> 1. Review the manuscript and submit your comments via track changes on the Word document.
> 2. Complete the attached table, so you are cited correctly in the manuscript.
> 3. If, as you review the manuscript, you find anything glaring that needs to

> change in the roadmap, please let us know. We still have time to make minor changes to the roadmap. Again, you can use track changes on the Word document of the roadmap.

Please also address the following question from Wellcome regarding the roadmap: For Nipah therapeutics we mention "By 2020 generate a reliable source of m102.4 to be used in clinical trials. We have not mentioned a specific vaccine or therapeutic for Lassa—is there a risk of promoting one candidate over others? This may be a redundant question since the Nipah field is far less advanced than other diseases."

WE WOULD VERY MUCH APPRECIATE YOUR COMMENTS AND FEEDBACK BY MONDAY, DECEMBER 3.

Thank you again for your support of this important effort, and thank you in advance for reviewing the manuscript. Please send any comments to me at kamoore@umn.edu.

Warm regards,

Kris

BOHRN

THE BAT / ONE HEALTH RESEARCH NETWORK

OVERVIEW

There is a long tradition of international cooperation in scientific research. Scientific networks can be instrumental to bridge cultural boundaries and build trust, addressing the global threat of emerging infectious diseases. Current trends in scientific research funding, specifically competition for ever-decreasing research budgets, necessitate international collaborations focused around specific and prioritized research questions.

Scientists posit that the Ebola outbreak of 2014 began with a Guinean toddler playing in a bat roost amongst fruit bats that had migrated 2,500 miles from Central Africa. Understanding bat migration patterns, the effect of humans on those patterns, and the challenges of conducting disease surveillance in free-range bat populations, will enable relevant policy makers to better identify, plan, and prepare for the next pandemic. Additionally, research coordinated networks have the ability to significantly impact threat reduction by identifying and prioritizing coordinated approaches to close these and other pressing knowledge gaps.

The Defense Threat Reduction Agency (DTRA) Biological Threat Reduction Program (BTRP) is sponsoring a multi-regional disease surveillance research coordinated network to mitigate the threat of bat-associated pathogens of security concern. This threat reduction network will identify and connect interdisciplinary expertise, convening an agile group to adapt to a wide spectrum of arising challenges and threats. The Bat / One Health Research Network (BOHRN) will enable shared learning and research opportunities, establish new research projects, and facilitate joint applications for funding; thus increasing the opportunity for peer review, especially if a cross-regional and multi-disciplinary team of authors are involved

The BOHRN kick-off meeting coincided with the 2nd International Symposium on Infectious Diseases of Bats in Fort Collins, CO on 29 June 2017. During this meeting, the group began preliminary actions to build a self-sustainable disease surveillance network and identified initial network objectives needed to develop a comprehensive research strategy to address bat-associated disease threats and mitigation solutions.

NETWORK OBJECTIVES

- Facilitate interdisciplinary collaboration to identify research goals and needs for bat-borne disease research and broader threat reduction
- Create a common action plan that yields collaborative and sustainable projects which: (1) better inform policy makers; (2) better inform scientific community regarding funding targets and gaps in areas of research and development; (3) better define threat to global health security from bat-associated pathogens; and (4) improve national, regional, and global capacity to detect and respond to pathogens of security concern
- Enable better communication, coordination, and outreach at the research and conservation interface

APPROACH AND IMPACT

BOHRN has four thematic focus areas, which were characterized and developed into research Working Groups at the kick-off meeting. These Working Groups (described below) will operationalize the network objectives by serving as subdivisions to the overall network to foster multi-national and multidisciplinary participation and mentorship. Each member of the BOHRN will identify with at least one Working Group based on field of research/practice. Working Group members will identify and prioritize research gaps and needs, and research project ideas will be solicited from BOHRN membership to address the identified gaps and needs.

Working Group 1: Host / pathogen biology interactions; specifically: (1) Bat physiology and immunology; (2) Bat pathogen community biology (e.g., co-infections and co-morbidities); and (3) Distribution of pathogens among species

Working Group 2: Pathogen surveillance, diagnostic capacity, and epidemiology; specifically: (1) Molecular epidemiology; (2) Distribution of pathogens geographically and phylogenetically; and (3) Detection, diagnosis, and reporting of bat-associated pathogens

Working Group 3: Ecology (bat, domesticated animal, and wildlife interface); specifically: (1) Bat behavior; (2) Domesticated animal and wildlife behavior, distribution, and movement impact; and (3) The effect of anthropogenic disturbance and modification on pathogen dynamics and spillover risks

Working Group 4: Human-bat interactions; specifically: (1) Hunting and commodity chain (e.g., bushmeat, guano, and pet trade); (2) Ecotourism; and (3) Interactions in human dwellings

Why Bats?

Bats act as natural reservoirs for over 60 pathogens, including some of the world’s most deadly viruses, such as Nipah, Hendra, Marburg, and SARS viruses. Understanding the role of bats as a reservoir and the risk of pathogen transmission from bats to humans and other animals could be a key to discovering novel pathogens, mitigating the impact of emerging and re-emerging pathogens, and preventing future pandemics.

There are a number of factors which make bats unique disease reservoirs, including their social behavior, distinct physiology and metabolism, ability to travel long distances, nocturnal activity, species diversity, and long life span (10-20 years). These specific bat characteristics, coupled with the impact of human-mediated interactions and environmental changes, create research challenges to understanding the role of bats in global zoonotic disease ecology. BOHRN will create opportunities for policy makers, scientists, conservationists, funders, and students to identify community challenges, develop priority research lists and implement associated action plans that target needs and gaps. The opportunities created will work at all levels to build awareness of bat-associated disease burden and transmission risks and improve the prevention, detection, diagnosis, and reporting of pathogens of security concern.

U.S. DoD and Health Security

BOHRN outcomes will also support the Global Health Security Agenda (GHSA) Zoonotic Disease Action Package, which has a five-year target for countries to adopt measured behaviors, policies, and/or practices that minimize the spillover of zoonotic diseases from lower animals into human populations.

Although not directly involved in implementation, DTRA BTRP supports the GHSA goals and milestones, and synchronizes with GHSA country projects through the DoD GHSA Coordination Cell. DTRA BTRP is the DoD’ premier biological nonproliferation division protecting the United States and its allies from especially dangerous pathogens by collaborating with partner countries and the international community to minimize the threat of deliberate, accidental, and natural infectious disease outbreaks through enhanced biosafety, security, and surveillance measures. DTRA BTRP investments build capacity to detect, diagnose, and report disease events and help reduce the magnitude and response costs of biological incidents.

Additionally, DTRA BTRP promotes scientific and technical collaborations among partner nations and the international community in the disciplines of biological safety, security, and surveillance to build constructive and sustainable international partnerships that address threats posed to health security. These science diplomacy-based activities engage scientists in peaceful application of biotechnology; building partner country disease surveillance capabilities; promoting adherence to international codes of conduct, security, and safety; and enhancing transparency and confidence building.

Although DTRA BTRP is committed to supporting BOHRN, there is no guarantee or obligation for DTRA BTRP to fund projects resulting from the network or its members.

DISTRIBUTION A: This document was cleared by the Defense Threat Reduction Agency Public Affairs Office on 27 September 2017 for public release; distribution is unlimited

Quad Chart Instructions: Please fill out all four portions of the quad chart. The chart is read in a clockwise direction starting with the technical description. This activity is intended to provide a big picture overview and not an in-depth report of your research. Please limit the text to provide only the most important aspects of each quad. You will be given 5 minutes to present the information within this chart. Refer to the questions in each box for more guided assistance.

TECHNICAL DESCRIPTION AND OBJECTIVES

Briefly describe the research you are currently conducting and why. What questions are you trying to answer and what is the importance of this research to your field and the region? What are the specific aims of your research? What is currently known about your research? Consider the following:

1. **Objectives of research**
2. **Current state of understanding**
3. **Location of research (city/country and or coordinates)**

KEY PARTNERS AND REGIONS OF STUDY

Briefly describe the key partners and funders in your research. List the region(s) your research is being conducted in and any networks you are working with formally or informally. Consider the following:

1. **Who are the key partners involved in your research?**
2. **Who are the key funders involved in your research?**
3. **What region(s) is your research being conducted in?**
4. **Are you working with any networks (formally or informally)?**

MILESTONES, STATUS, AND CHALLENGES

Briefly explain the timeline of your research. When do you anticipate your research to be completed? Are there deliverables or steps along the way that will show substantial progress? Identify the challenges you will face. Consider the following:

1. **Provide timeline for delivery**
2. **Overview on project status**
3. **List challenges or needs in your research**

REGIONAL IMPACT

Describe the potential regional impact of your research. What will the impact be for the regional area? Will this lead to the need for future studies? Consider the following:

1. **Define the quantitative impact of project.**
2. **Define the regional impact.**

BOHRN_QUADCHART[2].docx
image001.png

Dear Dr. Broder,

I wanted to follow up on your earlier discussion with Dr. Marty Stokes, the Southeast Asia Science Manager for the Defense Threat Reduction Agency, Biological Threat Reduction Program (formerly Cooperative Biological Engagement Program or CBEP), regarding the Bat One Health Research (BOHRN) Workshop in Vienna.

On behalf of Dr. Stokes we would like to extend an invitation for you to the BOHRN 1st Annual Workshop in Vienna, Austria on 8-9 November 2018. The two day meeting will be held at the Imlauer Wien hotel.

Established 2016, BOHRN convenes multi-disciplinary and One Health-focused scientists, policy makers, research scientists, and medical/veterinary practitioners with interests in bat-related research involving pathogens of security concern. The network builds on community standards and best practices for research. BOHRN identifies and shares information on research funding opportunities offered by multiple institutions. Most importantly, this network fosters international relationships among collaborators, agencies, and organizations, which can produce long-term, sustainable partnerships that withstand changes in government and organization budgets, priorities, postures, and policies. Please see the attached fact sheet for more information on BOHRN.

DTRA BTRP sponsors BOHRN a global networks that aims to characterize global threats of bat-borne pathogens and formalize community standards and conservation- conscious practices for One Health disease research. We hope to achieve the following objectives during the 1st
Annual BOHRN Workshop:

(1) Facilitate a multi-disciplinary forum for discussion on research methods and practices to characterize bat-borne pathogen spillover threats

(2) Engage available funding program representatives with interests in conservation-conscious bat-borne pathogen research

(3) Characterize global research interests and priorities, and align them with network research focus areas and available funding programs

(4) Discuss upcoming planning opportunities

Attached you will find the network fact sheet; you can also visit www.bohrn.net for more information.

We have secured a hotel room for you the nights of 7-8 November at the Imlauer hotel in Vienna prior to the IMED meeting. In addition, **please find a quad chart attached, we ask that you please fill in the attached quad chart and return as soon as possible.**

Each participant will be asked to present the attached quad chart during the workshop day 1 event (about five minutes per chart). The information presented will be used to aid breakout group and large group discussions. Along with the quad chart, we are requesting that you send a picture of yourself. The quad charts and pictures will be printed to display around the room during the two day workshop.

Please let us know if you have any questions regarding this meeting or the quad chart.

Kind Regards,

Megan

NipahResearch and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness,cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; some differences have been noted in the clinical features of infection with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in thise roadmap ranges from basic research to late-stage development~~, licensure, and early use ~~of MCMs to prevent and control NiV outbreaks and endemic diseasein humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updatingas needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), ensure hand hygiene and environmental hygiene, effective community engagement, adequate infection prevention and control practices,adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research ofNiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV(or related henipavirus species)in humans and virus transmission can occur at the human-animal interface.

Commented [EG1]: I would argue that enhanced surveillance systems are also crucial to the goals of development of MCM. Without active and effective surveillance, we do not have a platform with which to develop and test these new technologies. In addition, expanded surveillance could have an impact on the business case for these technologies. I think it's important to have this argument clearly articulated in the roadmap.

Commented [KM2]: Issues related to MCM development for animals have been deleted, since the decision was made at the July meeting to focus on human disease. However, further research in animals is critical, so this sentence was added.

VISION

Robust MCMs to detect, prevent, and control human outbreaks of NiV infection(and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research re~~s~~presents a substantial challenge, since e~~E~~conomic incentives to invest in Nipah research are not readily apparent because~~, as~~ the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence ~~is~~ has, so far, beenlow with small and sporadic outbreaks. ~~; therefore, securing funding for Nipah research represents a substantial challenge.~~ The development of a sustainable value propositionfor industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition ~~would ideally~~should be informed by a robust assessment of the risk of future outbreaksand the economic, societal,and health impacts that such outbreaks could generate. ~~and will likely require new systematic surveillance studies in humans and susceptibleanimal hosts in affected areas to strengthen the evidence base.~~

Commented [KM3]: Taken out because this is too long term for creating the value proposition.

- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions, which increases~~. This raises~~ the cost of MCM development.
- To date, NiV spillovers to human communities have been identified ~~almost exclusively~~ most commonly in rural communities in Bangladesh andIndia; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- ~~Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs older than 4 weeks old), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before~~

~~livestock are tested for NiV, which could cause large financial losses forlivestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.~~

- ~~NiV disease occurs in both humans and animals (particularly livestock). This creates two streams of research, which complicates the overall approach for moving NiV MCMs forward. For example, animal models for human disease will have different parameters than animal models for disease in animal species.~~
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research, ~~applicable to humans (and pigs and horses for research applicable to disease in animals),~~ the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions;however, phase 3 clinical efficacy trials will need to be conducted in endemic areas~~.~~ ~~However, B~~because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence ~~in endemic areas~~ poses a major challenge for conducting ~~phase 3 clinical efficacy~~suchtrials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by combining clinical trial data across outbreaks over time. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not ~~applicable~~feasible.

Commented [EG4]: And, possibly by expanding surveillance areas.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop an~~m~~d manufacture NiVMCMs.
- Enhanced clinical, laboratory, and public healthinfrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures.
- Additional prospective serosurveillance data from susceptible animal species and proximate human populations in areas of predicted risk to determine the level of human spillover and to build preparedness for detection of human cases and for limiting exposure. This is particularly important in areas where public health surveillance programs are not feasible.

Commented [KM5]: Even though this bullet deals primarily with animals, I left it in, since it also deals with the human-animal interface.

- Standardized and ~~validated~~ well characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)WHO

international standards should be used (when available) as calibrators and reported in Units/ml to harmonize assay results.

- ~~Efforts to establish the natural history of NiV infection in animals and define the animal modelsthat are most reflective of human disease.~~
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- ~~Efforts to design clinical efficacy trials in affected areas that are ethical, interpretable, and feasible. Researchers should explore the potential for conducting clinical trials before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).~~
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to cliniciansand community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and ~~facilitate effective communication with communities to~~ strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturingto endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus)is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other batspecies.

Commented [KM6]: Moved to vaccines.

- Additional research is needed to~~refine, standardize, and validate~~ optimize relevant animal challenge models(e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) ~~to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for~~ to promote development and evaluation of MCMs, particularly if investigators intend to use an alternative pathway(such as the United States Food and Drug Administration's [FDA's] Animal Rule)to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3)determine when after challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data ~~between~~ from animal models ~~and~~ to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hostsand pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume data palm sap and workers at the human-animal interface) ~~pig farmers, hunters, abattoir workers)~~ and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiVMCMs, especially if therapeutics and vaccines do not consistently prevent disease.
- ~~Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.~~

Commented [SP7]: May also need to include healthcare workers at hospital setting

Commented [KM8]: This is relatively redundant to the bullet above, so was deleted.

Strategic Goals and Aligned Milestones

Strategic Goal 1:Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Commented [KM9]: In the Lassa taskforce meeting, we discussed the need for a value proposition document, which can help justify the funding plan, so that was added here. We also talk about the value proposition at the beginning of this document. There actually is a template for a value proposition for vaccines (created by a WHO group), so perhaps that document could be used as a starting point.

Strategic Goal 2:Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiVsurveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the diseaseburden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform**phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.

- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- ~~**Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.~~
- ~~**Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.~~
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Commented [KM10]: These two bullets were moved to vaccines.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote**early communication between developers and appropriate NRAs forclarity and guidance on the regulatory aspects ofMCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacityto: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiVsurveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiVspillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiVtherapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorizationfrom appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an “affordable and fair” price is one that can reasonably be funded by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify**the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Critical Path Analysis

[See accompanying table.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species)appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional

pathogenic henipaviruses is an important challenge forensuring diagnostic preparednessto respond tofuture outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.

Commented [KM11]: Moved up from further down

- A TPP for NiV diagnostics~~,identifying~~ that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A ~~biobank~~virtual repository (with specimens being held and maintained in the countries of origin) of ~~human and animal~~clinical samples to assess and validate diagnostic tests.~~ and a process for how best to judiciously use the samples.~~ As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governace structure; (6~~3~~) identify who would have access to the samples; ~~and~~ (7~~4~~) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place.(Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- ~~Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.~~

Commented [KM12]: Moved up and shortened.

- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course,are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), ~~can be applied in both human and animal populations,~~ and have a high degree of sensitivity and specificity for different NiVstrains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

- Improved ~~D~~diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses ~~in humans and animals~~ as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiVdiagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- ~~If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.~~
- ~~If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.~~

Commented [KM13]: The group decided to take out any reference to multiplex assays, given the 5 year timeframe of the roadmap, so this was deleted.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. ~~Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.~~
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudo typed neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- ~~A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).

