for all such geographic units containing	☑	☐

20,000 or fewer people is changed to 000		
4. Dates including all elements (except year) directly related to an individual, including birth date, admission date, discharge date, and date of death	☑	☐
5. Ages over 89 and all elements of dates (including year) indicative of such age, unless you will only request a single category of “age 90 or older”	☑	☐
6. Telephone numbers	☑	☐
7. Fax numbers	☑	☐
8. Electronic mail addresses	☑	☐
9. Social Security numbers (SSNs)	☑	☐
10. Medical record numbers	☑	☐
11. Health plan beneficiary numbers	☑	☐
12. Account numbers	☐	☐
13. Certificate/license numbers	☐	☐
14. Vehicle identifiers and serial numbers, including license plate numbers	☐	☐
15. Device identifiers and serial numbers	☐	☐
16. Web Universal Resource Locators (URLs)	☐	☐
17. Internet Protocol (IP) address numbers	☐	☐
18. Biometric identifiers, including finger and voice prints	☐	☐
19. Full-face photographic images and any comparable images	☐	☐

20. Any other unique identifying number, characteristic, or code (DEERs ID, EDIPN, Rank)	☑	☐

If you are obtaining SSNs, provide a justification as to why and explain why a substitute cannot be used

We request to access potential subjects' medical records in order to evaluate them for recruitment for this protocol. PHI to be screened include (name, date of birth, social security number and health beneficiary numbers). These risks are no more than minimal because they are not greater than those ordinarily encountered by the patient during a medical visit.

Study investigators and personnel will review potential subjects' medical history to assess protocol eligibility. If the person consents to participate in the research study, the PHI will be stored in accordance with the protocol.

10.10 Is it possible that the data will become identifiable because of triangulation, a small cell size, or any unique data element(s)?

Triangulation means using different data elements that are not themselves identifiable but that when combined can be used to identify an individual. For example, triangulation would be using rank and race together to determine the identity of an individual with a particular health condition
Small cell size means that there are only a small number of eligible individuals that satisfy the category description. Guidance for acceptable cell size is available from the Centers for Medicare and Medicaid Services. For example, the rank category of four star generals with a particular diagnosis may be less than 30 so the rank category may need to be expanded to include lower ranks
A unique data element includes any unique features that are not explicitly enumerated in the categories of data in rows 1 – 19 of Table 1 above, but that could be used to identify an individual. Examples of unique data elements include: 1) a unique number, such as a medical record number or EDIPN; 2) a unique code, such as a diagnosis code or a bar code on an electronic health record; and 3) any unique characteristic, such as the rank of general or admiral, or a race or gender combined with another unique characteristic

● Yes, there is a reasonable possibility the data will become identifiable
○ No, there is no reasonable possibility the data will become identifiable

10.11 HIPAA Privacy Rule and Use of Protected Health Information in Research:

○ N/A – will not use or disclose protected health information (PHI)
○ HIPAA Authorization will be obtained
○ Use of a limited data set where a data use agreement will be obtained
● Waiver/alteration of HIPAA Authorization is being requested

10.12 Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for this Study:

Include in this section the plan for acquiring data (both electronic and hard copy), access during the study, data/specimen storage and length of time stored, shipment/transmission, and the plan for storage and final disposition at the conclusion of the study. Describe any data agreements in place for accessing data within and/or outside of your institution (e.g., Data Sharing Agreement, Data Use Agreement, Business Agreements, etc.)

Human Biological Specimens

1. Intended Use of the Samples/Specimens/Data

Specimens will be processed and handled as appropriate following applicable MTF enhanced precaution and Infection Control SOPs. Methods for specimen collection, handling, and processing are described in their respective SOPs. Details of specimen storage, maintenance, and QA/QC are described in their respective SOPs.

Samples and data collected under this protocol will be analyzed to study the pathogenesis of disease and the host immune response to infection. Genetic testing on human specimens
will be conducted to evaluate the host (subject's) immune response to SARS-CoV-2 infection and its association with clinical outcomes. Additional genetic testing will examine viral genetic markers and transcription signatures as predictors of infection severity, clinical course, and outcomes. Genetic testing results will not be provided to participants.

This is a purely observational study. Any experimental treatments will be done under other protocols for which separate IRB review and approval will be obtained.

2. How Samples/Specimens/Data Will Be Stored

Access to research samples will be limited using locked facilities and monitored freezers. Samples and data will be stored using codes assigned by the investigators or their designee(s). Data will be kept in password-protected computers. Only investigators or their designee(s) will have access to the samples and data.

3. How Samples/Specimens/Data Will Be Stored & Tracked

Samples from individuals found infected with a novel pathogen / emerging infectious disease of interest will be archived and stored at an appropriate biosafety level facility.

Samples acquired as part of the protocol will be tracked using appropriate software, such as Freezer Works, a sample tracking, biorepository management and freezer inventory program.

4. What Will Happen to the Samples/Specimens/Data at the Completion of the Protocol?

In the future, other investigators may wish to study these samples and/or data. IRB approval will be sought prior to any sharing of samples/data. Any clinical information associated with the sample, with or without patient identifiers, will be shared after IRB approval has been obtained.Upon study closure, all samples and data will be de-identified in accordance with the DHA-approved Data De-Identification Plan.

5. What Circumstances Would Prompt the PI to Report to the IRB Loss or Destruction of Samples/Specimens/Data

Any loss or unanticipated destruction of samples (for example, due to freezer malfunction) or data (for example, misplacing a printout of data with identifiers) that compromises the scientific integrity of the study will be reported to the IRB.

6. Storage and Tracking of Samples/Specimens/Data

Research use of data collected through this protocol will be coded and will not contain identifiers. These data will be coded with access maintained by a custodian not affiliated with the study team per IDCRP policy. Much of the subsequent research using the coded materials collected under the auspices of this study will be accomplishable through approved exempt or non-human use sub-studies. All research using the materials collected under this protocol will be conducted in accordance with an IRB-reviewed protocol. Data and specimens released for research use will be labeled by PIN only; data will be shared without any identifiers or links to individuals. The DCC custodian, the DCC Chief, will not share identifying information with investigators without explicit IRB approval.

A Defense Health Agency (DHA) Data Sharing Agreement will be implemented as needed to access MHS data. Appropriate data sharing agreements and other legal agreements will be implemented prior to sharing of data and specimens with collaborators.

10.13 Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for Future Research:

If the study involves collecting, storing, or banking human specimens, data, or documents (either by the Investigator or through an established repository) for FUTURE research, address. How the specimens /data will be used, where and how data/specimens will be stored (including shipping procedures, storage plan, etc.), whether and how consent will be obtained, procedures that will fulfill subjects' request as stated in the consent, whether subjects may withdraw their data/specimens from storage, whether and how subjects may be recontacted for future research and given the option to decline, whether there will be genetic testing on the specimens, who will have access to the data/specimens, and the linkage, the length of time that data/specimens will be stored and conditions under which data/specimens will be destroyed

Establishment of a specimen repository for future clinical and laboratory investigation for future emerging infectious disease research:

The study aims to build a repository of biological specimens (e.g. whole blood, serum, and PBMCs, as well as nasopharyngeal fluid, sputum, bronchioalveolar lavage fluid, oropharyngeal fluid, saliva, urine, semen, and rectal swab specimens, etc.) from an observational, longitudinal study of emerging infectious diseases. Specimens may be stored in an appropriate biosafety level facility at a protocol-approved biorepository. These specimen repositories will be linked to an extensive de-identified clinical database.

In the future, this repository might be used in the identification and validation of biomarkers for severe infection, identification and molecular characterization of novel pathogens, development and evaluation of new diagnostic platforms, and/or evaluation of host factors that may be associated with susceptibility and outcome. Coupled with detailed clinical history and risk factor information gleaned through electronic medical record review, this repository will ultimately be an invaluable resource for future investigations of emerging infectious diseases in clinical as well as laboratory settings. Moreover, the infrastructure developed through these activities will serve as a broad-based platform for a diverse portfolio of relevant sub-studies into emerging infectious diseases and strategies for its control and prevention.

Study Time Line

This natural history core protocol will be open indefinitely, although sites may close once an epidemic has passed.

11.0 Statistical/Data Analysis Plan

11.1 Statistical Considerations:

List the statistical methods to be used to address the primary and secondary objectives, specific aims, and/or research hypotheses. Explain how missing data and outliers will be handled in the analysis. The analysis plan should be consistent with the study objectives. Include any sub-group analyses (e.g., gender or age group). Specify statistical methods and variables for each analysis. Describe how confounding variables will be controlled in the data analysis

Statistical Considerations

This is an enhanced surveillance protocol using clinical observations and laboratory testing, supplemented by additional lab testing for research purposes. The frequency and expansion of such outbreaks is unknown, and hence this protocol will be activated on contingencies in many cases. Data from a given outbreak will be compiled into a dataset for descriptive analyses. Risk factors will be identified retrospectively using odds ratios. Comparison between similar outbreaks may be performed if sufficient data allows. It is recognized that a proportion (i.e., not all) of eligible subjects will consent to participate in this study. As such, the limitations and generalizability of the study findings will be acknowledged in associated reports and manuscripts.

11.2 Sample Size Estimation:

As determined by exigencies of the outbreak, and resource availability. Please see Appendix A for sample size considerations for the online cohort.

11.3 Data Analysis Plan:

Data Analysis Plan

Student’s t test (or Wilcoxon rank-sum test if appropriate) on continuous variables and Pearson’s chi-square tests (or Fisher’s exact test if appropriate) for categorical variable to summarize key outcomes of interest. Multivariate regression techniques will be used to assess relationships between key variables adjusted for potential confounders.

A data analysis plan will be created to meet the following reporting requirements:

- During an outbreak, descriptive clinical and laboratory data will be summarized per patient on a regular basis as appropriate for all investigators, involved hospitals, the respective service's public health agencies, AFHSB, and DHA leadership as a part of the epidemiologic reporting requirements. It is recognized this data may not be fully cleaned. Aggregate data report will be prepared monthly.
- At conclusion of an outbreak, a summary report per outbreak will be prepared once all data is cleaned. This will take an estimated 90 days.

With respect to the analysis of the study data, the following objectives will be addressed, and more fully articulated, in a statistical analysis plan:

1) Describe natural history of clinical disease.

Data items related to disease duration include duration of fever and other predominant symptoms, and days from onset of symptoms until hospital discharge/return to normal activity. Each variable will be summarized by mean, standard deviation, median, inter-quartile range, minimum and maximum overall and also for each group within several groupings: age categories, adult vs. minor, gender, different race groups, index cases vs. secondary cases, military rank and/or nature of duties for those with active duty military duty status. We will also use symptom severity data from the Flu-PRO questionnaire to explore the extent to which ARI symptom severity scores differs across the cohort.

Adverse binary outcomes where the time to event may also be of interest: These include requirement for ICU admission, development of any super infection, development of oxygen requirement, mortality, etc. For each of these, we will first give a simple summary of the number and percent experiencing each outcome. We will also summarize by different subgroups as above.

2) Identify risk factors for infection and severe clinical course.

One set of analyses will treat laboratory-confirmed diagnosis as the outcome in logistic regression models, with the following covariates: age, sex, race, military rank, service branch, type of exposure, use of personal protective equipment, etc. Similar logistic regression models will be developed to determine predictors of severe clinical course, such as mortality.

Another set of analyses will treat illness duration as a quantitative endpoint to be used as the outcome variable in multiple linear regressions. The key endpoint will be the total symptom score considered at three different time points: at symptom onset, at 48 hours post symptom onset, and at its maximum value whenever that occurs. Other potential confounders to be included as covariates are: age, sex, race, and number of days since presumed exposure.
Complementary methods of subject recruitment and data collection within the study will address the following specific aims:

1. Among COVID-19 confirmed cases, compare risk factors (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for:
    1. Those who get hospitalized vs. those who do not get hospitalized
    2. Those who get hospitalized with a ventilator vs. those who do not get hospitalized and those hospitalized but not placed on a ventilator
    3. Those who get hospitalized in the ICU vs. those who do not get hospitalized and those hospitalized but not in the ICU
    4. Those who go on to die vs. those who do not die

1. Compare risk factors (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for infection among the total COVID-19 tested study population of COVID-19 confirmed cases (test positive) vs. confirmed non-cases (test negative).
2. Compare symptoms between various groups:
    1. Among the total COVID_19 tested study population, COVID-19 confirmed cases vs. confirmed non-cases
    2. Among COVID-19 confirmed cases for those:
        1. who get hospitalized vs. those who do not get hospitalized
        2. who get hospitalized in the ICU vs. those who are hospitalized, but not in the ICU
        3. who go on to die vs. those who do not die
3. Among the COVID-19-confirmed cases and an appropriate and hypothesis-specific randomly selected comparison group, using medical record data, identify comorbidities and medications that are associated with reduced occurrence of COVID-19 symptoms as well as with becoming infected with COVID-19.

The proposed analytic strategy will be to report crude (non-adjusted), age and sex-adjusted, and multivariable adjusted probability of hospitalization in those with and without the exposures of interest.

1. Calculate crude (non-adjusted) likelihood of hospitalization in demographic sub-populations of interest (e.g. by age strata, sex, and race/ethnicity)

2. Determine the age-specific prevalence of the major comorbidities (obesity, hypertension, asthma) separately by sex and race/ethnicity
3. The primary model will be logistic regression, calculating adjusted predicted prevalence of hospitalization for those with each comorbidity alone and comorbidity clusters (since comorbidities are correlated)
    1. A priori, evaluate whether risk associated with each comorbidity is similar for men and women and for African Americans vs others (interaction by sex; interaction by race).

Conduct separate models for the active duty population and the beneficiary populations

3) Characterize host immune response.

We will examine the relationship between factors, such as the immune response (e.g., serum antibody concentration) and pathogen infection kinetics, and disease progression, symptom severity, and clinical outcomes of interest. We will look at both cross-sectional relationships (i.e., among people) and within person relationships. For cross-sectional relationships, we will start by plotting the total symptom severity score against the immune response, separately for each of the four blood samples. We anticipate a monotonic relationship, but it is possible for a U-shaped relationship in some cases, i.e., illness severity is greater if there is a too small immune response or a too large one. We will develop regression models with the outcome of the symptom severity or clinical course on the chosen function of immune response to see if there is a statistically significant relationship. We will add covariates to control for possible confounders, such as age, race, sex, military status, etc. and others mentioned above.

4) Evaluate correlations between symptom severity, virologic/microbiologic characteristics, host immune response and clinical course/outcome.

We will consider two groups: subjects with versus without a severe clinical course, such as mortality. We will compare the proportions with a significant serum antibody ‘response’ between the two groups by contingency table chi-square tests. We anticipate that the categorization of immune response will be binary (i.e., proportion of individuals exceeding a given concentration of serum antibody), in which case we will be comparing a binomial probability between the two groups. These analyses will form the backbone for more elaborate multivariate analyses.

5) Develop diagnostic and prognostic tools.

Data and specimens from this protocol may be used in the development of diagnostic and prognostic assays for novel pathogens. For example, the collection of blood and other body fluids from individuals with laboratory-confirmed infection may aid in the development of novel assays with higher sensitivity and specificity. Additionally, the collection of longitudinal clinical characteristics in addition to clinical laboratory data may aid in the development of prediction models to determine risk factors for severe clinical course, such as mortality.

12.0

Participant Information

12.1 Subject Population:

As this is an observational study, subjects of all ages will be enrolled. Military Treatment Facilities see a diverse population including all genders and races, and a wide range of ages. This study will examine the epidemiology of novel pathogens / emerging infectious diseases, seek to identify risk factors for severe disease and elucidate mechanisms of host immunity to these pathogens.

Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study also allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Males and females of all ages who are symptomatic or asymptomatic individuals (at high/some risk of exposure) meeting inclusion criteria are eligible for participation.

Participation in the online-only study group is limited to adults only.

12.2 Age Range:

☑ 0-17
☑ 18-24

☑ 25-34
☑ 35-44
☑ 45-54
☑ 55-64
☑ 65-74
☑ 75+

12.3 Gender:

☑ Male
☑ Female

12.4 Special categories:

☑ Minors /Children - “You must also consider the requirements of 45 CFR 46 Subpart D and DoDI 3216.02, Enclosure 3, paragraph 7.d.”
☐ Students
☐ Employees - Civilian - “You must also consider the requirements of DoDI 3216.02, paragraph 7.e.”
☐ Employees - Contractor
☐ Resident/trainee
☐ Cadets /Midshipmen - “You must also consider the requirements of DoDI 3216.02, Enclosure 3, paragraphs 7.e. and 12.”
☑ Active Duty Military Personnel - “You must also consider the requirements of DoDI 3216.02, Enclosure 3, paragraph 7.e.”
☐ Wounded Warriors - “Depending on your intended subjects’ status, you may also need to consider the requirements of DoDI 3216.02, Enclosure 3, paragraph 7.e.”
☐ Economically Disadvantaged Persons - “You must also consider the requirements of 32 CFR 219.111 (b).”
☐ Educationally Disadvantaged Persons - “You must also consider the requirements of 32 CFR 219.111 (b).”
☐ Physically Challenged (Physical challenges include visual and/or auditory impairment)
☑ Persons with Impaired Decisional Capacity - “You must also consider the requirements of 10 USC 980.”
☐ Prisoners - “You must also consider the requirements of 45 CFR 46 Subpart C and DoDI 3216.02, Enclosure 3, paragraphs 7.b. and 7.c.”
☑ Pregnant Women, Fetuses, and Neonates
☐ Non-English Speakers
☐ International Research involving Foreign Nationals - Headquarters Review is necessary

12.5 Inclusion Criteria:

Order Number	Criteria
1	Inclusion Criteria: Individuals of any age who are eligible for care at an MTF and meet at least one of the following criteria: 1. **Laboratory-confirmed presence of the pathogen of interest** (e.g., SARS-CoV-2, influenza A /H7N9, etc.) ***OR*** 2. **Meet criteria for testing for the pathogen of interest, as identified per current CDC guidelines** at **https://www.cdc.gov/coronavirus/2019-nCoV/hcp/clinical-criteria.html**
	Additional Inclusion Criteria for **Online Enrollment:**

2	1. An MHS Beneficiary who has been clinically tested for the pathogen of interest 2. Able to receive email communications and respond to web-based questionnaires 3. ≥18 years of age

12.6 Exclusion Criteria:

Order Number	Criteria
1	Individuals who decline participation in the study
2	Individuals who the study investigators believe are unable to comply with the requirements of the study

13.0

Recruitment and Consent

13.1 Identification and Selection of Subjects:

Given the dynamic nature of novel pathogens/emerging infectious diseases, there is no pre-defined target enrollment for the protocol. The main objective of this protocol is to recruit and enroll a representative proportion of cases of emerging infectious diseases to characterize the epidemiology and clinical characteristics of disease. Site study team members will engage with relevant clinical staff to identify eligible patients in inpatient wards, intensive care units, acute care clinics, and emergency departments. Participants will be identified through screening of medical records to identify individuals with the recent exposures and clinical manifestations of interest, and will be approached following the initial medical evaluation. The study will be described to patients, and their eligibility and willingness to participate will be assessed. For those with confirmed or suspected infection, room access may be limited and consent will be performed by study staff members with patient access.

Individuals presenting for care at MTFs, such as at clinics or in the inpatient and isolation setting, will be recruited and enrolled and will participate in serial collection of biological specimens over a 12-month period, with more intensive (i.e., daily, weekly) data collection occurring during the inpatient or isolation period. Information on current and prior medical conditions and hospitalizations will be collected via medical chart review and/or MDR data extractions. Information on specific epidemiologic risk factors during or related to deployment (e.g., travel history, zoonotic exposures, etc.) will be ascertained through participant interview or review of available medical records (e.g., AHLTA-T, ALTHA, CHCS, Essentris, MHS Genesis, JLV (accessed via AHLTA or MHS Genesis), MDR, DMSS, and/or DRSi). Study participants evaluated at MTFs and who are either 1. ambulatory cases advised to return home and remain home in isolation or 2. classified as asymptomatic individuals with high/some risk for exposure may also be evaluated for follow up through a study design including serial self-collection of nasal swabs, oropharyngeal swabs, rectal swabs, or other specimens appropriate for self-collection. A similar schedule of data collection and methods used for enrolled inpatients will be applied for ambulatory cases (non-hospitalized) and asymptomatic individuals as feasible.

Details on the recruitment, consent, and enrollment of subjects participating through the MHS-wide online process are included in Appendix A.

13.2 Recruitment Process:

Recruitment of study volunteers at the MTFs will rely heavily on the direct interface of healthcare providers with potential eligible participants. The study team will develop an MTF communications plan, outlined in the protocol’s Manual of Procedures, that will be implemented by local site teams to facilitate identification of potential eligible participants. Study volunteers may be recruited from clinics and inpatient or isolation settings. In addition, recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital. Another group of individuals who may be approached for recruitment as asymptomatic high/some risk participants, are healthcare providers who are in close contact with and potentially exposed to known cases. Adults and children are eligible for participation.

The study team will use multiple means of communicating study awareness to enhance recruitment efforts, including periodic briefings delivered by the site PI's and their study teams to their critical care and infectious disease staff and inpatient nursing staff. Information notices with points of contacts will be posted in clinical sites such as inpatient units, acute care clinics, and several points in the emergency room. Research team members who are Active Duty military personnel will not wear visible signs of their rank during recruitment. Site PI's or their authorized designees will conduct daily queries of MTF electronic health heath records (including infectious disease reportables list, DRSi, and searching in CHCS for patients with coronavirus lab code) to identify individuals who tested positive for disease of interest and will review daily admissions into the ICU, general pediatric and internal medicine wards with their study personnel to identify new inpatients. Information from infection control, preventive medicine and infectious disease departments may be obtained to find patients who may be managed / followed outside of the MTF.

J6 Data: Staff at the J6 CarePoint MHS Information Portal will provide subject identifiers (including names, Active Duty status, DoD Identifier, DOB, Email addresses, Date of Initial COVID-19 Respiratory Swab PCR Test, and all available COVID-19 Respiratory Swab PCR Test results) of AD members and beneficiaries who have been tested for COVID-19 to the approved research team using DoD SAFE. These data will be used to contact subjects for potential enrollment in the study and to contact subjects while enrolled. The original data file is retained only until a QC check determines the data have been uploaded successfully to REDCap, after which the file is destroyed. At study end, all PHI and PII shall be de-identified per the De-identification Plan.

Depending on age, severity of infection, and MTF requirements, study staff will determine if a potential subject is capable and/or allowed to provide a signed consent, verbal consent, or if an LAR is required according to IRB, HIPAA, and local MTF requirements.

13.3 Compensation for Participation:

In accordance with 24 USC 30:

MTF-enrolled subjects will be provided compensation in the form of a gift card. Subjects enrolled in the online-only group will receive compensation in the form of an electronic gift code sent via email.

Subjects will receive:

- $50 for each outpatient venipuncture
- $10 for each self-collected sample completed at home
- $10 for completion of each online questionnaire
- $10 for completion of 14-day Flu-PRO symptom diary

13.4 Eligibility Assessment Process:

As part of medical record review, the team will assess the eligibility of potential subjects. Individuals identified as having known risk factors for an emerging infectious disease (e.g., recent travel to a disease-endemic region, or close contact with a known or suspected infected individual or a returning traveler) who present to a participating MTF for medical care (e.g., febrile illness) or are placed into isolation are eligible for study participation. Additionally, asymptomatic high/some risk for exposure individuals may be enrolled at MTFs. Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Eligibility will be assessed and a final determination of subject eligibility will be made during the consent process. Please refer to section 12.5 for the inclusion criteria.

13.5 Consent Process:

Are you requesting a waiver or alteration of informed consent?

● Yes ○ No

What type?

☑ Waiver of documentation of informed consent
☐ Waiver or alteration of informed consent

Please explain why you qualify for a waiver or alteration of informed consent:

Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff. The study team is requesting a waiver of documentation of informed consent to allow for verbal subject/LAR informed consent, an Alteration of Authorization of HIPAA to allow for verbal subject/LAR HIPAA authorization, as well as a partial Waiver of HIPAA Authorization to identify eligible potential subjects and make initial contact with individuals to notify them regarding the study. These will be used as appropriate based on the circumstances of the disease being studied and MTF requirements. This study falls under the following criteria noted in 32 CFR 219.117: “That the research presents no more than minimal risk of harm to subjects and involves no procedures for which written consent is normally required outside of the research context."

Please explain the consent process:

ICD and Assent Regulatory Requirements

The Informed Consent Document (ICD) and Assent Form, including a HIPAA authorization, will be reviewed and approved by the IRB prior to initiation of the study. The ICD will contain a full explanation of the possible advantages and risks of study participation. The ICD will be compliant with applicable DoD regulations, 32 CFR 219, and the Belmont Principles, and the Health Insurance Portability and Accountability Act (HIPAA) Authorization. Informed consent includes the principle that it is critical the participant be informed about the principal potential risks and benefits. This information will allow the participant to make a personal risk versus benefit decision and understand the following general principles:

- Participation is entirely voluntary,
- Participants may withdraw from participation at any time,
- Refusal to participate involves no penalty; and
- The individual is free to ask any questions that will allow him/her to understand the nature of the protocol.

An ICD or Assent Form (with parental permission) will be signed by the participant before any study-related procedures are initiated for each participant. The investigators or their designees will present the protocol in lay terms to the participants. If access is limited, an authorized member of the study team accompanied by a witness may conduct the informed consent process. Questions on the nature of the protocol, the means by which it is to be accomplished, and the risks to the participants will then be solicited. Any question that cannot be answered will be referred to the principal investigator (PI). All participants will be given the opportunity to ask questions. No participant should grant consent until questions have been answered to his/her satisfaction. Documented parental permission will be received prior to obtaining assent from a minor. If rules allow, a copy should be provided to the volunteer or their guardian.

Minors:

An assent form (with parental permission) will be used for children aged 7-17. The ICD and Assent Form (with parental permission) indicate that by signature, the participant permits access to relevant medical records by the study investigators and regulatory authorities. Documented parental permission is required prior to assent by a minor using the ICD. A Waiver of Documentation of Assent will be used for children 6 and under, documenting that the study was explained to the child in age-appropriate terms and that the child has either expressed verbal assent or does not have the capacity to do so.

For adults who are incapacitated by the illness:

Consent may be obtained by a Legally Authorized Representative (LAR). The patients should be consented themselves at such time that they are able to provide consent.

For Hospital Staff who are Active Duty Military:

Hospital staff who are active duty military, and therefore eligible for care at a military treatment facility, may be approached for consenting to the study due to their potential exposure to coronavirus. If hospital staff who are active duty military are approached for participation in the study, supervisors will not be present at any human subject recruitment sessions or during the consent process in which hospital staff who are active duty military under their supervision are afforded the opportunity to participate as human subjects. Supervisors (e.g., military and civilian supervisors or anyone in the supervisory structure) will not influence the decisions of their subordinates regarding their participation as subjects in this study.

Verbal Informed Consent:

Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff.

The study team is requesting a waiver of documentation of informed consent, an Alteration of HIPAA Authorization, as well as a partial Waiver of HIPAA Authorization to use as appropriate based on the circumstances of the disease being studied and MTF requirements. When possible, the subject will provide signed ICD and HIPAA authorization. If the subject is unable to provide signed authorizations, the Alteration of HIPAA Authorization will be utilized, allowing the subject/LAR to provide verbal, rather than written, HIPAA Authorization. If study personnel are unable to work near the potential and/or active subject for safety reasons, the study personnel will contact the patient according to the requirements of the MTF. Options may include but are not limited to speaking with the patient from a safe distance in person, contacting the patient by phone in person with a barrier in between the potential and/or active subject and the study personnel, contacting the patient by phone from a separate location, or having a study physician trained in infectious disease safety procedures meet with the potential and/or active subject in close proximity (if allowed by the MTF).

Regardless of the method of delivery, the potential and/or active subject would be thoroughly briefed on the study's Informed Consent and HIPAA information. They would also be provided with an opportunity to ask any questions and an unsigned copy of the informed consent if permissible by the MTF. In turn, study staff will thoroughly document the informed consent process and the subject's verbal consent in the study chart. The study personnel will sign and file the ICD. The study personnel will also include a note in the study chart summarizing the informed consent process.

13.6 DoDI 3216.02 requires an ombudsman to be present during recruitment briefings when research involves greater than minimal risk and recruitment of Service members occurs in a group setting. If applicable, you may nominate an individual to serve as the ombudsman.

● N/A
○ Propose ombudsman

13.7 Withdrawal from Study Participation:

Explain the process for withdrawal and specify whether or not the subjects will be given the opportunity to withdraw their data their data/specimens in the event they wish to withdraw from the study

A subject may voluntarily end participation in the study at any time. If a subject withdraws, the investigator will make a reasonable effort to determine the reason for the subject's withdrawal from the study. Telephone calls, registered letters, and/or e-mail correspondence will be considered reasonable effort. Data and specimens collected up to the time of withdrawal will be retained and de-identified in accordance with IRB, HIPAA, and Safe Harbor requirements.

Subjects may be discontinued by the study team if there is a determination by the on-site physician that the volunteer may be unable to comply with the requirements of the study, or in the interest of the military mission.

The study team may consider discontinuation of study participants who have a negative test result for the pathogen of interest (based on current standard of care diagnostics) *and/or* are diagnosed with another respiratory pathogen other than the one of interest *and/or* the disease of interest is highly unlikely based on the primary clinical team assessment. This approach may need to be taken to conserve study staff time and resources depending upon local epidemiologic circumstances, e.g. very high incidence and subject accrual.

14.0
Risks and Benefits

14.1
Risks of Harm:

Identify all research-related risks of harm to which the subject will be exposed for each research procedure or intervention as a result of participation in this study. Consider the risks of breach of confidentiality, psychological, legal, social, and economic risks as well as physical risks. Do not describe risks from standard care procedures; only describe risks from procedures done for research purposes

Risks associated with obtaining specimens:

- Obtaining specimens could be associated with discomfort from a needle stick, swab, or other procedure, and occasionally associated with bleeding, bruising, local or systemic infection.
- Genetic testing may reveal sensitive information that subjects may not want disclosed, and may cause some emotional distress for the participant.

Risks associated with privacy:

- Despite meticulous precautions, breaches of confidential information (including genetic information) do occasionally occur, although the chances of such a breach are unlikely.

Expected Adverse Events from Research Risks and Reporting

a. Rare (Event Rate < 1%)
Secondary infection and syncope from vasovagal reactions occur from blood collection in rare cases. Risks of nasopharyngeal swab, rectal swab, cheek swab could include bleeding or mucous membrane irritation.

b. Less Likely (1% ≤ Event Rate < 5%)
No known risks

c. Likely (5% ≤ Event Rate < 10%)
Bruising and bleeding may occur as a result of blood collection procedures.

d. More likely (Event Rate ≥10%)
No known risks

14.2
Measures to Minimize Risks of Harm (Precautions, safeguards):

For each research procedure or intervention, describe all measures to minimize and/or eliminate risk of harms to subjects and study personnel

Participation in this protocol will impose minimal risks to the participant. As feasible, the study team will coordinate the collection of research purpose blood draws during timing of blood collection for clinical care to minimize discomfort to the patient. Blood volume collection per visit will be approximately 25 mL total. Total blood volumes collected over the 12 month duration of study will not exceed limitations for adults and children outlined in the CFR §46.110: Expedited review procedures for certain kinds of research involving no more than minimal risk, and for minor changes in approved research. Blood draw volumes will be reduced for pediatric subjects, small adults, and pregnant women in accordance with minimal risk and safety guidelines, and as needed per guidance from the primary care provider overseeing care of enrolled patients.

Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care. Specimen collection should be harmonized with the clinician’s requirements, and missed samples will not be re-drawn.

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII/PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment (PPE). PPE training will be conducted and documented for all personnel who may interact directly with patients and/or samples in order to mitigate any UPIRTSO related to accidental exposure of study staff and other individuals in the facility.

14.3
Confidentiality Protections (for research records, data and/or specimens):

Describe in detail the plan to maintain confidentiality of the research data, specimens, and records throughout the study and at its conclusion (e.g., destruction, long term storage, or banking). Explain the plan for securing the data (e.g., use of passwords, encryption, secure servers, firewalls, and other appropriate methods). If data will be shared electronically with other team members/collaborators outside the institution, describe the method of transmission and safeguards to maintain confidentiality. Explain whether this study may collect information that State or Federal law requires to be reported to other officials or ethically requires action, e.g., child or spouse abuse

A certificate of confidentiality will not be used in this protocol.

The only electronic links established between the participant name, SSN, and the Study ID number will be in the data management system managed by DCC and on a tracking spreadsheet used for scheduling purposes, which will both require a password to access and will only be accessed by authorized study personnel. During the study, source documents will be held in a secured cabinet with restricted access. Team members with access to the documents are counseled on the importance of confidentiality of participant medical records. All staff involved in this study have completed the required human subjects protection and ethics training. In all electronic records for data analysis, the participant is not referenced by name, but only Study ID number. This method is designed to protect the privacy of study participant medical information. All CRFs will be held at the individual study sites in the research spaces in secured cabinets with restricted access.

The only hard copy link between participant identifiers and Study ID will be on the Registry Form and Contact Information Form. This will be kept in a secure location separate from source document files. Any copies faxed to DCC personnel acting as a backup Registrar will be shredded after registration is complete.

In order to determine whether an individual has been enrolled previously at another study site, study staff at all active sites will have the ability to query DCC's data management system to locate an individual. The data management system is secure and can only be accessed via authorized individuals using a password.

What precautions will you take to protect the confidentiality of research source documents (Case Report Forms, questionnaires, etc.), the research data file, and the master code (if any)?

The only hard copy link established between the participant's name, SSN, and the study code number will be held in a secured cabinet with access restricted to research team members with a need to use the Registry Form or Contact Information Form. Team members with access to CRFs are counseled on the importance of confidentiality of participant medical records. In all electronic records for data analysis, the participant is not referenced by name, but only study code number.

The only electronic link will be stored on a secure password protected server. The file is only accessible directly to the DCC data custodian. The designated CRC at each site and two backups at DCC will also have access via DCC's data management system.

Will research data including Identifiable Protected Health Information be sent outside of Department of Defense facilities?

The study team may share coded data with collaborators at non-DoD facilities, and may work with participating MTFs to assist with appropriate public health data reporting requirements.

14.4
Potential Benefits:

Describe any real and potential benefits of the research to the subject and any potential benefits to a specific community or society

If the individuals in the research are considered experimental subjects (per 10 USC 980), and they cannot provide their own consent, the protocol must describe the intent to directly benefit all subjects

This is an observational study that does not test interventions that would offer direct benefit to study volunteers.

Study volunteers may indirectly benefit from enhanced clinical testing, physical examination, radiographic studies, and longitudinal follow up, or improved access to related trials of therapeutics.

14.5
Privacy for Subjects:

Describe the measures to protect subject's privacy during recruitment, the consent process, and all research activities, etc.