2. By 2020, identify funding and initiate creation ofthe virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2:Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.

3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3:Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks.For example, this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.

Priority Areas/Activities

Research

- **Create** a ~~biobank~~ virtual repositoryof clinical ~~human and animal~~reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- ~~**Continue to research** cross-reactivity of diagnostic tests in animal populations.~~

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- ~~**Define** use cases for diagnostic assays.~~
- **Develop** and ~~,~~ **evaluate**~~, and validate~~ point-of-care or near-patient rapid diagnostic tests for NiVinfection that are affordable, highly sensitive and specific (as needed, depending on their intended use), ~~available for use in humans and animals, and~~ can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.
- ~~**Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.~~
- ~~**Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.~~
- ~~**Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).~~

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed. ~~in humans and animals.~~

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiVdiagnostic tests across different geographic areas, as such tests become available.

Critical Path Analysis

[See accompanying table.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment and PEP to exposed persons.

- In ~~the~~ NiV-endemic ~~region of Bangladesh~~areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. ~~In the absence of confirmatory testing, t~~Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well ~~an~~ a therapeutic agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control ~~systems~~ programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- ~~A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.~~
- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- ~~Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.~~
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- ~~Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.~~
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacyof m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the mostpromising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- ~~Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.~~
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer.This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will impact response to therapeutic candidates and influence results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies,diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines and evidence-based policy decisions.

Commented [KM14]: Taken out because this was redundant to other statements above.

Strategic Goals and Aligned Milestones

Strategic Goal 1:Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2018, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.

3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.

Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as ~~ribavirin and~~ m102.4 and favipiravir) for treating and preventing NiV infection, including conducting ~~animal~~ studies in animal models andclinical trialsas appropriate and feasible.
- **Continue to** ~~**identify**~~**expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- ~~**Generate** a TPP for NiV infection therapeutics.~~
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized in advance of future outbreaks, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.

- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- ~~**Identify** a company or joint partnership to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and **secure** financing for its manufacture, and distribution, and post-marketing surveillance.~~
- **Generate** a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.
- **Develop**guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Critical Path Analysis

[See accompanying table.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could impact acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.

- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.These specific correlates may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed in target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populationsand identify additional areas of potential NiV spillover.

Commented [SP15]: It may also worthy to explore perceptions and/or concerns of the population/communities at risk for future vaccine implementation

- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiVand HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available),(4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- ~~Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into developing NiV/HeV vaccines for livestock(or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.~~
- ~~Additional research is needed to determine if development of multivalent vaccines for animals(that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.

2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2:Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.

2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.

3. By 2023, complete the followingif phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of thehumoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serological assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.

- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- ~~**Explore**whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.~~
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.

Product development

- ~~**License**~~ **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans. ~~and animals.~~
- ~~**License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.~~
- ~~**Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.~~

Key capacities

- **Improve**surveillance capabilities to assess the impact of vaccine use and vaccination strategies(once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of ~~licensed~~ NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide**guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptation and promotion within the community.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for more rapid spread.

Critical Path Analysis for Development of Nipah Virus Diagnostics, Therapeutics, and Vaccines

The table below provides a high-level description of the primary risks and barriers to achieving the milestones identified in the research and development (R&D) roadmap for Nipah virus and also identifies other milestones that are critical dependencies, meaning that in order for the milestone in question to either be initiated or completed, another milestone should be completed first. The focus of this critical path analysis is on R&D of medical countermeasures (MCMs) and does not encompass all aspects of Nipah virus prevention and control.

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
CROSS-CUTTING ISSUES		
Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.		
1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.	• Lack of resources to create a public value proposition (e.g., funding, availability and commitment of partners with the appropriate expertise) • Lack of accurate data sources and information to support the value proposition	--
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.	• The need to identify and engage appropriate industry partners as part of the process in creating a funding plan • Challenges with identifying funders willing to support elements of the funding plan	• A completed value proposition to support and justify the funding plan (Cross cutting: SG1, MS1)
Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.		
1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.	• Lack of ability to secure funding to enhance NiV surveillance • Challenges with developing consensus on the implementation protocol because of differing clinical and laboratory capabilities across catchment areas • Limited information regarding which areas may be at high risk for NiV spillover	--

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.	• The need to educate clinicians and community health workers about NiV infection to increase their index of suspicion and improve case detection	• A completed and agreed upon surveillance plan and related protocols(Cross cutting: SG2, MS1) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.		
1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.	• Limited BSL-4 capacity • Lack of dedicated funding to create research tools • Lack of consensus on criteria for standardization and characterization	• Availability of well-characterized clinical samples (including representation of the different NiV strains)(Diagnostics: SG1, MS2)
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.	• Limited BSL-4 capacity • Regulations and restrictions applicable to animal research, including ethical considerations regarding use of NHPs • The need for agreed-upon benchmark parameters (i.e., challenge strain, route, timing, and dose)	• Availability of standardized assays and challenge strains for animal research (Cross cutting: SG3, MS1) • Availability of well-characterized clinical samples (including representation of the different NiV strains) (Diagnostics: SG1, MS2)
DIAGNOSTICIS		
Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.		
1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).	• Complexities involved with creating a virtual reference repository • The need for coordination across multiple organizations and agencies within each of the primary NiV-affected countries • The need for international and in-country leadership to drive the process	--
2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.	• Lack of funding and resources to create the in-country repositories • Lack of adequate case numbers for sample collection (in part owing to lack of surveillance capabilities) • Challenges with international regulations for transport of clinical samples and other biologic	• Completion of the plans and protocols for creating the virtual reference repository (Diagnostics: SG1, MS1)

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
	materials • Challenges in completing the steps necessary to operationalize the plans (e.g., ensuring laboratory capacity, conducting training, having MTAs in place, having the governance structure in place)	
Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient-care NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.		
1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.	--	--
2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.	• The need for a coordinated process and leadership to engage and convene the appropriate regulatory agencies and other key partners	--
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Insufficient resources and funding for R&D to produce promising diagnostics • Low engagement in diagnostic development from commercial manufacturers • Adequate supplies of clinical samples or experimentally generated samples from research animals	• Availability of well-characterized samples from patients (Diagnostics: SG1, MS2)
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Lack of clinical and laboratory capacity for conducting field studies in different geographic areas of NiV spillover • The need to ensure proper test performance under field conditions	• Successful completion of preclinical evaluation of promising diagnostic assays (Diagnostics: SG2, MS3) • Adequate laboratory capacity to conduct the field studies (Diagnostics: SG3, MS1)
Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.		
1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example,	• The need for international leadership and engagement to assist with development of the national laboratory strategies • The need to engage and obtain support from key in-country partners	--

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap		
MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.	• Lack of necessary resources to enhance laboratory capacity	
THERAPEUTICS		
Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.		
1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to the operationalize protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate suppliesnecessary to conduct clinical trial research (Therapeutics: SG2, MS1)
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
3. By 2020, complete a broader, regional protocol for conducting clinical trials of promisingtherapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • The need to develop consensus across different countries to generate a regional approach and promote adoption by member states • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.	--	--
Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.		
1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.	• Obtaining consensus regarding prioritization of promising candidates • Lack of an adequate pipeline of promising	--

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
	therapeutic agents and lack of R&D resources to strengthen the pipeline	
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of dedicated R&D funding to conduct preclinical evaluation of novel NiV therapeutic agents • Limited BSL-4 capacity • Limited understanding regarding whether or not genetic diversity of NiV strains will impact therapeutic response to new treatment options	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1)
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of in-country capacity to conduct clinical trials • Hesitancy or opposition to clinical trials being conducted in at-risk populations • Difficulty in receiving approval from in-country NRAs to conduct clinical trials • Identifying sufficient cases to support an informative evaluation, especially if there are multiple potential therapeutic candidates • Develop guidance to engage with families of patients to explain the need for testing therapeutic candidates to avoid any potential mistrust on heath system and healthcare workers	• Successful completion of preclinical evaluation of promising therapeutic candidates (Therapeutics: SG2, MS2) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
VACCINES		
Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.		
1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.	• Need for regulatory engagement and guidance on whether or not clinical efficacy trials are feasible • Need for better characterization of clinical trial capacity in areas of NiV spillover • Lack of accurate information on the disease burden caused by NiV infection, which is important for assessing the likelihood of completing clinical efficacy trials	--

Formatted: Indent: Left: 0", Hanging: 0.11"

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the EMA), national and international public health agencies and organizations, and local and international researchers.	• Challenges with identifying the appropriate regional and international partners • Challenges with developing consensus among partners	• Determination the feasibility of conducting phase 3 clinical efficacy trials in NIV-affected areas (Vaccines: SG1, MS1)
Strategic Goal 2:Develop and evaluate NiV vaccines for prevention of NiV disease in humans.		
1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.	• Insufficient R&D funding to conduct preclinical evaluation of promising NiV vaccines • Limited BSL-4 capacity for conducting preclinical research on potential NiV vaccines	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1) • Availability of animal models that bridge to humans and can be used to demonstrate vaccine protection (Cross cutting: SG3, MS2)
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines, including in target populations.	• Hesitancy or opposition to clinical trials being conducted in at-risk populations ~~• Lack of in-country capacity to conduct clinical trials~~ • ~~Difficulty~~ Delaysin receiving approval from in-country NRAs to conduct clinical trials •	• Successful completion of preclinical evaluation of 1 or more promising vaccine candidates (Vaccines: SG2, MS1)
3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.	• The challenges of engaging partners and completing steps necessary to operationalize clinical trial protocols • The need to develop consensus across different countries • Lack of surveillance capacity and systemic estimates for NiV infection to assess vaccine efficacy and impact over time	• Successful completion of early clinical trials of 1 or more promising vaccine candidates (Vaccines: SG2, MS2)

Commented [SPL1]: Not really an issue with CEPI support.

Commented [SPL2]: This is relevant neither for Bangladesh nor India which each have a long history of such trials.

Critical Path Analysis of Milestones for Strategic GoalsIdentified in the WHO Nipah Virus R&D Roadmap		
MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
Abbreviations: BSL-4, biosafety level 4 (highest biosafety level); EMA, European Medicines Agency; FDA, US Food and Drug Administration; MCMs, medical countermeasures; MS, Milestone; MTA, material transfer agreement; NHP, nonhuman primate; NiV, Nipah virus; NRA, national regulatory authority; PEP, post-exposure prophylaxis; R&D, research and development; SG, Strategic Goal; TPP, target product profile; WHO, World Health Organization. *These dependencies focus only on the relationships between the milestones to show how the roadmap should be implemented over time; however, there are other critical dependencies for each of the milestones, such as adequate resources and funding.		

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; some differences have been noted in the clinical features of infection with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this~~e~~ roadmap ranges from basic research to late-stage development~~, licensure, and early use~~ of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

Commented [KM1]: Issues related to MCM development for animals have been deleted, since the decision was made at the July meeting to focus on human disease. However, further research in animals is critical, so this sentence was added.

VISION

Robust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research respresents a substantial challenge, since e~~E~~conomic incentives to invest in Nipah research are not readily apparent because~~, as~~ the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low with small and sporadic outbreaks. ~~; therefore, securing funding for Nipah research represents a substantial challenge.~~ The development of a sustainable value proposition for industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition ~~would ideally~~should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate. ~~and will likely require new systematic surveillance studies in humans and susceptible animal hosts in affected areas to strengthen the evidence base.~~
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions, which increases~~. This raises~~ the cost of MCM development.
- To date, NiV spillovers to human communities have been identified ~~almost exclusively~~ most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- ~~Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs older than 4 weeks old), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before~~

Commented [KM2]: Taken out because this is too long term for creating the value proposition.

~~livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.~~

- ~~NiV disease occurs in both humans and animals (particularly livestock). This creates two streams of research, which complicates the overall approach for moving NiV MCMs forward. For example, animal models for human disease will have different parameters than animal models for disease in animal species.~~
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research, ~~applicable to humans (and pigs and horses for research applicable to disease in animals),~~ the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. ~~However,~~ B~~b~~ecause NiV infection occurs as relatively small, focal outbreaks, the low disease incidence ~~in endemic areas~~ poses a major challenge for conducting ~~phase 3 clinical efficacy~~such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by combining clinical trial data across outbreaks over time. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not ~~applicable~~feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop amd manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries and to global stakeholder to ensure they understand the potential health, societal, and economic benefits of devoting ~~limited~~ resources to improving NiV surveillance, detection, prevention, and control measures.
- Additional prospective serosurveillance data on henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk should be explored as a strategy to ~~determine~~ assess the ~~level~~ risk of human spillover and to build preparedness for detection of human cases and for limiting exposure. ~~This is particularly important in areas where public health surveillance programs are not feasible.~~
- Standardized and ~~validated~~ well characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.) WHO

Commented [SPL3]: Potentially pandemic pathogen's put the whole world at risk. We should not expect the cost of surveillance to be borne exclusively (or even primarily) by low income countries where these diseases are most likely to be seen.

Formatted: Strikethrough

Commented [KM4]: Even though this bullet deals primarily with animals, I left it in, since it also deals with the human-animal interface.

Commented [SPL5]: Because survivors are rare and the illness is rare, this does not seem to be a cost-effective approach. We may be able to get some general Henipavirus antibodies, but this does not seem an efficient use of resources.

international standards should be used (when available) as calibrators and reported in Units/ml to harmonize assay results.

- ~~Efforts to establish the natural history of NiV infection in animals and define the animal models that are most reflective of human disease.~~
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- ~~Efforts to design clinical efficacy trials in affected areas that are ethical, interpretable, and feasible. Researchers should explore the potential for conducting clinical trials before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).~~
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and ~~facilitate effective communication with communities to~~ strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Commented [KM6]: Moved to vaccines.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other bat species.

- Additional research is needed to ~~refine, standardize, and validate~~optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) ~~to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for~~ to promote development and evaluation of MCMs, particularly if investigators intend to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data ~~between~~ from animal models ~~and~~ to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume data palm sap and workers at the human-animal interface) ~~pig farmers, hunters, abattoir workers)~~ and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.
- ~~Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.~~

Commented [KM7]: This is relatively redundant to the bullet above, so was deleted.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Commented [KM8]: In the Lassa taskforce meeting, we discussed the need for a value proposition document, which can help justify the funding plan, so that was added here. We also talk about the value proposition at the beginning of this document. There actually is a template for a value proposition for vaccines (created by a WHO group), so perhaps that document could be used as a starting point.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.

- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- ~~**Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.~~
- ~~**Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.~~
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Commented [KM9]: These two bullets were moved to vaccines.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be funded by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Critical Path Analysis

[See accompanying table.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional

pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics~~,~~ ~~identifying~~ that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A ~~biobank~~ virtual repository (with specimens being held and maintained in the countries of origin) of ~~human and animal~~ clinical samples to assess and validate diagnostic tests~~. and a process for how best to judiciously use the samples.~~ As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6~~3~~) identify who would have access to the samples; ~~and~~ (7~~4~~) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- ~~Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.~~
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), ~~can be applied in both human and animal populations,~~ and have a high degree of sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

Commented [KM10]: Moved up from further down

Commented [KM11]: Moved up and shortened.

- Improved ~~D~~diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses ~~in humans and animals~~ as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- ~~If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.~~
- ~~If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.~~

Commented [KM12]: The group decided to take out any reference to multiplex assays, given the 5 year timeframe of the roadmap, so this was deleted.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. ~~Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.~~
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- ~~A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).

Commented [SPL13]: I envision that governance of this virtual repository will be the most difficult aspect. Notably, it will require high-level approval by the Government of India. If we say that we will develop a plan for the governance structure in 2019, the earliest I can imagine approval is 2020, and even this would be quite optimistic. It will require focused attention and advocacy.

2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

Commented [SPL14]: Are we on track to do this? Do we want to give ourselves a little more time, perhaps by the first quarter of 2019?

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.

3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example, this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.

Commented [SPL15]: This seems to me to be less important, than figuring out a strategy for identifying samples with a high enough pretest probability for Nipah infection so that they are tested. The vast majority of patients with symptoms of encephalitis in the high risk areas do not have diagnostic tests of any type. If we tested all of them, Nipah would be a very low proportion, likely less than 1%. Thus, the key issue in terms of recognizing more Nipah, is figuring out whom to collect samples on and send the reference laboratory.

Priority Areas/Activities

Research

- **Create** a ~~biobank~~ virtual repository of clinical ~~human and animal~~reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- ~~**Continue to research** cross-reactivity of diagnostic tests in animal populations.~~

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- ~~**Define** use cases for diagnostic assays.~~
- **Develop and** ~~,~~ **evaluate**~~, and validate~~ point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), ~~available for use in humans and animals, and~~ can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.
- ~~**Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.~~
- ~~**Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.~~
- ~~**Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).~~

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed. ~~in humans and animals.~~

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Critical Path Analysis

[See accompanying table.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment and PEP to exposed persons.

- In ~~the~~ NiV-endemic ~~region of Bangladesh~~areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. ~~In the absence of confirmatory testing, t~~Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well ~~an~~ a therapeutic agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control ~~systems~~ –programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- ~~A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.~~
- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- ~~Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.~~
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- ~~Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.~~
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- ~~Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.~~

Commented [KM16]: Taken out because this was redundant to other statements above.

- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will impact response to therapeutic candidates and influence results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2018, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.

Commented [SPL17]: Outbreaks are chaotic and most are small. I believe that we would be better placed to evaluate therapeutics if we had rapid tests and embedded efficacy trials into our routine surveillance.

Commented [SPL18]: As above. It takes so long to recognize and respond to outbreaks that with Nipah most of them are over by the time we can respond. Instead, if this is part of surveillance for every case we diagnose, case accumulation still might be slow, but we could expect several cases per year, especially if we spread this over multiple improved surveillance sites.

3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.

Commented [SPL19]: As above.

Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Commented [SPL20]: These will need to be remarkably efficacious, in order for us to accumulate sufficient sample size to achieve this by 2023. Given the late presentation of patients, this strikes me as quite optimistic.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as ~~ribavirin and~~ m102.4 and favipiravir) for treating and preventing NiV infection, including conducting ~~animal~~ studies in animal models and clinical trials as appropriate and feasible.
- **Continue to ~~identify~~ expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- ~~**Generate** a TPP for NiV infection therapeutics.~~
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized in advance of future outbreaks, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.

Commented [SPL21]: As noted above, the should be part of routine surveillance, not something that has to be implemented during a chaotic large outbreak.

- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- ~~**Identify** a company or joint partnership to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and **secure** financing for its manufacture, and distribution, and post-marketing surveillance.~~
- **Generate** a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Critical Path Analysis

[See accompanying table.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could impact acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.

- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed in target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- ~~Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.~~
- ~~Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serological assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.

- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- ~~**Explore** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.~~
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.

Product development

- ~~**License**~~ **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans. ~~and animals.~~
- ~~**License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.~~
- ~~**Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.~~

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of ~~licensed~~ NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptation and promotion within the community.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for more rapid spread.

Critical Path Analysis for Development of Nipah Virus Diagnostics, Therapeutics, and Vaccines

The table below provides a high-level description of the primary risks and barriers to achieving the milestones identified in the research and development (R&D) roadmap for Nipah virus and also identifies other milestones that are critical dependencies, meaning that in order for the milestone in question to either be initiated or completed, another milestone should be completed first. The focus of this critical path analysis is on R&D of medical countermeasures (MCMs) and does not encompass all aspects of Nipah virus prevention and control.

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
CROSS-CUTTING ISSUES		
Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.		
1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.	• Lack of resources to create a public value proposition (e.g., funding, availability and commitment of partners with the appropriate expertise) • Lack of accurate data sources and information to support the value proposition	--
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.	• The need to identify and engage appropriate industry partners as part of the process in creating a funding plan • Challenges with identifying funders willing to support elements of the funding plan	• A completed value proposition to support and justify the funding plan (Cross cutting: SG1, MS1)
Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.		
1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.	• Lack of ability to secure funding to enhance NiV surveillance • Challenges with developing consensus on the implementation protocol because of differing clinical and laboratory capabilities across catchment areas • Limited information regarding which areas may be at high risk for NiV spillover	--

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.	• The need to educate clinicians and community health workers about NiV infection to increase their index of suspicion and improve case detection	• A completed and agreed upon surveillance plan and related protocols (Cross cutting: SG2, MS1) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.		
1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.	• Limited BSL-4 capacity • Lack of dedicated funding to create research tools • Lack of consensus on criteria for standardization and characterization	• Availability of well-characterized clinical samples (including representation of the different NiV strains) (Diagnostics: SG1, MS2)
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.	• Limited BSL-4 capacity • Regulations and restrictions applicable to animal research, including ethical considerations regarding use of NHPs • The need for agreed-upon benchmark parameters (i.e., challenge strain, route, timing, and dose)	• Availability of standardized assays and challenge strains for animal research (Cross cutting: SG3, MS1) • Availability of well-characterized clinical samples (including representation of the different NiV strains) (Diagnostics: SG1, MS2)
DIAGNOSTICIS		
Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.		
1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).	• Complexities involved with creating a virtual reference repository • The need for coordination across multiple organizations and agencies within each of the primary NiV-affected countries • The need for international and in-country leadership to drive the process	--
2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.	• Lack of funding and resources to create the in-country repositories • Lack of adequate case numbers for sample collection (in part owing to lack of surveillance capabilities) • Challenges with international regulations for transport of clinical samples and other biologic	• Completion of the plans and protocols for creating the virtual reference repository (Diagnostics: SG1, MS1)

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

	materials • Challenges in completing the steps necessary to operationalize the plans (e.g., ensuring laboratory capacity, conducting training, having MTAs in place, having the governance structure in place)	
Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient-care NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.		
1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.	--	--
2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.	• The need for a coordinated process and leadership to engage and convene the appropriate regulatory agencies and other key partners	--
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Insufficient resources and funding for R&D to produce promising diagnostics • Low engagement in diagnostic development from commercial manufacturers • Adequate supplies of clinical samples or experimentally generated samples from research animals	• Availability of well-characterized samples from patients (Diagnostics: SG1, MS2)
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Lack of clinical and laboratory capacity for conducting field studies in different geographic areas of NiV spillover • The need to ensure proper test performance under field conditions	• Successful completion of preclinical evaluation of promising diagnostic assays (Diagnostics: SG2, MS3) • Adequate laboratory capacity to conduct the field studies (Diagnostics: SG3, MS1)
Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.		
1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example,	• The need for international leadership and engagement to assist with development of the national laboratory strategies • The need to engage and obtain support from key in-country partners	--

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.	• Lack of necessary resources to enhance laboratory capacity	
THERAPEUTICS		
Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.		
1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to the operationalize protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • The need to develop consensus across different countries to generate a regional approach and promote adoption by member states • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.	--	--
Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.		
1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.	• Obtaining consensus regarding prioritization of promising candidates • Lack of an adequate pipeline of promising	--

	therapeutic agents and lack of R&D resources to strengthen the pipeline	
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of dedicated R&D funding to conduct preclinical evaluation of novel NiV therapeutic agents • Limited BSL-4 capacity • Limited understanding regarding whether or not genetic diversity of NiV strains will impact therapeutic response to new treatment options	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1)
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of in-country capacity to conduct clinical trials • Hesitancy or opposition to clinical trials being conducted in at-risk populations • Difficulty in receiving approval from in-country NRAs to conduct clinical trials • Identifying sufficient cases to support an informative evaluation, especially if there are multiple potential therapeutic candidates	• Successful completion of preclinical evaluation of promising therapeutic candidates (Therapeutics: SG2, MS2) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
VACCINES		
Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.		
1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.	• Need for regulatory engagement and guidance on whether or not clinical efficacy trials are feasible • Need for better characterization of clinical trial capacity in areas of NiV spillover • Lack of accurate information on the disease burden caused by NiV infection, which is important for assessing the likelihood of completing clinical efficacy trials	--
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from	• Challenges with identifying the appropriate regional and international partners • Challenges with developing consensus among partners	• Determination the feasibility of conducting phase 3 clinical efficacy trials in NIV-affected areas (Vaccines: SG1, MS1)

the following: in-country regulators, other regulatory agencies (such as FDA or the EMA), national and international public health agencies and organizations, and local and international researchers.		
Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.		
1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.	• Insufficient R&D funding to conduct preclinical evaluation of promising NiV vaccines • Limited BSL-4 capacity for conducting preclinical research on potential NiV vaccines	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1) • Availability of animal models that bridge to humans and can be used to demonstrate vaccine protection (Cross cutting: SG3, MS2)
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines, including in target populations.	• Hesitancy or opposition to clinical trials being conducted in at-risk populations ~~• Lack of in-country capacity to conduct clinical trials~~ • ~~Difficulty~~ Delays in receiving approval from in-country NRAs to conduct clinical trials •	• Successful completion of preclinical evaluation of 1 or more promising vaccine candidates (Vaccines: SG2, MS1)
3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.	• The challenges of engaging partners and completing steps necessary to operationalize clinical trial protocols • The need to develop consensus across different countries • Lack of surveillance capacity and systemic estimates for NiV infection to assess vaccine efficacy and impact over time	• Successful completion of early clinical trials of 1 or more promising vaccine candidates (Vaccines: SG2, MS2)

Abbreviations: BSL-4, biosafety level 4 (highest biosafety level); EMA, European Medicines Agency; FDA, US Food and Drug Administration; MCMs, medical countermeasures; MS, Milestone; MTA, material transfer agreement; NHP, nonhuman primate; NiV, Nipah virus; NRA, national regulatory authority; PEP, post-exposure prophylaxis; R&D, research and development; SG, Strategic Goal; TPP, target product profile; WHO, World Health Organization.

*These dependencies focus only on the relationships between the milestones to show how the roadmap should be implemented over time; however, there are

Commented [SPL1]: Not really an issue with CEPI support.

Commented [SPL2]: This is relevant neither for Bangladesh nor India which each have a long history of such trials.

other critical dependencies for each of the milestones, such as adequate resources and funding.		

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; some differences have been noted in the clinical features of infection with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this~~e~~ roadmap ranges from basic research to late-stage development~~, licensure, and early use~~ of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

Commented [KM1]: Issues related to MCM development for animals have been deleted, since the decision was made at the July meeting to focus on human disease. However, further research in animals is critical, so this sentence was added.

VISION

Robust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research respresents a substantial challenge, since e~~E~~conomic incentives to invest in Nipah research are not readily apparent because~~, as~~ the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low with small and sporadic outbreaks. ~~; therefore, securing funding for Nipah research represents a substantial challenge.~~ The development of a sustainable value proposition for industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition ~~would ideally~~should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate. ~~and will likely require new systematic surveillance studies in humans and susceptible animal hosts in affected areas to strengthen the evidence base.~~

Commented [KM2]: Taken out because this is too long term for creating the value proposition.

- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions, which increases~~. This raises~~ the cost of MCM development.
- To date, NiV spillovers to human communities have been identified ~~almost exclusively~~ most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- ~~Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs older than 4 weeks old), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before~~

~~livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.~~

- ~~NiV disease occurs in both humans and animals (particularly livestock). This creates two streams of research, which complicates the overall approach for moving NiV MCMs forward. For example, animal models for human disease will have different parameters than animal models for disease in animal species.~~
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research, ~~applicable to humans (and pigs and horses for research applicable to disease in animals),~~ the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. ~~However,~~ B~~b~~ecause NiV infection occurs as relatively small, focal outbreaks, the low disease incidence ~~in endemic areas~~ poses a major challenge for conducting ~~phase 3 clinical efficacy~~such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by combining clinical trial data across outbreaks over time. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not ~~applicable~~feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop amd manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures.
- Additional prospective serosurveillance data from susceptible animal species and proximate human populations in areas of predicted risk to determine the level of human spillover and to build preparedness for detection of human cases and for limiting exposure. This is particularly important in areas where public health surveillance programs are not feasible.

Commented [KM3]: Even though this bullet deals primarily with animals, I left it in, since it also deals with the human-animal interface.

- Standardized and ~~validated~~ well characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.) WHO

international standards should be used (when available) as calibrators and reported in Units/ml to harmonize assay results.

- ~~Efforts to establish the natural history of NiV infection in animals and define the animal models that are most reflective of human disease.~~
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- ~~Efforts to design clinical efficacy trials in affected areas that are ethical, interpretable, and feasible. Researchers should explore the potential for conducting clinical trials before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).~~
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and ~~facilitate effective communication with communities to~~ strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Commented [KM4]: Moved to vaccines.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other bat species.

- Additional research is needed to ~~refine, standardize, and validate~~optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) ~~to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for~~ to promote development and evaluation of MCMs, particularly if investigators intend to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data ~~between~~ from animal models ~~and~~ to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume data palm sap and workers at the human-animal interface) ~~pig farmers, hunters, abattoir workers)~~ and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.
- ~~Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.~~

Commented [KM5]: This is relatively redundant to the bullet above, so was deleted.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Commented [KM6]: In the Lassa taskforce meeting, we discussed the need for a value proposition document, which can help justify the funding plan, so that was added here. We also talk about the value proposition at the beginning of this document. There actually is a template for a value proposition for vaccines (created by a WHO group), so perhaps that document could be used as a starting point.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.

- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- ~~**Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.~~
- ~~**Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.~~

Commented [KM7]: These two bullets were moved to vaccines.

- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be funded by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Critical Path Analysis

[See accompanying table.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional

pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics~~,~~ ~~identifying~~ that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A ~~biobank~~ virtual repository (with specimens being held and maintained in the countries of origin) of ~~human and animal~~ clinical samples to assess and validate diagnostic tests.~~, and a process for how best to judiciously use the samples.~~ As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6~~3~~) identify who would have access to the samples; ~~and~~ (7~~4~~) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- ~~Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.~~
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), ~~can be applied in both human and animal populations,~~ and have a high degree of sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

Commented [KM8]: Moved up from further down

Commented [KM9]: Moved up and shortened.

- Improved ~~D~~diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses ~~in humans and animals~~ as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- ~~If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.~~
- ~~If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.~~

Commented [KM10]: The group decided to take out any reference to multiplex assays, given the 5 year timeframe of the roadmap, so this was deleted.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. ~~Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.~~
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- ~~A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).

2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.

3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example, this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.

Priority Areas/Activities

Research

- **Create** a ~~biobank~~ virtual repository of clinical ~~human and animal~~reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- ~~**Continue to research** cross-reactivity of diagnostic tests in animal populations.~~

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- ~~**Define** use cases for diagnostic assays.~~
- **Develop and ~~,~~ evaluate**~~, and validate~~ point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), ~~available for use in humans and animals, and~~ can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.
- ~~**Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.~~
- ~~**Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.~~
- ~~**Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).~~

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed. ~~in humans and animals.~~

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Critical Path Analysis

[See accompanying table.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment and PEP to exposed persons.

- In ~~the~~ NiV-endemic ~~region of Bangladesh~~areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. ~~In the absence of confirmatory testing, t~~Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well ~~an~~ a therapeutic agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control ~~systems~~ programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- ~~A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.~~
- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- ~~Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.~~
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- ~~Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.~~
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- ~~Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.~~
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will impact response to therapeutic candidates and influence results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines and evidence-based policy decisions.

Commented [KM11]: Taken out because this was redundant to other statements above.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2018, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.

3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.

Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as ~~ribavirin and~~ m102.4 and favipiravir) for treating and preventing NiV infection, including conducting ~~animal~~ studies in animal models and clinical trials as appropriate and feasible.
- **Continue to ~~identify~~ expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- ~~**Generate** a TPP for NiV infection therapeutics.~~
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized in advance of future outbreaks, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.

- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- ~~**Identify** a company or joint partnership to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and **secure** financing for its manufacture, and distribution, and post-marketing surveillance.~~
- **Generate** a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Critical Path Analysis

[See accompanying table.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could impact acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.

- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed in target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- ~~Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.~~
- ~~Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.

2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.

2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.

3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serological assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.

- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- ~~**Explore** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.~~
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.

Product development

- ~~**License**~~ **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans. ~~and animals.~~
- ~~**License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.~~
- ~~**Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.~~

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of ~~licensed~~ NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptation and promotion within the community.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for more rapid spread.

Critical Path Analysis for Development of Nipah Virus Diagnostics, Therapeutics, and Vaccines

The table below provides a high-level description of the primary risks and barriers to achieving the milestones identified in the research and development (R&D) roadmap for Nipah virus and also identifies other milestones that are critical dependencies, meaning that in order for the milestone in question to either be initiated or completed, another milestone should be completed first. The focus of this critical path analysis is on R&D of medical countermeasures (MCMs) and does not encompass all aspects of Nipah virus prevention and control.

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
CROSS-CUTTING ISSUES		
Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.		
1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.	• Lack of resources to create a public value proposition (e.g., funding, availability and commitment of partners with the appropriate expertise) • Lack of accurate data sources and information to support the value proposition	--
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.	• The need to identify and engage appropriate industry partners as part of the process in creating a funding plan • Challenges with identifying funders willing to support elements of the funding plan	• A completed value proposition to support and justify the funding plan (Cross cutting: SG1, MS1)
Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.		
1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.	• Lack of ability to secure funding to enhance NiV surveillance • Challenges with developing consensus on the implementation protocol because of differing clinical and laboratory capabilities across catchment areas • Limited information regarding which areas may be at high risk for NiV spillover	--

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.	• The need to educate clinicians and community health workers about NiV infection to increase their index of suspicion and improve case detection	• A completed and agreed upon surveillance plan and related protocols (Cross cutting: SG2, MS1) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.		
1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.	• Limited BSL-4 capacity • Lack of dedicated funding to create research tools • Lack of consensus on criteria for standardization and characterization	• Availability of well-characterized clinical samples (including representation of the different NiV strains) (Diagnostics: SG1, MS2)
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.	• Limited BSL-4 capacity • Regulations and restrictions applicable to animal research, including ethical considerations regarding use of NHPs • The need for agreed-upon benchmark parameters (i.e., challenge strain, route, timing, and dose)	• Availability of standardized assays and challenge strains for animal research (Cross cutting: SG3, MS1) • Availability of well-characterized clinical samples (including representation of the different NiV strains) (Diagnostics: SG1, MS2)
DIAGNOSTICIS		
Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.		
1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).	• Complexities involved with creating a virtual reference repository • The need for coordination across multiple organizations and agencies within each of the primary NiV-affected countries • The need for international and in-country leadership to drive the process	--
2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.	• Lack of funding and resources to create the in-country repositories • Lack of adequate case numbers for sample collection (in part owing to lack of surveillance capabilities) • Challenges with international regulations for transport of clinical samples and other biologic	• Completion of the plans and protocols for creating the virtual reference repository (Diagnostics: SG1, MS1)

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
	materials • Challenges in completing the steps necessary to operationalize the plans (e.g., ensuring laboratory capacity, conducting training, having MTAs in place, having the governance structure in place)	
Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient-care NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.		
1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.	--	--
2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.	• The need for a coordinated process and leadership to engage and convene the appropriate regulatory agencies and other key partners	--
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Insufficient resources and funding for R&D to produce promising diagnostics • Low engagement in diagnostic development from commercial manufacturers • Adequate supplies of clinical samples or experimentally generated samples from research animals	• Availability of well-characterized samples from patients (Diagnostics: SG1, MS2)
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.	• Lack of clinical and laboratory capacity for conducting field studies in different geographic areas of NiV spillover • The need to ensure proper test performance under field conditions	• Successful completion of preclinical evaluation of promising diagnostic assays (Diagnostics: SG2, MS3) • Adequate laboratory capacity to conduct the field studies (Diagnostics: SG3, MS1)
Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.		
1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example,	• The need for international leadership and engagement to assist with development of the national laboratory strategies • The need to engage and obtain support from key in-country partners	--

MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.	• Lack of necessary resources to enhance laboratory capacity	
THERAPEUTICS		
Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.		
1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to the operationalize protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.	• The challenges of engaging partners and completing steps necessary to operationalize the protocol (e.g., obtaining necessary reviews and approvals, performing training) • The need to develop consensus across different countries to generate a regional approach and promote adoption by member states • Potential issues regarding storage of candidate therapeutics and plans for deployment	• Prioritization of promising therapeutic candidates and ensuring adequate supplies necessary to conduct clinical trial research (Therapeutics: SG2, MS1)
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.	--	--
Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.		
1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.	• Obtaining consensus regarding prioritization of promising candidates • Lack of an adequate pipeline of promising	--

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES BY STRATEGIC GOAL	PRIMARY RISKS/BARRIERS	OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES*
	therapeutic agents and lack of R&D resources to strengthen the pipeline	
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of dedicated R&D funding to conduct preclinical evaluation of novel NiV therapeutic agents • Limited BSL-4 capacity • Limited understanding regarding whether or not genetic diversity of NiV strains will impact therapeutic response to new treatment options	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1)
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.	• Lack of in-country capacity to conduct clinical trials • Hesitancy or opposition to clinical trials being conducted in at-risk populations • Difficulty in receiving approval from in-country NRAs to conduct clinical trials	• Successful completion of preclinical evaluation of promising therapeutic candidates (Therapeutics: SG2, MS2) • Improved diagnostic assays to rapidly and accurately identify cases (Diagnostics: SG2, MS4) • Adequate laboratory capacity for diagnostic testing (Diagnostics: SG3, MS1)
VACCINES		
Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.		
1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.	• Need for regulatory engagement and guidance on whether or not clinical efficacy trials are feasible • Need for better characterization of clinical trial capacity in areas of NiV spillover • Lack of accurate information on the disease burden caused by NiV infection, which is important for assessing the likelihood of completing clinical efficacy trials	--
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the EMA),	• Challenges with identifying the appropriate regional and international partners • Challenges with developing consensus among partners	• Determination the feasibility of conducting phase 3 clinical efficacy trials in NIV-affected areas (Vaccines: SG1, MS1)

Critical Path Analysis of Milestones for Strategic Goals Identified in the WHO Nipah Virus R&D Roadmap		
MILESTONES BY STRATEGIC GOAL	**PRIMARY RISKS/BARRIERS**	**OTHER MILESTONES THAT ARE CRITICAL DEPENDENCIES***
national and international public health agencies and organizations, and local and international researchers.		
Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.		
1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.	• Insufficient R&D funding to conduct preclinical evaluation of promising NiV vaccines • Limited BSL-4 capacity for conducting preclinical research on potential NiV vaccines	• Availability of standardized and well-characterized clinical research tools (e.g., assays, reagents, stocks of NiV challenge strains) (Cross cutting: SG3, MS1) • Availability of animal models that bridge to humans and can be used to demonstrate vaccine protection (Cross cutting: SG3, MS2)
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines, including in target populations.	• Hesitancy or opposition to clinical trials being conducted in at-risk populations • Lack of in-country capacity to conduct clinical trials • Difficulty in receiving approval from in-country NRAs to conduct clinical trials	• Successful completion of preclinical evaluation of 1 or more promising vaccine candidates (Vaccines: SG2, MS1)
3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.	• The challenges of engaging partners and completing steps necessary to operationalize clinical trial protocols • The need to develop consensus across different countries • Lack of surveillance capacity and systemic estimates for NiV infection to assess vaccine efficacy and impact over time	• Successful completion of early clinical trials of 1 or more promising vaccine candidates (Vaccines: SG2, MS2)
Abbreviations: BSL-4, biosafety level 4 (highest biosafety level); EMA, European Medicines Agency; FDA, US Food and Drug Administration; MCMs, medical countermeasures; MS, Milestone; MTA, material transfer agreement; NHP, nonhuman primate; NiV, Nipah virus; NRA, national regulatory authority; PEP, post-exposure prophylaxis; R&D, research and development; SG, Strategic Goal; TPP, target product profile; WHO, World Health Organization. *These dependencies focus only on the relationships between the milestones to show how the roadmap should be implemented over time; however, there are other critical dependencies for each of the milestones, such as adequate resources and funding.

Dear Kris,

Please see the comments in the attached file. My comments in Nipah roadmap document are combined with Emily's one. For Nipah CPA table I included my comment with Steve's one.

Regards,
Shahana

Dear Kris:

Attached are my comments. I apologize that these are not combined with Emily's. I started working on this a couple of days ago, but only completed it after Emily's comments.

Steve

Kris Moore

Wednesday, August 08, 2018 5:54 AM

Dear Nipah WHO R&D roadmap taskforce members:

Attached please find the following:

- A revised version of the Nipah WHO R&D roadmap, with track changes so you can see the edits that were made on the documents in response to discussions that took place at the July meeting in London. We DID NOT use track changes on the strategic goals and milestones, since these were substantially changed; the goals and milestones are highlighted in gray and we would like you to pay particular attention to those.
- A revised Critical Path Analysis (CPA) table that incorporates the new goals and

> milestones and also looks at critical dependencies among milestones, rather than looking at possible mitigation steps. Please be aware that this version is still in draft and the final version may not use this format.

To those of you who were able to attend the meeting in person, we're very grateful for you time and input—the meeting was extremely valuable. To those of you who could not be there, we're still very interested in your edits and written comments on this next version.

We would very much appreciate your review of the roadmap and the current version of the CPA table. Please send us any edits or comments that you have by **AUGUST 17, 2018.** If we don't hear from you by then, we'll assume that the current drafts are acceptable to you.

Once again, thank you so much for your ongoing involvement and participation in this important process. It's a pleasure to work with all of you.

Warm regards,

Kris

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; some differences have been noted in the clinical features of infection with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this~~e~~ roadmap ranges from basic research to late-stage development~~, licensure, and early use~~ of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

Commented [EG1]: I would argue that enhanced surveillance systems are also crucial to the goals of development of MCM. Without active and effective surveillance, we do not have a platform with which to develop and test these new technologies. In addition, expanded surveillance could have an impact on the business case for these technologies. I think it's important to have this argument clearly articulated in the roadmap.

Commented [KM2]: Issues related to MCM development for animals have been deleted, since the decision was made at the July meeting to focus on human disease. However, further research in animals is critical, so this sentence was added.

VISION

Robust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research re~~s~~presents a substantial challenge, since e~~E~~conomic incentives to invest in Nipah research are not readily apparent because~~, as~~ the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence ~~is~~ has, so far, been low with small and sporadic outbreaks. ~~; therefore, securing funding for Nipah research represents a substantial challenge.~~ The development of a sustainable value proposition for industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition ~~would ideally~~should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate. ~~and will likely require new systematic surveillance studies in humans and susceptible animal hosts in affected areas to strengthen the evidence base.~~

Commented [KM3]: Taken out because this is too long term for creating the value proposition.

- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions, which increases~~. This raises~~ the cost of MCM development.
- To date, NiV spillovers to human communities have been identified ~~almost exclusively~~ most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- ~~Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs older than 4 weeks old), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before~~

~~livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.~~

- ~~NiV disease occurs in both humans and animals (particularly livestock). This creates two streams of research, which complicates the overall approach for moving NiV MCMs forward. For example, animal models for human disease will have different parameters than animal models for disease in animal species.~~
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research, ~~applicable to humans (and pigs and horses for research applicable to disease in animals),~~ the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. ~~However,~~ B~~b~~ecause NiV infection occurs as relatively small, focal outbreaks, the low disease incidence ~~in endemic areas~~ poses a major challenge for conducting ~~phase 3 clinical efficacy~~such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by combining clinical trial data across outbreaks over time. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not ~~applicable~~feasible.

Commented [EG4]: And, possibly by expanding surveillance areas.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop amd manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures.
- Additional prospective serosurveillance data from susceptible animal species and proximate human populations in areas of predicted risk to determine the level of human spillover and to build preparedness for detection of human cases and for limiting exposure. This is particularly important in areas where public health surveillance programs are not feasible.

Commented [KM5]: Even though this bullet deals primarily with animals, I left it in, since it also deals with the human-animal interface.

- Standardized and ~~validated~~ well characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.) WHO

international standards should be used (when available) as calibrators and reported in Units/ml to harmonize assay results.

- ~~Efforts to establish the natural history of NiV infection in animals and define the animal models that are most reflective of human disease.~~
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- ~~Efforts to design clinical efficacy trials in affected areas that are ethical, interpretable, and feasible. Researchers should explore the potential for conducting clinical trials before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).~~
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and ~~facilitate effective communication with communities to~~ strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Commented [KM6]: Moved to vaccines.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other bat species.

- Additional research is needed to ~~refine, standardize, and validate~~optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) ~~to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for~~ to promote development and evaluation of MCMs, particularly if investigators intend to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data ~~between~~ from animal models ~~and~~ to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume data palm sap and workers at the human-animal interface) ~~pig farmers, hunters, abattoir workers)~~ and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.
- ~~Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.~~

Commented [KM7]: This is relatively redundant to the bullet above, so was deleted.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Commented [KM8]: In the Lassa taskforce meeting, we discussed the need for a value proposition document, which can help justify the funding plan, so that was added here. We also talk about the value proposition at the beginning of this document. There actually is a template for a value proposition for vaccines (created by a WHO group), so perhaps that document could be used as a starting point.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.

- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- ~~**Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.~~
- ~~**Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.~~
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Commented [KM9]: These two bullets were moved to vaccines.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be funded by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Critical Path Analysis

[See accompanying table.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional

pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics~~,~~ ~~identifying~~ that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A ~~biobank~~ virtual repository (with specimens being held and maintained in the countries of origin) of ~~human and animal~~ clinical samples to assess and validate diagnostic tests. ~~and a process for how best to judiciously use the samples.~~ As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6~~3~~) identify who would have access to the samples; ~~and~~ (7~~4~~) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- ~~Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.~~
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), ~~can be applied in both human and animal populations,~~ and have a high degree of sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

Commented [KM10]: Moved up from further down

Commented [KM11]: Moved up and shortened.

- Improved ~~D~~diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses ~~in humans and animals~~ as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- ~~If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.~~
- ~~If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.~~

Commented [KM12]: The group decided to take out any reference to multiplex assays, given the 5 year timeframe of the roadmap, so this was deleted.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. ~~Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.~~
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- ~~A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).

2. By 2020, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2018, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.
2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks. For example, this may include strategies for development of mobile laboratories that can be deployed when outbreaks occur.

Priority Areas/Activities

Research

- **Create** a ~~biobank~~ virtual repository of clinical ~~human and animal~~reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- ~~**Continue to research** cross-reactivity of diagnostic tests in animal populations.~~

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- ~~**Define** use cases for diagnostic assays.~~
- **Develop** **and** ~~,~~ **evaluate**~~, and validate~~ point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), ~~available for use in humans and animals, and~~ can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.
- ~~**Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.~~
- ~~**Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.~~
- ~~**Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).~~

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed. ~~in humans and animals.~~

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Critical Path Analysis

[See accompanying table.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment and PEP to exposed persons.

- In ~~the~~ NiV-endemic ~~region of Bangladesh~~areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. ~~In the absence of confirmatory testing, t~~Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well ~~an~~ a therapeutic agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control ~~systems~~ –programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- ~~A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.~~
- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- ~~Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.~~
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- ~~Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.~~
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- ~~Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.~~
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will impact response to therapeutic candidates and influence results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines and evidence-based policy decisions.

Commented [KM13]: Taken out because this was redundant to other statements above.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2018, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas during future outbreaks and develop plans for operationalizing the protocol.

3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented during future NiV outbreaks and develop plans for operationalizing the protocol.
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.

Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as ~~ribavirin and~~ m102.4 and favipiravir) for treating and preventing NiV infection, including conducting ~~animal~~ studies in animal models and clinical trials as appropriate and feasible.
- **Continue to** ~~**identify**~~ **expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- ~~**Generate** a TPP for NiV infection therapeutics.~~
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized in advance of future outbreaks, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.

- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- ~~**Identify** a company or joint partnership to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and **secure** financing for its manufacture, and distribution, and post-marketing surveillance.~~
- **Generate** a reliable source of m102.4 to be used in clinical trials during future NiV outbreaks.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Critical Path Analysis

[See accompanying table.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could impact acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.

- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed in target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- ~~Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.~~
- ~~Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.~~

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.

2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.

2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.

3. By 2023, complete the following if phase 3 trials are considered feasible (per the first Strategic Goal): (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serological assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.

- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- ~~**Explore** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.~~
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.

Product development

- ~~**License**~~ **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans. ~~and animals.~~
- ~~**License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.~~
- ~~**Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.~~

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of ~~licensed~~ NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptation and promotion within the community.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for more rapid spread.

Subject: Revised Nipah R&D Roadmap and CPA table for taskforce member review

Dear Nipah WHO R&D roadmap taskforce members:

Attached please find the following:

- A revised version of the Nipah WHO R&D roadmap, with track changes so you can see the edits that were made on the documents in response to discussions that took place at the July meeting in London. We DID NOT use track changes on the strategic goals and milestones, since these were substantially changed; the goals and milestones are highlighted in gray and we would like you to pay particular attention to those.
- A revised Critical Path Analysis (CPA) table that incorporates the new goals and milestones and also looks at critical dependencies among milestones, rather than looking at possible mitigation steps. Please be aware that this version is still in draft and the final version may not use this format.

To those of you who were able to attend the meeting in person, we're very grateful for you time and input—the meeting was extremely valuable. To those of you who could not be there, we're still very interested in your edits and written comments on this next version.

We would very much appreciate your review of the roadmap and the current version of the

CPA table. Please send us any edits or comments that you have by **AUGUST 17, 2018.** If we don't hear from you by then, we'll assume that the current drafts are acceptable to you.

Once again, thank you so much for your ongoing involvement and participation in this important process. It's a pleasure to work with all of you.

Warm regards,

Kris

Nipah WHO R&D Roadmap Taskforce Meeting

July 9 and 10, 2018

DAY 1	
8:00 am	**REGISTRATION**
	Session 1: Welcome, Introductions, and Overview
8:30 am	Welcome *(Marie-Pierre Preziosi [WHO] and Charlie Weller [Wellcome])*
8:35 am	Introductions *(Michael Osterholm [CIDRAP])*
8:40 am	Overview and meeting objectives *(Kris Moore [CIDRAP])*
	Session 2: Nipah Cross-Cutting Issues
8:50 am	Comments on current roadmap draft: cross-cutting issues
9:05 am	Milestones for cross-cutting issues
9:35 am	Critical path analysis for cross-cutting issues
10:15 am	**BREAK**
10:30 am	Critical path analysis for cross-cutting issues (cont.)
	Session 3: Nipah Diagnostics
11:20 am	Comments on current roadmap draft: diagnostics
11:30 am	**LUNCH**
12:15 pm	Milestones for diagnostics
12:45 pm	Critical path analysis for diagnostics
2:15 pm	**BREAK**
	Session 3: Nipah Therapeutics
2:30 pm	Comments on current roadmap draft: therapeutics
2:45 pm	Milestones for therapeutics
3:15 pm	Critical path analysis for therapeutics
	Session 4: Nipah Vaccines
4:45 pm	Comments on current roadmap draft: vaccines
5:00 pm	Milestones for vaccines
5:30 pm	**ADJOURN DAY 1**
6:00 pm	**DINNER**
DAY 2	
8:00 am	Welcome: Day 2 *(Michael Osterholm [CIDRAP])*
8:05 am	Critical path analysis for vaccines
9:35 am	**BREAK**
	Session 5: Roadmap Implementation and Next Steps
9:50 am	Discussion: Roadmap implementation *(Louisa Tribe [Wellcome]*)
11:50 am	Discussion: Publication process *(Marie-Pierre Preziosi [WHO])*
12:20 pm	Wrap up and next steps *(Michael Osterholm [CIDRAP])*
12:30 pm	**ADJOURN DAY 2**
12:30 pm	**LUNCH**

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, ~~and~~ acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since~~, with~~. NiV infection ~~disease~~ has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India.~~; c~~Case fatality rates during outbreaks in ~~these~~ Bangladesh and India ~~countries~~ have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; some differences have been noted in the clinical features of infection with different strains ~~these strains provoke distinct but overlapping clinical features~~ in ~~both~~ humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.)