When possible, all means necessary will be taken to ensure participant privacy. This may entail conducting study procedures in a private area and keeping study documents coded. Non-coded study documents will be kept in a locked drawer and/or locked file in a locked room. Subjects will disclose information at their consent, if subjects choose not to disclose information, the study team will respect subject privacy and not inquire further.

14.6
Incidental or Unexpected Findings:

Describe the plan to address incidental findings and unexpected findings about individuals from screening to the end of the subject's participation in the research. In cases where the subject could possibly benefit medically or otherwise from the information, state whether or not the results of screening, research participation, research tests, etc., will be shared with subjects or their primary care provider. State whether the researcher is obligated or mandated to report results to appropriate military or civilian authorities and explain the potential impact on the subject

The study team will share relevant findings from research labs/imaging with the patient's healthcare provider(s).

Aspects of this study may include epidemiologic reporting to AFHSB and public health authorities at the respective services, state and local health departments, and CDC. That data transfer is not subject to Data Use Agreement or HIPAA requirements.

15.0
Study Monitoring

15.1 Data Monitoring Plan:

Describe the plan to monitor the data to verify that data are collected and analyzed as specified in the protocol. Include who will conduct the monitoring, what will be monitored and the frequency of monitoring

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as questionnaires may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, signed ICD and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves (questionnaires) or authorized study personnel. Only designated study personnel shall record or change data on a CRF. The data system includes password protection and internal quality checks, such as automatic range checks, to identify data that appear inconsistent, incomplete, or inaccurate. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. A Quality Management Plan (QMP) will be used for this study. The QMP will include a QC subject data review checklist, a QC Subject data review checklist, as well as automatic queries from the electronic database based on expected parameters for data entry, noting possible inconsistencies or omissions. The QC subject data review checklist will be completed at each site on 100% of subject's study files. This will be completed by another member of the study team who did not complete the original source document or CRF. A QA subject data review checklist will also be used on a small subset of study records at each site to ensure that quality management processes are being conducted appropriately for the study. QA review will be conducted by an individual on the study who is not involved in the day-to-day activities of the study.

Responsibilities of the Data Coordination Center (DCC)

1. Provides review of protocol, CRFs, data security plan and data management SOPs
2. Complies with protocol, SOPs, and all federal and local regulations and policies
3. Develops clinical database
4. Entry and quality control of CRF based study data
5. Receipt and management of specimen tracking and laboratory data
6. Provides study database to IDCRP Program Coordination Center (PCC)
7. Locks final study database

15.2 Safety Monitoring Plan:

Describe the plan to monitor the data to ensure the safety of subjects

Participation in this protocol will impose minimal risks to the participant. Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care. Specimen collection must be harmonized with the clinician's requirements, and missed samples will not be re-drawn. Proper safety training, following hospital Infection Control requirements, of study team members who come in contact with study participants will be implemented to mitigate disease transmission risk.

Termination of study participation will take place through 1) an expressed desire by the volunteer to terminate participation, 2) a determination by the on-site physician that the volunteer risks his/her health by further participation in the study, or 3) in the interest of the military mission.

15.3 Does your study require independent data and safety monitoring?

○ Yes ● No

16.0 Reportable Events

16.1 Reportable Events:

Consult with the research office at your institution to ensure requirements are met

- Describe plans for reporting expected adverse events. Identify what the expected adverse events will be for this study, describe the likelihood (frequency, severity, reversibility, short term management and any long term implications of each expected event)
- Describe plans for reporting unexpected adverse events and unanticipated problems. Address how unexpected adverse events will be identified, who will report, how often adverse events and unanticipated problems will be reviewed to determine if any changes to the research protocol or consent form are needed and the scale that will be used to grade the severity of the adverse event

Reporting Protocol Deviations

The PI or designee will be responsible for identifying and reporting all deviations, which are defined as isolated occurrences involving a procedure that did not follow the study protocol or study-specific procedure. Investigators will report protocol deviations to the USU IRB within 2 business days that:

- relate to participant safety
- relate to the informed consent process
- are any other protocol deviations which, in the opinion of the PI, should be promptly reported to the IRB.

A log of all deviations will be reported annually in the continuing review report to the IRB and in the Final Study Report.

Reportable events will also be submitted to reporting site's regulatory authorities as required.

Reporting Adverse Events and Serious Adverse Events

In this observational, no-greater-than-minimal risk study, the reporting of adverse events is limited to an analysis at the time of annual reporting. Prompt reporting is required for any related serious adverse event or unanticipated problems involving risk to subject or others (UPIRTSO).

An adverse event is defined as any untoward or unfavorable medical occurrence in a human subject, including any abnormal sign (e.g., abnormal physical exam or laboratory finding), symptom, or disease, temporally associated with the subject’s participation in the research, whether or not considered related to the research.

AEs that meet all of the following criteria will be recorded by the study team and reported to the IRB at the annual Continuing Review:

- At least possibly related to study procedures
- Unexpected (i.e. not included in the list of known risks in section 14)
- Moderate or greater severity

Additional AEs may be reported if the determined by the study site investigator to be of sufficient significance to require reporting to the IRB.

AEs are recorded and inspected by the supervising physician investigator to determine severity and relatedness to participation (definite, probable, possible, or unlikely). The physician investigator is responsible for directly managing or coordinating management of adverse events.

Reporting unanticipated problems involving risk to subjects or others

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII /PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment. Any sample collection for research purposes (as compared to clinical care) that results in an exposure to clinical staff is considered a UPIRTSO.

All UPIRTSOs will be collected and reported to the IRB within 24 hours of the PI recognition of the problem.

17.0

Equipment/non-FDA Regulated Devices

17.1 Does the study involve the use of any unique non-medical devices/equipment?

○ Yes ● No

18.0 FDA-Regulated Products

18.1 Will any drugs , dietary supplements, biologics, or devices be utilized in this study?

☐ Drugs
☐ Dietary Supplements
☐ Biologics
☐ Devices
☑ N/A

18.5 Sponsor (organization/institution/company):

☐ N/A

If applicable, provide sponsor contact information:

Infectious Diseases Clinical Research Program
Department of Preventive Medicine and Biometrics
Uniformed Services University of the Health Sciences

1.0 General Information

Title: Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC)
Protocol Number: IDCRP-085
Version/Date: Version 9.0, 01-JUN-2020

9. Study Details

9.1 Abstract/ Summary:

The overarching objective of the Epidemiology, Immunology and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EPICC) protocol is to provide the Military Health System (MHS) with a contingency protocol intended for activation at Military Treatment Facilities (MTFs) during outbreaks to allow clinical investigation of severe or potentially severe acute infections with pathogens of concern to public health and U.S. military medical readiness. The protocol outlines a systematic approach to collection of clinical specimens and data by adapting standard procedures for conducting clinical characterizations of severe emerging infections as published by the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) network (ISARIC/WHO Clinical Characterization Protocol for Severe Emerging Infections, version 3.1).

The EPICC protocol can be conducted as a multi-site study at participating MTFs, and overall protocol oversight will be coordinated centrally by the Uniformed Services University's Infectious Disease Clinical Research Program (IDCRP). EPICC activities will be executed by clinical study teams comprising existing IDCRP clinical research investigators and staff located at each MTF and protocol investigators from relevant hospital departments. MHS-wide enrollment for online survey participation will be coordinated by the IDCRP Program Coordinating Center (PCC).

The protocol is designed to be modified to accommodate longitudinal observational study of specific emerging or re-emerging pathogens. Protocol modifications will describe methods for serial collection and clinical characterization of specimens and associated demographic, laboratory, clinical, and other data specific for the pathogen of interest and associated study population(s).

9.3 Background and Significance:

The EPICC protocol is intended to serve as a foundation for modification to allow the observational, longitudinal study of specific emerging or re-emerging pathogens causing disease with pandemic potential within the MHS. Modifications responsive to specific diseases will be described to include a schedule for serial collection of clinical specimens and data and methods for recruiting, enrolling, and observational study within the desired MHS study population(s). In general, enrolled participants (eligible adults or children) who are known cases or Persons Under Investigation (PUIs) at MTFs as inpatients or in isolation settings will undergo serial collections of biological specimens and clinical and laboratory data at day of enrollment and during the duration of hospitalization or isolation, with follow-up specimen and data collection at convalescent and long-term follow up timepoints. The study design can also include clinical observational investigation in outpatients. The major focus of this protocol is to conduct clinical observational study in symptomatic individuals; however, there is also the opportunity to enroll and follow (potentially at a reduced specimen and data collection frequency relative to symptomatic participants) individuals who are asymptomatic but at increased risk for exposure. Inclusion of an asymptomatic comparator cohort could provide insight on risk factors or biomarkers associated with symptomatic versus asymptomatic presentations. The protocol supports observational, longitudinal collection of clinical specimens and data with a goal of identifying host biomarkers that predict severity of illness, resistance to infection, treatment failure, etc. If volunteers receive an experimental treatment product under eIND, the data collected through the EPICC protocol may help inform about the safety and efficacy of that product.

In subsequent sections, relevant background information on acute respiratory infections (ARI) of pandemic potential is provided, followed by specific schedule of events and other details to allow observational study of an ongoing outbreak of the 2019 novel coronavirus (COVID-19).

Acute Respiratory Infections of Pandemic Potential: Epidemiology, Immunology and Clinical Characteristics

ARI Case Definitions

To characterize the epidemiology, immunology and clinical features of novel pathogens associated with severe ARI, case definitions appropriate to emerging infection scenarios will be utilized. These definitions will vary by the availability and result of laboratory-based diagnostic tests.

I. *For laboratory-confirmed cases*, the case definition includes the presence of laboratory-confirmed infection with an agent of severe ARI (e.g., SARS-CoV-2, influenza A/H7N9, MERS-CoV, SARS, etc.).

OR

II. For persons under investigation (PUI), the case definition includes:

1. The current CDC case definition for a PUI for a respiratory pathogen under study.
2. An unknown or pending laboratory confirmation of an agent of severe ARI.

III. For individuals who are asymptomatic and have had recent high-risk exposure to the pathogen of interest such that they have increased their risk for infection, 1 or more of the following criteria must be met:

1. Unprotected exposure (for e.g., < 14 days of illness onset, modified commensurate with evolving epidemiologic information) with confirmed or suspected cases of human infection with a novel respiratory pathogen. Close contact is typically defined as coming within about 6 feet (2 meters) of a confirmed or suspected case while the case was ill (beginning 1 day prior to illness onset and continuing until resolution of illness).
2. Unprotected exposure to infectious pathogens in a laboratory setting.
3. If exigencies warrant, then asymptomatic/high exposure risk individuals in isolation may be considered for enrollment.

Acute respiratory infections (ARI) are among the most common infectious diseases. Due to conditions and circumstances of military training and deployment (e.g., crowding, inadequate hygiene practices, physical stress, etc.), military personnel in congregate settings are at increased risk for outbreaks due to ARI. There are a number of emerging viral respiratory pathogens to which military forces may be exposed, that carry substantial importation risk, and that also have significant pandemic potential. Recent and current examples are described below:

1. Influenza A/H5N1 was first identified in the human population in Hong Kong in 1997. Since 2003, 16 countries have reported 668 confirmed cases and 393 deaths due to influenza A/H5N1 (as of 1 Nov 2014). The global case fatality rate for influenza A/H5N1 infection is 60%, and the estimates range

widely (0% to 100%) by country. While the significant morbidity and mortality of influenza A/H5N1 infection is readily apparent, its occurrence among humans has been relatively infrequent to date. Circulation of H5N1 predominates in poultry, currently the main reservoir, in Asia and northeast Africa. Host-to-human (i.e., zoonotic transmission of A/H5N1) infections are unpredictable and “remain rare despite frequent and widespread contact with infected poultry and contaminated environments” (1). The majority (71%) of cases of influenza A/H5N1 have had recent exposure to live birds or contaminated areas. Cases of influenza A/H5N1 to date have been relatively young (median age: 19 years) (2). Exposure to other cases of influenza A/H5N1 has not been a major risk factor to date, suggesting that the likelihood of human-to-human transmission of this particular strain remains low (R0< 1) (3). The severity of influenza A/H5N1 is dependent upon the strain associated with infection/disease. Among strains with low pathogenicity, generally mild, non-fatal illnesses have been observed, ranging from conjunctivitis to influenza-like illness (e.g., fever, cough, sore throat, muscle aches) to lower respiratory disease (pneumonia). Among strains with high pathogenicity, the disease spectrum has ranged from a milder febrile respiratory illness to severe disease (e.g., dyspnea, hypoxemia, pneumonia, acute respiratory failure) with multi-organ disease, sometimes accompanied by nausea, abdominal pain, diarrhea, vomiting and delirium. The high mortality rate (~60%) associated with pathogenic strains of influenza A/H5N1 has been reported from multiple studies (2).

2. Influenza A/H7N9 infection of humans was first identified in China in March 2013. Since then China has reported 453 confirmed cases and 175 deaths due to influenza A/H7N9 (WHO 2014). As with influenza A/H5N1, most of the cases had recent exposures to live poultry or had visited areas where live poultry was sold (75%) (3). By contrast to influenza A/H5N1, the host reservoir, main exposures, routes of transmission, and distribution and prevalence of influenza A/H7N9 among humans and animals are unknown. Influenza A/H7N9 does not appear to transmit easily from birds or the environment to humans. In addition, reported cases of Influenza A/H7N9 have not demonstrated high transmissibility between humans to date, suggesting that the risk of pandemic potential currently remains low (4). Though limited in its reach, influenza A/H7N9 infection has been associated with significant mortality: approximately 39% of cases resulted in a fatal outcome (4).

The coronavirus associated with the Middle Eastern Respiratory Syndrome (MERS-CoV) was first identified in Saudi Arabia in 2012 (5). Several outbreaks have since occurred, originating in Middle Eastern countries and spreading globally, albeit to a limited extent, by international travelers. Symptoms including fever, rigors, malaise, cough, myalgia, headache, shortness of breath, anorexia, diarrhea and abdominal pain were observed in MERS-CoV cases (6,7). As of October 2014, a total of 897 confirmed cases and 325 deaths (case fatality rate [CFR]: 36%) have been reported worldwide (WHO 2014). In 2013, two studies concluded that MERS-CoV did not yet exhibit pandemic potential, with an estimated basic reproduction number less than 1.0 (8, 9). Some research indicates that camels may act as the host reservoir for MERS-CoV, although evidence is inconclusive (10). Human-to-human transmission of MERS-CoV has been observed in healthcare settings, possibly due to greater infectiousness in the later stages of illness; however, evidence that may further elucidate risk factors for transmission is limited (6, 7).

3. The 2002-3 pandemic of Severe Acute Respiratory Syndrome (SARS), also due to a novel Coronavirus, originated in China’s Guangdong Province and resulted in 8,422 probable cases and 916 deaths reported from 29 countries (mostly in mainland China, where 63% of cases and 38% of deaths occurred) (11). The global case fatality rate due to SARS was estimated to be 11% (11). Although the host reservoir remains unknown, some studies have found coronaviruses similar to the SARS coronavirus circulating in bat populations (12). Transmission in human populations occurs by direct contact with the infectious respiratory droplets and/or fomites via the eyes, nose, and mouth (13). The incubation period ranges from 1-14 days (mean 4-6 days) and transmissibility appears to increase with

severity of illness (greatest at day 10) (14). Attack rates ranged widely by geographic region from 2.2 per 100,000 in Guangdong Province to 25.6 per 100,000 in Hong Kong (14). Risk factors for infection include occupation as a healthcare worker (21% of all probable cases), household contact with a probable case, older age, male sex and existing illnesses (14). Symptoms include fever, dry cough, dyspnea, headache and hypoxemia (14).

4. Since December 2019 through March 2020, the **2019 novel coronavirus (SARS-CoV-2) causing “coronavirus disease 2019” (COVID-19)** has spread from Wuhan, China to 64 countries and has led to more than 88,948 confirmed cases globally, including 80,174 confirmed cases in China and 8,774 confirmed cases outside of China (15). To date, there have been 2,915 deaths in China and 128 deaths outside of China. As of 03 March 2020, in the United States there are 60 confirmed cases (22 travel-related, 11 person-to-person spread, 27 under investigation) and a total of 6 deaths (16). Individuals with COVID-19 can present with fever, and cough, ground-glass opacity on chest computed tomography (CT), and lymphocytopenia (17). The case- fatality rate (CFR) appears to be highly variable with early reports of 8-15% in older adults infected in Hubei Province (CFR is increased in adults with comorbid conditions who develop respiratory symptoms) but likely no higher than 1-2% outside of Hubei (though data is limited and this will depend on accurate detection of those with mild disease) (18). Several risk factors, including age, history of smoking, maximum body temperature on hospital admission, respiratory failure, albumin, and C-reactive protein, appear associated with increased risk for progression to pneumonia among COVID-19 hospitalized patients (19). Risk factors of disease progression and magnitude of clinical severity are incompletely understood and require further study. SARS-CoV-2 is believed to be transmitted primarily via person-to-person, such as through close contact (within about 6 feet) and exposure to respiratory droplets from an infected individual who coughs or sneezes (20). Evidence exists for transmission of SARS-CoV-2 via the oral-fecal route, as viral nucleotide was detected in rectal swabs and blood later in the course of infection when virus was not detected in oral swabs (21). On the population level, there is a poorly-defined risk of transmission via asymptomatic infection (22). The occurrence of asymptomatic infections has raised concerns about the rapid spread of transmission to vulnerable populations (21).

9.4 Objectives/Specific Aims/Research Questions:

General Goals and Objectives:

1. To describe the natural history of clinical disease
2. To identify risk factors for infection and severe clinical course
3. To characterize the host immune response to infection
4. To evaluate the correlation between symptom severity, virologic/microbiologic characteristics, the host immune response and clinical course and outcome
5. To develop diagnostic and prognostic tools for future clinical study of novel pathogens / emerging infectious diseases
6. To establish a clinical and laboratory database, and related specimen repository, for future studies of novel pathogens / emerging infectious diseases
7. To investigate efficacy of emergency Investigational New Drug (eIND) therapies that may be administered to enrolled study participants during the course of clinical care

For COVID-19 / SARS-CoV-2 infection, clinical and demographic data will be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest to include, but not limited to, the following:

- Incubation period

- Duration of illness / symptoms
- Duration of functional disability
- Duration of shedding from respiratory and gastrointestinal tract
- Incidence and duration of viremia
- Predictors of severe disease: clinical signs, symptoms, laboratory features; host factors, eg smoking, vaping, alcohol consumption, comorbid illness/conditions, occupational health factors influencing lung disease; host biomarkers; virologic (strain/virulence) attributes
- Supportive management required: O_2, HFNC, NIPPV, ventilation; hemodynamics
- Complications: e.g., bacterial pneumonia; bacteremia; AKI; liver injury; CNS involvement, etc.
- Outcomes: resolution of symptoms; return to pre-illness functional status; requirement for O_2; development / exacerbation of reactive airway disease; pulmonary function; resolution of medical complications; new Rx requirements, e.g. bronchodilators; other sequelae
- Development of immunity (i.e., correlates), kinetics, duration of antibody detection
- Relationship between acute illness (or pre-illness) CoV titer and infection, outcome, virologic parameters
- Costs of care, costs of duty days lost

9.5 Study Design:

A prospective, longitudinal cohort study of novel pathogens / emerging infections with pandemic potential

9.6 Target Population:

Study findings will be generalized and applicable to all populations that travel to or reside in disease endemic areas or live within an area that has been exposed to infectious pathogens with pandemic potential; some of which include military personnel and the general public.

9.7 Benefit to the DoD:

Infectious diseases are a significant source of morbidity among military forces. Infectious disease outbreaks compromise force readiness and interfere with training programs. Strategies to characterize and ultimately to treat and prevent the major infectious disease threats to military personnel are urgently needed.

10.0 Study Procedures and Data management

10.1 Study Procedures:

Recruitment and enrollment strategies will be dynamically responsive to the outbreak as the situation evolves. Study volunteers may be recruited from areas of the hospital where they present for care or in the inpatient and isolation settings. Informed consents and enrollments will be conducted by study staff included on the IRB approved protocol, including staff named on delegation log, and trained in study procedures. Clinical evaluations will be performed by the MTF healthcare team and may also be conducted by qualified study team members.

In addition to MTF enrollment, MHS beneficiaries who have been clinically tested for COVID-19 will be invited to participate in a limited schedule of assessments for EPICC, including completion of a series of online surveys and at-home capillary blood sample collection at three timepoints. See Appendix A for further details.

At the time of a participant's initial consultation at an MTF, study activities will consist of explanation of study goals and purpose, and obtaining informed consent (may include consultation with Legally Authorized Representative). The day of enrollment will be defined as Study Day 0. The team will subsequently conduct serial collection of data (demographics, vital signs, clinical findings, diagnostics and other laboratory results, etc.) through study participant interview and from medical record review from the time of onset of illness throughout study duration. Specific risk factors linked to pathogen exposure (e.g., travel history to disease endemic regions, contact with sick individuals or known reservoirs of disease, etc.) will also be acquired from study volunteers, mainly through interview at Day 0. Medical records collected prior to day of enrollment will also be evaluated to ascertain medical history information pertinent to understanding baseline health and analysis of underlying risk factors associated with disease progression and other outcomes. Study team members will collect for research purposes biological specimens (e.g., nasopharyngeal and oropharyngeal swabs, rectal swabs, and blood) from enrolled participants who are laboratory-confirmed cases and Persons Under Investigation (PUIs) at time of enrollment, during the duration of hospitalization and/or isolation, with follow-up specimen collections up to approximately 6 and 12 months post-enrollment.

When possible, the study team will also obtain residual volumes of specimens collected for clinical care that would otherwise be discarded. Sample types include but are not limited to bronchoalveolar lavage, blood, urine, sputum, saliva, stool, cerebrospinal fluid, semen (adults only), or vomit. As available, these residual samples will be obtained from the time of onset of the disease under study. For active duty servicemembers, the study team will also request a pre-illness (up to 2 years prior to enrollment) serum sample from the DoD Serum Repository (DoDSR)

Some subjects may undergo clinical imaging studies as part of regular patient care or as part of this protocol using clinical imaging devices. For example, point-of-care portable ultrasound may be used to image areas such as the lungs, heart, and lower extremity veins, to explore the prognostic use of ultrasound in early detection of pneumonia and cardiovascular sequelae associated with severe disease. These imaging studies, when available, will be part of the collected subject data.

Study participants recruited and enrolled at MTFs who are ambulatory cases may also be evaluated via serial self-collection of samples such as nasal swabs, oropharyngeal swabs, capillary blood samples, and/or other specimens appropriate for self-collection.

Recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital as well as healthcare providers who have potentially been exposed to known or suspected cases. Enrollees who are asymptomatic high/some risk will undergo serial collections of clinical and laboratory data as well as biological specimens (e.g., nasopharyngeal, oropharyngeal, and rectal swabs and blood) at enrollment, with follow-up specimen collections up to approximately 12 months post-enrollment. The study team may consider implementing a plan for asymptomatic study volunteers to conduct self-collection of clinical specimens (eg., nasopharyngeal swabs, oropharyngeal swabs, rectal swabs, capillary blood samples) through the follow-up period. Demographic, clinical, and other data as described above for symptomatic volunteers may also be acquired for asymptomatic high/some risk participants.

The Flu-PRO questionnaire (24-27) may be used to record the patient-reported outcome (PRO) on severity of clinical symptoms and the impact of clinical interventions on infection. A web link to the Flu-PRO questionnaire may be provided to participants to record the severity of ILI symptoms daily for 14 days from either the day of enrollment, or the date of onset of symptoms (for subjects who were asymptomatic at enrollment). Paper based versions of the Flu-PRO questionnaire may be administered as needed.

In addition, an online questionnaire will be administered at enrollment and follow-up timepoints to collect data on medical history, comorbidities, and subject-reported recovery status.

If a participant is dually-enrolled in a treatment protocol and scheduled to receive investigational products under an eIND, an additional sample may be collected in the first 48 hours after test article administration. If eligible, study participants may also be considered for enrollment concurrently in an interventional clinical trial evaluating efficacy of treatment regimens. The priority of collection of clinical specimens will be as follows: 1. specimens collected for clinical care; 2. specimens collected in support of an interventional clinical trial; and 3. specimens collected for observational study (i.e., EPICC protocol).

The study team may consider discontinuation of study participants who have a negative test result for the pathogen of interest (based on current standard of care diagnostics) and/or are diagnosed with another respiratory pathogen other than the one of interest and/or the disease of interest is highly unlikely based on the primary clinical team assessment. This approach may need to be taken to conserve study staff time and resources depending upon local epidemiologic circumstances, e.g. very high incidence and subject accrual.

Results obtained from research analyses will not be entered into the participant's medical record. However, the study team will communicate relevant findings to the participant's primary care provider overseeing care of the indicated infection of study. The study volunteer's primary healthcare provider is likely to be a member of the protocol study team, and as such will be directly aware of study findings. If the primary healthcare provider is not a part of the protocol team, relevant findings from the study will be communicated to the healthcare provider verbally in a private setting to protect patient confidentiality or via a secure encrypted electronic communication.

Pregnant participants will be followed monthly until delivery to collect information on pregnancy outcome and health of the child with regards to the disease under study, to the extent practicable. Cord blood (a clinical residual specimen) may be collected for research purposes from enrolled women following childbirth.

Specimens collected through this observational study will be evaluated in various laboratory assays to characterize the epidemiology, immunology, clinical characteristics, and other important outcomes of interest. Associated clinical and demographic data will also be evaluated, along with laboratory findings as appropriate, to assess key endpoints of interest as described above.

Schedule of Patient Evaluation and Data Collection

The table below shows the schedule of assessments for study participants enrolled in EPICC. Given the possibility of critical illness of the patient and the potential increased risk of exposure to medical personnel, assessments that cannot be completed due to patient care considerations, infection control measures, or other logistical challenges will not constitute protocol deviations. In addition, the frequency of specimen and data collection may be reduced to accommodate logistics of acquiring specimens and data among study volunteers who are outpatients.

Ambulatory subjects who do not have restrictions of movement for infection control purposes (i.e., not advised by their care provider/local health authority to remain home in isolation) will be invited to return to the hospital for follow-up assessment and collection of specimens.

If an asymptomatic and/or COVID-19-negative subject develops symptoms or receives a positive test result for COVID-19, they will be asked to contact study staff to report their symptoms/test result and will restart the schedule of assessments from Day 0.

Inpatient MTF-Enrolled Subjects

Specimen/ Data	Enrollment (Day 0)	Days 3, 7 (± 1 day)	Weekly until discharge (± 2 days)	Day 14 if Discharged (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Virology Samples – Nasal, Throat, and/or Oral specimen*	√	√	√	√			
Virology Sample - Rectal swab	√	√	√		√		
Blood¶	√	√	√	√¶	√¶	√¶	√¶
Residual clinical samples #	√	√	√	√	√	√	√
Radiologic images **	√	√					
Flu-PRO Symptom Diary ***	√	√	√	√			
Online Questionnaires	√				√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.
¶ Blood collection after discharge may be done using a commercial at-home microsampling blood collection kit.
# Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.
** Lung, cardiac, and/or venous ultrasound may be conducted on hospitalized subjects on days 0, 1, and 3 as resources and local patient care policy allows. Findings from any additional radiologic images obtained during routine clinical care will be collected for research.
*** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.

Outpatient MTF-Enrolled Subjects

Specimen/ Data	Enrollment (Day 0)	Day 7 (± 1 day)	Day 14 (± 3 days)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Virology Sample – Nasal, Throat, and/or Oral specimen*	√		√			
Blood¶	√	√	√	√	√	√
Flu-PRO Symptom Diary **	√	√	√			
Online Questionnaires	√			√	√	√
Residual clinical samples #	√	√	√	√	√	√

* To detect and analyze virus in the nose, throat, and/or mouth, the specimen collection method employed may change to follow updated best practices as reported in the scientific literature. Example sample types are swabs (nasal, nasopharyngeal, oropharyngeal) and/or saliva that may be collected by study staff or self-collected by subjects.
¶ Blood collection may be done using a commercial at-home microsampling blood collection kit.
# Residual samples from clinically-indicated lab tests will be collected for research. Sample types may include sputum, saliva, urine, stool, blood, semen (adults only) or vomit. Residuals may be obtained from samples collected starting at the date of disease onset, which may be prior to Study Day 0.
** Subjects aged 7 and older who are experiencing symptoms will be asked to complete the Flu-PRO diary for 14 days.

Online Cohort: See Appendix A

Specimen/ Data	Enrollment (Day 0)	Day 28 (± 7 days)	6 Months (± 14 days)	12 Months (± 28 days)
Online Questionnaires	√	√	√	√
Self-collected blood¶		√	√	√

¶ All blood collection for this cohort will be done using a commercial at-home microsampling blood collection kit.

Considerations for Pediatric Participants

- Flu-PRO symptom diary may be completed by subjects aged **7 and older**.
- Pediatric subjects will not be asked to complete the online questionnaires.
- Self-collection of specimens is an option for subjects aged **8 and older**.
- Blood collection volume and frequency may be reduced to comply with safety limits. For these subjects, the amount drawn may not exceed the lesser of 50 ml or 3 ml per kg in an 8 week period and collection may not occur more frequently than 2 times per week.

Research Laboratory Methods

Clinical specimens collected through this observational study will be evaluated in a variety of laboratory assays developed by laboratory partners. Specific laboratory assays to study the virologic, immunologic, and other relevant aspects of infections are unlikely to be available at the time of specimen collection (i. e., during the outbreak) given the time required to establish assays specific for novel, emerging pathogens. Below is a general description of laboratory assay methods and endpoints that may be used; however, this does not represent an exhaustive list to include new methodologies that are later developed in response to assaying novel pathogens.

To characterize virologic correlates (e.g., viremia) of clinical symptoms and disease severity, serum levels of viral genomes can be assessed by real time-PCR at various time points. Serum concentration of viral antigen can be evaluated by enzyme-linked immunosorbent assay (ELISA). These same assays may be utilized in the longitudinal detection of virus in body fluids (e.g., nasal mucosa, sputum, urine, stool, etc.) throughout the course of evaluation/illness.

In addition, serum may be assayed for concentrations of virus-specific IgM and IgG in the acute and convalescent stages of evaluation/illness. Cytokine profiles can be conducted via multiplex assay to describe the pro- versus anti-inflammatory cytokine responses of study volunteers throughout the course of illness. PBMCs may be collected to investigate cell-mediated immune responses in the acute and convalescent phases of illness.

Novel biomarkers, including transcriptomic and proteomic signatures, are promising for diagnosis and prognosis. Collection of appropriate specimens from individuals with well-characterized illnesses is required to inform assay development. Immune factors have been used as biomarkers for predicting clinical course and outcome, as well as the severity of clinical symptoms. For example, higher levels of cytokines IL2, IL7, IL10, GCSF, IP10, MCP1, MIP1A, and TNFα were observed in patients with SARS-CoV- 2 infection requiring ICU-level care compared to those receiving non-ICU care (21). Host specific responses may be evaluated using real-time PCR and other molecular methods to identify biomarkers, transcriptomic signatures, or other lab-based endpoints indicative of severity of clinical course of disease progression and other risk factors associated with clinical outcomes, etc. In addition, evaluation of host transcriptomic responses among symptomatic versus asymptomatic, high risk exposure individuals may identify an early warning means for identifying asymptomatic people who eventually develop disease.

RNA sequencing of blood specimens may also be conducted to assess viral transcription signatures as biomarkers for clinical outcomes. Blood specimens may also be used in phosphoproteomic assessments by measuring the proportion of host immune system proteins that are phosphorylated to evaluate novel biomarkers associated with activation of protein signaling pathways in response to infection.

10.2 Data Collection:

Diagnostic Tests and Laboratory Analysis to be Obtained:

As available, laboratory data elements, such as but not limited to hematologic, biochemical, and other clinical parameters; clinical images and associated reports; and clinical diagnosis of the pathogen of interest (SARS-CoV-2) and/or alternate or co-infective pathogens, will be abstracted from the medical record of study volunteers on the day of enrollment (Study Day 0), throughout the period of hospitalization (inpatients) and through duration of follow-up. In addition, laboratory and diagnostic data available in medical records prior to Day 0 will be abstracted for study of baseline health, existing co- morbidities, etc.

Data Elements

Case report forms (CRFs) for this protocol have been adapted from those of the International Severe Acute Respiratory Infection Consortium (ISARIC).

There are five main components of the data collection forms, encompassing study participant information at:

1. The time of enrollment (at time of presentation at MTF, hospital admission, or being placed in isolation),
2. Period prior to Day 0, as appropriate, to assess recent medical history,
3. Medical encounter data (inpatient or outpatient),
4. The time of discharge or death
5. Follow-up period (following hospital discharge or being released from isolation setting, or otherwise as an out-patient)

Major data variable categories to be collected include, but are not limited to the following:

- Day of enrollment
    - Demographics (Residence, Occupation, Military Status)
    - Signs and Symptoms at onset of illness and presentation for care
    - Epidemiological Risk Factors and Exposures
    - Pre-admission Medications
    - Review of recent medical history via medical record review
    - Flu-PRO symptom severity questionnaire
- Hospitalization or Isolation Period
    - Daily Observations (i.e., vital signs) and Treatments (i.e., receipt of IV fluids)
    - Daily Laboratory Results
    - Medications and Blood Products
    - Microbiology Results
    - Critical Care
    - Severe Symptoms and Complications
    - Flu-PRO symptom severity questionnaire
- Outcome
    - Final Diagnosis
    - Patient Status at Outcome
    - Follow-up period

Data Collection

Study data will be copied onto electronic CRFs at the study site. These transcriptions will occur on an ongoing basis during the study in accordance with Good Clinical Practice (GCP) guidelines. Data entered on CRFs, as well as corrections made, shall be performed by authorized individuals. This study will make use of electronic case report forms (eCRFs) using tablets with the Research Electronic Data Capture (REDCap). For cases where a tablet cannot be used because of infection control concerns or logistical issues, authorized personnel will capture CRF information using a paper based version and later electronically record results into REDCap. All data transmitted to and from the application is done using a secure, encrypted transmission (SSL/HTTPS). For increased security, the application additionally verifies the SSL certificate of the REDCap server that it is communicating with in order to validate the server's identity. The REDCap mobile application employs encryption-at-rest on the mobile device's hard drive, so all data and information stored on the device is protected from unauthorized users. REDCap has built-in safeguards such as username and PIN, and remote lockout. When resources are available, data from clinical devices including de-identified ultrasound or radiograph images, continuous vital signs, and/or cardiac telemetry will be locally stored on password-protected devices, and if possible, transmitted wirelessly to a secure Cloud backup. Henry Jackson Foundation (HJF) headquarters IT will host deidentified study data on HJF HQ secured servers. HJF is responsible for the purchase, setup, maintenance, and service of any its servers and technology.

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as surveys may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

Data Management/Quality Control

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, documentation of informed consent and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves or authorized study personnel. Only designated study personnel shall record or change data on a CRF. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. PHI will be removed from clinical devices, such as those used for radiology, and associated data will be labeled with the study participant's ID. For each pivotal analysis (e.g., for a sub-study, manuscript, or presentation), the 'snapshot' (or 'data freeze') database will be made and archived in the study data repository. After the study analysis ends, the database will be locked.

Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for this Study:

Human Biological Specimens

1. Intended Use of the Samples/Specimens/Data

Specimens will be processed and handled as appropriate following applicable MTF enhanced precaution and Infection Control SOPs. Methods for specimen collection, handling, and processing are described in their respective SOPs. Details of specimen storage, maintenance, and QA/QC are described in their respective SOPs.

Samples and data collected under this protocol will be analyzed to study the pathogenesis of disease and the host immune response to infection. Genetic testing on human specimens will be conducted to evaluate the host (subject's) immune response to SARS-CoV-2 infection and its association with clinical outcomes. Additional genetic testing will examine viral genetic markers and transcription signatures as predictors of infection severity, clinical course, and outcomes. Genetic testing results will not be provided to participants.

This is a purely observational study. Any experimental treatments will be done under other protocols for which separate IRB review and approval will be obtained.

2. How Samples/Specimens/Data Will Be Stored

Access to research samples will be limited using locked facilities and monitored freezers. Samples and data will be stored using codes assigned by the investigators or their designee(s). Data will be kept in password-protected computers. Only investigators or their designee(s) will have access to the samples and data.

3. How Samples/Specimens/Data Will Be Stored & Tracked

Samples from individuals found infected with a novel pathogen / emerging infectious disease of interest will be archived and stored at an appropriate biosafety level facility.

Samples acquired as part of the protocol will be tracked using appropriate software, such as Freezer Works, a sample tracking, biorepository management and freezer inventory program.

4. What Will Happen to the Samples/Specimens/Data at the Completion of the Protocol?

In the future, other investigators may wish to study these samples and/or data. IRB approval will be sought prior to any sharing of samples/data. Any clinical information associated with the sample with or without patient identifiers will be shared after IRB approval has been obtained. Upon study closure, all samples and data will be de-identified in accordance with the DHA-approved Data De-Identification Plan.

5. What Circumstances Would Prompt the PI to Report to the IRB Loss or Destruction of Samples/Specimens/Data

Any loss or unanticipated destruction of samples (for example, due to freezer malfunction) or data (for example, misplacing a printout of data with identifiers) that compromises the scientific integrity of the study will be reported to the IRB.

6. Storage and Tracking of Samples/Specimens/Data

Research use of data collected through this protocol will be coded and will not contain identifiers. These data will be coded with access maintained by a custodian not affiliated with the study team per IDCRP policy. Much of the subsequent research using the coded materials collected under the auspices of this study will be accomplishable through approved exempt or non-human use sub-studies. All research using the materials collected under this protocol will be conducted in accordance with an IRB-reviewed protocol. Data and specimens released for research use will be labeled by PIN only; data will be shared without any identifiers or links to individuals. The DCC custodian, the DCC Chief, will not share identifying information with investigators without explicit IRB approval.

A Defense Health Agency (DHA) Data Sharing Agreement will be implemented as needed to access MHS data. Appropriate data sharing agreements and other legal agreements will be implemented prior to sharing of data and specimens with collaborators.

Managing Data (Data Management and/or Sharing Plan) and/or Human Biological Specimens for Future Research:

If the study involves collecting, storing, or banking human specimens, data, or documents (either by the Investigator or through an established repository) for FUTURE research, address. How the specimens/data will be used, where and how data/specimens will be stored (including shipping procedures, storage plan, etc.), whether and how consent will be obtained, procedures that will fulfill subjects' request as stated in the consent, whether subjects may withdraw their data/specimens from storage, whether and how subjects may be re-contacted for future research and given the option to decline, whether there will be genetic testing on the specimens, who will have access to the data/specimens, and the linkage, the length of time that data/specimens will be stored and conditions under which data/specimens will be destroyed

Establishment of a specimen repository for future clinical and laboratory investigation for future emerging infectious disease research:

The study aims to build a repository of biological specimens (e.g. whole blood, serum, and PBMCs, as well as nasopharyngeal fluid, sputum, bronchioalveolar lavage fluid, oropharyngeal fluid, saliva, urine, semen, and rectal swab specimens, etc.) from an observational, longitudinal study of emerging infectious diseases. Specimens may be stored in an appropriate biosafety level facility at a protocol-approved biorepository. These specimen repositories will be linked to an extensive de-identified clinical database.

In the future, this repository might be used in the identification and validation of biomarkers for severe infection, identification and molecular characterization of novel pathogens, development and evaluation of new diagnostic platforms, and/or evaluation of host factors that may be associated with susceptibility and outcome. Coupled with detailed clinical history and risk factor information gleaned through electronic medical record review, this repository will ultimately be an invaluable resource for future investigations of emerging infectious diseases in clinical as well as laboratory settings. Moreover, the infrastructure developed through these activities will serve as a broad-based platform for a diverse portfolio of relevant sub-studies into emerging infectious diseases and strategies for its control and prevention.

Study Time Line

This natural history core protocol will be open indefinitely, although sites may close once an epidemic has passed.

11.0 Statistical/Data Analysis Plan

11.1 Statistical Considerations

This is an enhanced surveillance protocol using clinical observations and laboratory testing, supplemented by additional lab testing for research purposes. The frequency and expansion of such outbreaks is unknown, and hence this protocol will be activated on contingencies in many cases. Data from a given outbreak will be compiled into a dataset for descriptive analyses. Risk factors will be identified retrospectively using odds ratios. Comparison between similar outbreaks may be performed if sufficient data allows. It is recognized that a proportion (i.e., not all) of eligible subjects will consent to participate in this study. As such, the limitations and generalizability of the study findings will be acknowledged in associated reports and manuscripts.

11.2 Sample Size Estimation:

As determined by exigencies of the outbreak, and resource availability. Please see Appendix A for sample size considerations for the online cohort.

11.3 Data Analysis Plan:

Student’s t test (or Wilcoxon rank-sum test if appropriate) on continuous variables and Pearson’s chi-square tests (or Fisher’s exact test if appropriate) for categorical variable to summarize key outcomes of interest. Multivariate regression techniques will be used to assess relationships between key variables adjusted for potential confounders.

A data analysis plan will be created to meet the following reporting requirements:

- During an outbreak, descriptive clinical and laboratory data will be summarized per patient on a regular basis as appropriate for all investigators, involved hospitals, the respective service's public health agencies, AFHSB, and DHA leadership as a part of the epidemiologic reporting requirements. It is recognized this data may not be fully cleaned. Aggregate data report will be prepared monthly.

- At conclusion of an outbreak, a summary report per outbreak will be prepared once all data is cleaned. This will take an estimated 90 days.

With respect to the analysis of the study data, the following objectives will be addressed, and more fully articulated, in a statistical analysis plan:

1) Describe natural history of clinical disease.

Data items related to disease duration include duration of fever and other predominant symptoms, and days from onset of symptoms until hospital discharge/return to normal activity. Each variable will be summarized by mean, standard deviation, median, inter-quartile range, minimum and maximum overall and also for each group within several groupings: age categories, adult vs. minor, gender, different race groups, index cases vs. secondary cases, military rank and/or nature of duties for those with active duty military duty status. We will also use symptom severity data from the Flu-PRO questionnaire to explore the extent to which ARI symptom severity scores differs across the cohort.

Adverse binary outcomes where the time to event may also be of interest: These include requirement for ICU admission, development of any super infection, development of oxygen requirement, mortality, etc. For each of these, we will first give a simple summary of the number and percent experiencing each outcome. We will also summarize by different subgroups as above.

2) Identify risk factors for infection and severe clinical course.

One set of analyses will treat laboratory-confirmed diagnosis as the outcome in logistic regression models, with the following covariates: age, sex, race, military rank, service branch, type of exposure, use of personal protective equipment, etc. Similar logistic regression models will be developed to determine predictors of severe clinical course, such as mortality.

Another set of analyses will treat illness duration as a quantitative endpoint to be used as the outcome variable in multiple linear regressions. The key endpoint will be the total symptom score considered at three different time points: at symptom onset, at 48 hours post symptom onset, and at its maximum value whenever that occurs. Other potential confounders to be included as covariates are: age, sex, race, and number of days since presumed exposure.

Complementary methods of subject recruitment and data collection within the study will address the following specific aims:

1. Among COVID-19 confirmed cases, compare risk factors (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for:

    a. Those who get hospitalized vs. those who do not get hospitalized
    b. Those who get hospitalized with a ventilator vs. those who do not get hospitalized and those hospitalized but not placed on a ventilator
    c. Those who get hospitalized in the ICU vs. those who do not get hospitalized and those hospitalized but not in the ICU
    d. Those who go on to die vs. those who do not die
2. Compare <u>risk factors</u> (comorbidities, lifestyle factors, medications, exposure opportunities, general symptoms) for infection among the total COVID-19 tested study population of COVID-19 confirmed cases (test positive) vs. confirmed non-cases (test negative).
3. Compare <u>symptoms</u> between various groups:
    a. Among the total COVID-19 tested study population, COVID-19 confirmed cases vs. confirmed non-cases
    b. Among COVID-19 confirmed cases for those:
        i. who get hospitalized vs. those who do not get hospitalized
        ii. who get hospitalized in the ICU vs. those who are hospitalized, but not in the ICU
        iii. who go on to die vs. those who do not die
4. Among the COVID-19-confirmed cases and an appropriate and hypothesis-specific randomly selected comparison group, using medical record data, identify comorbidities and medications that are associated with reduced occurrence of COVID-19 symptoms as well as with becoming infected with COVID-19.

The proposed analytic strategy will be to report crude (non-adjusted), age and sex-adjusted, and multivariable adjusted probability of hospitalization in those with and without the exposures of interest.

1) Calculate crude (non-adjusted) likelihood of hospitalization in demographic sub-populations of interest (e.g. by age strata, sex, and race/ethnicity)
2) Determine the age-specific prevalence of the major comorbidities (obesity, hypertension, asthma) separately by sex and race/ethnicity
3) The primary model will be logistic regression, calculating adjusted predicted prevalence of hospitalization for those with each comorbidity alone and comorbidity clusters (since comorbidities are correlated)
    a. A priori, evaluate whether risk associated with each comorbidity is similar for men and women and for African Americans vs others (interaction by sex; interaction by race).

Conduct separate models for the active duty population and the beneficiary populations

3) Characterize host immune response.

We will examine the relationship between factors, such as the immune response (e.g., serum antibody concentration) and pathogen infection kinetics, and disease progression, symptom severity, and clinical outcomes of interest. We will look at both cross-sectional relationships (i.e., among people) and within person relationships. For cross-sectional relationships, we will start by plotting the total symptom severity score against the immune response, separately for each of the four blood samples. We anticipate a monotonic relationship, but it is possible for a U-shaped relationship in some cases, i.e., illness severity is greater if there is a too small immune response or a too large one. We will develop regression models with the outcome of the symptom severity or clinical course on the chosen function of

immune response to see if there is a statistically significant relationship. We will add covariates to control for possible confounders, such as age, race, sex, military status, etc. and others mentioned above.

4) Evaluate correlations between symptom severity, virologic/microbiologic characteristics, host immune response and clinical course/outcome.

We will consider two groups: subjects with versus without a severe clinical course, such as mortality. We will compare the proportions with a significant serum antibody ‘response’ between the two groups by contingency table chi-square tests. We anticipate that the categorization of immune response will be binary (i.e., proportion of individuals exceeding a given concentration of serum antibody), in which case we will be comparing a binomial probability between the two groups. These analyses will form the backbone for more elaborate multivariate analyses.

5) Develop diagnostic and prognostic tools.

Data and specimens from this protocol may be used in the development of diagnostic and prognostic assays for novel pathogens. For example, the collection of blood and other body fluids from individuals with laboratory-confirmed infection may aid in the development of novel assays with higher sensitivity and specificity. Additionally, the collection of longitudinal clinical characteristics in addition to clinical laboratory data may aid in the development of prediction models to determine risk factors for severe clinical course, such as mortality.

12.0 Participant Information

Subject Population:

As this is an observational study, subjects of all ages will be enrolled. Military Treatment Facilities see a diverse population including all genders and races, and a wide range of ages. This study will examine the epidemiology of novel pathogens / emerging infectious diseases, seek to identify risk factors for severe disease and elucidate mechanisms of host immunity to these pathogens.

Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study also allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Males and females of all ages who are symptomatic or asymptomatic individuals (at high/some risk of exposure) meeting inclusion criteria are eligible for participation.

Participation in the online survey-based cohort is limited to adults only.

12.5 Inclusion Criteria:

Inclusion Criteria for **MTF Enrollment:**

Individuals of any age who are located at a participating MTF and meet at least one of the following criteria:

1. **Laboratory-confirmed presence of the pathogen of interest** (e.g., SARS-CoV-2, influenza A /H7N9, etc.)
   OR
2. **Are a person under investigation (PUI) for the pathogen of interest, as identified per current CDC PUI case definition**

(refer to "Criteria to Guide Evaluation of PUI for COVID-19" at https://www.cdc.gov/coronavirus/2019-nCoV/hcp/clinical-criteria.html
OR

3. **Are asymptomatic and/or have tested negative for the pathogen of interest, but are considered per current CDC guidance to have had recent high/some risk for exposure to pathogen of interest**
   For assessing asymptomatic individuals, refer to guidance provided by the CDC for COVID-19 at: https://www.cdc.gov/coronavirus/2019-ncov/php/public-health-recommendations.html

Inclusion Criteria for **Online Enrollment:**

1. An MHS Beneficiary who has been clinically tested for the pathogen of interest
2. Able to receive email communications and respond to web-based surveys
3. ≥18 years of age

12.6 Exclusion Criteria:

1. Individuals who decline participation in the study
2. Individuals who the study investigators believe are unable to comply with the requirements of the study

13.0 Recruitment and Consent

13.1 Identification and Selection of Subjects:

Given the dynamic nature of novel pathogens/emerging infectious diseases, there is no pre-defined target enrollment for the protocol. The main objective of this protocol is to recruit and enroll a representative proportion of cases of emerging infectious diseases to characterize the epidemiology and clinical characteristics of disease. Site study team members will engage with relevant clinical staff to identify eligible patients in inpatient wards, intensive care units, acute care clinics, and emergency departments. Participants will be identified through screening of medical records to identify individuals with the recent exposures and clinical manifestations of interest, and will be approached following the initial medical evaluation. The study will be described to patients, and their eligibility and willingness to participate will be assessed. For those with confirmed infection or PUI, room access may be limited and consent will be performed by study staff members with patient access.

Individuals presenting for care at MTFs, such as at clinics or in the inpatient and isolation setting, will be recruited and enrolled and will participate in serial collection of biological specimens over a 12-month period, with more intensive (i.e., daily, weekly) data collection occurring during the inpatient or isolation period. Information on current and prior medical conditions and hospitalizations will be collected via medical chart review and/or MDR data extractions. Information on specific epidemiologic risk factors during or related to deployment (e.g., travel history, zoonotic exposures, etc.) will be ascertained through participant interview or review of available medical records (e.g., AHLTA-T, ALTHA, CHCS, Essentris, MHS Genesis, JLV (accessed via AHLTA or MHS Genesis), MDR, DMSS, and/or DRSi). Study participants evaluated at MTFs and who are either 1. ambulatory cases advised to return home and remain home in isolation or 2. classified as asymptomatic individuals with high/some risk for exposure may also be evaluated for follow up through a study design including serial self-collection of nasopharyngeal swabs, oropharyngeal swabs, rectal swabs, or other specimens appropriate for self-collection. A similar schedule of data collection and methods used for enrolled inpatients will be applied for ambulatory cases (non-hospitalized) and asymptomatic individuals as feasible.

Details on the recruitment, consent, and enrollment of subjects participating through the MHS-wide online process are included in Appendix A.

13.2 Recruitment Process:

Recruitment of study volunteers at the MTFs will rely heavily on the direct interface of healthcare providers with potential eligible participants. The study team will develop an MTF communications plan, outlined in the protocol's Manual of Procedures, that will be implemented by local site teams to facilitate identification of potential eligible participants. Study volunteers may be recruited from clinics and inpatient or isolation settings (to include PUI). In addition, recruitment of individuals who are asymptomatic at high/some risk of exposure may involve study team members approaching family or friends who escorted the sick individual to the hospital. Another group of individuals who may be approached for recruitment as asymptomatic high/some risk participants, are healthcare providers who are in close contact with and potentially exposed to known cases. Adults and children are eligible for participation.

The study team will use multiple means of communicating study awareness to enhance recruitment efforts, including periodic briefings delivered by the site PI's and their study teams to their critical care and infectious disease staff and inpatient nursing staff. Information notices with points of contacts will be posted in clinical sites such as inpatient units, acute care clinics, and several points in the emergency room. Research team members who are Active Duty military personnel will not wear visible signs of their rank during recruitment. Site PI's or their authorized designees will conduct daily queries of MTF electronic health heath records (including infectious disease reportables list, DRSi, and searching in CHCS for patients with coronavirus lab code) to identify individuals who tested positive for disease of interest and will review daily admissions into the ICU, general pediatric and internal medicine wards with their study personnel to identify new inpatients. Information from infection control, preventive medicine and infectious disease departments may be obtained to find patients who may be managed / followed outside of the MTF.

Depending on age, severity of infection, and MTF requirements, study staff will determine if a potential subject is capable and/or allowed to provide a signed consent, verbal consent, or if an LAR is required according to IRB, HIPAA, and local MTF requirements.

13.3 Compensation for Participation:

In accordance with 24 USC 30, enrolled subjects will be provided compensation in the form of a gift card. Subjects will receive:

- $50 for each outpatient venipuncture
- $10 for each self-collected blood sample and swab
- $10 for completion of online surveys and Flu-PRO

13.4 Eligibility Assessment Process:

As part of medical record review, the team will assess the eligibility of potential subjects. Individuals identified as having known risk factors for an emerging infectious disease (e.g., recent travel to a disease-endemic region, or close contact with a known or suspected infected individual or a returning traveler) who present to a participating MTF for medical care (e.g., febrile illness) or are placed into isolation are eligible for study participation. Additionally, asymptomatic high/some risk for exposure individuals may be enrolled at MTFs. Given the possibility of MTFs being used as surge capacity to support the care of individuals affected by an infectious disease outbreak, this study allows for enrollment of anyone meeting the inclusion criteria and obtaining care at a participating MTF. Eligibility will be assessed and a final determination of subject eligibility will be made during the consent process. Please refer to section 12.5 for the inclusion criteria.

13.5 Consent Process:

ICD and Assent Regulatory Requirements

Are you requesting a waiver or alteration of informed consent?

☑ Yes ☐ No

What type?

☑Waiver of documentation of informed consent

☐ Waiver or alteration of informed consent

Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff. The study team is requesting a waiver of documentation of informed consent as well as a full Waiver of HIPAA Authorization to use as appropriate based on the circumstances of the disease being studied and MTF requirements. This study falls under the following criteria noted in 32 CFR 219.117: “That the research presents no more than minimal risk of harm to subjects and involves no procedures for which written consent is normally required outside of the research context."

Please explain the consent process:

ICD and Assent Regulatory Requirements

The Informed Consent Document (ICD) and Assent Form, including a HIPAA authorization, will be reviewed and approved by the IRB prior to initiation of the study. The ICD will contain a full explanation of the possible advantages and risks of study participation. The ICD will be compliant with applicable DoD regulations, 32 CFR 219, and the Belmont Principles, and the Health Insurance Portability and Accountability Act (HIPAA) Authorization. Informed consent includes the principle that it is critical the participant be informed about the principal potential risks and benefits. This information will allow the participant to make a personal risk versus benefit decision and understand the following general principles:

- Participation is entirely voluntary,
- Participants may withdraw from participation at any time,
- Refusal to participate involves no penalty; and
- The individual is free to ask any questions that will allow him/her to understand the nature of the protocol.

An ICD or Assent Form (with parental permission) will be signed by the participant before any study-related procedures are initiated for each participant. The investigators or their designees will present the protocol in lay terms to the participants. If access is limited, an authorized member of the study team accompanied by a witness may conduct the informed consent process. Questions on the nature of the protocol, the means by which it is to be accomplished, and the risks to the participants will then be solicited. Any question that cannot be answered will be referred to the principal investigator (PI). All participants will be given the opportunity to ask questions. No participant should grant consent until questions have been answered to his/her satisfaction. Documented parental permission will be received prior to obtaining assent from a minor. If rules allow, a copy should be provided to the volunteer or their guardian.

Minors:
An assent form (with parental permission) will be used for children aged 7-17. The ICD and Assent Form (with parental permission) indicate that by signature, the participant permits access to relevant medical records by the study investigators and regulatory authorities. Documented parental permission is required prior to assent by a minor using the ICD. A Waiver of Documentation of Assent will be used for children 6 and under, documenting that the study was explained to the child in age-appropriate terms and that the child has either expressed verbal assent or does not have the capacity to do so.

For adults who are incapacitated by the illness:
Consent may be obtained by a Legally Authorized Representative (LAR). The patients should be consented themselves at such time that they are able to provide consent.

For Hospital Staff who are Active Duty Military:
Hospital staff who are active duty military, and therefore eligible for care at a military treatment facility, may be approached for consenting to the study due to their potential exposure to coronavirus. If hospital staff who are active duty military are approached for participation in the study, supervisors will not be present at any human subject recruitment sessions or during the consent process in which hospital staff who are active duty military under their supervision are afforded the opportunity to participate as human subjects. Supervisors (e.g., military and civilian supervisors or anyone in the supervisory structure) will not influence the decisions of their subordinates regarding their participation as subjects in this study.

Verbal Informed Consent:
Due to the contagious nature of the emergent infectious diseases being studied under this protocol, study staff may not always be allowed work near the potential and/or active study subjects or handle any items that they may have come in contact with per local MTF infection control policies. Therefore, obtaining signed ICDs and HIPAA Authorizations for subjects enrolled in this study may not always be feasible or safe for study staff.

The study team is requesting a waiver of documentation of informed consent as well as a full Waiver of HIPAA Authorization to use as appropriate based on the circumstances of the disease being studied and MTF requirements. When possible, the subject will provide signed ICD and HIPAA authorization. If the subject is unable to provide signed authorizations, the full Waiver of HIPAA Authorization will be utilized. If study personnel are unable to work near the potential and/or active subject for safety reasons, the study personnel will contact the patient according to the requirements of the MTF. Options may include but are not limited to speaking with the patient from a safe distance in person, contacting the patient by phone in person with a barrier in between the potential and/or active subject and the study personnel, contacting the patient by phone from a separate location, or having a study physician trained in infectious disease safety procedures meet with the potential and/or active subject in close proximity (if allowed by the MTF).

Regardless of the method of delivery, the potential and/or active subject would be thoroughly briefed on the study's Informed Consent and HIPAA information. They would also be provided with an opportunity to ask any questions and an unsigned copy of the informed consent if permissible by the MTF. In turn, study staff will thoroughly document the informed consent process and the subject's verbal approval of the ICD in the study chart. The study personnel will sign and file the ICD. The study personnel will also include a note in the study chart summarizing the informed consent process.

13.7 Withdrawal from Study Participation:

A subject may voluntarily end participation in the study at any time. If a subject withdraws, the investigator will make a reasonable effort to determine the reason for the subject's withdrawal from the study. Telephone calls, registered letters, and/or e-mail correspondence will be considered reasonable effort. Data and specimens collected up to the time of withdrawal will be retained and de-identified in accordance with IRB, HIPAA, and Safe Harbor requirements.

Subjects may be discontinued by the study team if there is a determination by the on-site physician that the volunteer may be unable to comply with the requirements of the study, or in the interest of the military mission.

14.0 Risks and Benefits

Risks of Harm:

Risks associated with obtaining specimens:

- Obtaining specimens could be associated with discomfort from a needle stick, swab, or other procedure, and occasionally associated with bleeding, bruising, local or systemic infection.

- Genetic testing may reveal sensitive information that subjects may not want disclosed, and may cause some emotional distress for the participant.

Risks associated with privacy:

- Despite meticulous precautions, breaches of confidential information (including genetic information) do occasionally occur, although the chances of such a breach are unlikely.

Expected Adverse Events from Research Risks and Reporting

- Rare (Event Rate < 1%)
  - Secondary infection and syncope from vasovagal reactions occur from blood collection in rare cases. Risks of nasopharyngeal swab, rectal swab, cheek swab could include bleeding or mucous membrane irritation.
- Less Likely (1% ≤ Event Rate < 5%)
  - No known risks
- Likely (5% ≤ Event Rate < 10%)
  - Bruising and bleeding may occur as a result of blood collection procedures.
- More likely (Event Rate ≥10%)
  - No known risks

Measures to Minimize Risks of Harm (Precautions, safeguards):

Participation in this protocol will impose minimal risks to the participant. As feasible, the study team will coordinate the collection of research purpose blood draws during timing of blood collection for clinical care to minimize discomfort to the patient. Blood volume collection per visit will be approximately 25 mL total. Total blood volumes collected over the 6 month duration of study will not exceed limitations for adults and children outlined in the CFR §46.110: Expedited review procedures for certain kinds of research involving no more than minimal risk, and for minor changes in approved research. Blood draw volumes will be reduced for pediatric subjects, small adults, and pregnant women in accordance with minimal risk and safety guidelines, and as needed per guidance from the primary care provider overseeing care of enrolled patients.

Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care. Specimen collection should be harmonized with the clinician’s requirements, and missed samples will not be re-drawn.

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII/PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment (PPE). PPE training will be conducted and documented for all personnel who may interact directly with patients and/or samples in order to mitigate any UPIRTSO related to accidental exposure of study staff and other individuals in the facility.

Confidentiality Protections (for research records, data and/or specimens):

A certificate of confidentiality will not be used in this protocol.

The only electronic links established between the participant name, SSN, and the Study ID number will be in the data management system managed by DCC and on a tracking spreadsheet used for scheduling purposes, which will both require a password to access and will only be accessed by authorized study personnel. During the study, source documents will be held in a secured cabinet with restricted access. Team members with access to the documents are counseled on the importance of confidentiality of participant medical records. All staff involved in this study have completed the required human subjects protection and ethics training. In all electronic records for data analysis, the participant is not referenced by name, but only Study ID number. This method is designed to protect the privacy of study participant medical information. All CRFs will be held at the individual study sites in the research spaces in secured cabinets with restricted access.

The only hard copy link established between the participant’s name, SSN, and the study code number will be held in a secured cabinet with access restricted to research team members with a need to use the Registry Form or Contact Information Form. Team members with access to CRFs are counseled on the

importance of confidentiality of participant medical records. In all electronic records for data analysis, the participant is not referenced by name, but only study code number.

The only electronic link will be stored on a secure password protected server. The file is only accessible directly to the DCC data custodian. The designated CRC at each site and two backups at DCC will also have access via DCC’s data management system.

The study team may share coded data with collaborators at non-DoD facilities, and may work with participating MTFs to assist with appropriate public health data reporting requirements.

Potential Benefits:

If the individuals in the research are considered experimental subjects (per 10 USC 980), and they cannot provide their own consent, the protocol must describe the intent to directly benefit all subjects

This is an observational study that does not test interventions that would offer direct benefit to study volunteers.

Study volunteers may indirectly benefit from enhanced clinical testing, physical examination, radiographic studies, and longitudinal follow up, or improved access to related trials of therapeutics.

Privacy for Subjects:

When possible, all means necessary will be taken to ensure participant privacy. This may entail conducting study procedures in a private area and keeping study documents coded. Non-coded study documents will be kept in a locked drawer and/or locked file in a locked room. Subjects will disclose information at their consent, if subjects choose not to disclose information, the study team will respect subject privacy and not inquire further.

Incidental or Unexpected Findings:

The study team will share relevant findings from research labs/imaging with the patient’s healthcare provider(s).

Aspects of this study may include epidemiologic reporting to AFHSB and public health authorities at the respective services, state and local health departments, and CDC. That data transfer is not subject to Data Use Agreement or HIPAA requirements.

15.0 Study Monitoring

Data Monitoring Plan:

The supervising principal investigator, or designated associate investigator, will be responsible for regular maintenance and review of CRFs for accuracy. Access to study files (e.g., CRFs) is restricted to care providers and research team members given specific tasks to perform. The files are kept in a secured location in each study site. Some participant-completed forms such as surveys may be completed through the web-based program. These will be transmitted directly into the study database. Research labs will transmit their testing data to the DCC using standard procedures for data handling and transmission.

During the study, the investigator will review study data from their site, including medical records, records detailing the progress of the study for each volunteer, laboratory reports, CRFs, signed ICD and authorization forms for each study volunteer, correspondence with the IRB, adverse event (AE) reports and information regarding volunteer discontinuation of the study. All required study data will be clearly and accurately recorded on source documents or CRFs by either the participant themselves (questionnaires) or authorized study personnel. Only designated study personnel shall record or change data on a CRF. The data system includes password protection and internal quality checks, such as automatic range checks, to identify data that appear inconsistent, incomplete, or inaccurate. During the study, the investigator will be responsible for the procurement of data and for quality of data recorded on the CRFs. Original observations entered directly onto the CRFs are defined as source data. A Quality Management Plan (QMP) will be used for this study. The QMP will include a QC subject data review checklist, a QC Subject data review checklist, as well as automatic queries from the electronic database based on expected parameters for data entry, noting possible inconsistencies or omissions. The QC subject data review checklist will be completed at each site on 100% of subject’s study files. This will be completed by another member of the study team who did not complete the original source document or CRF. A QA subject data review checklist will also be used on a small subset of study records at each site to ensure that quality management processes are being conducted appropriately for the study. QA review will be conducted by an individual on the study who is not involved in the day-to-day activities of the study.

Responsibilities of the Data Coordination Center (DCC)

1. Provides review of protocol, CRFs, data security plan and data management SOPs
2. Complies with protocol, SOPs, and all federal and local regulations and policies
3. Develops clinical database
4. Entry and quality control of CRF based study data
5. Receipt and management of specimen tracking and laboratory data
6. Provides study database to IDCRP Program Coordination Center (PCC)
7. Locks final study database

Safety Monitoring Plan:

Participation in this protocol will impose minimal risks to the participant. Staff safety in sample collection and handling is a concern that will be closely monitored by the Infection Control staff at the facility. Risk to staff is mitigated by minimizing an additional phlebotomy beyond that being done for clinical care.

Specimen collection must be harmonized with the clinician’s requirements, and missed samples will not be re-drawn. Proper safety training, following hospital Infection Control requirements, of study team members who come in contact with study participants will be implemented to mitigate disease transmission risk.

Termination of study participation will take place through 1) an expressed desire by the volunteer to terminate participation, 2) a determination by the on-site physician that the volunteer risks his/her health by further participation in the study, or 3) in the interest of the military mission.

16.0 Reportable Events

Reportable Events:

Reporting Protocol Deviations

The PI or designee will be responsible for identifying and reporting all deviations, which are defined as isolated occurrences involving a procedure that did not follow the study protocol or study-specific procedure. Investigators will report protocol deviations to the USU IRB within 2 business days that:

- relate to participant safety
- relate to the informed consent process
- are any other protocol deviations which, in the opinion of the PI, should be promptly reported to the IRB.

A log of all deviations will be reported annually in the continuing review report to the IRB and in the Final Study Report.

Reportable events will also be submitted to reporting site's regulatory authorities as required.

Reporting Adverse Events and Serious Adverse Events

An adverse event is any untoward or unfavorable medical occurrence in a human subject, including any abnormal sign (e.g., abnormal physical exam or laboratory finding), symptom, or disease, temporally associated with the subject's participation in the research, whether or not considered related to the research. For this minimal risk observational study, AEs that meet all of the following criteria will be recorded by the study team and reported to the IRB at the annual Continuing Review:

- At least possibly related to study procedures
- Unexpected (i.e. not included in the list of known risks in section 14)
- Moderate or greater severity

Additional AEs may be reported if determined by the study site investigator to be of sufficient significance to notify the IRB.

Prompt reporting is required for any related serious adverse events, and any unanticipated problem involving risk to subject or others (UPIRTSO).

AEs are recorded and inspected by the site PI or designee to determine severity and relatedness to study participation (definite, probable, possible, or unlikely). The physician investigator is responsible for directly managing or coordinating management of adverse events.

Because this is proposed to be a minimal risk study, the reporting of adverse events is limited to an analysis at the time of annual reporting. Prompt reporting is required for unless it is a related serious adverse event or unanticipated problem involving risk to subject or others (UPIRTSO).

Reporting unanticipated problems involving risk to subjects or others

Unanticipated problems involving risk to subjects or others (UPIRTSO) may also occur that are not related to a described harm (adverse event) to study subject, rather a potential harm (such as loss of accountability of PII/PHI) or risks to others including medical staff. Specifically in this study is a concern that collection of infection fluids may cause harm to study personnel. Collection of samples for this study must only be conducted by individuals trained and authorized to collect and handle serious biohazardous specimens wearing proper personal protective equipment. Any sample collection for research purposes (as compared to clinical care) that results in an exposure to clinical staff is considered a UPIRTSO.

All UPIRTSOs will be collected and reported to the IRB within 24 hours of the PI recognition of the problem.

20.0 References and Glossary

IDCRP-085 Appendix A – MHS-Wide Online Recruitment

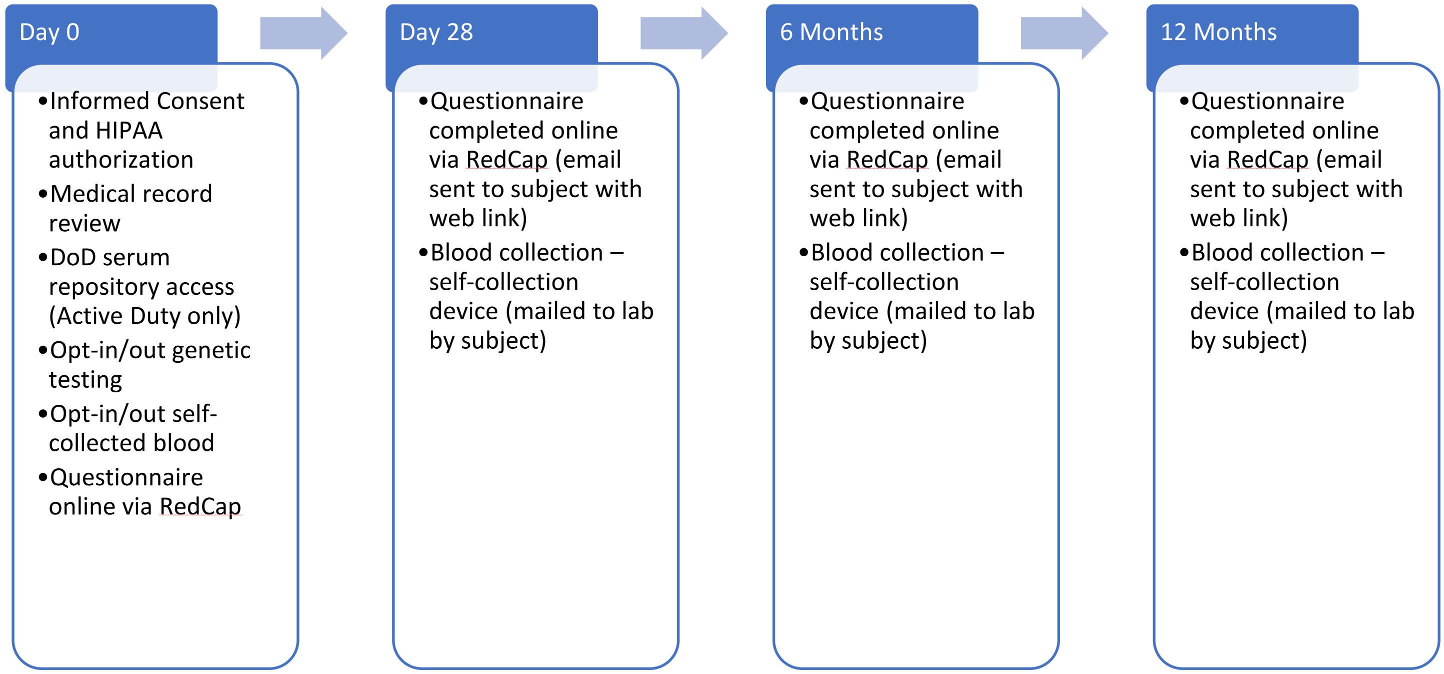
Target population: COVID-19-tested individuals who have not had contact with IDCRP study staff including at non-EPICC sites or do not wish to participate in MTF-based enrollment

Benefit: Increased enrollment and participation in limited survey; improved targeting of risk factors for infection

Procedures:

1) Consent completed electronically
    a) Medical record access
    b) DoD serum repository access, if active duty
    c) Opt-in/out self-collected blood
    d) Opt-in/out genetic testing
2) Day 0, Day 28, 6 months, 12 months – survey via REDCap
3) Day 28, 6 months, 12 months – self-collected blood

Figure 1, study schema:



Day 0
- Informed Consent and HIPAA authorization
- Medical record review
- DoD serum repository access (Active Duty only)
- Opt-in/out genetic testing
- Opt-in/out self-collected blood
- Questionnaire online via RedCap

Day 28
- Questionnaire completed online via RedCap (email sent to subject with web link)
- Blood collection – self-collection device (mailed to lab by subject)

6 Months
- Questionnaire completed online via RedCap (email sent to subject with web link)
- Blood collection – self-collection device (mailed to lab by subject)

12 Months
- Questionnaire completed online via RedCap (email sent to subject with web link)
- Blood collection – self-collection device (mailed to lab by subject)

MHS-wide Online Recruitment:

Study advertising via MHS CarePoint Information Portal messaging and MTF based flyers targeting individuals tested for either COVID19 PCR-based and/or serology tests

Recruitment approaches:

1. All adults within the MHS who have been tested for COVID-19 (irrespective of result) are identified within the Defense Health Agency (DHA) CarePoint Information Portal. In accordance with an approved DHA

DSA a weekly list of adult MHS beneficiaries who have been clinically tested for COVID-19 will be provided through secure file transfer to IDCRP Data Custodian. The list will contain the following information: patient name, DOB, DoD Number, COVID-19 test collection date, and email address.

2. An IRB-approved email message will be sent to each eligible DoD beneficiary containing a web link to consent and questionnaire. If there is no response after 1 week a second email invitation will be sent. The message to all eligible participants would inform them of eligibility in the study and direct them to contact the study website for further information and enrollment. The website will offer a description of the study objectives and procedures, as well as a consent form.
3. Upon local approval, IRB-approved recruitment flyers, with the link to the EPICC enrollment website, will also be handed out at MTFs COVID-19 evaluation/testing sites participating in the EPICC study.

Informed Consent

1. Patients will be given an opportunity to provide informed consent to enroll in the EPICC study. The prospective subject will be instructed through information on the website. There will be an opportunity to request a call from study personnel to answer questions; however, this is not required for enrollment.
2. The subject will be asked to provide their name, date of birth, last 4 of SSN, and contact information (email and phone number) in order to permit future contact as well as review and abstraction from the MHS electronic medical records related to management and outcomes of COVID-19 illness.
3. For active duty servicemembers, consent will be requested to obtain a pre-illness (up to 2 years prior) serum sample from the DoD Serum Repository (DoDSR) as well as a post-illness sample (2 months out to 1 year) in order to assess seroconversion
4. Subjects will be asked to provide an opt in to evaluate genetic susceptibility to COVID-19 (similar to current approved EPICC consent).

Study Procedures

1. Subjects will be directed on the website to completion of a questionnaire which will collect information on demographics, the illness or exposure that prompted COVID-19 testing, comorbidities, medications, and other risk factors. The subject will be contacted via email at 1, 6, and 12 months from enrollment with a link to questionnaires regarding resolution and outcomes related to the COVID-19 illness. Questionnaires will be administered at enrollment, Day 28 (± 1 week), 6 Months (± 2 weeks), and 12 Months (± 4 weeks)
2. Self-collected blood collection at home will be done using the Neoteryx Mitra® Collection Kits or similar. A subject who opts into this procedure will be mailed the collection kit closer to time of collection. The subject will collect 40 µL via finger prick using the all-in-one provided device (or a comparable microsampling kit). The Neoteryx sample dries on the collection tip. The subject will be asked to send their sample in a pre-paid mailer to the study laboratory. Information regarding the Neoteryx collection kits is available at URL: https://www.neoteryx.com/home-blood-blood-collection-kits-dried-capillary-blood (last accessed: 20 April 2020). Subjects will be provided the blood collection kits along with pre-addressed mailers for follow-up timepoints.

Sample Size Considerations and Analytic Strategy

Part I: Source Study Population

The study population will consist of MHS beneficiaries who have received SARS-CoV-2 testing. The following figures on TRICARE beneficiaries indicate the potential distribution of this population

Figure 2:

Population	Count	%
Active Duty Service Members	1.38 Million	15%
Active Duty Family Members	1.68 Million	18%
National Guard and Reserve	190,000	2%
Family Members National Guard and Reserve	780,000	8%
Retirees and Family Members < 65	3.2 Million	34%
Retirees and Family Members >= 65	2.29 Million	24%
Total	**9.5 Million**	**100%**

Uncertainties: Are all beneficiaries identifiable via DHA search or are some (e.g. retirees, dependents) who go outside of MHS for testing be captured? Uncertainty about how many minors are included in above. Source: https://www.health.mil/I-Am-A/Media/Media-Center/Patient-Population-Statistics/Patients-by-Beneficiary-Category

Part II: Approximate Demographics (Age and Sex) of Source Study Population

Tables 2a, 2b provide further details about the demographics of the TRICARE beneficiary population (active duty and other beneficiaries). Table 2a is the entire beneficiary population and Table 2b is the Active Component Population. Note from Table 2b that only about 6% of the AD population is older than 45 while 50-55% of the total TRICARE population is older than 45 (Table 2a).

Table 2a: Demographics of TRICARE Beneficiary / Adult Beneficiary Population

Age	Male	Female	Male*	Female*
<=4	6%	6%		
5-14	11%	12%		
15-17	4%	4%		
18-24	16%	11%	19%	13%
25-34	12%	11%	15%	13%
35-44	9%	10%	11%	12%
45-64	23%	24%	28%	29%
65+	19%	22%	23%	27%

*percentage of adults >= 18; Source: https://www.ncbi.nlm.nih.gov/books/NBK259169/; Estimated from Figure 2

Table 2b: Demographics of Active Component Population

Age	Male	Female	Total
15-19	5%	6%	5%
20-24	32%	34%	32%
25-29	26%	25%	26%
30-34	12%	13%	12%
35-39	11%	10%	11%
40-44	8%	8%	8%
45-49	3%	2%	3%
50-54	2%	1%	2%
55-59	1%	1%	1%

Note: 84% male; Source: Estimated from MSMR Figure 1; November 2013 Vol 20 Number 11

Table 2c: Age Distribution of Active Duty and Dependent / Retiree Population

Age	Active Duty
<=25	45%
26-30	21%

31-35	15%
36-40	10%
41+	8%

Source: file:///C:/Users/Admin/Desktop/EPICC/Stats/2017-demographics-report.pdf

Part III: Count of SARS-CoV-2 Test Positives on April 3 and April 8 2020

Limited surveillance data have been provided thus far about test results. The two tables below indicate an approximate doubling between April 3 and April 8 for military screen-positive patients. For the purpose of the sample size calculations, assume that approximately 2500 individuals (2000 active component) have been tested as of April 8 with hospitalization reported in approximately 5% thus far.

DoD COVID-19 Update April 3 2020

	Current Cases	**Hospitalized**	**Recovered**	**Deaths**
Military	978	34 (3.5%)	73	1
Dependent*	256	16 (6.3%)	12	1

DoD COVID-19 Update April 8 2020

	Current Cases	**Hospitalized**	**Recovered**	**Deaths**
Military	1975	61 (3.1%)	144	1
Dependent*	347	15 (4.3%)	35	1?

*does not include retirees as per Dr. Shauna Stahlman. Approximately the same number of retirees as dependents have been tested thus far.

60+	32%	38%	35%
Total	**34%**	**36%**	**35%**

Part V: Sample Size Calculation

The primary outcome of interest is hospitalization. We will explore whether hospitalization is associated with demographic factors (age, sex, race). We will determine whether risk is related to the presence and severity of underlying comorbidities and whether this risk is modified by the degree of controls, and medications taken, for comorbidities.

Assumptions:

- Approximately equal numbers of retirees as family member beneficiaries will access testing
- Prevalence of comorbidities in non-active duty beneficiaries will be approximately equal to the general population
- Likelihood of hospitalization is approximately 5% (although note that there are no data yet about the likelihood of hospitalization in the retiree population)
- Sample size calculations assume a study population of 5,000
- Sample size calculations based on 80% power with given study population to detect a change in prevalence of hospitalization from assumed prevalence of 5%

Prevalence of Risk Factor*	Examples	Hospitalization in Non-Exposed	Hospitalization in Exposed
20%	Hypertension, Obesity	5%	7.5%
15%	African American / All Others	5%	9%
5%	Asthma	5%	10%
2%	Diabetes	5%	15%

*Estimated weighted prevalence for tested population, assuming over-representation of AD vs beneficiaries / retirees

Interpretation:

Common risk factor (prevalence 20%): With a study population of 5000, there is 80% power to detect an approximate 1.5X risk of hospitalization vs baseline risk (e.g. 7.5% risk in those with hypertension vs 5% risk in others).

Rare risk factor (prevalence 2%): With a study population of 5000, there is 80% power to detect an approximate 3X risk of hospitalization vs baseline risk (e.g. 15% risk in those with diabetes vs 5% risk in others).

Hi all

Following up on the below:

1/ See current protocol and IRB approval to inform NIAID NHSR determination

2/ CCing in Stephanie Cammarata for agreements

3/ Eric and Chris: to confirm, is the proposed project synopsis essentially wt VNT of n = ?25 SARS-CoV-2 positive sera with and without cross binding to MERS and SARS-1 with an aim to examine how cross-binding correlates with wildtype cross-neutralization?

Thanks

Simon

Subject: RE: nhps and CoV-2 question

Dr Munster,

I am one of the AIs on the EPICC study and the director of the COVID19 research area at IDCRP. Pleased to meet you and looking forward to this EPICC subproject. Dr Brian Again is the EPICC PI and deputy science director of IDCRP and Caroline English the CRM of EPICC. Stephanie Cammarata is our IDCRP Agreements Officer (among other roles). Below are the relatively simple next logistic steps required to execute this really interesting serology subproject.

1. Ethics review (NIAID NHSR determination) - Attached is the EPICC protocol v 9 for your preliminary review. I will send ICF and protocol for version 10. Caroline are you able to send the relevant DoD determination?

2. I discussed with Stephanie Cammarata and this should just require a SLA between USU and NIAID. We can initiate this on our side.

3. Study synopsis – for the purposes of #2, we'd need a brief synopsis. Eric and Chris, this sounds like wt VNT of n = ?25 SARS-CoV-2 positive sera with and without cross binding to MERS and SARS-1 with an aim to examine how cross-binding correlates with wildtype cross-neutralization?

Happy to assist on all the above as needed

Simon

Hi Vincent,

Looping back to this topic regarding MERS/SARS-CoV VNs/PRNTs and bringing in the IDCRP leadership that can begin an approval process for non-human research determination.

We have a handful of SARS-CoV-2 IgG positive serum samples (~15 - 20) with fairly high cross-reactivity to SARS-CoV-1 and MERS-CoV. Some of these serum samples are longitudinal collections from the same subject; over time, the cross-reactivity decreases as the IgG response matures and becomes monotypic for SARS-CoV-2. It would be interesting to write a short letter about cross-reactivity and cross-neutralization between SARS-CoV-2 IgG antibodies and high priority zoonotic bCoVs.

ABSTRACT Nipah disease is listed as one of the WHO priority diseases that pose the greatest public health risk due to their epidemic potential. More than 200 experts from around the world convened in Singapore last year to mark the 20th anniversary of the first Nipah virus outbreaks in Malaysia and Singapore. Most of these AQ: A experts are now involved in responding to the coronavirus disease 2019 (COVID-19) pandemic. Here, members of the Organizing Committee of the 2019 Nipah Virus International Conference review highlights from the Nipah@20 Conference and reflect on key lessons learned from Nipah that could be applied to the understanding of the COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

KEYWORDS CEPI, COVID-19, Hendra virus, Nipah virus, epidemic, henipavirus, pandemic, paramyxovirus, public health, surveillance studies, vaccines, zoonotic infections

In December 2019, the Nipah Virus International Conference (Nipah@20) was cohosted by the Coalition for Epidemic Preparedness and Innovations (CEPI), World Health Organization (WHO), U.S. National Institute of Allergy and Infectious Disease (NIAID) of the National Institutes of Health (NIH), and Duke-NUS Medical School AQ: B (Duke-NUS). The conference marked the 20th anniversary of the first outbreak of Nipah virus infection, an emerging infectious disease (EID) that, together with coronavirus disease 2019 (COVID-19), is currently listed as one of the WHO priority diseases (1) that pose the greatest public health risk due to their epidemic potential and the insufficient countermeasures to mitigate them.

Since its first identification in Malaysia (1998) and Singapore (1999), Nipah virus infection has caused multiple outbreaks that have thus far been limited to the Asian continent. Nipah@20 provided a forum to review the history and key scientific findings over the last 20 years and to understand the current challenges in developing Nipah diagnostics, therapeutics, and vaccines. To foster international collaboration in the context of epidemic preparedness, the conference brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines, and Singapore) were represented at the conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the 2-day conference created a scientific evidence-based framework (i) to inform discussions between global health stakeholders participating in CEPI's Joint Coordination Group (JCG) on 11 December 2019 (2), (ii) to discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (iii) to identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The proceedings from the conference are now publicly available and may be consulted using the link in reference 3. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1. Make a sound investment case for preparedness. Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis, and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2002–2003 severe acute respiratory syndrome coronavirus 1 (SARS-CoV-1) outbreak. It is no surprise that most of these scientists are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of pathogen X and about the need to invest in preparedness against such a pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development, and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah disease has been known for more than 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has estimated that, to bring four Nipah vaccine candidates through successful phase 2a clinical trials, an investment of up to 200 million U.S. dollars (USD) would be required, assuming no risk of failure (4). This figure may seem high, but it pales in comparison to the economic and nonfinancial impact that a pandemic can create, as currently being demonstrated by COVID-19. Studies estimating the economic impact of past and present henipavirus outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah virus, Hendra virus, and other henipaviruses with pandemic potential. To maximize investments, the possibility of a pan-henipavirus vaccine should also be considered, similar to programs considering the development of pan-sarbecovirus vaccines (5).

Lesson 2. Articulate how to transform surveillance in animals into impact for humans. Regarding progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research are needed to propose policy and to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity (6).

Lesson 3. Articulate diagnostics use cases and target product profiles. In terms of Nipah diagnostics, the need for international reference standards was highlighted. Organizing and coordinating the collection of sera and virus isolates in the midst of an epidemic are of great importance for the timely establishment of standard material. International standards are needed for assay validation, calibration, comparison, and quality controls, but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid-based Nipah diagnostic system is being used and validated in India and Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. These and other methods for Nipah diagnostics were presented at the conference, together with a draft Nipah diagnostics target product profile (TPP) developed by the WHO R&D Blueprint team (7).

In the absence of an effective, Nipah-specific treatment, it could be argued that there is no clinical justification or direct clinical benefit to an individual patient when testing. However, what may not benefit the individual patient will undoubtedly benefit public health at large, and thus, save lives. Two use cases for Nipah diagnostics include rapid detection of Nipah virus infections at a peripheral health center or hospital and confirmation of active Nipah virus infection at a centralized laboratory. For the former, a TPP would envision a near-patient/point-of-care (NPT/POC) test for rapid screening; for the latter, the TPP would envision a NPT/POC for rapid confirmation in settings with higher infrastructures (8).

NPT/POC testing, contact tracing, and proactive quarantine of suspected cases are indicated at the onset of an outbreak and can quickly halt further spread, as evidenced by the Nipah outbreaks that were successfully contained by Indian authorities in Kerala in 2018 and 2019 (9). In an outbreak situation involving a novel pathogen of pandemic potential, referring to previously developed diagnostics use cases and TPPs can help to quickly articulate diagnostics strategies. In the early stages of a pandemic, widespread NPT/POC diagnostics may need to prioritize sensitivity at the expense of specificity, if needed. Widespread sensitive diagnostic testing combined with appropriate prevention and control measures has so far been the fastest way to bring the COVID-19 reproduction number (R_0) to less than 1 in some countries.

Lesson 4. Diversify the preclinical testing portfolio and create direct dialogue between lab scientists, pathologists, and health workers in the field. Two conference sessions were dedicated to Nipah pathogenesis in animal models and to transmission and case management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah virus-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected animals to reach the level of myocarditis deterioration observed in some Nipah virus-infected humans. There was also mention of relapse and late onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease, although many investigators have proposed such research and its importance.

For Nipah and henipaviral diseases, it is conceivable that an animal rule or similar regulatory pathway may be necessary to achieve licensure of vaccines and other countermeasures. Direct dialogue between preclinical scientists, pathologists, and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, henipavirus research has benefited from having a diverse preclinical testing portfolio, as many different animal species are susceptible AQ: C to disease, which means that preclinical studies do not have to be limited to the use of nonhuman primates (NHPs). This is also proving important for SARS-CoV-2, as research with NHPs, hamsters, mice, and ferrets ensures that COVID-19 vaccines can be tested simultaneously, according to each model, in a wider range of biosafety level 3 (BSL3) laboratory facilities for large and small animals across the world (10). It is conceivable that there will be different animal models for different endpoints such as infection, disease, and transmission. In addition, the use of human organoids is also being explored as a model to better understand SARS-CoV-2 biology in human tissue (11).

Lesson 5. Plan for clinical trials by bringing together local and regional regulators. Three sessions were dedicated to epidemiological needs for clinical trials and to

sph-sph/sph00420/sph3327d20z | xppws | S=5 | 6/25/20 | 16:41 | ArtID: | DOI:10.1128/mSphere.00602-20 | CE: CB

review progress in the development of Nipah medical countermeasures. There are several therapeutics in development, including the following: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*. One monoclonal antibody (m102.4) has completed a phase I trial in Australia and has been approved for compassionate use in humans. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that passive immunization with Nipah neutralizing antibodies can also prevent central nervous system (CNS) involvement if administered at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e., in the absence of feasible randomized controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration [DGDA]) and India (Drug Controller General of India [DCGI]). Partnerships are being built locally, with a focus on equitable access and low-cost interventions. Recognizing that pathways to Nipah vaccine licensure are likely to vary across countries, early dialogue between regulators from Asia, Europe, and North America was facilitated during the conference, and an international, Nipah-focused regulatory group was created. Similarly, bringing regulators together early during COVID-19 medical countermeasure development could result in the identification of actions that can be harmonized or accelerated to meet common requirements or convergences along the pathway to licensure across multiple national regulatory agencies.

Lesson 6. Invest in diversified platform technologies that can be harnessed for speed, scale, and access during a pandemic. One Nipah@20 session was devoted to the Nipah vaccine pipeline. At least 13 vaccine candidates have been confirmed to be under development in preclinical stages (4). Five of these active vaccine developers presented their latest preclinical data, with two speakers presenting on platform technologies that are being used for the development of COVID-19 vaccines.

AQ: D Keith Chappell and Paul Young from the University of Queensland, in Brisbane, Australia, presented their molecular clamp approach to produce a highly stable prefusion form of the Nipah virus F glycoprotein, which is responsible for membrane fusion, and could be an additional target for neutralizing antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza virus, Ebola virus, Nipah virus, and Middle East respiratory syndrome (MERS) coronavirus. This same principle is also being supported by CEPI to develop a recombinant, spike protein-based COVID-19 vaccine, with phase I trials expected to begin by July 2020.

Sarah Gilbert from the Jenner Institute, at Oxford University, United Kingdom, presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding Nipah virus (NiV) glycoprotein (G) Bangladesh. ChAdOx1 is a replication-deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, inducing strong and well-maintained humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. A single dose of a ChAdOx1-vectored Nipah vaccine protects against homologous (Bangladesh strain) and heterologous (Malaysia strain) change in the intraperitoneal Syrian golden hamster challenge model (12). Sarah Gilbert's team is now using the same chimpanzee adenoviral platform technology to develop a COVID-19 vaccine candidate, supported in part by CEPI. A single dose of the vaccine, which encodes the spike protein of SARS-CoV-2, may confer protection against disease in a rhesus macaque pneumonia model (13). This COVID-19 vaccine candidate has now entered phase I/II trials in the United Kingdom (EU Clinical Trials Register [https://www.clinicaltrialsregister.eu/ctr-search/trial/2020-001072-15/GB]), thus becoming the first CEPI-supported vaccine technology platform to move from pathogen sequence availability to phase I trials in less than 18 weeks.

AQ: E

Investment in many other vaccine platform technologies has resulted in an unprecedented speed, moving quickly from pathogen sequence availability in early 2020 to a diverse portfolio of more than 70 vaccine candidates in less than 4 months (14). Although regulatory agencies are adapting to keep up with such a rapidly evolving vaccine pipeline, preparedness for future pandemics may necessitate regulatory frameworks to preapprove specific platforms with consistent safety data in order to save precious time when plugging in a novel pathogen sequence into a vaccine platform technology. For many COVID-19 platform technologies, dialogue is ongoing to articulate strategies for large-scale manufacturing (15) and access (16).

Lesson 7. Engage regionally and locally, not just globally. The final conference session was dedicated to collaboration and synergy. Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences (CAS), described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the institute had an annual call launched around April each year for external organizations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic 16 years later.

Nivedita Gupta, from the Indian Council of Medical Research (ICMR), described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) platform. The RESEARCH platform was established on 28 August 2019, with ICMR as the secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region, 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks and to conduct clinical trials—not only on Nipah virus, but also other EIDs.

Epilogue. Unbeknownst to the scientists attending the Nipah@20 conference in Singapore in December 2019, the COVID-19 outbreak had already begun. We started the year 2020 confronted with a new EID that required rapid mobilization for vaccine development. Nipah@20 was a scientific drill, a timely dialogue about the need to invest in the development of vaccines and medical countermeasures against EIDs with pandemic potential. CEPI has since mobilized early investment for several COVID-19 vaccine candidates. As stated earlier, for two awardees, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Transparency and a collaborative spirit underpinned the Nipah@20 conference. Although Nipah virus may not seem like a priority in the current COVID-19 context, we hope that the scientific momentum will continue, with high-value EID-related research being undertaken and published. When will Henipavirus experts next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus, which was the founding member of the Henipavirus genus, sometime in 2024.

AUTHOR QUERIES

Below are queries from the copy editor indicating specific areas of concern. Please respond in-line in the main text above, either by marking a change or indicating "ok."

AQau—Please make certain that all authors' names are spelled correctly, and confirm the given-names and surnames are identified properly by the colors (this is important for how the names are indexed).
🟥= Given-Name, 🟦= Surname

AQau—An ORCID ID was provided for at least one author during submission. Please click the name associated with the ORCID ID icon (🟢) in the byline to verify that the link is working and that it links to the correct author.

AQabbr—Please check any added introductions of abbreviations and correct them if necessary.

AQA—Proofread the entire article carefully to ensure that sense was not inadvertently changed incorrectly during processing of electronic file and editing. Check that abbreviations have been introduced or spelled out correctly throughout. Check symbols (Greek symbols, diacritical marks, etc.) throughout. Correct city locations added for Duke-NUS Medical School and Icahn School of Medicine at Mount Sinai? City location must be given per ASM style.

AQfund—The table below includes funding information that you provided on the submission form when you submitted the manuscript. This funding information will not appear in the article, but it will be provided to CrossRef and made publicly available. Please check it carefully for accuracy and mark any necessary corrections. If you would like statements acknowledging financial support to be published in the article itself, please make sure that they appear in the Acknowledgments section. Statements in Acknowledgments will have no bearing on funding data deposited with CrossRef and vice versa.

Dear All,

Please find the proof for our mSphere paper, which will be published in the July/August issue of the journal. Kindly have a quick look for any last minute *editing* changes. The Editor is asking for a 48 hour turnaround; so I will send your compiled changes (if any) on Saturday 5pm, CET(Oslo). In addition:

1. @De wit, Emmie (NIH/NIAID) [E] & @Lee, Benhur, please see the question on funding sources for cross-referencing and kindly advise.
2. @Jodie Rogers, please advise if anything else should be included in the Acknowledgements section.

Also, please note that the Editor will include an accompanying editorial piece. He is currently writing this.

Many thanks to all for the final push in this.

Best wishes,

Raúl

Nipah@20: Lessons learned from another virus with pandemic potential

In December 2019, the Nipah Virus International Conference (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS). The Conference marked the 20th anniversary of the first outbreak of Nipah, an emerging infectious disease (EID) that, together with COVID-19, is currently listed as one of the WHO priority diseases that pose the greatest public health risk due to their epidemic potential and the insufficient countermeasures to mitigate them.

Since its first identification in Malaysia (1998) and Singapore (1999), Nipah virus infection has caused multiple outbreaks that have thus far been limited to the Asian continent. Nipah@20 provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines. To foster international collaboration in the context of epidemic preparedness, the conference brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all Henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in *CEPI's Joint Coordination Group (JCG) on December 11, 2019*, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The Proceedings from the Conference are now publicly available and may be consulted using this link. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1: Make a sound investment case for preparedness.

Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2002-2003 SARS-CoV-1 outbreak. And it is no surprise that most of them are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of Pathogen X, and about the need to invest in preparedness against such pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah has existed for over 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has estimated that, to bring four Nipah vaccine candidates through successful Phase 2a clinical trials, an investment of up to 200 million USD would be required, assuming no risk of failure (*Gouglas et al. 2018*). This figure may seem high, but it pales in comparison to the economic and non-financial impact that a pandemic can create, as currently being demonstrated by COVID-19. Studies estimating the economic impact of past and present henipavirus outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah, Hendra, and other henipaviruses with pandemic potential. To maximise investments, the possibility of a pan-henipavirus vaccine should also be considered, similar to programs considering the development of pan-sarbecovirus vaccines (*Burton & Walker, 2020*).

Lesson 2: Articulate how to transform surveillance in animals into impact for humans.

Regarding progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research is needed to propose policy and to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity (*Daszak et al. 2020*).

Lesson 3: Articulate Diagnostics Use Cases and Target Product Profiles.

In terms of Nipah diagnostics, the need for international reference standards was highlighted. Organizing and coordinating the collection of sera and virus isolates in the midst of an epidemic is of great importance for the timely establishment of standard material. International standards are needed for assay validation, calibration, comparison and quality controls; but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid based Nipah diagnostic system is being used and validated in India & Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. These and other methods for Nipah diagnostics were presented in the Conference, together with a draft Nipah Diagnostics Target Product Profile (TPP) developed by the WHO R&D Blueprint team (*see WHO Nipah Diagnostics webpage*).

In the absence of an effective, Nipah-specific treatment, it could be argued that there is no clinical justification or direct clinical benefit to an individual patient when testing. However, what may not benefit the individual patient will undoubtedly benefit public health at large, and thus, save lives. Two Use Cases for Nipah diagnostics include: rapid detection of Nipah virus infections at a peripheral health center or hospital, and confirmation of active Nipah virus infection at a centralized laboratory.

For the former, a TPP would envision a near-patient/point-of-care (NPT/POC) test for rapid screening; for the latter, the TPP would envision a NPT/POC for rapid confirmation in settings with higher infrastructures (*see WHO draft Nipah Diagnostics TPPs*).

NPT/POC testing, contact-tracing and proactive quarantine of suspected cases is indicated at the onset of an outbreak and can quickly halt further spread, as evidenced by the Nipah outbreaks that were successfully contained by Indian authoritities in Kerala in 2018 and 2019 (*Arunkumar et al. 2019*). In an oubreak situation involving a novel pathogen of pandemic potential, referring to previously developed Diagnostics Use Cases and TPPs can help to quickly articulate diagnostics strategies. In the early stages of a pandemic, wide-spread NPT/POC diagnostics may need to prioritise sensitivity at the expense of specificity, if needed. Wide-spread sensitive diagnostic testing combined with appropriate prevention and control measures has so far been the fastest way to bring the COVID-19 reproduction number (R_o) to less than 1 in some countries.

Lesson 4: Diversify the pre-clinical testing portfolio and create direct dialogue between lab scientists, pathologists and health workers in the field.

Two Conference sessions were dedicated to Nipah pathogenesis in animal models and to Transmission & Case-management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected-animals to reach the level of myocarditis deterioration observed in some Nipah-infected humans. There was also mention of relapse and late-onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease although many investigators have proposed such research and its importance.

For Nipah and henipaviral diseases, it is conceivable that an Animal Rule or similar regulatory pathway may be necessary to achieve licensure of vaccines and other countermeasures. Direct dialogue between preclinical scientists, pathologists and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, Henipavirus research has benefited from having a diverse pre-clinical testing portfolio, as many different animal species are susceptible to disease, which means that pre-clinical studies do *not* have to be limited to the use of non-human primates (NHPs). This is also proving important for SARS-CoV-2, as research in NHPs, hamsters, mice and ferrets ensures that COVID-19 vaccines can be tested simultaneously, according to each model, in a wider range of BSL3 laboratory facilities for large and small animals across the world (*Cohen, J. 2020*). It is conceivable that there will be different animal models for different endpoints such as infection, disease, and transmission. In addition, the use of human organoids is also being explored as a model to better understand SARS-CoV-2 biology in human tissue (*Lamers et al., 2020*).

Lesson 5: Plan for clinical trials by bringing together local and regional regulators.

Three sessions were dedicated to epidemiological needs for clinical trials and to review progress in the development of Nipah medical countermeasures. There are several therapeutics in development, including: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*. One (m102.4) has completed a Phase I trial in Australia and has been approved for compassionate use in humans. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that passive immunization with Nipah neutralizing antibodies can also prevent CNS involvement if administered at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e. in the absence of feasible randomised controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration, DGDA) and India (Drug Controller General of India, DCGI). Partnerships are being built locally, with a focus on equitable access and low-cost interventions. Recognising that pathways to Nipah vaccine licensure are likely to vary across countries, early dialogue between regulators from Asia, Europe and North America was facilitated during the Conference, and an international, Nipah-focused regulatory group was created. Similarly, bringing regulators together early during COVID-19 medical countermeasure development could result in the identification of actions that can be harmonised or accelerated to meet common requirements or convergences along the pathway to licensure across multiple national regulatory agencies.

Lesson 6: Invest in diversified platform technologies that can be harnessed for speed, scale and access during a pandemic.

One Nipah@20 session was devoted to the Nipah vaccine pipeline. At least 13 vaccine candidates have been confirmed to be under development in pre-clinical stages (*Gouglas et al. 2018*). Five of these active vaccine developers presented their latest pre-clinical data, with two speakers presenting on platform technologies that are being used for the development of COVID-19 vaccines.

Dr. Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their molecular clamp approach to produce a highly stable pre-fusion form of the Nipah virus F glycoprotein, which is responsible for membrane fusion, and could be an additional target for neutralising antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is also being supported by CEPI to develop a recombinant, spike protein-based COVID-19 vaccine, with Phase I trials expected to begin by July 2020.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, United Kingdom, presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. ChAdOx1 is a replication-deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, inducing strong and well maintained humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. A single dose of a ChAdOx1-vectored Nipah vaccine protects against homologous (Bangladesh strain) and heterologous (Malaysia strain) change in the intraperitoneal Syrian Golden Hamster challenge model (*van Doremalen et al. 2019*). Professor Gilbert's team is now using the same chimpanzee adenoviral platoform technology to develop a COVID-19 vaccine candidate, supported in part by CEPI. A single dose of the vaccine, which encodes the Spike protein of SARS-CoV-2, may confer protection against disease in a rhesus macaque pneumonia model (*van Doremalen et al. 2020*). This COVID-19 vaccine candidate has now entered Phase I/II trials in the UK (*EU Clinical Trials Register*), thus becoming the first CEPI-supported vaccine technology platform to move from pathogen sequence availability to Phase I trials in less than 18 weeks.

Investment in many other vaccine platform technologies has resulted in an unprecedented speed, moving quickly from pathogen sequence availability in early 2020 to a diverse portfolio of more than 70 vaccine candidates in less than 4 months (*Le et al. 2020*). Although regulatory agencies are adapting to keep up with such a rapidly evolving vaccine pipeline, preparedness for future pandemics may necessitate regulatory frameworks to pre-approve specific platforms with consistent safety data in order to save precious time when plugging in a novel pathogen sequence into a vaccine platform technology. For many COVID-19 platform technologies, dialogue is ongoing to articulate strategies for large-scale manufacturing (*see WHO Manufacturers meeting*) and access (*Yamey et al. 2020*).

Lesson 7: Engage regionally and locally, not just globally.

The final Conference session was dedicated to collaboration and synergy. Professor Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences (CAS), described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the Institute had an annual call launched around April each year for external organisations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic sixteen years later.

Dr. Nivedita Gupta, from the Indian Council of Medical Research (ICMR), described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform. The RESEARCH platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region, 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on Nipah virus, but also other EIDs.

Epilogue

Unbeknownst to the scientists attending the Nipah@20 conference in Singapore in December 2019, the COVID-19 outbreak had already begun. We started the year 2020 confronted with a new EID that required rapid mobilisation for vaccine development. Nipah@20 was a scientific drill, a timely dialogue about the need to invest in the development of vaccines and medical countermeasures against EIDs with pandemic potential. CEPI has since mobilised early investment for several COVID-19 vaccine candidates. As stated earlier, for two awardees, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Transparency and a collaborative spirit underpinned the Nipah@20 conference. Although Nipah virus may not seem like a priority in the current COVID-19 context, we hope that the scientific momentum will continue, with high value EID-related research being undertaken and published. When will Henipavirus experts next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus, which was the founding member of the Henipavirus genus, sometime in 2024.