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and ~~,~~ accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ~~TOPICS AND~~ ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low with small and sporadic outbreaks; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition would ideally be informed by a robust assessment of the risk of future outbreaks (with risk mapping and identification of hotspots), and will likely require new systematic surveillance studies in humans and susceptible animal hosts in affected areas to strengthen the evidence base.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway~~s for MCMs~~, can be prohibitively expensive for product developers in the absence of a predictable demand. ~~For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore~~In addition, licensure of vaccines and therapeutics using alternative regulatory pathways ~~also~~ can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. This raises the cost of MCM development.
- To date, NiV spillovers to human communities have ~~occurred~~ been identified almost exclusively in rural communities in Bangladesh and ~~East~~ India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs older than 4 weeks old), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- NiV disease occurs in both humans and animals (particularly livestock). This creates two streams of research, which complicates the overall approach for moving NiV MCMs forward. For example, animal models for human disease will have different parameters than animal models for disease in animal species.

- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans (and pigs and horses for research applicable to disease in animals), the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions. ~~Conducting phase 1 and phase 2 clinical trials is potentially feasible in endemic regions.~~ However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence in endemic areas poses a major challenge for conducting phase 3 clinical efficacy trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by combining clinical trial data across outbreaks over time. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways ~~and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time)~~ may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop amd manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Additional prospective serosurveillance data from susceptible animal species and proximate human populations in areas of predicted risk to determine the level of human spillover and to build preparedness for detection of human cases and for limiting exposure. This is particularly important in areas where public health surveillance programs are not feasible ~~or justifiable~~.
- Standardized and validated assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.) WHO international standards should be used (when available) as calibrators and reported in Units/ml to harmonize assay results.
- Efforts to establish the natural history of NiV infection in animals and define the animal models that are most reflective of human disease.
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.

- ~~A determination regarding the feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection which is needed~~ Efforts to design clinical efficacy trials in affected areas that are ethical, interpretable, and feasible. Researchers should explore the potential for conducting clinical trials before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities ~~may~~ will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools ~~to improve NiV awareness and training, and to ensure availability of diagnostic tools~~ in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data ~~under the authority of local leadership~~.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and facilitate effective communication with communities to strengthen disease prevention and preparedness activities. ~~facilitate effective communication with communities regarding disease prevention~~ Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes~~manufacture~~, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other bat species.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize

the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage ~~at-risk~~ populations at high risk of exposure (such as pig farmers, hunters, abattoir workers) and ~~(including~~ vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.
- Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. ~~Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.”~~ Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

2. Undertake surveillance activities (including research studies) to estimate the relative risk and global spread of NiV outbreaks and public value of MCM development.

3. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.

4. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.

5. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

Milestones

1. By 20XX, create a living biobank of human and animal reference samples for development of NiV MCMs.

2. By 20XX, generate standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.

3. By 20XX, standardize animal models for use in preclinical studies of NiV MCMs and for bridging data between animals and humans.

4. By 20XX, complete a multi-center epidemiologic or enhanced surveillance study in areas of known or potential NiV spillover to better characterize NiV epidemiology in humans and animals, including improved understanding of reservoir species.

5. By 20XX, convene an expert working group to assess feasibility of conducting clinical trials of NiV therapeutics and vaccines and to determine the most appropriate regulatory pathways for licensure.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate (i.e., determine that an animal model resembles disease and therapeutic response in humans), and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- ~~**Determine** the feasibility of conducting phase 3 clinical trials or identify~~ **Explore** possible strategies for conducting clinical efficacy trials in affected areas that are ethical, interpretable,

and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.

- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an “affordable

and fair" price is one that can reasonably be funded by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)

- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Critical Path Analysis

[See accompanying table.]

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and institution of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- A TPP for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobank of human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.

2. Develop and assess affordable, highly sensitive and specific, point-of-care NiV diagnostic tests for use in humans and animals that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.

3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Milestones

1. By 20XX, delineate use cases for NiV diagnostic assays.

2. By 20XX, generate a TPP for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.

3. By 20XX, advance at least 2 promising NiV point-of-care or near-patient-care diagnostic tests through field studies.

4. By 20XX, obtain regulatory clearance/market authorization by a relevant regulatory agency or NRA for at least 1 validated NiV point-of-care or near-patient-care diagnostic assay that is aligned with the TPP.

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Critical Path Analysis

[See accompanying table.]

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided ~~as a compassionate use~~under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-~~4734~~ 5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.

2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Milestones

1. By 20XX, generate a TPP for NiV therapeutics identifying optimal and desirable characteristics.

2. By 20XX, conduct clinical trials on m102.4 for safety, tolerability, and efficacy.

3. By 20XX, identify a company or joint partnerships to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and secure financing for its manufacture, distribution, and post-marketing surveillance.

4. By 20XX, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least 2 new therapies for treatment of NiV infection.

5. By 20XX, complete phase 1 and 2 clinical trials for at least 1 additional promising therapeutic agent for treatment of NiV infection.

6. By 20XX, complete phase 3 clinical trials for at least 1 additional promising therapeutic agent that is aligned with the TPP.

7. By 20XX, obtain regulatory approval for a new NiV therapeutic agent that is aligned with the TPP for treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ~~ribavirin and~~ m102.4 and possibly ribavirin) for treating and preventing NiV infection, including conduct of animal studies and clinical trials as appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company or joint partnerships to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and **secure** financing for its manufacture, ~~and~~ distribution, and post-marketing surveillance.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Critical Path Analysis

[See accompanying table.]

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human and ~~,~~veterinary ~~,~~clinical and public health systems, which could impact acceptance of NiV vaccines for use in humans or animals.
- Currently, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generation of new NiV vaccines.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains in humans and animals, and (3) ~~that~~ provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines (or broader henipavirus vaccines) to include vaccination strategies, potentially in both humans (including special populations such as children, immunocompromised individuals, and pregnant women) and animals, for different epidemiologic scenarios and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- ~~While neutralizing antibodies are likely a primary mediator of protection against NiV infection cellular immunity appears to also play a role.~~ Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since ~~While~~ neutralizing antibodies are likely the~~a~~ primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development. ~~cellular immunity appears to also play a role.~~
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection in humans and animals and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.
- Pre-licensure ~~E~~evaluation of vaccine safety ~~in target populations~~ is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed in target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations.
- ~~If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas. (Satterfield 201 6 – status of vaccine R&D [combining NV w/ another vaccine to increase likelihood of financing])~~
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5~~4~~) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into

developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.

- Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, ~~and~~ prequalify, deploy, and ensure access to NiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).

2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).

3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Milestones

1. By 20XX, identify and standardize correlates and/or surrogates of protection to facilitate NiV vaccine research.

2. By 20XX, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least 1 new NiV vaccine candidate.

3. By 20XX, complete phase 1 and phase 2 clinical trials for at least 1 of the most promising NiV vaccines.

4. By 20XX, complete phase 3 clinical trials for at least 1 of the most promising candidate NiV vaccines.

5. By 20XX, obtain regulatory approval for least 1 vaccine for NiV via phase 3 clinical trials or an alternative regulatory pathway.

Priority Areas/Activities

Research

- **Improve understanding** of the ~~**Determine** the innate, cell-mediated, and~~ humoral immune response~~s~~ to infection to inform development and evaluation of~~that contribute to protective immunity against NiV infection for use in developing and evaluating~~ NiV vaccines.~~.~~
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serological assays for vaccine potency analyses.

- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- **Explore** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **License** safe and effective monovalent NiV vaccines for humans and animals.
- **License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptation and promotion within the community.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Critical Path Analysis

The table below provides a high-level description of the *primary* (or most critical) risks/barriers to achieving the milestones identified in the R&D roadmap for Nipah virus, along with their associated *potential* mitigations that may allow achievement of the milestones by the target deadlines. The focus of this critical path analysis is on R&D of MCMs and it does not encompass all aspects of Nipah virus prevention and control. For cross-referencing, milestones may be related to one another and the corresponding risks/barriers and mitigations may be the same as, similar to, or related to those for other milestones.

Critical Path Analysis of Milestones Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES	**PRIMARY RISKS/BARRIERS** - Severity Level (S1-3)[1] - Likelihood Level (L1-3)[2]	**POTENTIAL MITIGATION STEPS**	**CRITICAL IMPLEMENTATION PARTNERS**
CROSS-CUTTING ISSUES			
1. By 20XX, create a living biobank of human and animal reference samples for development of NiV MCMs.	• Lack of dedicated funding (S3, L3)	• Prioritize funding for development of a biobank of NiV reference samples.	
	• Lack of policies for sample collection, storing, and use (S2, L3)	• Facilitate collaborative development of plans for and creation of a biobank, including policies for ongoing sample collection, storage, and use.	
	• Lack of adequate case numbers for sample collection (S2, L3)	• Improve surveillance capabilities (including the ability to transport samples) in areas of NiV spillover to promote case detection. • Ensure that plans are in place to collect samples over multiple years.	
	• Challenges with international regulations for transport of clinical samples and other biologic materials (S2, L3)	• Review and harmonize all applicable international regulations for transport of biological materials. • Develop a process for expediting MTA development to promote transfer of materials.	
2. By 20XX, generate standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate	• Lack of dedicated funding (S3, L2)	• Prioritize funding to produce critical research materials.	
	• Limited BSL-4 capacity to produce critical research materials (S3,L2)	• Ensure availability of BSL-4 facilities for production of critical research materials.	

Critical Path Analysis of Milestones Identified in the WHO Nipah Virus R&D Roadmap			
MILESTONES	**PRIMARY RISKS/BARRIERS** - Severity Level (S1-3)[1] - Likelihood Level (L1-3)[2]	**POTENTIAL MITIGATION STEPS**	**CRITICAL IMPLEMENTATION PARTNERS**
R&D of NiV MCMs, using WHO international standards, when available, as calibrators.	• Lack of clinical samples (including representation of the different NiV strains (S3, L3)	• Create a biobank of reference samples from different areas of NiV spillover. (See Cross-Cutting Issues: Milestone 1.)	
	• Lack of consensus on criteria for standardization and validation (S3, L2)	• Convene an expert working group to create a consensus document on standardization and validation criteria for critical research materials.	
3. By 20XX, standardize animal models for use in preclinical studies of NiV MCMs and for bridging data between animals and humans.	• Lack of dedicated funding, particularly for high-cost NHP studies (S3, L3)	• Prioritize funding for NiV animal studies.	
	• Limited capacity of BSL-4 facilities for animal studies of NiV infection (S3, L2)	• Ensure availability of BSL-4 facilities for animal studies of NiV infection.	
	• Regulations and restrictions applicable to animal research, including ethical considerations regarding use of NHPs (S2, L3)	• Request that the R&D Blueprint SAG consider the establishment of a workgroup or process to address this issue.	
	• Lack of standardized assays for animal study research (S3, L3)	• Prioritize funding to develop standardized immunologic assays for use in animal models. (See Cross-Cutting Issues: Milestone 2.)	
	• Lack of benchmark parameters (i.e., challenge strain, route, timing, and dose) (S3, L3)	• Convene an expert working group to establish benchmark parameters for animal studies of NiV infection.	
4. By 20XX, complete a multi-center epidemiologic or enhanced surveillance study in areas of known or potential NiV spillover to better characterize NiV epidemiology in humans and animals, including improved understanding of reservoir	• Limited availability of funding in endemic and at-risk areas for epidemiologic research and surveillance (S2, L3)	• Target funding for a multi-center epidemiologic study or enhancements of existing surveillance systems.	
	• Limited capacity to conduct a coordinated research study on NiV epidemiology in humans and animals (S2, L3)	• Conduct a capacity assessment in potential study sites. • Provide necessary training and resources to ensure capacity in study/surveillance sites.	

Critical Path Analysis of Milestones Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES	**PRIMARY RISKS/BARRIERS** - Severity Level (S1-3)[1] - Likelihood Level (L1-3)[2]	**POTENTIAL MITIGATION STEPS**	**CRITICAL IMPLEMENTATION PARTNERS**
species.	• Lack of standardized and validated NiV diagnostic assays available for field use in various conditions (S3, L3)	• Prioritize development of standardized and validated diagnostic assays. (See Cross-Cutting Issues: Milestone 2.)	
5. By 20XX, convene an expert working group to explore options for designing clinical efficacy trials for NiV MCMs, (2) determine feasibility of conducting such clinical efficacy trials, and (3) identify the most appropriate regulatory pathways for licensure.	• Need for regulatory involvement and guidance (S2, L2)	• Ensure involvement of regulators in the working group.	
	• Need for better characterization of clinical trial capacity in areas of NiV spillover (S2, L2)	• Conduct a capacity assessment in potential study sites to determine ability to conduct clinical trials.	
DIAGNOSTICS			
1. By 20XX, delineate use cases for NiV diagnostic assays.	• Lack of a process to determine use cases (S2, L2)	• Identify partners and convene an expert working group to define use cases (including testing of at-risk animals and testing in animal reservoirs). • Use cases should clarify the viral targets for diagnostic assays (e.g., NiV only, NiV and HeV, other henipaviruses).	
2. By 20XX, generate a TPP for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.	• Lack of resources for TPP development (e.g., oversight from WHO, subject-matter expertise, and broad stakeholder input) (S3, L1)	• Identify leadership and partners, establish the process, and prioritize development of a TPP for NiV diagnostics.	
3. By 20XX, advance at least 2 promising NiV point-of-care or near-patient-care diagnostic tests through field studies. [4]	• Lack of clinical and laboratory capacity for conducting field studies in different geographic areas of NiV spillover (S2, L3) • The need to ensure proper test performance under field conditions (S2, L3)	• Provide necessary training and resources to ensure clinical and laboratory capacity for conducting field studies and monitoring test performance.	

Critical Path Analysis of Milestones Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES	**PRIMARY RISKS/BARRIERS** - Severity Level (S1-3)[1] - Likelihood Level (L1-3)[2]	**POTENTIAL MITIGATION STEPS**	**CRITICAL IMPLEMENTATION PARTNERS**
	• Insufficient resources for R&D funding to produce promising diagnostics (S3, L3)	• Incentivize and provide funding streams for supporting R&D of diagnostics (including diagnostic testing in at-risk animals). • Consider development of public-private partnerships to foster diagnostic development. • Consider development of multiplexed tests for detection of multiple pathogens, which may have broader commercial appeal (particularly for testing in livestock).	
4. By 20XX, obtain regulatory clearance/market authorization by a relevant regulatory agency or NRA for at least 1 validated NiV point-of-care or near-patient-care diagnostic assay that is aligned with the TPP. [4]	• Lack of clear guidance from regulatory authorities regarding information needed for regulatory clearance/market authorization (S3, L3)	• Ensure regulatory involvement, including appropriate in-country NRAs, to obtain advance guidance on regulatory requirements.	
	• Insufficient regulatory capacity in countries with NiV spillover (S2, L2)	• Strengthen national regulatory capacity in countries with NiV spillover. • Through WHO-led initiatives, encourage collaboration between national and external regulatory agencies.	
	• The cost to developers of preparing regulatory dossiers (S3, L3)	• Incentivize and provide funding streams to support preparation and submission of regulatory dossiers. • Streamline the regulatory approval process as much as possible.	
THERAPEUTICS			
1. By 20XX, generate a TPP for NiV therapeutics identifying optimal and desirable characteristics.	• Lack of resources for TPP development (e.g., oversight from WHO, subject-matter expertise, and broad stakeholder input) (S3, L1)	• Identify leadership and partners, establish the process, and prioritize development of a TPP for Lassa fever therapeutics.	