Nipah@20: Lessons learned from another virus with pandemic potential

In December 2019, the Nipah Virus International Conference (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS). The Conference marked the 20th anniversary of the first outbreak of Nipah, an emerging infectious disease (EID) that, together with COVID-19, is currently listed as one of the WHO priority diseases that pose the greatest public health risk due to their epidemic potential and the insufficient countermeasures to mitigate them.

Since its first identification in Malaysia and Singapore in 1999, Nipah virus infection has caused multiple outbreaks that have thus far been limited to the Asian continent. Nipah@20 provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines. To foster international collaboration in the context of epidemic preparedness, the conference brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all Henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in *CEPI's Joint Coordination Group (JCG) on December 11, 2019*, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The Proceedings from the Conference are now publicly available and may be consulted in the following link: *(in progress, under construction by CEPI Communications)*. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1: Make a sound investment case for preparedness.

Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2002-2003 SARS-CoV-1 outbreak. And it is no surprise that most of them are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of Pathogen X, and about the need to invest in preparedness against such pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah has existed for over 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has

estimated that, to bring four Nipah vaccine candidates through successful Phase 2a clinical trials, an investment of up to 200 million USD would be required, assuming no risk of failure (*Gouglas et al. 2018*). This figure may seem high, but it pales in comparison to the economic and non-financial impact that a pandemic can create, as currently being demonstrated by COVID-19. Studies estimating the economic impact of past and present henipavirus outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah, Hendra, and other henipaviruses with pandemic potential. To maximise investments, the possibility of a pan-henipavirus vaccine should also be considered, similar to programs considering the development of pan-sarbecovirus vaccines (*Burton & Walker, 2020*).

Lesson 2: Articulate how to transform surveillance in animals into impact for humans.

Regarding progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research is needed to propose policy and to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity (*Daszak et al. 2020*).

Lesson 3: Articulate Diagnostics Use Cases and Target Product Profiles.

In terms of Nipah diagnostics, the need for international reference standards was highlighted. Organizing and coordinating the collection of sera and virus isolates in the mist of an epidemic is of great importance for the timely establishment of standard material. International standards are needed for assay validation, calibration, comparison and quality controls; but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid based Nipah diagnostic system is being used and validated in India & Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. These and other methods for Nipah diagnostics were presented in the Conference, together with a draft Nipah Diagnostics Target Product Profile (TPP) developed by the WHO R&D Blueprint team (*see WHO Nipah Diagnostics webpage*).

In the absence of an effective, Nipah-specific treatment, it could be argued that there is no clinical justification or direct clinical benefit to an individual patient when testing. However, what may not benefit the individual patient will undoubtedly benefit public health at large, and thus, save lives. Two Use Cases for Nipah diagnostics include: rapid detection of Nipah virus infections at a peripheral health center or hospital, and confirmation of active Nipah virus infection at a centralized laboratory. For the former, a TPP would envision a near-patient/point-of-care (NPT/POC) test for rapid screening; for the latter, the TPP would envision a NPT/POC for rapid confirmation in settings with higher infrastructures (*see WHO draft Nipah Diagnostics TPPs*).

NPT/POC testing, contact-tracing and proactive quarantine of suspected cases is indicated at the onset of an outbreak and can quickly halt further spread, as evidenced by the Nipah outbreaks that

were successfully contained by Indian authoritities in Kerala in 2018 and 2019 (*Arunkumar et al. 2019*). In an oubreak situation involving a novel pathogen of pandemic potential, referring to previously developed Diagnostics Use Cases and TPPs can help to quickly articulate diagnostics strategies. In the early stages of a pandemic, wide-spread NPT/POC diagnostics may need to prioritise sensitivity at the expense of specificity, if needed. Wide-spread sensitive diagnostic testing combined with appropriate prevention and control measures has so far been the fastest way to bring the COVID-19 reproduction number (R_o) to less than 1 in some countries.

Lesson 4: Diversify the pre-clinical testing portfolio and create direct dialogue between lab scientists, pathologists and health workers in the field.

Two Conference sessions were dedicated to Nipah pathogenesis in animal models and to Transmission & Case-management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected-animals to reach the level of myocarditis deterioration observed in some Nipah-infected humans. There was also mention of relapse and late-onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease although many investigators have proposed such research and its importance.

For Nipah and henipaviral diseases, it is conceivable that an Animal Rule or similar regulatory pathway may be necessary to achieve licensure of vaccines and other countermeasures. Direct dialogue between preclinical scientists, pathologists and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, Henipavirus research has benefited from having a diverse pre-clinical testing portfolio, as many different animal species are susceptible to disease, which means that pre-clinical studies do *not* have to be limited to the use of non-human primates (NHPs). This is also proving important for SARS-CoV-2, as research in NHPs, hamsters, mice and ferrets ensures that COVID-19 vaccines can be tested simultaneously, according to each model, in a wider range of BSL3 laboratory facilities for large and small animals across the world (*Cohen, J. 2020*). It is conceivable that there will be different animal models for different endpoints such as infection, disease, and transmission. In addition, the use of human organoids is also being explored as a model to better understand SARS-CoV-2 biology in human tissue (*Lamers et al., 2020*).

Lesson 5: Plan for clinical trials by bringing together local and regional regulators.

Three sessions were dedicated to epidemiological needs for clinical trials and to review progress in the development of Nipah medical countermeasures. There are several therapeutics in development, including: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two

monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*. One (m102.4) has completed a Phase I trial in Australia and has been approved for compassionate use in humans. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that passive immunization with Nipah neutralizing antibodies can also prevent CNS involvement if administered at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e. in the absence of feasible randomised controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration, DGDA) and India (Drug Controller General of India, DCGI). Partnerships are being built locally, with a focus on equitable access and low-cost interventions. Recognising that pathways to Nipah vaccine licensure are likely to vary across countries, early dialogue between regulators from Asia, Europe and North America was facilitated during the Conference, and an international, Nipah-focused regulatory group was created. Similarly, bringing regulators together early during COVID-19 medical countermeasure development could result in the identification of actions that can be harmonised or accelerated to meet common requirements or convergences along the pathway to licensure across multiple national regulatory agencies.

Lesson 6: Invest in diversified platform technologies that can be harnessed for speed, scale and access during a pandemic.

One Nipah@20 session was devoted to the Nipah vaccine pipeline. At least 13 vaccine candidates have been confirmed to be under development in pre-clinical stages (*Gouglas et al. 2018*). Five of these active vaccine developers presented their latest pre-clinical data, with two speakers presenting on platform technologies that are being used for the development of COVID-19 vaccines.

Dr. Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their molecular clamp approach to produce a highly stable pre-fusion form of the Nipah virus F glycoprotein, which is responsible for membrane fusion, and could be an additional target for neutralising antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is also being supported by CEPI to develop a recombinant, spike protein-based COVID-19 vaccine, with Phase I trials expected to begin by July 2020.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, United Kingdom, presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. ChAdOx1 is a replication-deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, inducing strong and well maintained

humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. A single dose of a ChAdOx1-vectored Nipah vaccine protects against homologous (Bangladesh strain) and heterologous (Malaysia strain) change in the intraperitoneal Syrian Golden Hamster challenge model (*van Doremalen et al. 2019*). Professor Gilbert's team is now using the same chimpanzee adenoviral platoform technology to develop a COVID-19 vaccine candidate, supported in part by CEPI. A single dose of the vaccine, which encodes the Spike protein of SARS-CoV-2, may confer protection against disease in a rhesus macaque pneumonia model (*van Doremalen et al. 2020*). This COVID-19 vaccine candidate has now entered Phase I/II trials in the UK (*EU Clinical Trials Register*), thus becoming the first CEPI-supported vaccine technology platform to move from pathogen sequence availability to Phase I trials in less than 18 weeks.

Investment in many other vaccine platform technologies has resulted in an unprecedented speed, moving quickly from pathogen sequence availability in early 2020 to a diverse portfolio of more than 70 vaccine candidates in less than 4 months (*Tung Thanh Le et al. 2020*). Although regulatory agencies are adapting to keep up with such a rapidly evolving vaccine pipeline, preparedness for future pandemics may necessitate regulatory frameworks to pre-approve specific platforms with consistent safety data in order to save precious time when plugging in a novel pathogen sequence into a vaccine platform technology. For many COVID-19 platform technologies, dialogue is ongoing to articulate strategies for large-scale manufacturing (*see WHO Manufacturers meeting*) and access (*Yamey et al. 2020*).

Lesson 7: Engage regionally and locally, not just globally.

The final Conference session was dedicated to collaboration and synergy. Professor Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences (CAS), described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the Institute had an annual call launched around April each year for external organisations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic sixteen years later.

Dr. Nivedita Gupta, from the Indian Council of Medical Research (ICMR), described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform. The RESEARCH platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region, 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on Nipah virus, but also other EIDs.

Epilogue

Unbeknownst to the scientists attending the Nipah@20 conference in Singapore in December 2019, the COVID-19 outbreak had already begun. We started the year 2020 confronted with a new EID that required rapid mobilisation for vaccine development. Nipah@20 was a scientific drill, a timely dialogue about the need to invest in the development of vaccines and medical countermeasures against EIDs with pandemic potential. CEPI has since mobilised early investment for several COVID-19 vaccine candidates. As stated earlier, for two awardees, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Transparency and a collaborative spirit underpinned the Nipah@20 conference. Although Nipah virus may not seem like a priority in the current COVID-19 context, we hope that the scientific momentum will continue, with high value EID-related research being undertaken and published. When will Henipavirus experts next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus, which was the founding member of the Henipavirus genus, sometime in 2024.

Acknowledgments*: The authors wish to thank Tung Thanh Le for his comments in the preparation of this summary. Emmie de Wit is supported by the Intramural Research Program of NIAID, NIH.*

Dear Benhur, Dear All,
Thank you all for your final comments.
All co-authors have now agreed to submit the attached version to *mSphere*. Benhur has kindly agreed to submit this and will let us know if anything else is needed.
Thanks again to all for your continued patience and contributions in this effort.
Best wishes,
Raúl

Nipah@20: Lessons learned from another virus with pandemic potential

In December 2019, the Nipah Virus International Conference (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS). The Conference marked the 20th anniversary of the first outbreak of Nipah, an emerging infectious disease (EID) that, together with COVID-19, is currently listed as one of the WHO priority diseases that pose the greatest public health risk due to their epidemic potential and the insufficient countermeasures to mitigate them.

Since its first identification in Malaysia and Singapore in 1999, Nipah virus infection has caused multiple outbreaks that have thus far been limited to the Asian continent. Nipah@20 provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines. To foster international collaboration in the context of epidemic preparedness, the conference brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all Henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

Commented [MR1]: Please check, Malaysia outbreak was in 1998

In terms of outcomes, the two-day conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in *CEPI's Joint Coordination Group (JCG) on December 11, 2019*, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The Proceedings from the Conference are now publicly available and may be consulted in the following link: *(in progress, under construction by CEPI Communications)*. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1: Make a sound investment case for preparedness.

Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2002-2003 SARS-CoV-1 outbreak. And it is no surprise that most of them are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of Pathogen X, and about the need to invest in preparedness against such pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah has existed for over 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has

estimated that, to bring four Nipah vaccine candidates through successful Phase 2a clinical trials, an investment of up to 200 million USD would be required, assuming no risk of failure (*Gouglas et al. 2018*). This figure may seem high, but it pales in comparison to the economic and non-financial impact that a pandemic can create, as currently being demonstrated by COVID-19. Studies estimating the economic impact of past and present henipavirus outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah, Hendra, and other henipaviruses with pandemic potential. To maximise investments, the possibility of a pan-henipavirus vaccine should also be considered, similar to programs considering the development of pan-sarbecovirus vaccines (*Burton & Walker, 2020*).

Lesson 2: Articulate how to transform surveillance in animals into impact for humans.

Regarding progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research is needed to propose policy and to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity (*Daszak et al. 2020*).

Lesson 3: Articulate Diagnostics Use Cases and Target Product Profiles.

In terms of Nipah diagnostics, the need for international reference standards was highlighted. Organizing and coordinating the collection of sera and virus isolates in the mist of an epidemic is of great importance for the timely establishment of standard material. International standards are needed for assay validation, calibration, comparison and quality controls; but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid based Nipah diagnostic system is being used and validated in India & Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. These and other methods for Nipah diagnostics were presented in the Conference, together with a draft Nipah Diagnostics Target Product Profile (TPP) developed by the WHO R&D Blueprint team (*see WHO Nipah Diagnostics webpage*).

In the absence of an effective, Nipah-specific treatment, it could be argued that there is no clinical justification or direct clinical benefit to an individual patient when testing. However, what may not benefit the individual patient will undoubtedly benefit public health at large, and thus, save lives. Two Use Cases for Nipah diagnostics include: rapid detection of Nipah virus infections at a peripheral health center or hospital, and confirmation of active Nipah virus infection at a centralized laboratory. For the former, a TPP would envision a near-patient/point-of-care (NPT/POC) test for rapid screening; for the latter, the TPP would envision a NPT/POC for rapid confirmation in settings with higher infrastructures (*see WHO draft Nipah Diagnostics TPPs*).

NPT/POC testing, contact-tracing and proactive quarantine of suspected cases is indicated at the onset of an outbreak and can quickly halt further spread, as evidenced by the Nipah outbreaks that

were successfully contained by Indian authoritities in Kerala in 2018 and 2019 (*Arunkumar et al. 2019*). In an oubreak situation involving a novel pathogen of pandemic potential, referring to previously developed Diagnostics Use Cases and TPPs can help to quickly articulate diagnostics strategies. In the early stages of a pandemic, wide-spread NPT/POC diagnostics may need to prioritise sensitivity at the expense of specificity, if needed. Wide-spread sensitive diagnostic testing combined with appropriate prevention and control measures has so far been the fastest way to bring the COVID-19 reproduction number (R_o) to less than 1 in some countries.

Lesson 4: Diversify the pre-clinical testing portfolio and create direct dialogue between lab scientists, pathologists and health workers in the field.

Two Conference sessions were dedicated to Nipah pathogenesis in animal models and to Transmission & Case-management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected-animals to reach the level of myocarditis deterioration observed in some Nipah-infected humans. There was also mention of relapse and late-onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease although many investigators have proposed such research and its importance.

For Nipah and henipaviral diseases, it is conceivable that an Animal Rule or similar regulatory pathway may be necessary to achieve licensure of vaccines and other countermeasures. Direct dialogue between preclinical scientists, pathologists and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, Henipavirus research has benefited from having a diverse pre-clinical testing portfolio, as many different animal species are susceptible to disease, which means that pre-clinical studies do *not* have to be limited to the use of non-human primates (NHPs). This is also proving important for SARS-CoV-2, as research in NHPs, hamsters, mice and ferrets ensures that COVID-19 vaccines can be tested simultaneously, according to each model, in a wider range of BSL3 laboratory facilities for large and small animals across the world (*Cohen, J. 2020*). It is conceivable that there will be different animal models for different endpoints such as infection, disease, and transmission. In addition, the use of human organoids is also being explored as a model to better understand SARS-CoV-2 biology in human tissue (*Lamers et al., 2020*).

Lesson 5: Plan for clinical trials by bringing together local and regional regulators.

Three sessions were dedicated to epidemiological needs for clinical trials and to review progress in the development of Nipah medical countermeasures. There are several therapeutics in development, including: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two

monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*. One (m102.4) has completed a Phase I trial in Australia and has been approved for compassionate use in humans. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that passive immunization with Nipah neutralizing antibodies can also prevent CNS involvement if administered at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e. in the absence of feasible randomised controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration, DGDA) and India (Drug Controller General of India, DCGI). Partnerships are being built locally, with a focus on equitable access and low-cost interventions. Recognising that pathways to Nipah vaccine licensure are likely to vary across countries, early dialogue between regulators from Asia, Europe and North America was facilitated during the Conference, and an international, Nipah-focused regulatory group was created. Similarly, bringing regulators together early during COVID-19 medical countermeasure development could result in the identification of actions that can be harmonised or accelerated to meet common requirements or convergences along the pathway to licensure across multiple national regulatory agencies.

Lesson 6: Invest in diversified platform technologies that can be harnessed for speed, scale and access during a pandemic.

One Nipah@20 session was devoted to the Nipah vaccine pipeline. At least 13 vaccine candidates have been confirmed to be under development in pre-clinical stages (*Gouglas et al. 2018*). Five of these active vaccine developers presented their latest pre-clinical data, with two speakers presenting on platform technologies that are being used for the development of COVID-19 vaccines.

Dr. Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their molecular clamp approach to produce a highly stable pre-fusion form of the Nipah virus F glycoprotein, which is responsible for membrane fusion, and could be an additional target for neutralising antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is also being supported by CEPI to develop a recombinant, spike protein-based COVID-19 vaccine, with Phase I trials expected to begin by July 2020.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, United Kingdom, presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. ChAdOx1 is a replication-deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, inducing strong and well maintained

humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. A single dose of a ChAdOx1-vectored Nipah vaccine protects against homologous (Bangladesh strain) and heterologous (Malaysia strain) change in the intraperitoneal Syrian Golden Hamster challenge model (*van Doremalen et al. 2019*). Professor Gilbert's team is now using the same chimpanzee adenoviral platoform technology to develop a COVID-19 vaccine candidate, supported in part by CEPI. A single dose of the vaccine, which encodes the Spike protein of SARS-CoV-2, may confer protection against disease in a rhesus macaque pneumonia model (*van Doremalen et al. 2020*). This COVID-19 vaccine candidate has now entered Phase I/II trials in the UK (*EU Clinical Trials Register*), thus becoming the first CEPI-supported vaccine technology platform to move from pathogen sequence availability to Phase I trials in less than 18 weeks.

Investment in many other vaccine platform technologies has resulted in an unprecedented speed, moving quickly from pathogen sequence availability in early 2020 to a diverse portfolio of more than 70 vaccine candidates in less than 4 months (*Tung Thanh Le et al. 2020*). Although regulatory agencies are adapting to keep up with such a rapidly evolving vaccine pipeline, preparedness for future pandemics may necessitate regulatory frameworks to pre-approve specific platforms with consistent safety data in order to save precious time when plugging in a novel pathogen sequence into a vaccine platform technology. For many COVID-19 platform technologies, dialogue is ongoing to articulate strategies for large-scale manufacturing (*see WHO Manufacturers meeting*) and access (*Yamey et al. 2020*).

Lesson 7: Engage regionally and locally, not just globally.

The final Conference session was dedicated to collaboration and synergy. Professor Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences (CAS), described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the Institute had an annual call launched around April each year for external organisations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic sixteen years later.

Dr. Nivedita Gupta, from the Indian Council of Medical Research (ICMR), described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform. The RESEARCH platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region, 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on Nipah virus, but also other EIDs.

Epilogue

Dear Raul,

Greetings from Bangladesh !!!

Thanks for sharing the final version. I have one issue to raise, please check the year of Nipah outbreak in Malaysia. To my knowledge is was in 1998.

I concur with the content and agree to be a co-author and is also in agreement with the authorship order.

Best regards,

Mahmud

Nipah@20: Lessons learned from another virus with pandemic potential

In December 2019, the Nipah Virus International Conference (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS). The Conference marked the 20th anniversary of the first outbreak of Nipah, an emerging infectious disease (EID) that, together with COVID-19, is currently listed as one of the WHO priority diseases that pose the greatest public health risk due to their epidemic potential and the insufficient countermeasures to mitigate them.

Since its first identification in Malaysia and Singapore in 1999, Nipah virus infection has caused multiple outbreaks that have thus far been limited to the Asian continent. Nipah@20 provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines. To foster international collaboration in the context of epidemic preparedness, the conference brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all Henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in *CEPI's Joint Coordination Group (JCG) on December 11, 2019*, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The Proceedings from the Conference are now publicly available and may be consulted in the following link: *(in progress, under construction by CEPI Communications)*. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1: Make a sound investment case for preparedness.

Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2002-2003 SARS-CoV-1 outbreak. And it is no surprise that most of them are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of Pathogen X, and about the need to invest in preparedness against such pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah has existed for over 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has

estimated that, to bring four Nipah vaccine candidates through successful Phase 2a clinical trials, an investment of up to 200 million USD would be required, assuming no risk of failure (*Gouglas et al. 2018*). This figure may seem high, but it pales in comparison to the economic and non-financial impact that a pandemic can create, as currently being demonstrated by COVID-19. Studies estimating the economic impact of past and present henipavirus outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah, Hendra, and other henipaviruses with pandemic potential. To maximise investments, the possibility of a pan-henipavirus vaccine should also be considered, similar to programs considering the development of pan-sarbecovirus vaccines (*Burton & Walker, 2020*).

Lesson 2: Articulate how to transform surveillance in animals into impact for humans.

Regarding progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research is needed to propose policy and to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity (*Daszak et al. 2020*).

Lesson 3: Articulate Diagnostics Use Cases and Target Product Profiles.

In terms of Nipah diagnostics, the need for international reference standards was highlighted. Organizing and coordinating the collection of sera and virus isolates in the midst of an epidemic is of great importance for the timely establishment of standard material. International standards are needed for assay validation, calibration, comparison and quality controls; but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid based Nipah diagnostic system is being used and validated in India & Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. These and other methods for Nipah diagnostics were presented in the Conference, together with a draft Nipah Diagnostics Target Product Profile (TPP) developed by the WHO R&D Blueprint team (*see* *WHO Nipah Diagnostics webpage*).

In the absence of an effective, Nipah-specific treatment, it could be argued that there is no clinical justification or direct clinical benefit to an individual patient when testing. However, what may not benefit the individual patient will undoubtedly benefit public health at large, and thus, save lives. Two Use Cases for Nipah diagnostics include: rapid detection of Nipah virus infections at a peripheral health center or hospital, and confirmation of active Nipah virus infection at a centralized laboratory. For the former, a TPP would envision a near-patient/point-of-care (NPT/POC) test for rapid screening; for the latter, the TPP would envision a NPT/POC for rapid confirmation in settings with higher infrastructures (*see WHO draft Nipah Diagnostics TPPs*).

NPT/POC testing, contact-tracing and proactive quarantine of suspected cases is indicated at the onset of an outbreak and can quickly halt further spread, as evidenced by the Nipah outbreaks that

were successfully contained by Indian authoritities in Kerala in 2018 and 2019 (*Arunkumar et al. 2019*). In an oubreak situation involving a novel pathogen of pandemic potential, referring to previously developed Diagnostics Use Cases and TPPs can help to quickly articulate diagnostics strategies. In the early stages of a pandemic, wide-spread NPT/POC diagnostics may need to prioritise sensitivity at the expense of specificity, if needed. Wide-spread sensitive diagnostic testing combined with appropriate prevention and control measures has so far been the fastest way to bring the COVID-19 reproduction number (R_o) to less than 1 in some countries.

Lesson 4: Diversify the pre-clinical testing portfolio and create direct dialogue between lab scientists, pathologists and health workers in the field.

Two Conference sessions were dedicated to Nipah pathogenesis in animal models and to Transmission & Case-management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected-animals to reach the level of myocarditis deterioration observed in some Nipah-infected humans. There was also mention of relapse and late-onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease although many investigators have proposed such research and its importance.

For Nipah and henipaviral diseases, it is conceivable that an Animal Rule or similar regulatory pathway may be necessary to achieve licensure of vaccines and other countermeasures. Direct dialogue between preclinical scientists, pathologists and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, Henipavirus research has benefited from having a diverse pre-clinical testing portfolio, as many different animal species are susceptible to disease, which means that pre-clinical studies do *not* have to be limited to the use of non-human primates (NHPs). This is also proving important for SARS-CoV-2, as research in NHPs, hamsters, mice and ferrets ensures that COVID-19 vaccines can be tested simultaneously, according to each model, in a wider range of BSL3 laboratory facilities for large and small animals across the world (*Cohen, J. 2020*). It is conceivable that there will be different animal models for different endpoints such as infection, disease, and transmission. In addition, the use of human organoids is also being explored as a model to better understand SARS-CoV-2 biology in human tissue (*Lamers et al., 2020*).

Lesson 5: Plan for clinical trials by bringing together local and regional regulators.

Three sessions were dedicated to epidemiological needs for clinical trials and to review progress in the development of Nipah medical countermeasures. There are several therapeutics in development, including: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two

monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*. One (m102.4) has completed a Phase I trial in Australia and has been approved for compassionate use in humans. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that passive immunization with Nipah neutralizing antibodies can also prevent CNS involvement if administered at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e. in the absence of feasible randomised controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration, DGDA) and India (Drug Controller General of India, DCGI). Partnerships are being built locally, with a focus on equitable access and low-cost interventions. Recognising that pathways to Nipah vaccine licensure are likely to vary across countries, early dialogue between regulators from Asia, Europe and North America was facilitated during the Conference, and an international, Nipah-focused regulatory group was created. Similarly, bringing regulators together early during COVID-19 medical countermeasure development could result in the identification of actions that can be harmonised or accelerated to meet common requirements or convergences along the pathway to licensure across multiple national regulatory agencies.

Lesson 6: Invest in diversified platform technologies that can be harnessed for speed, scale and access during a pandemic.

One Nipah@20 session was devoted to the Nipah vaccine pipeline. At least 13 vaccine candidates have been confirmed to be under development in pre-clinical stages (*Gouglas et al. 2018*). Five of these active vaccine developers presented their latest pre-clinical data, with two speakers presenting on platform technologies that are being used for the development of COVID-19 vaccines.

Dr. Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their molecular clamp approach to produce a highly stable pre-fusion form of the Nipah virus F glycoprotein, which is responsible for membrane fusion, and could be an additional target for neutralising antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is also being supported by CEPI to develop a recombinant, spike protein-based COVID-19 vaccine, with Phase I trials expected to begin by July 2020.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, United Kingdom, presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. ChAdOx1 is a replication-deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, inducing strong and well maintained

humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. A single dose of a ChAdOx1-vectored Nipah vaccine protects against homologous (Bangladesh strain) and heterologous (Malaysia strain) change in the intraperitoneal Syrian Golden Hamster challenge model (*van Doremalen et al. 2019*). Professor Gilbert's team is now using the same chimpanzee adenoviral platoform technology to develop a COVID-19 vaccine candidate, supported in part by CEPI. A single dose of the vaccine, which encodes the Spike protein of SARS-CoV-2, may confer protection against disease in a rhesus macaque pneumonia model (*van Doremalen et al. 2020*). This COVID-19 vaccine candidate has now entered Phase I/II trials in the UK (*EU Clinical Trials Register*), thus becoming the first CEPI-supported vaccine technology platform to move from pathogen sequence availability to Phase I trials in less than 18 weeks.

Investment in many other vaccine platform technologies has resulted in an unprecedented speed, moving quickly from pathogen sequence availability in early 2020 to a diverse portfolio of more than 70 vaccine candidates in less than 4 months (*Tung Thanh Le et al. 2020*). Although regulatory agencies are adapting to keep up with such a rapidly evolving vaccine pipeline, preparedness for future pandemics may necessitate regulatory frameworks to pre-approve specific platforms with consistent safety data in order to save precious time when plugging in a novel pathogen sequence into a vaccine platform technology. For many COVID-19 platform technologies, dialogue is ongoing to articulate strategies for large-scale manufacturing (*see WHO Manufacturers meeting*) and access (*Yamey et al. 2020*).

Lesson 7: Engage regionally and locally, not just globally.

The final Conference session was dedicated to collaboration and synergy. Professor Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences (CAS), described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the Institute had an annual call launched around April each year for external organisations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic sixteen years later.

Dr. Nivedita Gupta, from the Indian Council of Medical Research (ICMR), described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform. The RESEARCH platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region, 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on Nipah virus, but also other EIDs.

Epilogue

Expected length: No more than 5 pages/2800 words (currently 2800 words)

Unbeknownst to the scientists attending the Nipah@20 conference in Singapore in December 2019, the COVID-19 outbreak had already begun. We started the year 2020 confronted with a new EID that required rapid mobilisation for vaccine development. Nipah@20 was a scientific drill, a timely dialogue about the need to invest in the development of vaccines and medical countermeasures against EIDs with pandemic potential. CEPI has since mobilised early investment for several COVID-19 vaccine candidates. As stated earlier, for two awardees, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Transparency and a collaborative spirit underpinned the Nipah@20 conference. Although Nipah virus may not seem like a priority in the current COVID-19 context, we hope that the scientific momentum will continue, with high value EID-related research being undertaken and published. When will Henipavirus experts next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus, which was the founding member of the Henipavirus genus, sometime in 2024.

Hi Raul

Thanks for sending through the final version. This article is looking great. I just found one grammatical error:
Page 2 – Lesson 3: it should be the "midst" of an epidemic (not mist). I have also captured this in the attached document for tracking changes.

I am happy with the authorship order.

Kind regards
Kim

Nipah@20: Lessons learned from another virus with pandemic potential

In December 2019, a Nipah Virus International Conference (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS).

The Conference marked the 20th anniversary of the discovery of Nipah virus. Since its first identification in Malaysia and Singapore in 1999, the understanding of Nipah virus infection and its pandemic potential has advanced substantially. The Conference provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines.

To foster international collaboration in the context of epidemic preparedness, Nipah@20 brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all Henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day Conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in CEPI's Joint Coordination Group (JCG) on December 11, 2019, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

The Proceedings from the Conference are now publicly available and may consulted in the following link: *(in progress, under construction by CEPI Communications)*. Highlights and commentaries from members of the International Organising Committee follow, with an emphasis on lessons learned from Nipah that could be applied to our understanding of the current COVID-19 pandemic and to preparedness against future emerging infectious diseases (EIDs) of pandemic potential.

Lesson 1: Make a sound investment case for preparedness.

Nipah@20 brought together a community of scientists who, over the past 20 years, have passionately studied the epidemiology, virology, pathogenesis and therapeutics of viruses that have pandemic potential. Many of the invited speakers were involved in understanding and responding to the 2003 SARS-CoV-1 outbreak. And it is no surprise that most of them are currently involved in responding to the COVID-19 pandemic. For the past 15 years, this scientific community has been heavily involved in warning governments about the possible emergence of Pathogen X, and about the need to invest in preparedness against such pathogen.

In terms of policy and implementation, however, prior to the emergence of SARS-CoV-2, this scientific community had struggled to convince policy makers about the benefits to invest in research, development and vaccine manufacturing preparedness against pandemics. As an example, even though Nipah has existed for over 20 years, investment on Nipah vaccine development has been limited. The development of a sound business/investment case remains a priority to conduct advocacy and to move forward the development of effective Nipah countermeasures. CEPI has

estimated that, to bring four Nipah vaccine candidates through successful Phase 2a clinical trials, an investment of up to 1300 million USD would be required (*Gouglas et al. 2018*). This figure may seem high, but it pales in comparison to the economic impact that a pandemic can create. Studies estimating the economic impact of past and present Nipah outbreaks could provide valuable data to model a sound investment case for medical countermeasures against Nipah and other henipaviruses with pandemic potential.

Lesson 2: Articulate how to transform surveillance in animals into impact for humans.

With regard to progress and challenges in surveillance, scientists from several countries presented their research on Nipah and Henipavirus-like sequences found in bat samples throughout Asia and Africa. In addition, the Indian Council for Medical Research (ICMR) has found several new viruses among bats and is exploring their EID potential. Opinions may vary on how to translate bat surveillance into policy and prevention of disease. However, it is clear that international collaboration and further investment on surveillance research is needed to prepare against potential new pathogens that will continue to emerge from bats and other animals in areas with high biodiversity.

Lesson 3: Articulate a strategy for a potential diagnostics conundrum.

In terms of diagnostics, the need for international reference standards was highlighted. International standards are needed for assay validation, calibration, comparison and quality controls; but cost-effective diagnostic kits and devices are also needed. For example, a mobile, nucleic acid based Nipah diagnostic system is being used and validated in India & Bangladesh, with potential applications in clinical trials and outbreak response against other EIDs. In the absence of an effective, Nipah-specific treatment, however, it could be argued that there is no clinical justification or clinical incentive for testing. This is a dilemma that may also apply to other EIDs of pandemic potential: testing and surveillance are beneficial for containment, contact-tracing and rapid response; but in the absence of a specific treatment, what are the benefits to the patient, and how should health providers prioritise diagnostic allocation in resource-constrained settings? Though all countries *should*, not all countries *can* provide diagnostics to test suspect cases of Nipah or other EIDs of pandemic potential. Clear guidance must be developed on how to prioritise diagnostic resources when resources are limited in a pandemic situation in which resources are likely to be limited.

Lesson 4: Diversify the pre-clinical testing portfolio and create direct dialogue between lab scientists, pathologists and health workers in the field.

Two Conference sessions were dedicated to Nipah pathogenesis in animal models and to Transmission & Case-management in humans. Data were presented on aerosol and intranasal challenges in African green monkeys (AGM), intratracheal challenge in cynomolgus macaques, and intranasal challenge in ferrets. Although models vary in recapitulating specific aspects of Nipah disease observed in humans, there was no specific mention of myocarditis observed in heart tissue. Myocarditis has been a consistent observation among Nipah-infected patients in India and Bangladesh, but this has not yet been reported in animal models. It is possible that this difference may be due to early humane endpoints not allowing the heart tissue from infected-animals to reach the level of myocarditis deterioration observed in some Nipah-infected humans. There was also mention of relapse and late-onset of infection observed in Malaysian patients several years after the acute infection. There is no evidence of renewed viremia during relapsed encephalitis in humans, and there is currently no animal model for relapsing Nipah disease although many investigators have proposed such research and its importance. Direct dialogue between preclinical scientists, pathologists and health workers can better inform the design of animal models suitable for EID countermeasure development. Importantly, Henipavirus research has benefited from having a diverse pre-clinical testing portfolio, as many different animal species are susceptible to disease, which means that pre-clinical studies do not have to be limited to the use of non-human primates (NHPs). This is also proving important for SARS-CoV-2, as research in NHPs, hamsters, mice and ferrets ensures that COVID-19 vaccines can be tested simultaneously in a wider range of BSL3 laboratory facilities for large and small animals across the world.

Lesson 5: Plan for therapeutics and vaccine clinical trials by engaging locally.

Three sessions were dedicated to epidemiological needs for clinical trials and to review progress in the development of Nipah vaccines and therapeutics. There are several therapeutics in development, including: lipid-anchored peptides to prevent viral fusion, low-cost compounds such as heparin, and a nasal spray with compounds for potential prophylactic use. There are also two monoclonal antibodies that can neutralize the virus and protect against Henipavirus infection and disease *in vivo*, and one (m102.4) has completed a Phase I trial in Australia and approved for compassionate use in humans. Preclinical data from five Nipah vaccine candidates were also presented, along with one Nipah vaccine candidate, a recombinant subunit G glycoprotein, has already entered Phase I clinical trial in United States. Since antibodies do not cross the blood-brain barrier, for monoclonal antibody-based therapeutics to be effective, virus neutralization will likely have to occur in the respiratory tract, blood, and other tissues before the virus disseminates into the brain. However, multiple Nipah challenge models including NHPs indicate that vaccine-induced antibodies prevent CNS invasion, and passive immunization with Nipah neutralizing antibodies can also prevent CNS involvement if administered at least at the first signs of Nipah disease.

There was discussion on what the optimal Nipah clinical trial design would be in the context of an EID with very low incidence, i.e. in the absence of feasible randomised controlled trials (RCTs), observational studies such as case-control studies could still provide valuable evidence. Relevant clinical trials for Nipah countermeasures will require engagement of local regulatory authorities in Bangladesh (Directorate General of Drug Administration, DGDA) and India (Drug Controller General of India, DCGI). Partnerships are being built locally, with a focus on equitable access and low-cost interventions.

Lesson 6: Invest in platform technologies that can be harnessed during a pandemic.

Two Nipah@20 Conference speakers presented on Nipah vaccines using technology that has recently been used for the development of COVID-19 vaccines.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, UK presented the ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. The ChAdOx1 is a replication deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens, in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, including strong and well maintained humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. Professor Gilbert's team is now using the same approach to develop a COVID-19 vaccine candidate, supported by CEPI.

Dr. Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their molecular clamp approach to produce a highly stable pre-fusion form of the F glycoprotein which is responsible for membrane fusion, and could be an additional target for neutralising antibodies. The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. This technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is also being supported by CEPI to develop a recombinant spike protein which will be used as a COVID-19 vaccine candidate.

Lesson 7: Engage regionally and locally, not just globally.

The final Conference session was dedicated to collaboration and synergy. Professor Zhengli Shi, from the Wuhan Institute of Virology/Chinese Academy of Sciences, described how a Sino-French agreement to collaborate on EIDs was established in 2004, following the SARS-CoV outbreak. BSL4 labs were established in the Wuhan Institute of Virology as a result of the SARS-CoV outbreak. Prior to the COVID-19 pandemic, the Institute had an annual call launched around April each year for external organisations wanting access to the facility to test their own samples or to have access to samples from the in-house repositories. The many years of research experience and international collaborations built by the CAS since 2004 have provided a preparedness framework through which Chinese scientists have responded and continue to respond to the SARS-CoV-2 epidemic sixteen years later.

Dr. Nivedita Gupta, from the Indian Council of Medical Research, described the Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform. The RESEARCH platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. Of the 11 member states in the WHO Southeast Asia Region (SEAR), 10 participated in the second RESEARCH platform meeting. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on Nipah virus, but also other EIDs.

Epilogue

Unbeknownst to the scientists attending the Nipah@20 conference in Singapore in December 2019, the COVID-19 outbreak had already begun in China. We started the year 2020 confronted with a new EID that required rapid mobilisation for vaccine development. Nipah@20 was a scientific drill, a timely dialogue about the need to invest in the development of vaccines and medical countermeasures against EIDs with pandemic potential. CEPI has since mobilised early investment for several COVID-19 vaccine candidates. As stated earlier, for two awardees, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Transparency and a collaborative spirit underpinned the Nipah@20 conference. Although Nipah virus may not seem like a priority in the current COVID-19 context, we hope that the scientific momentum will continue, with high value EID-related research being undertaken and published. When will Henipavirus experts next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus, which was the founding member of the Henipavirus genus, sometime in 2024.

Dear All,

Thanks again to those of you who have sent contributions to earlier versions on the summary from the Nipah Conference.

Please see the third version of the document here. Co-authors are those who have provided specific feedback, comments and content.

This version will now go for internal review at CEPI prior to submission to mSphere.

I wish to acknowledge the remaining IOC members who are not able to contribute to authorship this time. I understand all of us are swamped with the current pandemic situation, and not all of you will be available to comment or contribute this time.

Best wishes,

Raúl

Dear All,

We would like to thank those of you who have sent your comments and suggestions. Please find the second draft of the Nipah@20 summary paper for *mSphere*. This incorporates comments received thus far into a more refined version in which the table has been removed.

Kindly send any comments/edits back to us **before April 10th**. We will only include as authors those of you who have expressed a wish to co-write this summary. We will include the remaining IOC members in the acknowledgements section.

Dear Benhur and All – please hang in there and receive our solidarity in these difficult times.

Best wishes,
Raúl

Dear Benhur

Wow! How confronting. It is one thing to see a clip on the news, but another to hear it from someone in the hot zone. I am so sorry that you, and the rest of your colleagues, are experiencing this. Modern medicine wasn't supposed to be like this. This really is a tsunami.

Please don't hesitate to reach out if I can help you in anyway.

Thinking of you,
Kindest regards
Kim

Subject: Re: Proceedings from Nipah Virus International Conference

Benhur no longer remembers what day it is anymore. Raul, you'll have to remind me.

As of yesterday we have 1,249 COVID-19 positive patients in our hospitals. That includes 233 patients in our ICUs. We only had ~130 ICU beds . . now we walk by this in our lobby (everything is public so no confidentiality breached here) as every square inch gets gradually taken up by temp beds for COVID-19 patients. If New York was a country, we would be No. 5 in the world in no. of COVID-19 cases. By the time I wake up tomorrow, NY would have surpass the maximal number of cases in Hubei province.

We are trying innovative ways of re-using N95s and/or impregnating them with virucides. Innovative ways of trying to consent patients for longitudinal studies, developing serology testing to identify sero-converters for both human plasma therapy and de-risk front-line responders . . .our dept works as one now. On staggered shifts as we all work only on COVID-19 related research while still maintaining social distancing

I know this is not related to our Nipah conference but thought you all might like to know what it is being in the middle of the world's hottest zone. Being spat on by strangers while taking the subway to work does not make it easier. I no longer take public transport.

#BeSafe #FlattenTheCurve #SocialDistancingWorks

Subject: [WARNING : MESSAGE ENCRYPTED]Proceedings from Nipah Virus International Conference

Dear International Organizing Committee (IOC) members for the Nipah Virus International Conference,

Please find a ***draft*** (pdf) with the Proceedings from the Nipah Virus International Conference, which took place in Singapore last December. The password for this document is [redacted]. Please consider this document under 'embargo' until cleared by the the respective Communications departments from CEPI and its Conference organizing partners (WHO, NIAID, Duke-NUS).

We hope this email finds you well. We apologise for not sharing the Proceedings with you sooner, but we hope you will understand all of us have been swamped with the present COVID-19 situation. Although we do appreciate the Nipah Conference may be perceived as less of a global priority now comparted to COVID-19, we believe the Proceedings contain relevant insights that should be shared with the global community in a pandemic situation.

Our plan is to upload a refined and cleared version of the Proceedings into a suitable online platform for distribution with our partners, ideally within 4 months of the Conference having taken place (i.e. before April 11th).

In addition, and thanks to Benhur Lee, the Editor-in-Chief for *mSphere* has also agreed to publish a *summary*version of this and we have started working on that. Please also find the *word* document with a *draft* summary of Conference. We would like to invite you to co-author this summary and edit/add comments to this **by Monday, March 30**. If you do not wish to co-author the summary, please let us know.

Again, we do recognise that this may be perceived as less of a priority now, but we hope the insights from the Conference can shed light in some of the scientific issues being discussed now. We would like to thank you again for your valuable contributions to this Conference, and we look forward to your participation in this process.

Best wishes,
Raúl

<Summary and Outline for mSphere_v1_KH.docx>

Confidential *Draft 19.03.2020*
Authors: Members of the International Organising Committee for Nipah@20
Target audience: scientific (mSphere)
Expected length: ideally no more than 5 pages

Draft summary/outline for mSphere

The Nipah Virus International Conference of 2019 (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS).

The Conference marked the 20th anniversary of the discovery of Nipah virus. Since its first identification in Malaysia and Singapore in 1999, the understanding of Nipah ~~disease~~ virus infection and its pandemic potential has advanced substantially. The Conference provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines.

To foster international collaboration in the context of epidemic preparedness, Nipah@20 brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day Conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in CEPI's Joint Coordination Group (JCG) on December 11, 2019, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

Highlights from the Conference are summarized in **Table 1.** The page numbers refer to the Proceedings from the Conference, which are publicly available at (**CEPI Communications** working on the branded document and website for citation).

Table 1. Highlights from Nipah Virus International Conference

	Session	Highlighted Topics in Proceedings	Page number in Proceedings
1	Historic Review of Nipah Outbreaks		
2	WHO Nipah R&D Roadmap	Policy and implementation issues: 1) Without effective therapy available at a medical facility, there is no clinical justification or ~~/~~incentive for testing and~~/~~surveillance. 2) Development of a sound business case for product development is needed to move medical countermeasures forward.	21-22
3	Progress and challenges in surveillance of Nipah virus	1) ICMR has found several new viruses among bats and is exploring EID potential. Pathogen X implications and possible candidates for test runs of rapid response.	27, 29

	Session	Highlighted Topics in Proceedings	Page number in Proceedings
		2) A Ghanian henipavirus sequence has been isolated in S. Africa. 3) A lot of work on bat surveillance, but unclear how to translate into impact.	
4	Progress and challenges in diagnostics	1) International reference standards needed for validation, calibration, comparison, and quality controls. 2) A mobile diagnostic system (MolBio) is being used in India & Bangladesh and could have applications in epi, clinical trials, and outbreak response. ~11USD per test. 3) FLI ELISAs use henipavirus sG proteins expressed in *Leishmania tarentolae.* Could be alternative for sourcing protein for assays.	34, 35, 38
5	Pathogenesis and animal models	1) NIH working on **aerosol** challenge model in AGMs. Importantly, no apparent role for antibodies in protection against challenge! 500 pfu used. 2) UTMB using an ***intranasal*** atomization device. 2,000 – 20,000 pfu uniformly lethal in AGMs. 500,000 ***intratracheal*** in cynos, not uniformly lethal. 3) CSIRO working on ***intranasal*** challenge in ferrets. Shedding not sufficient to cause transmission, arguing against aerosol route. No animal model is yet exploring myocarditis – a key clinical attribute of the disease observed in India & Bangladesh.	41-47
6	Transmission/Case management	1) Several key clinical observations that are currently not being contemplated in animal model development, for example, myocarditis and hypoxia in ABG analysis. Would be easy to implement in animal models. 2) Relapse and late-onset henipavirus infections observed in Malaysian patients several years after the acute infection – unclear if there is viremia during relapse. No animal model for relapsing disease.	48-49, 51
7	Epidemiological needs for clinical trials	1) In the absence of randomised controlled trials (RCTs), observational studies such as case-control studies can provide valuable evidence, according to WHO.	54-55, 56, 57

	Session	Highlighted Topics in Proceedings	Page number in Proceedings
		2) A case-control study with vaccination in Faridpur and Rajbari (Bangladesh) and recruitment of 10 matched controls whenever a case is identified would require only 7 years to be completed (provided 70 % vaccine coverage), according to S. Luby. 3) DGDA, the regulatory authority in Bangladesh, has several requirements outlined on top of pg. 56. 4) 3 of 279 close contacts from the 2018 Kerala outbreak had subclinical infection. Similarly, 8 % of Nipah-infected Malaysian patients had subclinical infection with positive serology. Could be important to analyse immune responses in subclinical infections, to try to emulate this type of immunity with a vaccine.	
8	Progress and challenges in vaccine development	Someone asked if the PHV/Crozet VSV-based vaccine caused neurovirulence. G. Hepner replied neurovirulence studies are planned and will be discussed with authorities.	67-68
9	Progress and challenges in therapeutics development	1) Monoclonal antibody shipped from Australia to be tested therapeutically in the outbreak was left unused. 2) To facilitate access of therapeutics to future outbreaks, ICMR has taken the lead in ensuring free production and supply, as well as putting in place shipping agreements with manufacturers. Interesting equitable access example. 3) Other CMCs: antibodies to sG and F, though abs don't cross the brain-blood barrier; heparin as low-cost method; lipid-anchored peptides to prevent viral fusion. Working on a nasal spray with these compounds to be used prophylactically vs NiV. Keep an eye on non-vaccine MCM portfolio.	69, 73
10	Collaboration and Synergy	1) A Sino-French agreement to collaborate on emerging infectious diseases was established in 2004, following the SARS outbreak. *BSL4 labs were established in Wuhan as a result of SARS.*	75-76

	Session	Highlighted Topics in Proceedings	Page number in Proceedings
		2) (Before the COVID-19 days), the Wuhan BSL-4 facility has an annual call around April for external organisations wanting access to the facility to test their own samples or use samples from the in-house repositories. 3) The Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on NiV, but also other EIDs.	

Opinion/Commentary – (open for comments from IOC)

The Nipah@20 conference brought together a community of scientists passionate about infectious diseases – focusing on the epidemiology, virology, pathogenesis and therapeutics of a virus that has pandemic potential. The WHO R&D Nipah Blueprint and Roadmap provides a solid framework from which to organise, collaborate and prioritise the different research areas. The global approach to developing a vaccine for Nipah has involved a multi-pronged approach for vaccine candidates, many of which were presented at the Nipah@20 conference.

The Nipah@20 conference facilitated early mobilisation for vaccine development with COVID-19, with CEPI leading the way, investing in seven potential vaccine candidates. For two groups, this builds on work already undertaken with Nipah virus vaccine projects which were showcased at the Nipah@20 conference.

Professor Sarah Gilbert from the Jenner Institute, at Oxford University, UK presented their ChAdOx1 Nipah vaccine, a simian adenovirus-based vaccine encoding NiV glycoprotein (G) Bangladesh. The ChAdOx1 is a replication deficient simian adenoviral vector which has been used for the development of vaccines against many pathogens, in preclinical and clinical studies. It is safe for use in all ages and in patients who are immunocompromised, including strong and well maintained humoral and T cell responses against the encoded antigen without the requirement for an adjuvant. Professor Gilbert's team are using the same approach with their COVID-19 vaccine candidate.

Dr Keith Chappell and Professor Paul Young from the University of Queensland, in Brisbane, Australia presented their approach which uses a molecular clamp to produce a highly stable pre-fusion form of the F protein which is responsible for membrane fusion, and is one of the main targets for neutralising antibodies (and therefore a major focus of vaccine research). The molecular clamp is a novel way of locking synthetic versions of viral surface proteins into the same shape that appears on the virus surface. The technology has been designed as a platform approach to generate vaccines against a range of human and animal viruses and has shown promising results in the laboratory targeting viruses such as influenza, Ebola, Nipah and MERS coronavirus. This same principle is being used to develop a recombinant spike protein which will be used in their COVID-19 vaccine candidate.

Transparency, and a collaborative spirit underpinned the Nipah@20 conference, and it is hoped that the momentum will continue, and we will see high value Henipavirus research being undertaken and published. When will we next meet? An unofficial suggestion has been to commemorate the 30th anniversary of the discovery of Hendra virus which was the founding member of the Henipavirus genus, sometime in 2024.

Table of Contents

Day 1

Day 2

Acronyms and Abbreviations

A – answer
AAHL – Australian Animal Health Laboratory
Ad – adenovirus
AEFI – adverse events following immunisation
AES – acute encephalitis syndrome
Ag – antigen
AGM – African green monkey
AMES – Acute Meningo Encephalitis Surveillance system
APVMA – Australian Pesticides and Veterinary Medicines Authority
ARDS – Acute Respiratory Distress Syndrome
BBB – blood-brain barrier
BSA – baseline situation analysis
BSL – biosafety level
C – comment
CD – cluster of differentiation
CDC – Centers for Disease Control and Prevention
CDSCO – Central Drugs Standard Control Organization
CDV – canine distemper virus
CFIA – Canadian Food Inspection Agency
CFR – case fatality rate
CHO – chinese hamster ovary
CM – cynomolgus monkeys
CNS – central nervous system
CoA – certificates of analysis
CRO – clinical research organisation
CSF – cerebrospinal fluid
CT – computed tomography
CTA – clinical trial agreement
CTM – clinical trial material
DC – dendritic cell
DGDA – Directorate General of Drug Administration (Bangladesh)
DHR – Department of Health Research (India)
DIC – disseminated intravascular coagulation
DPI – days post infection
DRC – Democratic Republic of Congo
DSMB – Data and Safety Monitoring Board
Dx – diagnostics
EBOV – Ebola virus
EGFP – enhanced green fluorescent protein
EID – emerging infectious disease
ELISA – enzyme-linked immunosorbent assay
EMA – European Medicines Agency
ERC – ethical review committee
EUA – emergency use authorisation (FDA)
EUL – emergency use listing (WHO)
FDA – Food and Drug Administration
FIND – Foundation for Innovative New Diagnostics
G – NiV glycoprotein
GAG – glycosaminoglycans
GCM – global coordination mechanism
GLP – good laboratory practice
GHSA – Global Health Security Agenda
GMO – genetically modified organisms
GMP – good manufacturing practice
gp – glycoprotein
F – NiV fusion protein
HCW – health care workers
HeV – Hendra virus
HRC – C-terminal Heptad repeat
HRN – N-terminal Heptad repeat
HRP – horseradish peroxidase
HS – heparan sulphate
HV – herpes virus
icddr,b – International Centre for Diarrhoeal Disease Research, Bangladesh
ICF – informed consent form
ICMR – Indian Council of Medical Research
ICP – infection control practice
ICTV – International Committee on the Taxonomy of Viruses
ICU – intensive care unit
IDRI – Infectious Disease Research Institute (U.S.)
IEDCR – Institute of Epidemiology, Disease Control and Research (Bangladesh)
IFAT – indirect fluorescence antibody test
IFN-γ – interferon gamma
ILI – influenza-like illness
IND – investigational new drug
ip – intraperitonea
IRB – institutional review board
JE – Japanese encephalitis
km – kilometres
LASV – Lassa virus
LMICs – low- and middle income countries
mAb – monoclonal antibody
mcsF – molecular clamp-stabilised NiV F
MERS – middle east respiratory syndrome
MERS-CoV – MERS coronavirus
MLV – modified live virus
MoH – Ministry of Health
MRI – magnetic resonance imaging
MTA – material transfer agreement
MV – measles virus
NAT – nucleic acid test

NCFAD – National Centre for Foreign Animal Disease (Canada)
NCID – National Centre for Infectious Diseases (Singapore)
NCPV – National Collection of Pathogenic Viruses
NGS – next-generation sequencing
NHP – non-human primate
NIAID – National Institute of Allergy and Infectious Diseases
NIID – National Institute of Infectious Diseases (Japan)
Nipah@20 – Nipah Virus International Conference
NiV – Nipah virus
NiV-B – Bangladesh isolate of NiV
NiV-M – Malaysian isolate of NiV
NIV – National Institute of Virology (India)
NPT – near-patient
OIE – World Organisation for Animal Health
PEG – polyethyleneglycol
PEP – post-exposure prophylaxis
pfu – plaque-forming units
PHEIC – public health emergencies of international concern
POC – point of care / proof of concept
PPE – personal protective equipment
PRIME – PRIority MEdicines
PRNT – plaque reduction neutralization test
PRRSV – porcine reproductive and respiratory syndrome virus
PTT – partial thromboplastin time
Q – question
Q&A – questions and answers
R 0 – basic reproduction number
R&D – research and development
RCT – randomised controlled trial
RFP – request for proposals
RITM – Research Institute of Tropical Medicine (Philippines)
RNA – ribonucleic acids
RRC – Research Review Committee
RSV – respiratory syncytial virus
RT-PCR – reverse transcriptase polymerase chain reaction
RVF – rift valley fever
rVSV – recombinant VSV
SAG – scientific advisory group
SARS – Severe Acute Respiratory Syndrome
SEAR – WHO South-East Asia Region
SEARO – South-East Asia Regional Office of WHO
sG – soluble G protein
SNT – serum neutralisation test
SOC – standard of care
SOP – standard operating procedure
SPEAC – Safety Platform for Emergency vACcines
SSPE – subacute sclerosing panencephalitis
TNF-α – tumour necrosis factor alpha
TPP – target product profile
Tx – therapeutics
UTMB – University of Texas Medical Branch
VRDL – Virus Research and Diagnostic Laboratory (India)
VSPB – Viral Special Pathogens Branch
VSV – vesicular stomatitis virus
Vx – vaccines
vWF – von Willebrand factor
WHO R&D Blueprint – WHO research and development Blueprint for action to prevent epidemics
ZEBOV – Zaire Ebola virus

Executive Summary

The Nipah Virus International Conference of 2019 (Nipah@20) marked the 20-year anniversary of the first Nipah outbreak in humans, which happened in Malaysia and Singapore in 1998-1999 and resulted from spillover of Nipah virus (NiV) from fruit bats to pigs, and from pigs to humans. In total, 283 individuals were infected, causing 110 deaths. There have since been Nipah outbreaks in Bangladesh, India, and the Philippines. In total, only about 600 people have been infected in these 20 years. However, the devastating epidemic potential of NiV has placed it on the WHO list of priority diseases. In the largest outbreaks, human-to-human transmission and superspreaders were important drivers for viral spread. Family members or healthcare workers had the highest risk of infection, with prolonged exposure to the patient or exposure to body fluids being the primary causes of human-to-human transmission.

Nipah disease is characterised by acute encephalitis and acute respiratory distress syndrome. The severity and duration of disease may vary from outbreak to outbreak, depending (among other things) on the pathogenic potential and tropisms of the circulating NiV strain. The two main strains are NiV Bangladesh (NiV-B) and NiV Malaysia (NiV-M), but a variety of sub-strains have been isolated. Typically, the first symptoms of disease occur between 3 and 21 days post infection, and the case fatality rate ranges from 50 % (NiV-M) to about 75 % (NiV-B).

Fruit bats constitute the main reservoir host of NiV, as well as of other (known and unknown) emerging infectious diseases. Thus, the migration and roosting areas of bats are considered a major determinant for risk of Nipah outbreaks, and active surveillance deemed an important preventive measure. It has been shown that virus spills over into other animals and humans through the consumption of fruits that have been contaminated by bats and, in particular, palm tree sap. This may be one reason why outbreaks in Bangladesh, where the consumption of palm tree sap is part of local food culture, are so common. In later years, the number of cases in Bangladesh has dropped, which may be attributed, at least in part, to increased awareness regarding the risk of ingesting raw palm tree sap harvested overnight. For efficient surveillance and response to outbreaks, a One Health approach should be taken, where not only human transmission but also the circulation of virus in reservoir host populations is accounted for.

In addition to bats and pigs, NiV has been found to infect a number of other animals, including mice, hamsters, ferrets, cats, dogs, goats, cattle, and monkeys. Especially hamsters, ferrets, and monkeys represent important model animals for NiV research, and for the development of therapeutics and vaccines. Animal studies with live virus need to be conducted at biosafety level 4, which is a major limitation for preclinical research on NiV. Field research also requires important safety measures, and it is hoped that new assays allowing for rapid inactivation of virus will improve point of care diagnosis.

Currently, there are no licensed vaccines or therapeutics against Nipah infection. However, there are a number of promising candidates in the pipeline, and some (like the m102.4 monoclonal antibody) have already been used clinically with apparent success. One important barrier for licensure, is the conduct of controlled phase I and II clinical trials. Due to the irregular occurrence of NiV outbreaks, and the usually small number of cases, the conduct of robust trials poses a serious challenge. Furthermore, delayed onset of disease, late presentation of cases at clinical facilities, symptoms that are easily confused with other diseases, and lack of point of care rapid diagnostics all contribute to slowing down the response to a new outbreak. As a result, many treatment opportunities and trial participants may be lost. However, international and regional collaboration, development of new and improved diagnostics for field use, as well as improved surveillance and innovative trial designs, may serve to solve this. With respect to the latter, a multinational, multi-outbreak, multi-intervention clinical trial is being prepared, with regional and international collaboration on planning and implementation, and support from several of the Nipah-endemic countries.

Nipah virus is but one of a growing number of the closely related henipaviruses. While NiV is a frightening, lethal virus, other viruses that have not yet emerged may prove worse. So far, Hendra virus is perhaps the best known of the other henipaviruses, for its role in lethally infecting horses (and a few humans) through outbreaks along the Australian East coast. Traces of henipavirus infection have been found throughout a large geographic area covering Australia, South Asia, as well as sub-Saharan Africa, even in the absence of known outbreaks. Being able to predict the next outbreak would require advanced modelling based on a long list of risk factors, and an incredible amount of scientific data. However, as pointed out by CEPI's CEO, Richard Hatchett: "Unless something is done, Nipah will continue to re-emerge in smaller outbreaks, until it finds the perfect combination of circumstance and opportunity to explode again, as it did some 20 years ago". On the other hand, when the next epidemic comes, we may be facing a different pathogen altogether. Still, preparing for Nipah also means improving preparedness for other emerging infectious diseases, known or unknown.

Day 1

Opening ceremony

Co-chairs: Professor Linfa Wang, Duke-NUS / Dr. Raúl Gómez Román, CEPI

A warm welcome to everybody for joining the Nipah Virus International Conference (Nipah@20). This conference is the result of an initiative taken by the Coalition for Epidemic Preparedness Innovations (CEPI) in March 2019, and it was put together in a relatively short time. The conference has 215 participants from 24 countries, which exceeded the organisers' expectations by about 50 %! Impressively, most of the people who were invited to the conference, on relatively short notice, are now present.

As organisers, we are grateful for the contributions made by the scientific community in preparing the conference. Scientists from nine different countries have taken part in the preparations, and the conference programme is the result of their experience and input. We would also like to thank our hosts, organisers, partners, and sponsors, who have entrusted us with the responsibility and privilege of preparing the conference. On behalf of the international organising committee, we would like to wish you a productive and scientifically stimulating Nipah@20.

Message from Ministry of Health, Singapore

SMS Dr. Lam Pin Min, Senior Minister of State for Health and Transport

Nipah@20 marks the 20th anniversary of the discovery of Nipah virus (NiV). There was also a conference marking the 10th anniversary, but hopefully there will not be a need for a 30th anniversary conference – by then, an effective vaccine should ideally have been discovered. It is important to come together at a conference like this, to take stock of the latest developments in global health, and discuss how we may better address emerging infectious diseases (EIDs).

EIDs remain a threat to countries around the world, Singapore included. In addition to Nipah, Singapore has experienced recent outbreaks of Severe Acute Respiratory Syndrome (SARS), endemic Influenza (H1N1), and Zika. We are not able to predict where and when the next EID may emerge, but we are able to prepare for its emergence and mitigate its impact. Our defence against EIDs include three elements: Public health capabilities, cooperation, and commitment to research.

Strong public health capabilities and -systems are important for managing and responding to public health crises. Singapore adopts an integrated and dedicated approach to the management of EIDs, with capability to deliver clinical services as well as public health functions to detect, respond to, and contain EIDs. The National Centre for Infectious Diseases (NCID) was opened this year, to strengthen

Singapore's capabilities in public health preparedness and infectious disease management and prevention. In the event of an epidemic, the capabilities of our healthcare professionals are critical. Recognising this, Singapore continues to invest in training for healthcare professionals and public health practitioners.

The responsibility for addressing EIDs does not rest with one institution, one sector, or one country alone. This brings in the aspect of cooperation – or rather, cooperation, collaboration, and coordination. Management of zoonotic diseases, such as Nipah, underscores the need for coordination across sectors. Singapore has adopted an interdisciplinary "one health" approach, integrating human, animal, and environmental health surveillance and response. Robust animal and human surveillance, combined with infrastructure capabilities, are critical in providing early warnings to the animal and human health authorities. The Ministry of Health works closely together with a number of other agencies to develop capabilities and strengthen surveillance.

During the 1998-1999 Malaysia and Singapore Nipah outbreak, international collaboration was instrumental to the identification of pigs as an intermediate amplifying host for NiV infection. Fostering partnerships across regional and national borders is necessary to deal with infectious agents that are not constrained by such borders. In addition, the emergence of new infectious diseases stresses the importance of research investments.

CEPI was established in Davos in 2017, as a private-public partnership with the ambition to accelerate the development of vaccines against EIDs. This conference is yet another example of how different players can come together to support work and research concerning EIDs. Our hope is that the conference may lead to new partnerships and innovations that may boost the fight against Nipah virus.

Message from the Ministry of Health, Malaysia

Datuk Dr. Christopher Lee Kwok Choong, Deputy Director General of Health (Research & Technical Support)

Thank you to the organisers and Singapore for hosting this event. Nipah virus was named after the Malaysian village Sungai Nipah. To many Malaysians, the word Nipah evokes memories of the devastating zoonotic outbreak in 1998, where the pig farming industry was hit hard. A total of 283 cases were confirmed infected, resulting in 110 fatalities. The outbreak also reached Singapore, reminding us that borders are unable to stop infectious diseases.

Since the 1998 NiV outbreak, the ministry of health (MoH) has put in place a number of measures to protect the people of Malaysia from future zoonotic outbreaks. This includes strengthening of the surveillance systems in both human and animal health sectors, and in particular a structured and continuous engagement platform where information may be shared and analysed, and decisions are made collectively. The platform, corresponding to Singapore's "one health" approach, has been in place since 1999.

While the Nipah outbreak in 1998 would ideally have been a one-off event, the last 20 years have proven the opposite. Although Malaysia has not had another outbreak, NiV outbreaks have occurred a number of times in Bangladesh and India. These outbreaks have been traced to food contaminated by fruit bats, which are now known to be the natural host of NiV. Transmission from human-to-human has been confirmed in South India, primarily affecting family members or healthcare personnel. Fatality rates range from 40 to 75 %, yet interest in NiV has been more or less confined to the countries affected.

To this day, there is no cure, vaccine, or specific treatment for Nipah, and affected individuals receive only supportive care. In the 20 years that have passed, WHO estimates that there has been about 600 Nipah cases worldwide, limited to countries in Southeast Asia. There are, however, concerns regarding the devastating zoonotic potential of NiV, as stated by the World Organisation for Animal Health (OIE). The WHO considers the risk of geographical spread of Nipah to be low, yet the migration patterns and distribution of fruit bats are extensive. Evidence from Bangladesh shows that viral spillovers from bats to humans happen regularly, providing opportunities for a more highly transmissible strain to infect and adapt in humans.

For effective countermeasures to Nipah, a broader and more comprehensive approach, with investments in therapeutics, diagnostics, and vaccines as well as surveillance infrastructure, is urgently needed. Furthermore, strengthened capabilities are warranted in rapidly detecting and verifying cases, conducting detailed contact tracing, investigating spillovers, and gaining a better understanding of NiV and its mode(s) of transmission. Equally important is the need for behavioural change, and improved support to local communities for prevention and control measures. The goal is to reduce transmission, especially in the healthcare setting.

Nipah@20 is a timely opportunity for assessing the many gaps that still remain in our understanding of NiV and, hence, our ability to prevent and treat Nipah infection. Malaysia is grateful to be involved in this meeting, and looks forward to learn from the many experts gathered at the event, as well as to engage with the other stakeholders present in the interest of moving towards more effective management of NiV infection.

Message from the WHO

Dr. Michael Ryan, Executive Director, WHO Health Emergencies Programme

Nipah virus and the related henipaviruses are severe emerging diseases with the potential to impact vulnerable populations, generating public health emergencies. Many aspects of the management and treatment of the henipaviral diseases remain unknown, and they have therefore been included on the list of WHO priority diseases, as well as on the WHO research and development Blueprint for action to prevent epidemics (WHO R&D Blueprint). The WHO R&D Blueprint is a global strategy to ensure implementation of critical research findings on highly infectious diseases in a safe, effective and timely way. In collaboration with leading experts, WHO R&D Blueprint allows for fast-tracking of effective medical technologies in the context of an epidemic.

The Nipah virus has a significant epidemic potential. Its bat reservoir has been found in a number of countries, and it has the ability to amplify in livestock, which is a source of exposure to humans. Human infection results in severe neurological disease and respiratory symptoms, causing significant long-term sequelae, and high mortality.

Our current knowledge of the henipaviruses results from remarkable collaborative, long-term efforts of the scientific community, including many of the participants at Nipah@20. WHO R&D Blueprint has contributed to developing the key R&D priorities in the fight against Nipah, by building on these collaborations and bringing together experts from around the world.

During the third Nipah outbreak in India, in May 2018, the WHO R&D Blueprint's coordinated approach led to quick identification of the most promising available therapeutic agent (the monoclonal antibody m102.4), and access to the agent within 48 hours. This case study demonstrates that proactive research planning before an outbreak allows for a quicker outbreak response, allowing for prompt implementation of potentially life-saving medical interventions.

Epidemic risk can only be addressed by accelerating global preparedness, with an integration of research into all of our preparedness and response activities. This conference represents a unique opportunity to share knowledge, and to lay the groundwork for a clear and coordinated research agenda for Nipah, at the regional and national levels.

Message from NIAID

Dr. Cristina Cassetti, Deputy Director, Division of Microbiology and Infectious Diseases, NIAID, NIH

Emerging infectious diseases have been an important research priority at the U.S. National Institute of Allergy and Infectious Diseases (NIAID) for years. The aim is to gain a better understanding of these pathogens and why the emerge, and to develop countermeasures such as diagnostics, therapeutics, and vaccines. With substantial biodefence funding from U.S. Congress, the institute has been able to support Nipah research since the early 2000s, contributing to important advances such as identification of the receptor used by NiV for cellular entry and the development of animal models to be used in the evaluation of vaccines and therapeutics.

NIAID has been involved in the development of therapeutic and vaccine candidates, some of which have now been transferred to CEPI and other partners for further development. The Nipah programme of NIAID remains very active, with about 17 currently ongoing extramural programmes and a number of internal programmes focusing on the development of vaccine candidates, as well as studies on the pathogenesis of NiV using non-human primates (NHP). At Nipah@20, NIAID hopes to reconnect with old friends and partners, as well as to learn about new advances in the field of NiV research.

Welcome Address

Professor Thomas Coffman, Dean of Duke-NUS Medical School

Emerging infectious diseases constitute an important part of the research portfolio of Duke-NUS, and Professor Linfa Wang, who is the co-chair of Nipah@20, runs the Duke-NUS emerging diseases research programme. Duke-NUS is very excited to bring this conference to Singapore, partly because this was where the first Nipah outbreak happened. At the conference venue, there is a storyboard with news clippings from the first outbreak, clearly depicting the terror the disease caused when it first emerged.

Another reason why Singapore is a suitable location for such a conference, is the many travellers that come through its airport, as well as its large volume of shipping. Singapore was very significantly affected by SARS, and emerging diseases represent a topic for concern to authorities as well as the public. Nipah@20 brings together experts from all over the world, and highlights the importance of facilitating global communication between experts from different disciplines such as epidemiology, surveillance, basic science, vaccine development, and clinical treatment. Nothing can replace face-to-face discussions among experts in bringing the field forward.

Inaugural Address

Dr. Richard Hatchett, CEO of CEPI

Nipah virus and the related henipaviruses are some of the world's most frightening causes of disease. WHO has included these as one of 10 pathogens on its list of priority pathogens, since the epidemic potential of henipaviruses poses a grave risk to public health, and because there are no effective countermeasures.