Critical Path Analysis of Milestones Identified in the WHO Nipah Virus R&D Roadmap

MILESTONES	**PRIMARY RISKS/BARRIERS** - Severity Level (S1-3)[1] - Likelihood Level (L1-3)[2]	**POTENTIAL MITIGATION STEPS**	**CRITICAL IMPLEMENTATION PARTNERS**
2. By 20XX, conduct clinical trials on m102.4 for safety, tolerability, and efficacy.	• Lack of funding to conduct clinical trials for m102.4 (S3, L3)	• Develop a funding stream for m102.4 clinical trials.	
	• Hesitancy or opposition to clinical trials being conducted in at-risk populations (S2, L3)	• Conduct social science research with at-risk populations to elucidate appropriate social outreach regarding participation in clinical trials. • Work with social science experts and local partners to gain trust in at-risk communities, particularly regarding sensitive sociocultural issues surrounding clinical trials. • Develop locally appropriate consent procedures and ethical review.	
3. By 20XX, identify a company or joint partnerships to advance therapeutic use of m102.4 (including conduct of additional collaborative research) and secure financing for its manufacture, distribution, and post-marketing surveillance.	• Lack of business interest in producing m102.4 (S3, L3)	• Explore incentives for funding m102.4 production or create a sustainable value proposition, possibly through public-private partnerships.	
4. By 20XX, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least 2 new therapies for treatment of NiV infection.	• Lack of dedicated R&D funding to conduct preclinical evaluation of novel NiV therapeutic agents (S3, L3)	• Prioritize R&D funding to promote preclinical evaluation of novel NiV therapeutics. • Consider development of public-private partnerships to foster R&D of novel NiV therapeutics.	
	• Limited capacity of BSL-4 facilities for conducting preclinical research on potential	• Ensure availability of BSL-4 facilities for conducting preclinical research on NiV

5. By 20XX, obtain regulatory approval for least 1 vaccine for NiV via phase 3 clinical trials or an alternative regulatory pathway. [4]	• The cost to developers of preparing regulatory dossiers (S2, L2)	• Incentivize developers and provide funding streams to support preparation, submission, and management of regulatory dossiers. • Streamline the regulatory approval process as much as possible.	
	• Lack of surveillance capacity and systemic estimates for NiV infection to assess vaccine efficacy and impact over time (S2, L2)	• Target funding to enhance surveillance capacity in areas of known NiV spillover.	

Abbreviations: BSL-4, biosafety level 4 (highest biosafety level); HeV, Hendra virus; MCMs, medical countermeasures; MTA, material transfer agreement; NHP, nonhuman primates; NiV, Nipah virus; NRA, national regulatory authority; R&D, research and development; SAG, scientific advisory group; NRA, national regulatory authority; TPP, target product profile; WHO, World Health Organization.

[1] The scale for seriousness ranges from least serious consequence (S1) to most serious consequence (S3).
[2] The scale for likelihood ranges from least likely to occur (L1) to most likely to occur (L3).
[3] In this table, the term “capacity” refers to infrastructure (including physical facilities and equipment as well as systems and processes), workforce, and/or capability.
[4] These milestones assume that selected MCMs demonstrate adequate performance characteristics to be advanced toward licensure and use. An additional risk to note is that MCMs may not demonstrate adequate performance in field studies or in preclinical or clinical trials; if that occurs, then additional R&D would be needed to develop and advance alternative MCMs and the cycle of milestones would need to be repeated.

Subject:	Revised Nipah R&D Roadmap and Critical Path Analysis table for your review
Date:	Wednesday, June 27, 2018 2:08:33 PM
Attachments:	Agenda.Nipah R&D TF Meeting.final.062618.docx Nipah Roadmap.with edits from public comment.062618.docx Nipah.CPA table.for taskforce review. June 27.docx
Importance:	High

Dear Nipah taskforce members,

We have revised the Nipah R&D draft roadmap based on comments received during the public comment period; I have attached it here for your review. The new edits are in track changes, so you can see them easily. You will also note that we have included a set of milestones for implementation under each main topic area (these are not in track changes). The milestones don't yet have dates attached to them—we need your input for that.

I have also attached a draft of the Critical Path Analysis (CPA) table that builds on the milestones.

We have structured the upcoming taskforce meeting to be relatively informal. Our primary goal is to walk through the roadmap and the CPA table in detail over the course of our time together. We very much need your input on these documents before we can move them forward.

These materials will form the basis of all of our discussions during the meeting, so please review them carefully before you come to London. I have attached a draft agenda as well, so you can see how the time will flow.

If you can't attend the meeting, we would still very much appreciate your review and hope that you can find time to send us some written comments.

Again, thank you so much for your time on this important project and I look forward to seeing you again in London!

Warm regards,

Mike

---

Dear All,

Thank you very much for your time on the call today. A special thanks to our chair, Dr Ed Cox, and to our country colleagues for their valuable updates.

As agreed, we are inviting you all for a second teleconference tomorrow, Friday 25 May 2018, at the same time (14:00-15:00 CET).
The call will be 60 min long and will mainly focus on the development of a PEP protocol. Dial in details below:

Please join my meeting from your computer, tablet or smartphone.
website).

Many thanks and looking forward to our discussion tomorrow,
Virginia Benassi

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also identified periodically in eastern India; case fatality rates during outbreaks in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India; these strains provoke distinct but overlapping clinical features in both humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing zoonotic NiV transmission, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition would ideally be informed by a robust assessment of the risk of future outbreaks, and will likely require new systematic surveillance studies in humans and susceptible animal hosts in affected areas to strengthen the evidence base.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers in the absence of a predictable demand. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. This raises the cost of MCM development.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 and phase 2 clinical trials is potentially feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Additional prospective serosurveillance data from susceptible animal species and proximate human populations in areas of predicted risk to determine the level of human spillover and to build preparedness for detection of human cases and for limiting exposure. This is particularly important in areas where public health surveillance programs are not feasible or justifiable.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- A determination regarding the feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians to improve NiV awareness and training, and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data under the authority of local leadership.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of Pteropus bats and potentially other bat species.

- Additional research is needed to refine, standardize, and validate relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole genome sequencing of NiV viruses are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials, (2) assess MCM acceptability in at-risk populations, (3) determine culturally appropriate messaging to enhance MCM acceptance, and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.

2. Undertake surveillance activities (including research studies) to estimate the relative risk and global spread of NiV outbreaks and public value of MCM development
3. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.
4. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.
5. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability henipaviruses in order to improve understanding of their global distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and institution of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and etiologic diagnosis is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate which henipaviruses are in circulation using serologic assays. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- A TPP for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobank of human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly

specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.

- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- If NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals (such as the Differentiating Infected from Vaccinated Animals (DIVA) test) will be needed.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiV diagnostic tests for use in humans and animals that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.
4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.

- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.

- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection may be warranted.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against a strain from Bangladesh/India to be shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.

- Additional studies, as needed, of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies and clinical trials as appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccines for use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against different NiV strains in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines (or broader henipavirus vaccines) to include vaccination strategies, potentially in both humans (including special populations such as children, immunocompromised individuals, and pregnant women) and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.

- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac® HeV from Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection in humans and animals and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), and (4) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses and available evidence suggests this vaccine is cross-protective against NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deploy NiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluating NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- **Explore** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **License** safe and effective monovalent NiV vaccines for humans and animals.
- **License** safe and effective multivalent vaccines for use in humans that protect against more than one disease for use in human populations (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a sustainable approach.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

NIPAH Baseline Situation Analysis

M. Denis, consultant

Draft, Jan 27 2018

Contents

List of abbreviations

AAV	Adeno-associated virus
AGM	African green monkey
CNS	central nervous system
ELISA	enzyme-linked immunosorbent serologic assay
HeV	Hendra virus
IFN	interferon
NK	Natural Killer
NiV	Nipah virus
NP	Nucleoprotein
NHP	Non-human primates
Poly-IC	Polyinosinic:polycytidylic acid
R&D	research and development
RT-PCR	real-time polymerase chain reaction
VEE	Equine Venezuelan Encephalitis
VLP	Virus-like particle
VSV	Vesicular Stomatitis Virus

Introduction

Epidemiology overview

Nipah virus (NiV) is a paramyxovirus (genus Henipavirus) that was first identified in 1999 in Malaysia, where it caused an outbreak of respiratory and neurological disease in pigs and encephalitis in people. Three years later, a genetically distinct NiV independently emerged in India as well as in Bangladesh, where human NiV outbreak events have been reported nearly every year since. A putative NiV also caused an outbreak of disease in horses and people in the Philippines in 2014. To date, there is no reported evidence of NiV outbreaks in humans emerging in any other country than Malaysia, Singapore, Bangladesh, India and Philippines. More than 600 cases of NiV human infections have been reported globally. However, given the delay in identification of the Indian outbreak and large distribution of bats that can carry NiV, it is possible that more human cases have occurred where NiV has not been detected. A total of 276 cases were reported with 106 fatalities (38%) in Malaysia, but case fatalities in later outbreaks in India and Bangladesh were associated with significantly higher case fatality rates of 43 to 100%. NiV infection in humans has a range of clinical presentations, from asymptomatic infection to acute respiratory syndrome and fatal encephalitis. The natural reservoir of the virus consists of the widely distributed fruit bats from the Pteropodidae family. Virus transmission from bats to humans occurs through inhalation, contact or consumption of NiV contaminated foods. NiV is transmitted by zoonotic (from bats to humans, or from bats to pigs and then to humans) as well as human-to-human routes. Human-to-human transmission is particularly notable in the outbreaks in India and Bangladesh, where it has been reported to account for 75% and 51% of cases, respectively. At present no vaccines or antiviral drugs are available for NiV disease and the treatment is just supportive. Current prevention strategies focus on raising disease awareness in affected areas.

The virus

NiV was first isolated by Chua et al. in 1999 after a severe outbreak of viral encephalitis among pig-farmers in Malaysia. The virus, cultured from the cerebrospinal fluid of two patients, was causing syncytial formation of Vero cells after 5 days, and it was found to be a previously undescribed paramyxovirus related to the Hendra virus (HeV). The Henipavirus genus in the subfamily Paramyxovirinae (family Paramyxoviridae) was then created for these two pathogenic viruses, HeV and NiV (Wang 2001). Subsequently, other viruses were added to this genus.

NIV is an enveloped, negative-sense, single-stranded RNA virus. The genome is unusually large, comprising more than 18 000 nucleotides. Its 6 genes code for the nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion glycoprotein (F), attachment glycoprotein (G) and the large polymerase. The viral G protein attaches to the host cell ephrin B2 and/or B3 receptor, and activates the F protein to initiate viral envelope and host membrane fusion and viral entry (reviewed by Ong 2015). Of note, membrane fusion is not only essential for viral entry but also for cell-cell fusion and the process of syncytia formation, which makes it an attractive target for therapeutic development. Numerous studies have been conducted to decipher the mechanisms of NiV and other paramyxoviruses replication.

Relatively few isolates of NiV have been obtained from human cases across different infection outbreaks

The nucleotide sequence of a fair number of NiV isolates has been determined. A relative heterogeneity has been observed among nucleotide sequences obtained from Bangladesh/India as compared with sequences from samples obtained during the initial Malaysian outbreak. This observation led to the classification of two distinct lineages of NiV. Currently available sequences obtained from Malaysia and Cambodia were designated genotype M, while sequences obtained from Bangladesh and India were designated genotype B (Lo 2012, reviewed by Angeletti 2016). A 729 nucleotide region of the N protein gene of NiV has been proposed that can be used for such genotyping. Predicted amino acid identities between NiV-M and NiV-B range from 92% to 100% (reviewed by Rockx 2012).

The variation of nucleotide and amino acid sequences within the Malaysia genotype (NiV-M) has been reported to range, respectively, between 0.19 and 2.21% and 0.18 and 3.67%; and within the Bangladesh genotype (NiV-B) between 0.28 and 1.06% and 0.28 and 0.56%. In Malaysia, very limited variation was observed between human NiV isolates and isolates obtained from bats years later. Interestingly, molecular evidence suggests that at least two major strains of NiV were circulating in pigs during the 1998 outbreak in Malaysia. No data are available to indicate whether these 2 strains represent 2 independent introductions of NiV into the pig population, or if the latter strain evolved from the initial NiV strain. Interestingly, the NiV diversity observed among isolates from bats in Malaysia and Thailand was associated with co-circulation of multiple strains within populations rather than co-evolutionary patterns (Angeletti 2016).

Sequence homology at the level of G and F, the glycoproteins involved in virus binding and entry, is sufficient to allow for antigenic cross-reactivity between HeV and NiV, but NiV-B and NiV-M G and F share a much higher homology

In Bangladesh, genetic heterogeneity in human isolates suggests multiple introductions of NiV in the human population from different colonies of fruit bats.

The NiV attachment glycoprotein G and fusion protein F are essential for virus binding and entry and as such are the primary targets for protective antibody responses. The 83% and 88% amino acid identity between HeV and NiV G and F, respectively, results in antigenic cross-reactivity between these viruses (Rockx 2012). The NiV-M and NiV-B strains share 95% amino acid homology in the G protein and 98% homology in the F protein.

Other henipaviruses

HeV was first isolated in 1994 in Australia from fatal cases of severe respiratory disease in horses. Since its first identification in 1994, it has caused 7 confirmed cases in humans and 4 deaths in Australia, all acquired from contact with infected horses (Broder 2013). Infection of horses results from spill-over events from the natural host reservoir, which has been identified as pteropid bats (Black flying-fox, Pteropus Alecto, and Spectacled flying-fox, Pteropus conspicillatus). In humans, HeV begins as an influenza-like illness, but the involvement of the lung and brain, as with Nipah, can also manifest as an acute severe respiratory syndrome, encephalitis or a combination of both.

Other henipaviruses are not known to cause human disease, except for Mojiang paramyxovirus (MojPV), a henipavirus-like virus, which has been implicated in the death of three miners in China in 2012, following potential zoonotic transmission from rats (Wu 2014).

Immune Responses to NiV Infection

Innate immunity

(adapted from Prescott 2012)

Innate immunity generally refers to the ability of cells to detect the invasion of a microbe by the engagement of pathogen-associated molecular patterns (PAMPs) with host encoded pattern recognition receptors (PRRs). This interaction leads to the expression of several antiviral proteins, as well as type I and type III interferons (IFNs), which activate additional antiviral responses via the Jak/STAT pathway. The NiV genomic RNA is recognized by cellular cytoplasmic RNA helicases. In vitro, endothelial cells (an important cell type targeted in vivo) infected with NiV produce IFNβ as well as innate chemokines and cytokines, including IP-10 and IL-6. IP-10 is a chemokine that attracts activated T lymphocytes, whereas IL-6 is a cytokine that stimulates acute-phase proteins and acts as an inflammatory molecule. These chemokines have the ability to functionally recruit T cells. This mechanism likely contributes to the extensive vasculitis reported in virtually all histopathology studies. In vivo, little is known about the activation of the innate immune system. The expression of innate immune genes has been documented as a response to NiV infection in animal models of disease, including the upregulation of IP-10 and IL-6.

Nevertheless, this innate response is balanced by the ability of NiV (as other RNA viruses causing disease in humans) to stimulate antagonising mechanisms. NiV has been extensively characterized in vitro for this ability to subvert innate immunity and several mechanisms have been identified, as presented below.

Mechanisms of inhibition of innate immunity

The P gene of NiV is transcriptionally edited to produce not only the phosphoprotein but also two alternate V and W proteins, and an alternate ORF expresses a C protein. These proteins possess multiple capabilities to inhibit IFN production, as well as downstream signalling. In addition, the expression of these antagonistic genes is temporally regulated during infection. Both STAT1 and STAT2, which are required for IFNβ signalling, are antagonized by P gene products. The antagonistic function of the P, V, W and C proteins has been assessed in vivo. Hamsters inoculated with recombinant virus lacking the ability to produce either the C or the V protein displayed no pathology, and the viral genome was almost undetectable in these animals, suggesting that the antagonistic properties for these proteins are responsible for pathogenesis. The results were subsequently confirmed by Satterfield (2015). A V-deficient virus was found strongly attenuated, behaving as a replicating non-lethal virus in ferrets.

Bharaj (2016) also reported that the matrix protein (M), which is important for virus assembly and budding, can also inhibit IFN-I responses by targeting TRIM6, IKKε and unanchored polyubiquitin chains.

Finally, the nucleoprotein (N) was shown to impact host innate immune responses by preventing the nucleocytoplasmic trafficking of STAT1 and STAT2, resulting in an antagonistic activity against the JAK/STAT signalling pathway (Sugai 2017).

Adaptive immunity

Adaptive immune responses to NiV infection in humans have been very poorly characterized

Little is known about the adaptive immune response to NiV infection in humans. Studies are lacking to identify protective responses. And the immunological mechanisms that may explain the different patterns of disease severity have not been better elucidated.

Sera from infected patients contain measurable NiV-specific IgM antibodies as early as four days after exposure, persisting for at least 3 months (reviewed by Ong 2015, Mathieu 2015, Prescott 2012). Of note, no difference has been observed in clinical features or mortality between seropositive or seronegative patients. Specific IgG can also be detected by day 25 following infection and were shown to persist for several years. The IgG3 and IgG1 subclass distribution observed in NiV infection is similar to the IgG subclass responses seen in measles (Wong 2001).

The presence of antibodies suggests that both B-cell and CD4+ T-cell responses are elicited in response to virus infection, but the cellular arm of the immune response has not been studied in convalescent subjects, and the role it may play in protection following natural infection or vaccination remains unknown.

The NiV N protein is considered as a highly immunogenic protein in human infections and therefore has been proposed as a target for serological diagnosis (Yu 2006). Of note, using immunoblot assays, the serum from one patient with a relapsing NiV encephalitis complication has recently been shown to not react as robustly with the NiV proteins as compared to the other positive patients'sera, and to bind mainly to the NiV G protein (Tiong 2017).

NiV-neutralizing antibodies have been detected in patients' sera. Animal studies suggest that they are highly protective when elicited/administered before or shortly after infection.