It is highly appropriate that Nipah@20 convenes in Singapore, a beacon for globalism and a city that embodies the modern economic order. When Nipah first emerged in Malaysia, it rapidly spread to Singapore. In the last few decades, other frightening diseases like SARS, Ebola, and MERS have fared similarly, spreading from rural areas to densely populated cities, where the damage they can cause is amplified immensely. No city is more globally interconnected, and thus at greater risk, than Singapore.

Nipah has demonstrated its global potential, with recent outbreaks in Kerala, India – more than 3,000 kilometres (km) from Singapore, and more than 2,000 km from Bangladesh and Eastern India, where other recent outbreaks have occurred. As a result, more than 2 billion people live in areas at risk for Nipah. Unless something is done, Nipah will continue to re-emerge in smaller outbreaks, until it finds the perfect combination of circumstance and opportunity to explode again, as it did some 20 years ago.

CEPI is delighted to co-host Nipah@20 with the Duke-NUS Medical School, WHO, and NIAID. Meetings like this are important, not only because of the opportunity to share knowledge, but because of the momentum created in addressing the threat of Nipah, so that it does not become the next Ebola. In addition to being the 20th anniversary of Nipah, 2019 marks 50 years since the discovery of Lassa fever, and one of the inspirations for Nipah@20 was found in a similar meeting on Lassa fever in Abuja, Nigeria, in January 2019.

Lassa fever has haunted physicians in West Africa for half a century, occasionally flaring up in explosive outbreaks, and likely causing thousands of deaths. The burden of disease has not been known, due to poor or non-existent surveillance systems. In recent years, however, the Nigeria Centre for Disease Control, in collaboration with WHO and other international partners, has been able to draw more attention to the disease and establish Nigeria's research priorities for Lassa fever. Through the Lassa meeting in January 2019, where several hundred physicians, scientists, and public health officials participated, concerted and coordinated action against the disease was established. Subsequently, CEPI and WHO have helped Nigeria and other affected countries establish a network to support important epidemiology studies, which will lead to the design of better and more efficient clinical trials of vaccines. CEPI has also helped move the two first Lassa fever vaccines into clinical trials, with more to follow. The world has woken up to Lassa, and begun to move to take this threat off the table.

CEPI embraces the notion that the countries at greatest risk of the WHO priority diseases should be the ones to set the research agenda for these diseases. Thankfully, more than 100 scientists, public health officials, and policy makers from countries at risk of Nipah have registered for Nipah@20.

Another inspiration for this conference was the major progress the world has made against Ebola over the last year. While Ebola remains a frightening and disruptive threat, a clinical trial conducted in the Democratic Republic of the Congo for a therapeutic against Ebola was recently terminated early due to positive results. Even more recently, Merck received conditional marketing authorisation from the European Medicines Agency (EMA) for its vaccine. Within the last week before Nipah@20, GAVI announced that they will open a new funding window to establish a global emergency stockpile of Ebola vaccines. Low- and middle income countries will be able to access the vaccine free of charge, and will receive support for the operational costs of vaccination campaigns. As a result, we are approaching the day when Ebola is no longer the terrifying disease that it has been for the last 40 years.

It has taken tremendous effort by countless people to get the results seen with Ebola, but the demonstration that we can move from outbreak response to a global R&D effort that results in a fully accessible stockpile of licensed vaccine is a major victory for global health. This experience provides a roadmap for emerging infectious disease preparedness, where CEPI and the other partners present at Nipah@20 will play a critical role. Beginning today, we can do the same thing for Nipah. We can defeat Nipah, but only if we come together as a community and coordinate our efforts. The triumvirate of capabilities, cooperation, and commitment mentioned by Dr. Lam will be essential to any progress against Nipah. Fostering these was the intention with Nipah@20, and CEPI is confident that the participants will rise to the challenge.

SESSION 1 – Historic review of Nipah outbreaks

Chair: Dr. Marie-Pierre Preziosi, WHO

Overview of outbreaks

Professor John Mackenzie, PathWest & Curtin University, Perth

Outbreaks of henipaviruses, notably Hendra virus (HeV) and NiV, have affected Australia and several countries of Southeast Asia over the past two to three decades (see Figure 1). Outbreaks of HeV have been limited to the east coast of Australia, whereas NiV outbreaks have been found in Malaysia, Singapore, Bangladesh, India (West Bengal and Kerala), and the Philippines. Whereas HeV uses horses as intermediate host, NiV infects pigs. One exception was in the 2014 outbreak in the Philippines, where ten horses were found to be infected by NiV, and culled.

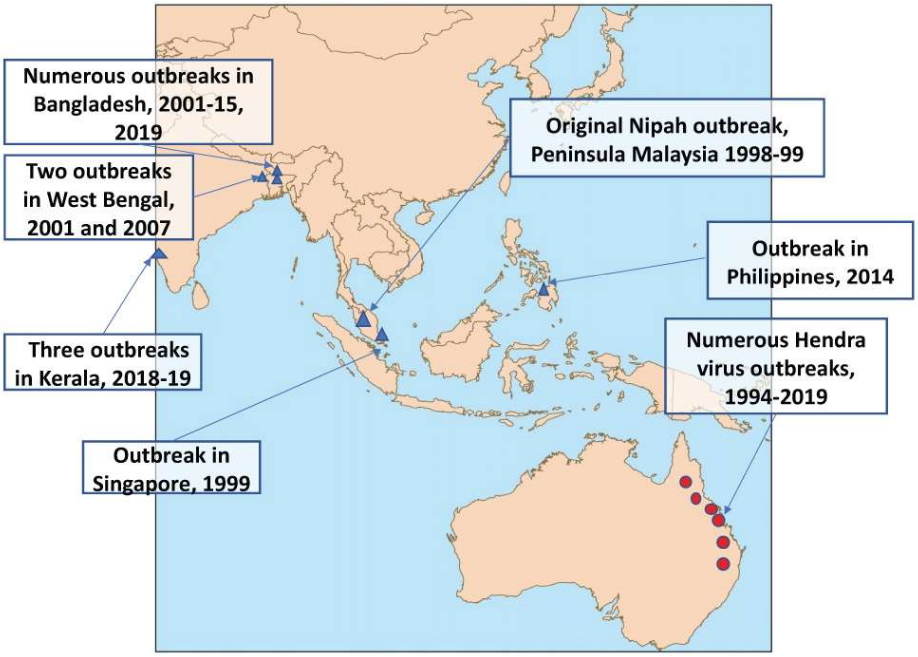

Figure 1. Map showing approximate sites of Nipah and Hendra outbreaks (Prof. John Mackenzie)

The Nipah outbreak in Malaysia and Singapore in 1998-99 was first believed to be caused by Japanese encephalitis. People were vaccinated and premises and surrounding areas fogged, but to no effect. The outbreak first started in Perak state, and later moved about 200 km south to the more intensive pig farm areas of Negeri Sembilan and Selangor, through the movement of infected pigs. During this outbreak, there was no communication between clinicians and veterinarians – an aspect that is now considered very important to the management of zoonotic diseases, as is clear from the widely used One Health approach. Other lessons learned were: 1) a previously unknown pathogen could emerge from a wildlife source at any time, in any place, and without warning, to threaten the health, well-being, and economy of a country – or even globally; 2) there is a clear need for countries to have the capability and capacity to maintain an effective alert and response system to detect and quickly react to outbreaks of international concern, and to share information about such outbreaks rapidly and transparently; 3) responding to novel disease threats of possible international concern requires global cooperation and global participation.

Australia

Dr. Hume Field, Science & Policy Advisor, EcoHealth Alliance & University of Queensland

The Brisbane suburb of Hendra was close to racing tracks, and there are a number of small training stables in the area. In August of 1994, after a trainer brought a sick horse to his stable to better care for it, there was an outbreak of acute respiratory disease, and a cascade of cases that, within a week, saw 13 horses dead, and the trainer and a stable hand in hospital. The trainer died whereas the stable hand recovered. This was an unprecedented event, all the stables were quarantined, and the movement of horses in South East Queensland was brought to a standstill.

Within a week, a novel paramyxovirus was identified by the Australian Animal Health Laboratory. When inoculated into a healthy horse, it caused the same acute, rapidly progressing, fatal infection that was observed in the Hendra stables. While initially named Equine morbillivirus, it was later found that the new virus did not fit into any existing genus. In the subsequent years, there have been nearly 100 equine cases and 7 human cases. The case fatality rate (CFR) for horses approaches 90 %, and in humans 60 %. Both respiratory and neurological presentations are recorded in horses. An effective vaccine has been available for horses for over five years, but is still not widely used due to concerns about cost and exaggerated reports of side effects. Equine cases of Hendra continue to occur almost annually.

Extensive wildlife studies have shown that species of pteropid fruit bats, or "flying foxes", are the natural reservoir of Hendra virus. Infection prevalence fluctuates in these populations, and urine is the primary route of viral excretion. Transmission to horses is likely caused by ingestion of urine-contaminated pasture, or direct inoculation of mucous membranes while horses are grazing under trees where flying foxes are feeding. All human cases have had direct contact with infected horses; direct transmission from bats to humans has not been recorded, and neither has human-to-human transmission.

The multiple similarities between HeV and NiV, and Dr. Field's role in the identification of bats as the natural host of HeV, led to his joining the Nipah outbreak veterinary response team that was assembled by the Malaysian government in early 1999. Epidemiologically, it appeared that pigs were the source of Nipah infection in humans, and the first task of the team was to perform pig necropsies at "hot" farms and collect tissue samples. They were able to isolate the same virus that caused human infection from multiple pigs, at multiple farms. The work then shifted towards gaining a better understanding of the nature of infection and transmission in pigs. It was clear that not all pigs were affected at "case" farms, and they therefore sought out "recovered" farms to serologically survey different classes of pigs, and collect convalescent serum. Parallel to these investigations, the mass culling of pigs was underway. The urgency and logistics of culling meant that the animals were typically killed and buried on the farm, which frequently involved the destruction of pig sheds and other farm infrastructure.

Two other components of the veterinary response were the investigation of infection and/or disease in non-pig species, and the origin of infection in pigs. Horses, dogs, and cats were identified as incidental hosts. As with Hendra, serological studies identified species of local bats as the likely source of infection in pigs, and the reservoir of the virus in nature. Subsequent studies have confirmed this, and further shown that henipaviruses are widespread in many bat populations, and likely have an evolutionary association with bats. While there may have been deficiencies in the early response to the Nipah outbreak in Malaysia, at this stage the Malaysian government had established collaborative and coordinated efforts to control the outbreak, in a One Health perspective.

Nipah virus outbreak in Malaysia

Dr. Chua Kaw Bing, Sr. Principal Investigator, Temasek Lifesciences Laboratory

One believes that NiV was infecting pigs and humans even prior to the 1998-99 outbreak in Malaysia, though the cases were never picked up on. There were reports, prior to the outbreak, of pigs coming down with encephalitis, which were assumed to be afflicted by "classical swine fever". Once transmitted to humans, public health authorities suspected an outbreak of Japanese encephalitis (JE), which was confirmed by what was later found to be false positive test results (found in about 20 % of the patients) for circulating JE IgM and viral particles. The Malaysian MoH launched an intensive campaign with JE vaccination and fogging of pig farms and surrounding areas to eradicate the supposed JE mosquito vector. When the outbreak persisted, in spite of the authorities' efforts, the possibility of a novel pathogen was finally considered.

The first direct observation of NiV was made on March 15, 1999, by electron microscopy of a sample section made by Dr. Bing, with the help of the U.S. CDC at Fort Collin. At U.S. CDC Atlanta, the same sample preparation later tested positive to Hendra antibodies in an indirect immunofluorescence assay, and it was thus determined that the outbreak was caused by a Hendra-like virus. Final identification of the virus was achieved by molecular characterisation (amplification of a 120 base-pair fragment of the Phosphoprotein gene by reverse transcriptase polymerase chain reaction (RT-PCR), followed by nucleotide sequencing) at U.S. CDC Atlanta. The new virus was named after Kampung Sungai Nipah, the village were it was first discovered.

Already with the first electron micrographs, it became clear that the Malaysia outbreak was not caused by JE, and Malaysian public health authorities were able to implement more appropriate control measures. Malaysia paid dearly for the inaccurate and untimely diagnosis, with 265 patients suffering from acute viral encephalitis, and 105 fatalities. The local swine industry also suffered great losses; about 1 million pigs were culled, and 800 pig farms were demolished.

The 1999 Nipah outbreak in Singapore

Professor Leo Yee Sin, Executive Director, National Centre for Infectious Diseases

The Singapore Nipah outbreak was, in fact, an integrated part of the Malaysia outbreak, yet much more limited in time and space. At the time, there were two abattoirs in Singapore, and the outbreak quickly resolved when the import of live pigs from Malaysia was banned, and the abattoirs closed. The eleven cases of the outbreak, of which there was only one fatal case, were all identified within a period of 9 days in March 1999. All of them had had close contact with live animals. In the Singapore outbreak, there was no human-to-human transmission, and all of the abattoir and healthcare workers screened after the outbreak tested negative for NiV antibodies. It was estimated that about 50 % of the infections were asymptomatic.

In spite of being limited in nature, the Nipah outbreak in Singapore provided several important lessons that have later proven useful, for example in the context of the Singapore SARS outbreak in 2003. Key lessons were to facilitate collaboration across borders, as well as to take a multidisciplinary, One Health approach to infectious disease prevention and control.

Nipah Encephalitis in Bangladesh

Professor Mahmudur Rahman, Consultant, Programme for Emerging Infections, icddr,b

Nipah was first identified as the cause of an outbreak of encephalitis in 2001 in the Meherpur district of Western Bangladesh, though the link to Nipah was discovered three years after the outbreak, in 2004. In 2006, Bangladesh established its Nipah surveillance system and laboratory. Since then, a total of 313 cases have been identified, of which 226 (72 %) have died. Looking only at the outbreaks, and eliminating independent cases, 37 outbreaks have led to 221 cases and 171 deaths, resulting in a very high CFR of 77 %. Many of the outbreaks have been small and localised, often limited to individual households and frequently resulting in 100 % mortality of cases.

Among the 64 districts of Bangladesh, 31 have been affected by Nipah. The affected districts may be said to form a "belt" concentrated in West Bangladesh. The majority of cases are children and young adults. Among the cases, about 60 % report to have consumed date palm sap. The sap is collected overnight, and bats have been found to contaminate the sap by urination.

Nipah outbreak investigations are conducted in a systematic way and with a One Health approach, involving epidemiologists, veterinarians, and anthropologists. In most cases, transmission is successfully traced back to its source, which has often been found to be the ingestion of raw date palm sap. The second most common route of transmission is human-to-human. There is a seasonality to outbreaks, with more outbreaks occurring from December to May. The median incubation period is eight days, and about 35 % of cases are secondary cases.

India

Dr. Nivedita Gupta, Scientist F, Division of Epidemiology & Communicable Diseases, ICMR

Whereas the first Nipah outbreak in Malaysia and Singapore did not involve human-to-human transmission, the outbreaks in India and Bangladesh in 2001 both did. The 2001 outbreak in Siliguri, West Bengal, India, represents the biggest Indian outbreak to date, involving 66 confirmed cases and 45 deaths (CFR: 68 %). Subsequent outbreaks have occured in Nadia, 2007 (5 confirmed cases, 5 deaths – CFR 100 %), Kozhikode, 2018 (19 confirmed cases, 17 deaths – CFR 90 %), and Ernakulum, 2019 (1 single case – CFR 0 %). Surprisingly, the two latter outbreaks were both in Kerala state, at the opposite side of the country as compared to the first two outbreaks.

During the 2001 outbreak, the Indian healthcare system was unable to diagnose Nipah, and instead mistook it for measles infection, since these are related viruses. With the help of U.S. CDC, they were able to confirm cases of NiV infection, but this took a long time. By the time of the 2007 outbreak, diagnosis had been established, with serological and molecular tests provided by the U.S. CDC. At this time biosafety level (BSL)-3 labs were available, yet early detection failed. In 2015, India had one operational BSL-4 laboratory, and capacity for bat surveillance was established. During the 2018 outbreak, early diagnosis and containment was available, though the index case was not correctly diagnosed. Finally, in the 2019 outbreak, the index case was quickly diagnosed and contained, and the outbreak stopped there.

For the two first outbreaks of 2001 and 2007, the origin of infection remains unknown. However, for the Kozhikode outbreak in 2018, *Pteropus* bats have been identified as the source. Since there is no tradition for palm sap consumption in Kerala, one does not know how transmission happens, though the close similarity of viral gene sequences of viruses isolated from cases and local bats clearly suggests that the outbreak originated with the bats.

Philippines

Dr. Fidel Malbas Jr., Research Institute for Tropical Medicine

Following a preliminary investigation into a cluster of deaths in the south of the Philippines, the Philippine government requested technical assistance from the WHO representatives to the Philippines on May 12, 2014. A multidisciplinary team investigated further, and clinical, epidemiological, and laboratory findings indicated an outbreak of a viral infection lasting from March to May. Seventeen cases were identified, displaying symptoms compatible with henipavirus infection. Eleven of the cases had acute encephalitis, and nine of them died.

Epidemiological data suggest that the primary route of human infection was through direct exposure to body fluids from infected horses. At least five cases were considered infected by direct human-to-human transmission, presumably through infected respiratory secretions or contact with other bodily fluids from sick patients. Laboratory results include serological evidence of exposure to henipavirus in recovering or fully recovered patients. Importantly, this is the first time a henipavirus has been detected in humans and domestic animals on the Philippines. The environmental source of infection has not yet been firmly established, but evidence points to the Megabats as a possible reservoir.

Recommendations for further actions, aiming to reduce transmission between bats, horses, and humans, are as follows: 1) Focus on prevention and control of infection in healthcare settings; 2) Use personal protective equipment (PPE) and ensure high levels of hygiene among healthcare workers, butchers, and people dealing with horses; 3) Avoid slaughter and consumption of sick horses; 4) Strengthen surveillance of human and animal cases; 5) Conduct further testing on clinical specimens; 6) Study the bat reservoir host; 7) Develop coordinated response plan between human and animal health agencies; 8) Ensure flow of information from the Department of Health to regional authorities in human and animal health, as well as agriculture.

Session 1 Q&A

Q: It was estimated that 50 % of Nipah cases in the 1999 Singapore outbreak were asymptomatic. Is this not unusual?

A: Thirteen asymptomatic cases were detected as part of the serological screening of abattoir workers. Although they had not had any symptoms, magnetic resonance imaging (MRI) conducted on some of the cases revealed that they had the hyper dense brain lesions typical for Nipah encephalitis. In India, serological surveys among close contacts of Nipah patients from the Kerala outbreak showed seropositivity in only two of about 300 subjects, suggesting a very low proportion of asymptomatic cases. In Bangladesh, four out of 212 subjects exposed to sap and/or bats tested positive for circulating antibodies against NiV. In the first HeV outbreak, 13 horses died, 4 had mild symptoms but were euthanised, and 3 tested positive for circulating HeV antibodies without any preceding signs of disease.

Q: Can asymptomatic cases be a source of infection?

A: There have been no reports of that, so far.

SESSION 2 – WHO Nipah R&D Roadmap

Chair: Dr. Christina Spiropoulou, CDC

WHO Nipah Research and Development Roadmap

Professor Steve Luby, Stanford University

Professor Luby presented the WHO Nipah R&D Roadmap (view draft here) as a member of the taskforce involved in preparing it. The purpose of the Roadmap was *to provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritising areas and activities for accelerating the collaborative development of* ***medical countermeasures*** *against Nipah virus infection*. The Roadmap has three big development priorities: 1) Rapid and accurate point-of-care diagnostics; 2) Safe and effective treatment and post-exposure prophylaxis; 3) Safe and effective vaccines.

In the Roadmap, three important issues were identified: 1) The market failure to create medical countermeasures; 2) The centrality of improved Nipah diagnostics; 3) Promise and barriers for Nipah therapeutics. On the positive side, the technologies required for developing effective counter-measures to Nipah are available, and NiV seems to be a fairly easy pathogen to deal with. The reason why effective countermeasures are still not in place, is a lack of incentives for private industry to develop the products: There are few people affected, typically in rural and low-income areas, and when the focus is on prevention of disease, rather than treatment of annual cases, the standard measures of cost-effectiveness are not met.

While the impact of a Nipah epidemic would be high, the probability is low: Over the past two decades, several outbreaks have happened, but sustained human-to-human transmission in a larger geographic area remains to be seen. However, prudent actions should be guided by both probability and impact. Thus, the primary justification for public investment in NiV countermeasures is not the management of the smaller outbreaks that seem to occur on a regular basis, but the prevention of a pandemic where perhaps millions of people could be affected by an infection that has a CFR of 75 %. Importantly, however, cognitive biases discourage attention to low probability events, making them more difficult to prepare for. The low probability of a NiV pandemic creates a setting where the market fails to meet societal needs. This is especially true when obtaining the necessary countermeasures involves expensive research and development, with requirements for licensure, BSL-4 work, and the use of costly animal models.

In the interest of creating a sustainable business model for the development of Nipah medical countermeasures, the Roadmap considers several supportive actions: 1) Public/philanthropic funding for R&D; 2) Clarifying regulatory pathways; 3) Assessing market size. For the latter, important insights were: 1) Increased surveillance would increase demand for diagnostics; 2) Treatments that can be used to treat several pathogens will have a stronger business case; 3) Demand for treatments and vaccines will come from healthcare and laboratory workers, in addition to patients and people at risk;

4) Rotating stockpile and mass vaccination would result in stronger business cases. Moving forward, one strategic goal of the Roadmap committee is to *identify sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV medical countermeasures*. They are currently working on a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Improved availability and use of Nipah diagnostics can provide insight on the prevalence of human infection. The range of *Pteropus* bats covers areas inhabited by 2-3 billion people, who are potentially at risk of Nipah infection. Given the spread of confirmed human Nipah infections, many human cases are likely to go unrecognised. Better diagnostics would serve to 1) improve response; 2) increase visibility to decision makers; 3) improve risk forecasting. In the low-resource settings were Nipah typically occurs, the ability to distinguish between Nipah infection and other types of encephalitis (NiV accounts for less than 5 % of cases, even in the "Nipah belt" in Bangladesh) would be essential to guide therapy. However, there are several reasons for why realising widely available Nipah diagnostics is made difficult: 1) NiV is uncommon and occurs in poor communities; 2) Without effective therapy available at the medical facility, there is no clinical justification for testing; 3) The testing of NiV comes with biosafety concerns; 4) There is limited availability of clinical samples for assessing new products. Thus, from a business case perspective, a successful diagnostic requires a successful therapeutic, and vice versa. In order to facilitate further development of NiV diagnostics, the Roadmap committee has defined the following prioritised activities: 1) Create a virtual repository of clinical reference samples for use in R&D; 2) Generate a target product profile (TPP) for NiV diagnostics; 3) Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk.

Several promising Nipah therapeutic agents are in development, of which m102.4, fusion inhibitory peptides, favirpiravir, and GS-5734 are but a few. However, patients generally present late in the course of illness, and they often present to facilities with limited capacity, commitment, and practice in diagnostics. Thus, effective treatment requires more than just making a therapeutic agent available. The Roadmap has defined the following strategic goals regarding therapeutics: 1) Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks; 2) Develop and evaluate therapeutic agents for the treatment of NiV infection and for post exposure prophylaxis to prevent NiV infection. With CEPI on board, the Roadmap committee has been less concerned with vaccine development. However, the following strategic goals have been developed for vaccines: 1) Engage national regulatory authorities and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure of a vaccine against NiV; 2) Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

These are exciting times, and people are now understanding that the low probability, high impact event of a pandemic NiV outbreak is worth preparing for. Promising technologies are in development for diagnostics, therapeutics, and vaccines against NiV. Currently, the issues that need the most attention are: 1) Development of a sound business case to support product development; 2) Enabling work within the constraints of sporadic cases / outbreaks in settings with limited resources. These are crucial for succeeding with the development of medical countermeasures against Nipah in the next 10 years.

WHO Nipah R&D Roadmap – Monitoring its implementation

Dr. Marie-Pierre Preziosi, WHO R&D Blueprint (on behalf of Dr. Claudia Nannei, WHO Monitoring & Evaluation)

The WHO R&D Blueprint efforts focus on both **research preparedness** and **research during outbreak response**. The aim of the R&D Blueprint is to fast-track the development of effective diagnostics, therapeutics, and vaccines to respond to outbreaks effectively and to prevent them. The R&D Blueprint preparedness activities are organised around three main approaches: 1) Improving coordination and fostering an enabling environment; 2) Accelerating R&D processes; 3) Developing norms and standards tailored to the epidemic context.

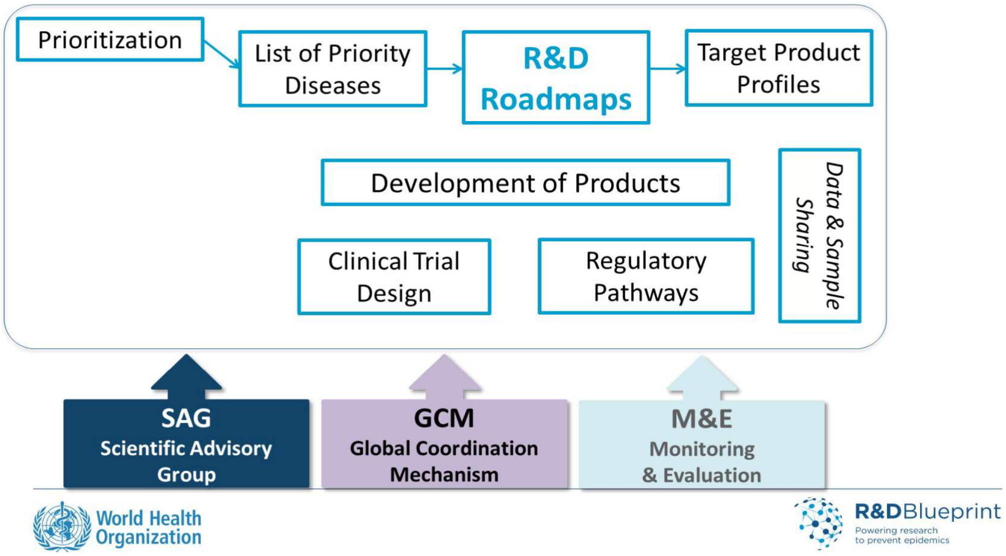

Figure 2. Overview of the WHO R&D Blueprint (WHO)

On an annual basis, WHO R&D Blueprint update their list of prioritised diseases, and for each of the diseases listed, R&D Roadmaps are prepared (see Figure 2). When relevant, TPPs are prepared to guide the development of products. Furthermore, WHO R&D Blueprint take part in developing clinical trial designs for each pathogen, and address the regulatory pathways. They are governed and receive input from a scientific advisory group (SAG), and through a global coordination mechanism (GCM). The monitoring and evaluation (M&E) is important to ensure assessment of progress and observation of any changing circumstance, thus allowing the accomplishment of strategic goals and the realisation of the vision.

The R&D Roadmap needs to be clearly and concisely defined and must, to remain relevant and useful, represent a living document that is monitored and updated regularly. The document itself is not enough – the true measure of success is whether or not the R&D Roadmap is implemented and achieves the desired outcome. To help in this, it is proposed that the R&D Roadmap sets 1) a results chain for each of the strategic goals, implementable over a limited period of time and verifiable in the form of milestones; 2) a framework for monitoring, using performance indicators; 3) regular (mid-term) reviews for assessing risks and assumptions in the critical path towards implementation.

A draft R&D Roadmap has been published for Nipah, with invitations to comment, and the final version is expected to be published shortly – on the WHO website, as well as in a scientific journal.

Session 2 Q&A

C: In the context of Nipah outbreaks, with such short duration, it is important to strengthen clinical research capacity to the extent where it is available on demand – if outbreaks are to be prevented (described in the "Money & Microbes" report from The World Bank).

A: Response from Prof. Steve Luby: Given the wide spread of NiV, it is hard to predict where the next outbreak is going to be. It will require an investment that may not be efficient, but could be resilient in terms of capturing all emerging cases and allow for data capture to serve the development of diagnostics as well as therapeutics. Definitely an important issue.

Q: Do you have any examples of products that have successfully overcome the low probability high impact context?

A: Response from Prof. Steve Luby: Outside of the U.S. and Milton Friedman's "free market", market failures are real. There is a role for the State in funding projects that lack financial interest from private investors. One example is NASA's tracking of asteroids to prevent asteroids from causing serious damage to the Earth. Solutions exist, even if the private market fails to address them, but involvement of the State is likely to be necessary.

Q: How can we bring scientists together in closer collaboration, in between meetings like this, to be able to address the different market needs more effectively?

A: Response from Prof. Steve Luby: CEPI is a good example, for having put together a large coalition of the different players needed in the development and implementation of new vaccines. They have both public and philanthropic funds available that serve to de-risk the investments of private investors. It is hard to envision a mechanism that addresses the markets in the way asked, if it doesn't share the holistic and strategic approach adopted by CEPI. An integrated approach across affected geographies, as well as across the various components of diagnostics, therapeutics, vaccines, surveillance, and emergency response, is likely to lower overall costs and make the process more efficient.

SESSION 3 – Progress and challenges in surveillance of NiV

Dr. Peter Daszak, EcoHealth

Southeast Asia is a hotspot for EIDs, as demonstrated in two recent publications. The risk of novel emerging zoonosis is high, and wildlife in the area is brimming with potentially zoonotic viruses. This is why there is such a focus on Southeast Asia and Nipah infection: While NiV is a frightening, lethal virus, other viruses that have not yet emerged may prove worse.

For us to be able to prepare for future EIDs, it is vital to discuss surveillance, and a session dedicated to surveillance at Nipah@20 is very welcome.

Nipah surveillance and outbreak response in Bangladesh

Professor Mahmudur Rahman, Programme for Emerging Infections, icddr,b

Following the first Bangladesh Nipah outbreaks in 2001, 2003, 2004, and 2005, the country established its Nipah surveillance system and laboratory in 2006, in a collaboration between Institute of Epidemiology, Disease Control and Research (IEDCR) and the U.S. CDC. So far, Bangladesh is the only country to have implemented dedicated Nipah surveillance. The surveillance system was originally established as a joint JE and Nipah surveillance system (the Acute Meningo Encephalitis Surveillance system, AMES), with 11 sites across the country. Currently, there are five active and two passive sites, with an additional 47 sub-district- and 3 district hospitals added during Nipah season. In addition to surveillance at the sites, IEDCR operates a 24/7 hotline, nationwide media monitoring, and follows up on any informal reports.

IEDCR distinguishes between probable and confirmed cases, where probable cases are linked to deaths in a Nipah-affected community around an outbreak, where sampling was not possible. In total, there have been 313 cases since the surveillance started, and 226 (72 %) deaths. Surveillance case definitions used in Bangladesh are: 1) Axillary temperature > 38.5°C AND evidence of acute brain pathology [*e.g.*, altered mental status, seizures], or 2) Axillary temperature > 38.5°C AND illness < 7 days AND severe shortness of breath [*i.e.*, dyspnoea prevents patient from walking unassisted for 10 steps] AND chest radiograph consistent with diffuse acute respiratory distress syndrome. In addition to fulfilling at least one of the two definitions, an epidemiological link is always sought after. This can be geographic location close to an outbreak, that the time of year is within the Nipah season, or recent consumption of date palm sap. A cluster of Nipah cases is defined as at least two cases within a walking distance of 30 minutes, and with clinical onset within 21 days of each other. All suspected cases are investigated, but clusters of cases receive immediate attention and are prioritised.

The surveillance procedure starts with the reporting of a suspected case or cluster of cases from one of the surveillance sites (see Figure 3), and ends with laboratory-based diagnosis. Some tests are performed by IEDCR and some by the International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b). The U.S. CDC, Atlanta, conducts quality controls. Outbreaks are evaluated in a One Health approach, including epidemiological investigations, animal studies, environmental contamination assessment, behavioural studies, and case control studies.

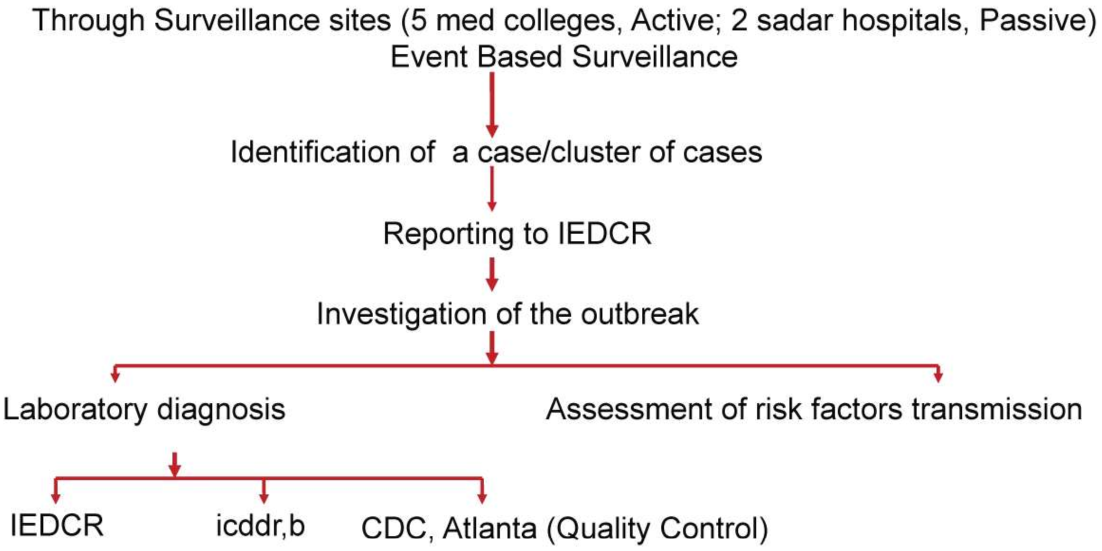

Figure 3. Nipah detection in Bangladesh (Dr. Mahmudur Rahman)

Immediately after a case has been identified, all contacts are listed and accounted for. Symptomatic contacts are subjected to a Nipah IgM test, and all contacts receive weekly follow-up for up to 21 days. All contacts are interviewed for relevant details and contact history. At the end of the follow-up, contacts are tested for Nipah IgG.

Nipah virus dynamics in bats and implications for zoonotic spillover to humans

Dr. Jon Epstein, EcoHealth Alliance

Part of understanding the probability of outbreaks, is understanding how NiV operates in its natural reservoir, and understanding the risk of spillover. Given the wide distribution of the reservoir host, the *Pteropus medius* bat, why are we not seeing more outbreaks?

We should be prepared for NiV outbreaks anywhere where the bats and virus coexist. As such, the Kerala outbreak should not have been a surprise, in spite of the long distance from other outbreaks. The outbreaks in Bangladesh and Malaysia are linked by the fact that, in both places, the source of infection was a human-provided (anthropogenic) source of food. In Malaysia it was a mango orchard planted next to a pig enclosure, in Bangladesh it was the date palm sap. The bats thrive in the company of humans, and through human harvesting of date palm sap during the winter months, they have been able to access a food source that would otherwise not have been available to them – in a time when food is otherwise scarce. As a result, humans are creating opportunities for the Nipah virus to spill over.