Complement has been reported to significantly enhance neutralization by antibodies specific for the NiV F and G glycoproteins (Johnson 2011).

Pathophysiology and clinical disease, case definition

Clinical disease

(adapted from the reviews by Ong 2015, Kulkarni 2013, Wong 2012 and Rockx 2012)

In the majority of cases, the incubation period of Nipah has been reported to be 5 days to 2 weeks; however, a maximum delay of 2 months between exposure and the onset of illness has also been observed during the outbreak in Malaysia (Goh 2000). The majority of patients initially develop influenza-like signs and symptoms, including fever, headache, myalgia and vomiting. In general, the more severe clinical features manifest as either an acute encephalitic syndrome or less frequently a pulmonary syndrome. It is also very likely that a considerable number of infections remain asymptomatic but the exact prevalence is unknown.

Goh (2000) described the clinical features of the largest cohort of 94 patients with NiV encephalitis who were admitted to a single hospital during the outbreak in Malaysia. Clinical signs such as areflexia/hyporeflexia with hypotonia, pinpoint pupils with variable reactivity, tachycardia, hypertension and abnormal doll's eye reflex were more frequently seen in patients with reduced level of consciousness. Segmental myoclonus characterized by focal, rhythmic jerking of the diaphragm and muscles in the limbs, neck and face was present in 32% of patients, and may be unique to acute NiV encephalitis. Other clinical features (e.g. meningism, generalized tonic-clonic convulsions, nystagmus and cerebellar signs) were also observed. A pulmonary syndrome has been described in some patients who presented with cough, atypical pneumonia, acute respiratory distress syndrome and abnormal chest X-ray findings.

Interestingly, a higher prevalence of respiratory disease was observed during the Bangladesh outbreaks with cases experiencing atypical pneumonia and developing an acute respiratory distress syndrome (Hossain et al., 2008). In Bangladesh, altered mental status and/or unconsciousness was reported in more than 70% of patients, severe weakness in 67% and areflexia/hyporeflexia in 65% of cases, consistent with a high prevalence of acute encephalitis.

In Bangladesh, based on a review of 196 cases, the median duration from onset of illness to death was 6 days (ranging from 1 to 47 days) (Rahman 2012). Overall, mortality was high, ranging from about 40% to 100%. In a large cohort of patients who survived, the majority had no or few sequelae. However approximately 20% of patients were reported to have neurological deficits, neuropsychiatric sequelae and gait/movement disorders. The most intriguing complication of Nipah is probably relapsing encephalitis which may occur weeks to years after symptomatic infection and even after asymptomatic NiV infection. So far, more than 20 cases of relapsing NiV encephalitis have been reported, one of which occurred 11 years after an asymptomatic infection. Clinical and radiological findings suggest that relapsing NiV encephalitis is distinct from acute NiV encephalitis. The brain MRI in relapsing encephalitis shows more extensive and confluent hyperintense cortical lesions. Virus could not be cultured from samples collected in a series of NiV relapsing encephalitis. There are currently no known risk factors for relapsed encephalitis, and the mechanisms for persistent CNS infection and disease recrudescence have not been elucidated.

Risk factors and mechanisms for persistent CNS infection and disease recrudescence are unknown

Pathological features are characterized by disseminated, multi-organ vasculopathy comprising endothelial infection/ulceration, vasculitis, vasculitis-induced thrombosis/occlusion, parenchymal ischemia/microinfarction, and parenchymal cell infection in the central nervous system (CNS), lung, kidney and other major organs. This unique dual pathogenic mechanism of vasculitis-induced microinfarction and neuronal infection causes severe tissue damage in the CNS.

Case definition

To our best knowledge, there is no standard case definition of Nipah disease. Epidemiological investigations have used various definitions. At least a temporal association with a disease outbreak and the need for laboratory confirmation were shared across definitions. For instance, the definition used during the 2004 outbreak in Bangladesh is presented below (WHO 2004)

Can a standard case definition of Nipah disease be developed and used widely?

*A **suspect case** was any person with fever AND one or more of the following isolated neurological signs: altered mental state, confusion, convulsions, unconsciousness or neck stiffness, focal weakness/paralysis after 15 December 2003 OR an individual with fever and vomiting or respiratory symptoms or headache AND having had physical contact or shared daily activities with or lived near to a probable or laboratory-confirmed case after 15 December2003.*
*A **probable case** was any patient, dead or alive, who developed fever AND one or more of the following isolated neurological signs: altered mental state, confusion, convulsions, unconsciousness or neck stiffness, focal weakness/paralysis after 15 December 2003 AND who was living in the same district as a laboratory-confirmed case after 15 December 2003.*
*A **laboratory-confirmed case** was any case positive for Nipah IgM antibody after 15 December 2003.*

Pathophysiology of Nipah

Viral tropism

Infections caused by henipaviruses are characterized by their ability to infect multiple organ systems, with a predominant neurological or respiratory tropism. In human cases of NiV infection, NiV can be detected in bronchiolar epithelial cells and is shed mainly by nasopharyngeal and tracheal secretions in the early phase of the illness (reviewed by Escaffre 2013). During the late stages of disease, virus replication spreads from the respiratory epithelium to the endothelium in the lungs. The infection can sometimes trigger a prominent vasculitis in small vessels and capillaries as characterized by endothelial syncytium and mural necrosis. Without being infected themselves, circulating leukocytes could transfer the virus to endothelial vascular cells (Mathieu 2015). NiV was shown indeed to not infect but to efficiently bind to human lymphocytes, and co-culturing with permissive endothelial cells resulted in virus amplification and infection of these target cells. Moreover, mononuclear leukocytes isolated from infected hamsters transferred lethal infection to naive animals. Leukocytes would thus be used as a vehicle to spread the virus to other organs by the haematogenous route. In addition to the lungs, important target organs are the brain, spleen and kidneys, and viremia following respiratory infection can lead to multi-organ failure.

Entry into the brain may actually occur through two distinct pathways: i.e. via the hematogenous route through the choroid plexus and cerebral blood vessels, or anterogradely via the olfactory nerve. In animal models of infection, early virus replication was indeed observed in the olfactory epithelium (Baseler 2016). In addition, Borisevich (2017) showed that human olfactory neurons are highly susceptible to infection with henipaviruses. Nevertheless, it is currently unknown whether the route of virus transmission seen in animal models is relevant in human infections, since the olfactory epithelial surface is relatively large in these species compared to man (Escaffre 2013).

Determinants of pathogenicity

The determinants of NiV pathogenicity are poorly understood. Clinical observations as well as data generated in non-human primates (NHPs) indicate pathogenic differences between NiV-M and NiV-B isolates. For instance, in African green monkeys (AGM), while NiV-B was uniformly lethal, only 50% of NiV-M-infected animals succumbed to infection. Histopathology of lungs and spleens from NiV-B-infected AGMs was significantly more severe than NiV-M-infected animals. These data showed that NiV-B is more pathogenic than NiV-M in AGMs, as observed in human subjects (Mire 2016). However, the mechanisms underlying these differences remain unknown.

Similarly experimental infections in ferrets suggest that NiV-B is shed at higher levels than NiV-M, which may be sufficient to enable the former virus to transmit more efficiently between humans (Hayman 2014).

As presented above, several gene products of NiV have the capacity to inhibit the early proinflammatory response at sites of infection, thereby preventing control of the infection by the immune system. Immunopathology is another possible mechanism. For instance, it was shown that NiV infection resulted in overexpression of CXCL10 (IP-10) in endothelial cells and perivascular infiltrating cells in the brain of patients, as well as Syrian hamsters. CXCL10 is an important chemoattractant involved in the generation of inflammatory immune response and neurotoxicity. Its expression likely plays a role in the accumulation of inflammatory cells in infected areas of the brain (reviewed by de Wit 2015).

Case detection

The epidemic of Nipah virus in Malaysia in 1998/1999 required more than six months before being effectively controlled, as a consequence of the misdiagnosis of the etiologic agent and the resulting implementation of incorrect control measures (Chua 2013). National systems for surveillance of infectious disease in countries such as Malaysia subsequently recognised Nipah as a zoonotic disease of interest, and included it in their list of notifiable diseases. Hospital-based surveillance was developed, as it is considered necessary to quickly detect NiV outbreaks and initiate appropriate control measures (Rahman 2011). However, surveillance in rural areas of the countries where NiV is endemic in bats can be expected to be of moderate quality, so that many cases likely go undetected (Satterfield 2016b). Veterinary surveillance of NiV encephalitis in pigs is organised as well, as the disease appears among the “OIE-Listed diseases, infections and infestations” in force in 2017.

Case management

Guidelines for the clinical management of Nipah patients have been made available in various countries, including affected countries such as Bangladesh (Rahman 2011) and Malaysia. Such management is based on general, supportive treatment (ensuring fluid and electrolyte balance, oxygen inhalation if required…etc.), symptomatic treatment (fever, convulsions, shock…etc), and procedures to prevent further spread of the disease (isolation, barrier nursing, safe handling of deceased bodies…etc.).

Special populations

To our knowledge, there has been no evidence of increased incidence or increased severity of Nipah in special populations such pregnant women, infants or immunocompromised subjects. However, in the case series reported by Goh (2000) older patients, especially those having diabetes mellitus and those with severe brain-stem involvement, carried a poorer prognosis than other Nipah patients.

Animal models

Small animal models

Mice

Standard laboratory mouse strains such as Balb/c and C57BL/6 do not develop disease upon intraperitoneal or intranasal inoculation with NiV (reviewed by de Wit 2015). However, intracerebral inoculation of these animals results in a lethal infection. In aged mice, intranasal NiV inoculation did not result in clinical disease, but most animals seroconverted and vRNA and infectious virus could be detected between 2 and 15 days after inoculation in the lungs of most animals. In IFNAR-KO mice lacking the type I IFN receptor, intraperitoneal inoculation resulted in neurological disease. Histologically, these animals developed vasculitis, perivascular cuffing and meningeal inflammation; the lungs exhibited bronchointerstitial pneumonia.

Of note, a human lung xenograft model has also been developed to study the pathogenesis of NiV infection in human lung in vivo (Valbuena 2014). The model uses the severely immunodeficient NOD/SCID/γcnull (NSG) mice as hosts to support the successful engraftment of human lung xenografts.

Guinea pigs

NiV infection in guinea pigs has been reported to be often mild and variable, ranging from an inapparent infection following challenge to sudden death (reviewed by Geisbert 2012). One study demonstrated that intraperitoneal inoculation with high doses of NiV resulted only a transient fever with minor weight loss after 5–7 days. Guinea pigs are thus not considered a suitable animal model of NiV infection.

Hamster

The Golden Syrian Hamster is a commonly used model to study henipaviruses pathogenesis as the clinical signs and pathological lesions observed following inoculation highly resemble those observed in humans, even though the disease course seems to be affected by the route of inoculation and the inoculum dose. The virus used for infection also influences the disease course, as NiV-M-infected Syrian hamsters show accelerated virus replication, pathology and death when compared to NiV-B-infected animals (DeBuysscher 2013).

Like human patients, the main histopathological finding in Syrian hamsters infected with NiV is systemic vasculitis. Moreover, animals develop encephalitis, with infection of neurons in the CNS. In hamsters that develop severe respiratory disease, usually upon intranasal inoculation with a high inoculum dose, rhinitis can be observed, with virus replicating in the respiratory as well as olfactory epithelium; bronchointerstitial pneumonia develops in the lungs of these animals (reviewed by Dhondt 2013 and de Wit 2015).

Ferrets

Ferrets inoculated oronasally with NiV develop respiratory as well as neurological signs of disease. Systemic vasculitis is present in infected ferrets. Histologically, the upper respiratory tract, with rhinitis, tonsillitis and nasopharyngitis, as well as the lower respiratory tract, with necrotizing bronchointerstitial pneumonia, are affected; focal necrosis has been detected in the spleen. Encephalitis has not been detected, but non-suppurative meningitis occurred in a subset of animals and viral antigen was detected in brain endothelial cells and meninges, and occasionally in neurons and glial cells close to infected endothelium (de Wit 2015).

Non-Human Primates

Preclinical tests of vaccines and therapeutic products are ideally conducted in an animal species that not only develops similar symptoms of the disease as observed in humans, but also shares similar pathophysiological and immunological mechanisms. Non-human primates typically best meet these requirements. The first NHP model described for NiV infection was the Squirrel monkey. However, more recent studies favoured AGMs.

African Green Monkey

A consistent lethal infection and disease is observed in AGMs with low dose NiV challenge. Infection by intratracheal inoculation results in a rapid spread of the virus within 3–4 days and the establishment of infection in multiple organ systems (reviewed by Dhondt 2013, Geisbert 2012, Geisbert 2010). Severe respiratory pathology, neurological disease, endothelial syncytia, and generalized vasculitis all occur in AGMs infected with NiV, providing an accurate reflection of what is observed in infected humans. This conclusion was further confirmed by a comprehensive study reported in 2015 (Johnston), that captured physiological data together with clinical pathology information and virological testing in 4 AGMs inoculated by intra-tracheal route. Increases in heart rate and respiratory rate seen in most animals during acute phase suggested responses to fever, to a developing hypoxic state, and/or to a state of compensatory shock. Animals that succumbed appeared to enter a state of irreversible decompensated shock with hypothermia, azotemia, hyperglycemia, and signs of liver disease. Similar to NiV disease in humans, pneumonitis, systemic vasculitis, and coagulopathy were prominent findings in these animals, and significant histopathologic lesions were present in most tissues assessed, including lymphoid tissues and the lungs. Virus antigen was often associated with areas of necrosis and/or inflammation. Interestingly, in all animals that survived beyond the acute disease phase, relapse encephalitis was identified.

Other animals

Cats

Cats inoculated with NiV subcutaneously or intranasally and orally develop signs of respiratory disease. Histologically, cats develop bronchointerstitial pneumonia and, in some animals, meningitis (reviewed by de Wit 2015). The virus can be found in the lungs, but also in kidneys, spleen and lymph nodes. The model may be used for evaluation of vaccines or therapies, but its interest in limited by the poor availability of reagents and limited characterization of the pathogenic mechanisms in this species.

Pigs

Efforts have been undertaken in view of the development of a NiV veterinary vaccine for pigs, which explains the large number of studies conducted in this animal species. Oronasal and ocular routes of NiV infection mimic quite well natural infection and most infected animals remain asymptomatic even if viral shedding is observed following challenge (reviewed by Dhondt 2013). Sick animals present fever, depression, cough, shivering, and rarely, neurological signs including abnormal posture and seizures. A subcutaneous route of inoculation was also tested, causing symptomatic infections in pigs. The disease shares a number of features with human infection. However, a number of species-specific differences of NiV replication in porcine and human cells have been identified. Sauerhering (2016) found that NiV growth substantially differs in primary airway epithelial cells between pigs and humans, with a more rapid spread of infection in human airway epithelia. Increased replication in human cells correlated with higher endogenous expression levels of the main NiV entry receptor ephrin-B2. On the other hand, porcine monocytes, natural killer cells, and CD6+/CD8+ T cells have been found to support NiV replication, which may facilitate dissemination of the virus (Prescott 2012).

Comparison of models

The advantages and disadvantages of the various animal models described in the literature are presented in Table 1 below.

Table 1. Summary of advantages / disavantages of the different animal models of NiV infection

Model	Advantages	Disadvantages
Mice	Low cost	Intracranial challenge route not relevant to human infection
IFNAR-/- mice	Low cost Some resemblance with pathology in humans (vasculitis, bronchointerstitial pneumonia, meningeal inflammation but no encephalitis)	Not suited to vaccine studies Intraperitoneal route of infection
Syrian hamsters	Low cost Good resemblance with infection in humans (extensive lesions, respiratory and neurological disease; systemic vasculitis)	Limited availability of reagents
Ferrets	Some resemblance with infection in humans (respiratory disease, systemic vasculitis, but encephalitis not detected)	Limited availability of reagents
AGM	Good resemblance with disease in humans (infection in multiple organ systems, neurological disease and severe respiratory pathology along with generalized vasculitis) Resemblance with immune response in humans	High cost Small sample size
Cats	Intranasal or oral route of challenge Very limited resemblance with disease in humans (respiratory disease, but no neurological signs)	Limited availability of reagents, limited characterization of the model
Pigs	Some resemblance with disease in humans (respiratory disease, encephalitis, as well as congestion and haemorrhagic lesions)	Various species-specific differences of NiV replication identified

More detailed tables describing the disease and histopathological lesions in each animal model can be found in the reviews by Dhondt (2013) and Geisbert (2012). While there is today no ideal animal model to study novel vaccines or therapies against NiV infections, various options are available for preclinical testing of such candidates.