In a study of viral ecology, Dr. Epstein and colleagues are trying to answer two questions: 1) Is there a spatial difference in infection patterns in Bangladesh, between the "Nipah belt" and the rest of the country?; 2) Are there seasonal infection patterns? Results were collected over a period of 8 years, from 2006 to 2014, and a publication is currently in review. Although seroprevalence varied, the team found no difference in seroprevalence inside and outside of the "Nipah belt". Traces of NiV infection were found in all of the eight different bat colonies studied. In Faridpur, one bat colony was followed longitudinally, with sampling every 3 months to follow seroprevalence over time. This resulted in a cyclical pattern, where levels of circulating antibodies waxed and waned. As a rule, circulating antibodies do wane over time, and it is believed that the waxing was in response to active viral transmission in the colony. Modelling suggested that bat epidemics occurred biannually, that it was driven by adults (not births, as has been suggested), and that the population density was an important determining factor.

The Bangladeshi bats are less mobile than the Malaysian bats, but sufficient evidence exists to suggest that the different colonies are still connected, creating a metapopulation of bats where viral strains may circulate. In fact, there is no genetic distinction between different colonies across Bangladesh. There is even evidence of hybridisation with other bat species, such as *P. lylei* of Myanmar and *P. vampyrus* of Malaysia. Considering the genetic diversity of viral strains within a colony, there seems to be little variation. However, genetic variation between colonies at different geographic locations is considerable. Due to the mobility of the bats, strains typically found in one location may be transferred to another, contributing to the overall genetic diversity of NiV.

A recent study on the evolutionary history of NiV, based on all available genetic sequences, suggests that NiV originally migrated from India to Bangladesh in 1941, spread within Bangladesh, and then migrated back to India, including Kerala. The *P. medius* bat is common throughout the Indian subcontinent, and the Nipah virus travels with it. Nipah or related henipaviruses have also been found in many domesticated animals, including cattle, goats, and pigs. One mode of transmission between bats and domestic animals could be the feeding of animals with fruit bitten by bats. The mode of transmission causing the Kerala outbreak in humans is still unknown.

Considering the wide distribution of bats and NiV, improved surveillance systems are necessary to better understand where there are potential hotspots for spillovers.

Survey of Pteropus *bats during Nipah outbreak in India revealed its association*

Dr. Pragya Yadav, National Institute of Virology, ICMR

Only four human outbreaks of Nipah infection have so far occurred in India, yet the *Pteropus* bats serve as a reservoir for the virus. Cues for the ongoing risk of a new outbreak may be found in the bats, so surveys of the bats are conducted regularly. In the laboratory, samples are handled at the BSL-3 level. In the field, however, some of the security measures that are otherwise found in the lab, such as directional airflow and HEPA filtration, will be missing. Thus, field work involves careful preparations including training, health measures, and risk assessments.

Capacity for bat surveillance in India was first established in 2011, yet a permanent surveillance system still does not exist. The first report to confirm the presence of NiV RNA in *P. giganteus* in India was published in 2012, following a survey of bats in West Bengal. Dr. Yadav and her team collected samples from five different species of bats, and isolated viral RNA. In addition to NiV, they also found RNA from other viruses, some of which were isolated for the first time. None of the other viruses have so far been detected in humans, but the viral diversity observed in bats underscores their ability to serve as a natural reservoir for pathogens and, potentially, as the source of new EIDs.

During the 2018 outbreak in Kerala, NiV RNA was collected from humans and bats, and sequenced. A large proportion of the bats (23.07 %) proved to be infected with virus that was almost identical to the virus causing the outbreak (99.7-100 % sequence homology), thereby identifying *Pteropus* bats as the likely source of infection. Similarly, in response to the single transmission of NiV to a 21-year old college student in Kerala in 2019, five sites the patient had recently visited were surveyed for infected bats. Again, some of the bats were found to carry NiV, and 21 % were seropositive. The NiV strains from the 2018 and 2019 Kerala outbreaks were found to be closely related (97.9 % sequence homology) to several Bangladesh strains circulating at the time.

Effective surveillance is necessary for detection, response to, and prevention of Nipah infection. Currently, a nationwide Nipah virus survey in *Pteropus* bats is underway in India, with eight states (out of 28) and two union territories (out of nine) surveyed since January 2019.

Long-term One Health surveillance of Nipah virus in Thailand forewarns risk of outbreak

Dr. Supaporn Wacharapluesadee, Chulalongkorn University, Bangkok

Thailand is an at-risk country for a Nipah outbreak, due to the abundance of *Pteropus* bats carrying the virus, the country's proximity to Malaysia which has previously experienced an outbreak, and the large swine industry (though the pigs have so far tested negative for NiV). Since 2002, Thailand has developed its capacity for Nipah surveillance, as shown in Figure 5.

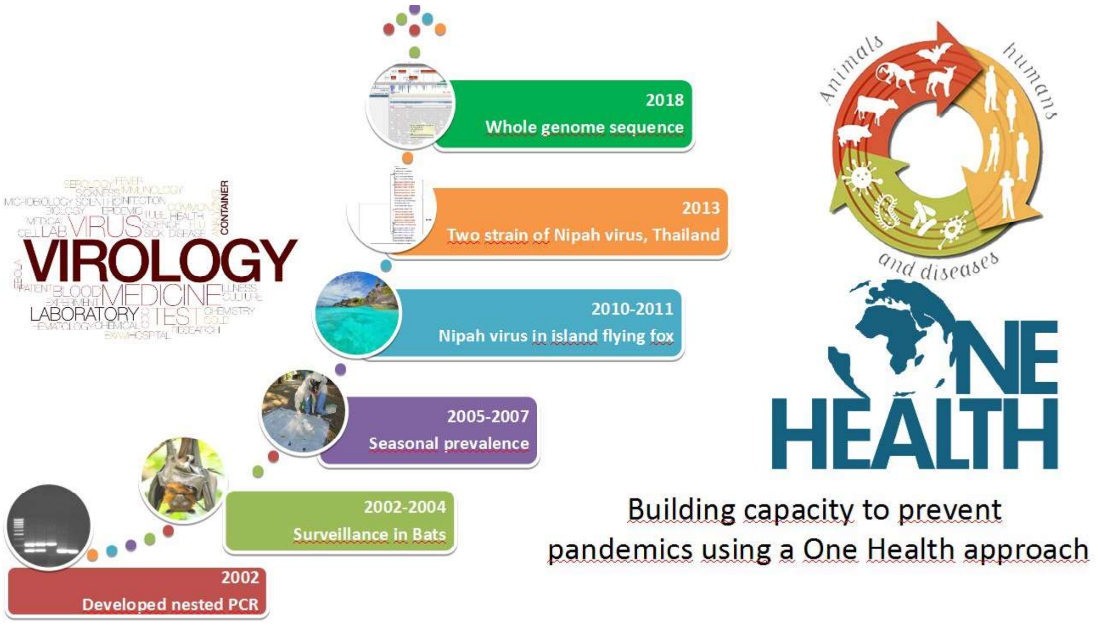

Figure 4. Thailand: Building capacity to prevent pandemics using a One Health approach (Dr. Wacharapluesadee)

In a large survey published in 2005, including six species of fruit-eating bats ($n = 1{,}041$) and six species of insect-eating bats ($n = 263$), Nipah viral RNA was found in urine and saliva from *Pteropus lylei* ($n = 76$, 9.3 %) and saliva of *Hipposideros larvatus* ($n = 1$). These results were followed by a longitudinal study at 7 sampling sites in central Thailand of the prevalence of NiV in *P. lylei* bats, to see if the viral prevalence was seasonal, as had been demonstrated in Bangladesh. Indeed, pooled urine collected on plastic sheets laid out underneath roosts were found positive for NiV RNA in the months of December through June. Later it was found that *Pteropus hypomelanus* living on the islands in South West Thailand carried Malaysian NiV, whereas the *Pteropus lylei* of central Thailand carried a NiV strain akin to the ones in Bangladesh. Different bat species → different location → different Nipah strain.

A longitudinal study in *Pteropus lylei*, lasting 17 years from 2002-2019, demonstrated the genetic stability of NiV: Among 119 NiV-positive pooled urine specimens collected throughout the study, sequence homology in a partial coding sequence of the nucleocapsid gene was 99.44-100 %. Whole genome sequencing of a NiV-positive Thailand bat revealed 99 % sequence homology to NiV isolated from a patient in Bangladesh in 2004, and 98 % sequence homology to NiV isolated from one of the patients from the 2018 outbreak in India.

In a One Health surveillance study of NiV in Thailand in 2012, bats ($n = 374$), pigs ($n = 248$), and humans ($n = 418$) were tested for NiV RNA and circulating NiV IgG. Among the bats, 2 % tested positive for NiV RNA and 10 % were seropositive. The pigs and humans were all seronegative. A public awareness campaign was conducted in relation to the study.

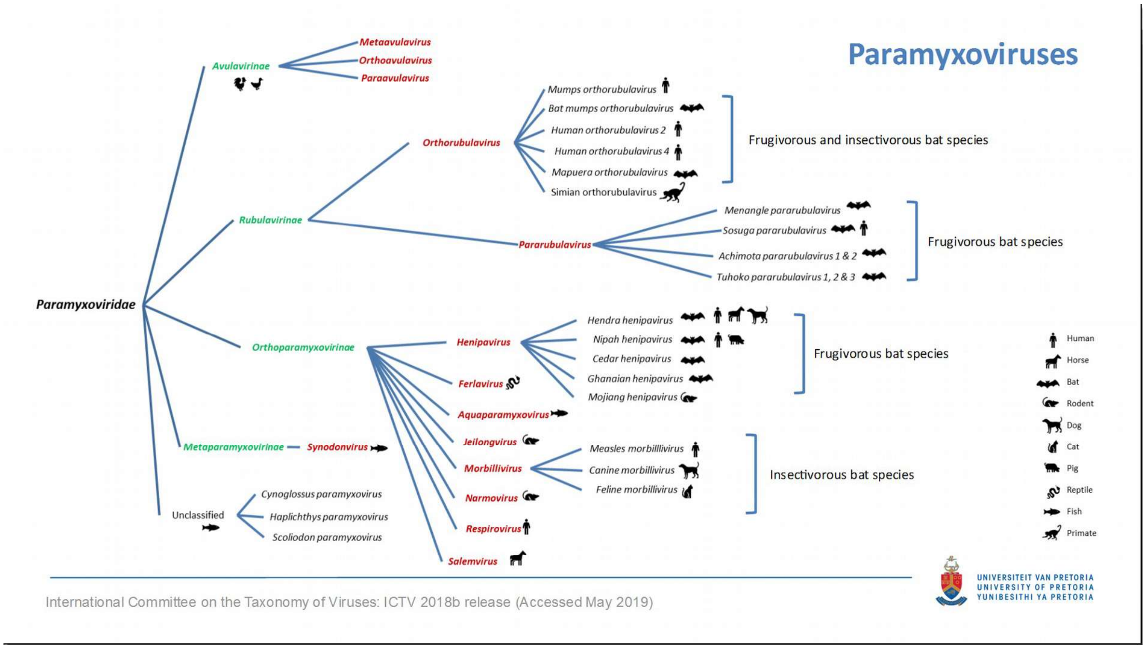
GPS tracking of *Pteropus lylei* showed that maximum linear distances between day roosts and foraging areas varied greatly between individuals, and ranged from 2.2 to 23.6 km. With this information, Dr. Prateep Duengkae has been able to draw Nipah risk maps for central Thailand, based on the estimated density and activity of bats.

Long-term One Health Surveillance of Nipah virus in Thailand forewarns risk of outbreak, for two main reasons: 1) *P. lylei* bats have tested positive at the same location for 18 years, indicating that *P. lylei* is a natural reservoir for NiV; 2) High sequence homology between NiV carried by Thai bats and the 2004 Bangladeshi patient indicates that virus circulating in Thailand is capable of infecting humans.

Henipavirus biosurveillance in South African bats –A research overview

Professor Wanda Markotter – Centre for Viral Zoonoses, University of Pretoria, South Africa

Nipah and Hendra viruses are not present in Africa, and neither are the reservoir *Pteropus* bats. However, one related virus was recently identified in Ghana and added to the henipavirus family under the name of *Ghanaian henipavirus* (see Figure 5). This virus is known to infect bats, notably fruit bats, and since fruit bats of different species are found all over Africa outside of Sahara, the virus is expected to be widespread. So far, henipavirus RNA has been detected in South Africa and several Central African countries.



International Committee on the Taxonomy of Viruses: ICTV 2018b release (Accessed May 2019)

Figure 5. Phylogeny of paramyxoviruses (ICTV, 2019)

There is very little evidence to support spillover of African henipaviruses, though one study has found antibodies to henipa-like viruses in domestic pigs in Ghana, and another found evidence of spillover into human populations. No outbreaks have been reported, and longitudinal studies are non-existent.

At a study site in Limpopo, South Africa, Prof. Markotter and her team study bats roosting in a local cave, with primary attention to the Egyptian fruit bat, *Rousettus aegyptiacus*. This is a cave-dwelling fruit bat species found throughout Africa. In pooled urine collected from the bats, a number of different viruses have been identified (by RT-PCR and next-generation sequencing [NGS]), of which some are henipaviruses and some are henipa-like viruses. Through monthly sampling over 14 months, it was found that virus excretion varied over time, with a characteristic peak in July on two consecutive years. This peak coincided with the breeding season of *R. aegyptiacus*, as well as the dry winter period (nutritional stress?) and the waning of maternal antibodies in juveniles (susceptible individuals). Other factors may also influence the observed excretion pattern.

In conclusion, the *Rousettus aegyptiacus* population in South Africa hosts a diversity of paramyxoviruses including henipaviruses. The detected viruses group closely with ones previously described from other African countries, either due to co-evolution or the forming of meta-populations. The first study reporting on the paramyxoviral excretion dynamics in *R. aegyptiacus* identified the dry winter as a high-risk period for potential paramyxovirus transmission and spillover.

Session 3 Q&A

Q: Prof. Markotter showed very nice peaks of excretion, up to 60 %. It seems this is very high in terms of nucleic acid detection?

A: Yes, in the peak seasons, 60-70 % of the collected samples can be positive. Keep in mind that these are pooled urine samples. Assuming the observed frequencies reflect the true prevalence, one explanation could be the high density of *R. aegyptiacus*, which lives in larger populations than the *Pteropus* species.

Q: Have you been able to look at other virus species through NGS?

A: Not on these samples, but we have also studied other virus families, including the other paramyxoviruses, coronaviruses, and rubulaviruses. Corona- and rubulaviruses have different excretion patterns, where coronaviruses seem to be present at all times, whereas rubulaviruses have a second peak during the pregnancy season of the bats.

Q: While Nipah and Hendra represent pressing needs of Southeast Asia, one should keep in mind the diversity in viruses found there and elsewhere. Polyclonal, neutralising antibodies made for NiV and HeV are often unable to cross-neutralise even closely related viruses, such as *Ghanaian henipavirus*, and this needs to be considered in developing therapeutics and vaccines. There is also the question of how pathogenic these related viruses can be, if they were to spill over into humans.

Q: The longitudinal data were interesting to see, as were the data illustrating differences between the different countries, concerning bats and virus shedding. Notably, there seemed to be an inverse relationship between viral shedding and the frequency of outbreaks. For example, Thailand has a high prevalence of NiV in bats, but no outbreak. How could this be?

A: A lot of the high shedding rates were from pooled urine samples from whole colonies, and these may not be comparable to individual samples. There may also be large variation between colonies, so that the low shedding documented in one colony may not reflect the overall shedding in the area, especially if the colonies are out of sync in terms of viral prevalence. Studies in Bangladesh have observed elevated shedding over a period of time around spillover events, which seems to contradict the assumption made in the question. Another factor that affects transmission rates is human behaviour, as exemplified in outbreaks caused by the drinking of date palm sap. Public awareness on safe practices is key to prevent outbreaks.

Chair: We are all extremely grateful for everything WHO, NIAID, and CEPI are doing to push the agenda for improved surveillance, in spite of criticisms from other scientists. What we have seen here, is that the Nipah vaccine initiative is likely to be only the beginning, with many more initiatives following, due to the wide diversity of circulating viruses. Imagine what spillovers we would catch if we had the same level of surveillance everywhere, as around hospitals in Thailand and Bangladesh. The challenge is to cover all high-risk interfaces, not only in Southeast Asia, but in Africa, too. Hopefully, this sort of initiative will go down in history as the beginning of the end of pandemic risk.

SESSION 4 – Progress and challenges in diagnostics

Chair: Dr. Joel Montgomery, CDC

Overview of Nipah diagnostics

Dr. Jillian Sacks, FIND

The Foundation for Innovative New Diagnostics (FIND) is a global non-profit organization driving innovation in the development and delivery of diagnostics to combat major diseases affecting the world's poorest populations. With diversified public and private funding, they partner to develop and deliver field-adapted diagnostic solutions to low- and middle income countries (LMICs). Their pandemic preparedness programme, which covers many of WHO's priority pathogens, has been crafted on the premise that diagnostics are fundamental to the identification, containment, and resolution of outbreaks. They partner with WHO and others, and perform pathogen, technology, and partner landscape assessments, to identify critical needs and gaps in diagnostics – and address these through requests for proposals (RFPs) and funding of prioritised R&D initiatives.

Concerning Nipah, a TPP has already been developed by WHO, and is currently open for comments. Some diagnostic tests are already available, such as nucleic acid test (NAT), plaque reduction neutralization test (PRNT), and enzyme-linked immunosorbent assay (ELISA), for use in centralised labs (see Figure 6). There are also tests available for veterinary diagnostics (not shown). What is still missing, is NAT, rapid diagnostic test (RDT) or panels to be used in decentralised settings. We also lack a standard, which would be required for the development of new diagnostics and to ensure proficiency of testing in existing laboratories.

	Target Use Setting						
	Facility-based, recommended diagnostic technology						**Non-facility based testing**
Health Care Level	4. National Reference Lab	3. Regional/ Provincial Lab	2. District Hospital			1. Health Center	0. Health Post/ Community
Type of technology	NAT, PRNT, ELISA	NAT, ELISA	POC NAT	ELISA	RDT	RDT	RDT

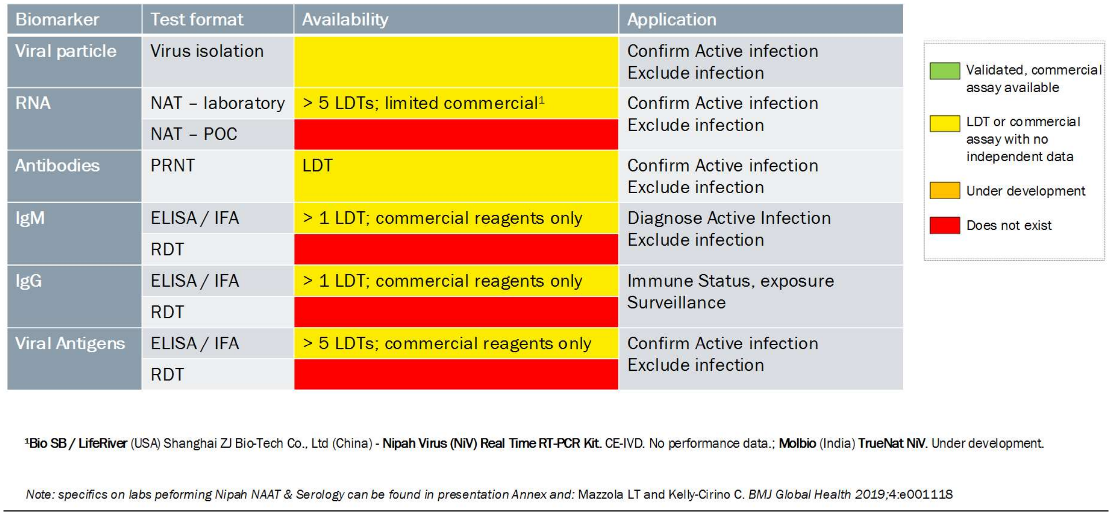
Tests available 🟩
Lab and/or field trials ongoing 🟨
Late-stage development 🟧
Needed - or needs improvement 🟥
Not needed/useful 🟫

Figure 6. Nipah diagnostics heat map of available test technology for a given target use setting (FIND)

Since the symptoms of Nipah are easily confused with other conditions, it is useful to have testing panels, covering multiple pathogens, that can be used in a non-outbreak setting for syndromic case management. These are available for centralised labs, but not in a decentralised setting. Some of the tests that can be used to confirm a Nipah diagnosis, such as virus isolation and neutralisation assays, require a BSL-4 lab, which serves to drastically limit the availability of these tests. Other tests that are suitable for detecting circulating virus are based on the detection of RNA, antibodies, or viral antigens. For these, a number of laboratory-developed tests (LDTs) exist, typically intended for local use, but they are not validated or commercially available (see Figure 7). Though appropriate for select countries, LDTs are generally not easily implementable or scalable for response to new outbreaks. NATs for use at the point of care (POC) have not been developed, and neither has RDTs. FIND strongly advocates for the development of commercially available tests to ensure quality and facilitate comparison across testing sites.



Biomarker	Test format	Availability	Application
Viral particle	Virus isolation	🟨	Confirm Active infection Exclude infection
RNA	NAT – laboratory	🟨 > 5 LDTs; limited commercial[1]	Confirm Active infection Exclude infection
	NAT – POC	🟥

Figure 7. Nipah diagnostic test availability (FIND)

There are important diagnostic gaps for rapid identification and response to Nipah outbreaks: 1) Limited availability of commercialised or standardised kits with regulatory approval; 2) Lack of an international reference standard, and a sample repository to aid in development of new diagnostics; 3) Lack of tests suitable for POC or community settings; 4) Lack of tests that can be used on minimally invasive samples, to minimise biosafety requirements. Better understanding of Nipah epidemiology and viral kinetics will facilitate the development of appropriate NiV diagnostic tests to serve both outbreak and non-outbreak intended uses.

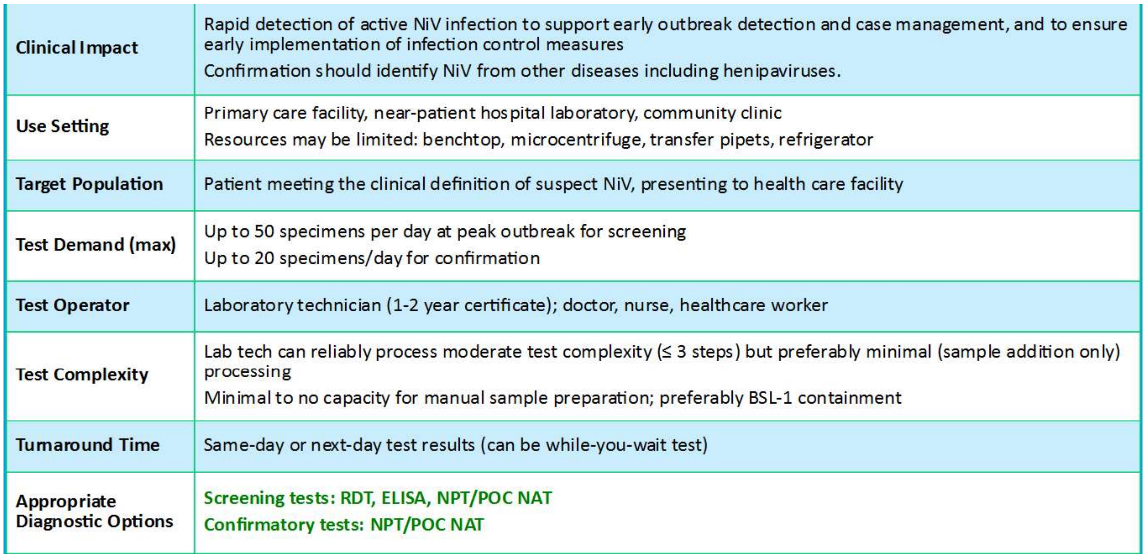
Note: A list of in-house NAT and LDT serology tests for NiV is provided in the presentation Annex and in Mazzola LT and Kelly-Cirino C. *BMJ Global Health 2019*;4:e001118.

The WHO Nipah diagnostics target product profile (TPP)

Dr. Laura Mazzola, WHO

Following the WHO R&D Blueprint, published in 2016, a 5-year framework for Nipah in the form of the Nipah R&D Roadmap was drafted in May 2018. The R&D Roadmap addresses current primary challenges, key needs, and knowledge gaps for diagnostics, therapeutics, and vaccines; sets strategic goals for all of these; and defines priority areas and activities for obtaining the goals. From the needs and knowledge gaps described in the Roadmap, use cases and TPPs for Nipah diagnostics were developed and recently published for consultation on WHO's website. In this document, key priority actions needed to drive new NiV diagnostic test development were identified, with the following two use cases in mind: 1) Screening for active NiV infection; 2) Confirmation of active NiV infection. Screening is typically done in the field, in a POC or near-patient (NPT) setting, where laboratory infrastructure is limited or non-existent. Confirmation is typically done at a centralised reference laboratory, though often without BSL-3/4 capacity. Nipah being a BSL-4 pathogen, some sort of on-site or immediate inactivation procedure would be desirable.

For the priority use case, detection of active NiV at a peripheral health centre or hospital, a set of requirements were established as shown in Figure 8. These laid the basis for the development of TPPs for rapid screening and confirmation, respectively.



Clinical Impact	Rapid detection of active NiV infection to support early outbreak detection and case management, and to ensure early implementation of infection control measures Confirmation should identify NiV from other diseases including henipaviruses.
Use Setting	Primary care facility, near-patient hospital laboratory, community clinic Resources may be limited: benchtop, microcentrifuge, transfer pipets, refrigerator
Target Population	Patient meeting the clinical definition of suspect NiV, presenting to health care facility
Test Demand (max)	Up to 50 specimens per day at peak outbreak for screening Up to 20 specimens/day for confirmation
Test Operator	Laboratory technician (1-2 year certificate); doctor, nurse, healthcare worker
Test Complexity	Lab tech can reliably process moderate test complexity (≤ 3 steps) but preferably minimal (sample addition only) processing Minimal to no capacity for manual sample preparation; preferably BSL-1 containment
Turnaround Time	Same-day or next-day test results (can be while-you-wait test)
Appropriate Diagnostic Options	**Screening tests: RDT, ELISA, NPT/POC NAT** **Confirmatory tests: NPT/POC NAT**

Figure 8. Use case: Rapid detection (screening & confirmation) for suspected NiV infection at peripheral setting during an outbreak (WHO)

The TPPs were made to describe the requirements for a rapid screening and a rapid confirmation diagnostic test, respectively, for human use in an outbreak setting. They specify minimal and optimal requirements – a newly developed test is expected to at least meet the minimal requirements, whereas being able to meet the optimal requirements will yield a better test. A **screening** test is 1) intended for the detection of NiV-specific IgM and/or NiV antigen (Ag); 2) an ELISA or RDT kit; 3) validated for at least NiV-B and NiV-M strains; 4) quicker than 4 hours to get results; 5) used on at least serum; 6) appropriate for biosafe collection and includes inactivation protocol; 7) sensitive (> 90-95 %); 8) specific (> 80-90 %); 9) minimally cross-reactive with other pathogens, may have some cross-reactivity to other henipaviruses. A **confirmation** test is 1) intended for the detection of NiV ribonucleic acids (RNA) by RT-PCR; 2) semi-automated or fully automated; 3) validated for at least NiV-B and NiV-M strains; 4) quicker than 6 hours to get results; 5) used on at least plasma and serum; 6) conducted in three or fewer steps, including inactivation (sample preparation); 7) detecting down to 1,000 copies/ml; 8) sensitive (> 95-98 %); 8) specific (> 95-98 %); 9) not cross-reactive with other pathogens, including other henipaviruses.

There are other issues related to the development of new Nipah diagnostics, besides the diagnostics themselves: 1) For clinical validation, access to specimens is critical, and specimen repositories that are representative for endemic and at-risk regions should be established; 2) International reference standards need to be developed for calibration, comparison, and quality control; 3) Criteria for test performance and use need to be established; 4) Harmonisation of regulatory requirements is desirable; 5) For biosafety, a safe and simple method of sample inactivation needs to be devised that does not interfere with diagnosis. Then there are also a number of issues related to the procurement, implementation, training, proficiency testing, and post-market surveillance of new diagnostics. Finally, there needs to be put in place appropriate geographic deployment strategies for outbreak preparedness.

By 2021, WHO hopes to have completed preclinical evaluation of at least two POC or NPT diagnostics that align with the TPP. By 2022, the aim is to complete field studies for these.

Role of early diagnosis during Nipah virus outbreak in India

Dr. Pragya Yadav – National Institute of Virology, ICMR

In the initial phase of the Kerala outbreak in 2018, the logistics of sample analysis and clinical management proved somewhat chaotic. Systems were not in place for safe handling of samples and clinical cases. Additionally, as Nipah is a frightening disease, many wanted to be tested, and the resulting rapid increase in workload put severe strains on the available diagnostic capacity. Two major infrastructural requirements were identified during the outbreak: 1) Laboratory facilities for quick diagnosis; 2) Isolation wards for confirmed and suspected cases. In spite of the difficulties, Indian healthcare workers eventually succeeded in containing the outbreak. The lessons learned from 2018, and the resulting awareness campaign, led to rapid response and the successful containment of the ensuing 2019 outbreak, which affected only one person, who survived.

There is a need for NiV diagnostics that can ensure rapid and reliable diagnosis in the event of an outbreak, to achieve early implementation of infection control measures. Affordable POC diagnostics are a top priority. The ability to detect and confirm infection on-site allows not only for proper case management, but also for early public health interventions such as contact tracing, isolation, and prophylactic measures. It is important that POC diagnostics are easy and safe to use, with minimal training.

The National Institute of Virology has developed a number of diagnostic tools to be used in India: 1) Anti-Nipah human IgM ELISA; 2) Anti-Nipah bat IgG ELISA; 3) POC assay for NiV detection. These are being validated by IEDCR, Bangladesh. A mobile diagnostic system developed in collaboration with MolBio, as private industry partner, has received approval for clinical use by the Indian Central Drugs Standard Control Organization. The system includes an automated RNA extraction machine and a real-time PCR device tailored to detecting NiV. It is portable and battery-operated, uses stabilised, disposable consumables, and requires minimal handling and, thus, training. The lysis buffer included in the kit has been shown to inactivate NiV, allowing for POC use. Suitable sample materials include throat swabs, serum/plasma, urine, whole blood, other body fluids, and tissue materials (including bat tissues).

The mobile diagnostic system is especially suited for outbreak response in remote areas, and offers easily deployable state-of-the-art technology for effective field diagnosis. However, it does not replace the need for centrally located containment laboratories, more of which are still needed in India. Effective surveillance is key to effectively managing future outbreaks of NiV.

Nipah virus diagnostics at CDC – current strategies

Dr. John Klena – Viral Special Pathogens Branch, U.S. CDC

The Viral Special Pathogens Branch (VSPB) of the U.S. CDC provides support to outbreaks around the world. They have a BSL-4 high-containment laboratory, which is used for high hazard virus diagnostics and research: They also contribute to rapid detection and control during outbreaks through epidemiology support, provision of mobile labs, and health communications. Finally, they conduct ecological investigations to detect the source of zoonotic outbreaks (most EIDs are zoonotic RNA viruses), and devise strategies for disease prevention and control. In the context of Nipah, CDC is working to improve assays for both serological detection and nucleic-acid based detection. While they do not seek commercialisation of their own assays, they are happy to support others who are working to commercialise new diagnostic tests. CDC willingly shares serological and PCR assay components with partners, but this has become increasingly difficult in recent years, due to stricter regulations on shipping of biological materials – something that is especially challenging with the shipping of positive viral controls.

The ELISA-based serological assay of CDC has been known to be difficult to work with, and some changes have been implemented over the past couple of years to improve the assay's sensitivity. One major change has been to replace the historically used goat anti-human IgM capture antibody with goat IgM F(ab')2 (Thermo Scientific A24490). This change will be implemented in the testing in Bangladesh this season. Furthermore, the use of chinese hamster ovary (CHO) cell slurry with recombinant antigen (N-protein), rather than Vero E6 cell slurry with infected cells, seems to improve the background signal, but comes with a loss of sensitivity of the NiV IgM assay. When testing survivors for IgG, serology results remain positive for more than 5 years. Still, more systematic testing of survivor serum is needed to evaluate the longevity and protection of the IgG response.

Nucleic acid testing, using real-time RT-PCR, seems very sensitive and suitable for use in the field when testing for NiV. CDC has historically run these tests against the nucleocapsid (N) protein, and are looking to improve their assay. With sequences from the 21 Nipah whole genomes sequenced by CDC so far, one new domain in the N gene has been identified that has no mismatches among the 21 different viruses. Therefore, this seems a promising target for a new and improved RT-PCR-based diagnostic test, and a set of primer and probe is currently being used to screen samples collected from Bangladesh in the seasons 2017-2018 and 2018-2019. As new, full-length genome sequences are being made available, further revisions to the test will be made.

Hendra DIVA assay for the detection of antibodies in vaccinated horses

Dr. Kim Halpin – Australian Animal Health Laboratory (AAHL)

Horses are highly susceptible to HeV infection, and will often die. However, it was infection in humans that led to the development of a vaccine against Hendra. The Equivac® HeV vaccine by Zoetis is a subunit vaccine containing the soluble G protein (sG), which is a HeV glycoprotein responsible for attachment of HeV to target cells. It was released late 2012 upon approval by the Australian Pesticides and Veterinary Medicines Authority (APVMA) for minor use, and fully registered in 2015. The vaccine requires three doses initially, and a yearly booster to remain effective.

The Hendra DIVA test is a serological test to assess whether a horse has been infected by or vaccinated against HeV. It is an ELISA-based assay, in which the plates are coated with HeV antigen (HeV sG or recombinant N protein, in separate wells) and detected by a specific mouse monoclonal antibody (mAb; anti-sG or anti-N, as appropriate). The secondary antibody is anti-mouse IgG, conjugated with the enzyme responsible for colorimetric reaction. When first incubating with serum from infected horses, binding of the mAb is blocked, resulting in a "blank" color reaction for both sG and N antigen wells. For vaccinated horses, only the sG wells will be "blank", since this is the only protein used in the vaccine. Serum from previously unexposed horses will yield colorimetric results for both sG and N wells.

The test is being validated in 1,000 unvaccinated and 1,000 vaccinated horses, so that it can be used for healthy horses that need to be transported internationally. HeV vaccination is entered in a national database in Australia, which allows for assessment of the number of vaccines given to a particular horse, and see the time elapsed since the last vaccination. In the current validation, where about 250 horses have so far been included, most horses appear to achieve protective antibody titres upon the third vaccination, as evaluated by serum neutralisation tests (SNTs). In these horses, the protective antibody titres seem to last for at least 20 months after the last vaccination. The vaccine thus appears to be effective, and the hope is that documenting efficacy of the vaccine will counter some of the negative attention the vaccine has received from certain circles in the general population.