Preclinical models are available for evaluation of NiV vaccine and therapy candidates

Epidemiology, Prevention and Control

Transmission and maintenance

The widely distributed fruit bats from Pteropodidae family are considered to form the natural reservoir of NiV. Serological studies demonstrated evidences of NiV infection in multiple bat species, including frugivorous and insectivorous bats. As summarized by Wacharapluesadee (2016), NiV-B has been found in Pteropus giganteus (India), and Pteropus lylei (Thailand). NiV-M has been found Pteropus hypomelanus (Malaysia and Thailand), Pteropus vampyrus (Malaysia and Indonesia), Pteropus lylei (Cambodia and Thailand), Hipposideros larvatus (Thailand), Taphozous species (Thailand) and Rousettus amplexicaudatus (East Timor). However, viral isolation and molecular characterization was usually only successful in Pteropus species (Simons 2014). Henipavirus infection in bats seems to be asymptomatic. Experimental infection by subcutaneous route has been followed by seroconversion in the majority of animals in the absence of visible clinical disease, while a range of histopathological changes was observed within the tissues. Nipah virus was excreted in urine. As suggested by Middleton (2007), this intermittent, low-level excretion may be sufficient to sustain the net reproductive value of the virus in a species where there is regular urine contamination of the fur, mutual grooming, and where urine droplets are a feature of the environment.

Introduction of NiV infection into the human population occurs by two mechanisms of spill-over from bats: transmission via an intermediate animal host, which precipitated the outbreak in Malaysia; and bat-to-human transmission, which has occurred in Bangladesh and India (Clayton 2017).

In Malaysia, the highest risk of human NiV infection was associated with activities involving close contact with and handling of pigs, and transmission to people is thought to have occurred through direct contact with infectious secretions or excretions of pigs. Importation of infected pigs into Singapore from Malaysia precipitated a cluster of infections in abattoir workers in Singapore, whose exposure risks were also associated with close contact with pigs or their excretions. In Malaysia, NiV was highly infectious for pigs, with all classes of pigs susceptible. The pattern of on-farm infection was consistent with respiratory transmission; between-farm spread was generally associated with the movement of pigs. An extensive post-outbreak surveillance program in Malaysia showed that farms that did not receive pigs at the time of the outbreak generally remained uninfected, even when neighbouring farms were infected (Breed 2006). Human infections were predominantly attributed to contact with live pigs. A small number of infected people had no history of contact with or proximity to pigs, and human-to-human transmission is suspected in a few cases. No human case was attributed to contact with bats.

In Bangladesh, a most common risk factor for human NiV infection is drinking contaminated date palm sap or its fermented product. Date palm sap is harvested from December through to March by cutting into the tree trunk and allowing the sap to flow overnight into an open clay pot. Infrared camera studies have demonstrated that Pteropus giganteus bats frequently visit date palm sap trees and lick the sap during collection, potentially contaminating it with NiV from saliva and/or urine (Simons 2014). The other common risk factor for human infection is contact with a patient with Nipah encephalitis. Overall, these two risk factors reflect the two main mechanisms of human infection observed in Bangladesh as well as in India: bat-to-human and human-to-human transmission. In a small number of instances, direct contact with infectious material left by foraging

Possible NiV outbreak in the Philippines in 2014

(adapted from Ching 2015)

In April 2014, 2 human deaths were reported in the municipality of Senator Ninoy Aquino, island of Mindanao in the Philippines. An outbreak investigation identified additional human deaths and non-fatal infections as well as concurrent neurologic disease and sudden deaths in several horses. Subsequently, a human case was defined as illness in any person with an epidemiologic link to the municipality of Senator Ninoy Aquino and who had experienced acute encephalitis syndrome, severe influenza-like illness, or meningitis during the period from March 3 to May 24, 2014. This case definition was met by 17 persons (11 acute encephalitis syndrome, 5 influenza-like illness, 1 meningitis).

Of the 17 case-patients, a total of 7 (41%) had participated in horse slaughtering and horse meat consumption, and 3 (18%) had only consumed horse. Five (29%) case-patients had been exposed to other human case-patients, but not to any horses.

Neutralizing antibodies against NiV and correspondingly lower neutralizing antibody titers against HeV were found for 3 patients. A serum sample from a patient was positive by real-time PCR for NiV, and a 71 nucleotides long sequence of the P gene of NiV was detected from another patient. This short segment had 99% nucleotide identity with NiV-M and 94%-96% identity with NiV-B. Further attempts to amplify additional genome and isolate the virus were unsuccessful.

This outbreak led to the conclusion that ongoing surveillance is needed to help with prompt response to future potential additional outbreaks of Nipah, including not only diagnosis, but also investigation of risk factors associated with spill-over and virus transmission, implementation of control measures, and further characterization of the virus involved. Another important lesson from this outbreak is the fact that a NiV isolate not identical to the one currently circulating in Bangladesh has the potential to emerge and cause disease in human.

bats in trees or on fruit may have also played a role in bat-to-human transmission, and domesticated animals such as cows, goats and pigs may also pose infection risks to people.

Person-to-person transmission has been identified as a pathway for infection of people in India and Bangladesh. In Siliguri, India, 75% of the patients had a history of hospital exposure, i.e. they were members of the hospital staff or had attended to or visited patients in the hospital (Chadha 2006). Similarly, a study of human NiV infections between 2001 and 2007 in Bangladesh attributed 51% of all cases to onward transmission from an infected person, although only 7% of people were identified as having transmitted their infection. In these instances, close contact between infected and naïve individuals appears to drive transmission, and specific risk factors for exposure are associated with direct contact with a clinically unwell patient or their secretions, in particular patients with severe illness and who later died as a result of their infection. Several studies evaluated the risk factors associated with transmission and suggested that the main mode of human-to-human transmission is via direct contact with the infectious secretions of a patient with clinical disease; this is further supported by isolation of NiV from respiratory secretions and urine of patients (Clayton 2017). So far, the basic reproductive number (R_0) of the strains of NiV that have spilled over in Bangladesh has remained very low, averaging 0.48 (Luby 2013).

What is the potential for NiV and other hendraviruses to cause a pandemic ?
(adapted from Luby 2013)

Human-to-human transmission of NiV remains very limited in current outbreaks. However, humans are susceptible to the virus; and as an RNA virus, NiV is characterized by a high rate of mutation, which has the potential to lead to the emergence of a strain better adapted to spread from human to human. Moreover, if such adapted virus were to infect communities in South Asia, high population densities and global interconnectedness could be expected to rapidly spread the infection.

At risk populations

As demonstrated by the Ebola epidemic in 2013-2016, there is potential for highly pathogenic emerging infections that normally cause only small, isolated and containable outbreaks to occasionally result in large epidemics that inflict a significant mortality and morbidity burden. In this regard, the number of people at risk of acquiring NiV in Bangladesh and the neighboring West Bengal state of India (regions that experience more frequent outbreaks) exceeds 250 million. The total number of people at risk, including all countries that experience NiV outbreaks and in which the Pteropus bats occur naturally, exceeds two billion (Satterfield 2015).

Due to the different mode of virus transmission during the outbreaks in Malaysia and Singapore compared to more recent outbreaks, the definition of at risk populations has evolved. Following the NiV outbreak in March 1999 in Singapore, a serological survey screened individuals potentially exposed to NiV, and found that all of the antibody positive individuals had direct contact with pigs (Chan 2002). Subsequent observations in Bangladesh and India led to very different results.

The risk of NiV transmission is underpinned by social and environmental factors, which should be taken into account for control measures

A review of 196 cases in Bangladesh indicated that cases were distributed in all age groups, with a median age of 25 years (range: 6 months to 75 years) and 124 (63%) cases were observed in males (Rahman 2012).

Human cases of Nipah were found to generally occur in areas near inland water, predominantly the Ganges, which provides a suitable habitat for date palm trees (Simons 2014). The disease was also characterized by seasonality in Bangladesh, with cases occurring only between December and April, roughly coinciding with the time that palm sap is collected (Simons 2014, Stone 2011). The central role for palm sap consumption as a risk factor was identified by a number of studies. For instance, Hedge (2016) analysed a large dataset of 157 cases and 632 controls over the period 2004–2012 in Bangladesh, and found that Nipah cases were 4.9 times more likely to consume raw date palm sap.

Human-to-human NiV transmission is the source of additional risk factors, as illustrated by the study by Hedge (2016), who observed that cases in Bangladesh were 7.3 times more likely to have contact with a Nipah case than controls. Specific cultural practices may underlie the fact that transmission commonly occurs between infected patients and their caregivers. In Bangladesh, societal norms dictate that such care is provided by patients' family members even in hospital settings, where trained health-care professionals adopt a "hands off" approach to patient management. A number of cases of human infection in Bangladesh were attributed to corpse-to-human transmission, through embracing the body of a loved one soon after their death, or through ritual preparation of a corpse for religious burial (Clayton 2017).

Distribution

Table 2 below presents the human cases of NiV that have been confirmed since first identification of the virus.

Table 2. Morbidity and mortality due to Nipah or Nipah-like virus encephalitis

(adapted from http://www.searo.who.int/entity/emerging_diseases/links/nipah_virus_outbreaks_sear/en/)

Year(s)	Country	Reported number of human cases	Reported number (%) of deaths among cases
1998-1999	Malaysia Singapore	276	106 (38%)
2001	India	66	45 (68%)
2001	Bangladesh	13	9 (69%)
2003	Bangladesh	12	8 (67%)
2004	Bangladesh	67	50 (75%)
2005	Bangladesh	12	11 (92%)
2007	Bangladesh	18	9 (50%)
2007	India	5	5 (100%)
2008	Bangladesh	11	9 (82%))
2009	Bangladesh	4	1 (25%)
2010	Bangladesh	16	14 (88%)
2011	Bangladesh	44	40 (91%)
2012	Bangladesh	12	10 (83%)
2013	Bangladesh	24	21 (88%)
2014	*Philippines*	*17**	*9 (53%)*
2014	Bangladesh	18	9 (50%)
2015	Bangladesh	9	6 (67%)

* possible NiV outbreak

Since 2001, outbreaks of Nipah have occurred almost annually in Bangladesh, affecting from 4 to more than 60 subjects (reviewed by Clayton 2017).

NiV has been shown to circulate in Pteropus bats in the countries where outbreaks of human disease have occurred. A 3-year longitudinal study of Pteropus hypomelanus bats (Rahman 2013) in Malaysia indicated an overall NiV seroprevalence of 9.8%, with nonseasonal temporal variation. Viral circulation was demonstrated within the study period.

Evidence of hendravirus or hendravirus-like infection was demonstrated by serological and/or molecular testing in bat samples collected from numerous countries (reviewed by Breed 2013), such as Bangladesh, India, Thailand, Cambodia, Vietnam, Indonesia or Madagascar where samples were found positive for NiV; China with a NiV-like virus; or Australia, Papua New Guinea and Indonesia with HeV. Bat infection was even detected in West African countries, with samples from Ghana and Equatorial Guinea found henipavirus-positive. These bat viruses may have the potential to spill-over into other mammalian hosts, including human. Actually, Pernet (2014) showed evidence of henipavirus infection in human samples from Cameroon.

Current prevention and control strategies

Current strategies for the management of henipaviruses are generally directed at minimising direct or indirect contact with the natural host (e.g. with palm sap), monitoring intermediate hosts, improving biosecurity on farms, and better disease recognition and diagnosis (Breed 2006). Prevention efforts also focus on interventions to interrupt transmission of NiV through person-to-person contact.

In Malaysia, the central strategy has been the implementation of sound farm management practices, such as monitoring herd health and early recognition of disease syndromes (Breed 2006). Several simple on-farm measures can also be taken to reduce the likelihood of spill-over events occurring. They include removal of fruit tree plantations from the immediate vicinity of pig sheds, wire screening of open-sided pig sheds, or ensuring roof run-off does not enter pig pens to avoid contact with bat urine or faeces or partially eaten fruits.

In Bangladesh, interrupting bat-to-human transmission is a main objective. People's knowledge of NiV was found low in a study conducted in randomly selected villages in Bangladesh (Nahar 2015), indicating a need for implementing strategies to increase awareness about the risks associated with this virus. Research was also conducted on methods to protect palm sap from bats. Studies compared methods to protect sap (Khan 2012). Bamboo, dhoincha, jute stick and polythene skirts covering the sap producing areas of a tree effectively prevented bat-sap contact. Pasteurizing date palm sap is another option. Moreover, the Government of Bangladesh issued a recommendation to abstain from drinking raw sap. However, such prevention methods rely on behaviour modifications. While these approaches appear to be effective strategies of prevention, their implementation is often problematic due to cultural factors (Satterfield 2015). Research was then conducted on behaviour change communication interventions. Nahar (2017) reported for instance that a 'do not drink raw sap' message is less effective than an encouragement to only drinking sap if it has been protected from bat contamination, 'safe palm only'. In addition, Parveen (2016) found that during outbreaks, one-way behaviour change communication without meaningful causal explanations is unlikely to be effective. Based on the cultural context, interactive communication strategies in lay language with supporting evidence may help make prevention messages credible in affected communities.

Similar communication is also necessary during outbreaks to interrupt person-to-person transmission. The National Guideline for Management, Prevention and Control of NiV Infection developed in Bangladesh identified a variety of prevention messages and levels of communication, to address risks associated with patient to care giver/contact, patient to health care worker, touching objects used by patients or handling deceased bodies (Rahman 2011). Specific measures are also taken in the hospital setting to avoid further spread of the disease, including isolation of patients, using personal protective equipment and applying standard precautions such as environmental decontamination and safe waste disposal. Another precaution is the safe handling of corpses of suspected Nipah patients.

Summary of epidemiology, prevention and control

Because of their wide distribution and flying range that can cover huge areas of human habitat, pteropid bats are highly effective in NiV dissemination. Moreover, the changing climate can be expected to affect the distribution of this virus reservoir in the future. Hence, the likelihood of additional henipavirus outbreaks in new areas/countries can be considered very high (Ong 2015). In view of the very high case fatality associated to the disease and the lack of safe and effective vaccine and therapies, this is a serious source of concern.

To date, outbreaks have resulted from two main transmission modes, consumption of contaminated palm sap (Bangladesh, India) or direct contact with infected pigs (Malaysia, Singapore). Since 2001, outbreaks of Nipah have been observed almost annually in Bangladesh. Current prevention of disease essentially relies on behaviour modifications to prevent spill-over from bats, even though the implementation of such measures is often challenging.

Human-to-human transmission has contributed significantly to the spread of NiV in Bangladesh and India, as well as during the first recognised (putative) outbreak in the Philippines. Human-to-human transmission is driven by close contact with patients who are clinically unwell, and factors such as patient care and basic infection control measures will be critical considerations for the mitigation of onward transmission of NiV infection in future outbreaks in people (Clayton 2017).

Diagnostics

Reliable detection of markers of NiV infection remains a key to establishing diagnosis both in animals and humans because the diagnosis may not be suspected initially, and disease manifestations can be rather nonspecific (Ong 2015).

Diagnostic Technologies

Various assays have been developed for laboratory confirmation of NiV infections. ELISA and RT-PCR are preferred methods. Virus isolation in cell culture is complicated by the requirement for high containment facilities.

Serological methods

ELISA

Several ELISA systems have been developed for serological testing after the initial investigations of NiV outbreaks in Malaysia and Singapore. Subsequently in Bangladesh, the first NiV outbreaks were only suspected after these tests were found to be positive in patients. These tests have also been used widely for investigative field studies in bats and other animals. ELISAs have been used both for detection of the viral antigen and evaluation of antibody responses (see Table 3 below). Chiang (2010), for instance, reported the development of monoclonal antibody-based antigen capture ELISAs for virus detection and for differentiation between NiV and HeV. Such viral antigen capture ELISAs provide a high throughput format at relatively low cost for screening of samples, and thereby could serve as an alternative to PCR for rapid diagnostic and virus detection (Kulkarni 2013). ELISAs developed for serology testing (IgM or IgG) may use infected cell lysate antigens for coating the plates. However, their use is limited to BSL4 laboratories. To overcome this problem, NiV recombinant proteins, and the N protein in particular, have been produced as an alternative antigen for serological detection of infection.

The specificity and sensitivity of available ELISAs has not been often reported. One such validation study concluded in 92% assay sensitivity and specificity of a NiV-N protein-based IgM capture ELISA, but used as a reference method the ELISA developed at CDC (Yu 2006), which performance documentation had not been disclosed.

Luminex

Two different Luminex assay formats were developed for detection of NiV-specific antibodies, a binding assay and a blocking or inhibition assay (reviewed by Wang 2012). The inhibition assay measures antibodies that block ephrin-B2 receptor binding. Such assay can be considered as a surrogate neutralization test. Similar Luminex assays have been used successfully for HeV diagnosis in human as well as veterinary settings.

Rapid test

From an outbreak investigation/control point of view, it is most useful in some situations to have access to a rapid (point-of-care) test for both human and animal applications. Rapid tests, usually consisting of lateral flow immunochromatographic assays, have been developed for detection of antigen and/or antibody corresponding to a variety of infectious diseases. However, as of today, no such test has been made available for Nipah serology.

Virus neutralization

Serum neutralization tests are considered as the reference for serology testing, and NiV neutralization tests were developed soon after the first outbreak in Malaysia. In a conventional NiV neutralization test, sera are incubated with virus in the wells of 96-cell microtiter plates prior to the addition of Vero cells. Those sera that completely block development of a cytopathic effect are designated as positive. A more rapid plaque assay neutralization procedure has also been developed to detect NiV-neutralizing antibodies, in which a specific number of plaque-forming units of the virus are incubated with dilutions of test serum prior to adsorption to the cell monolayers, and foci of infection detected immunologically after fixation of the cells with methanol (reviewed by Wang 2012, Daniels 2001).

Neutralization testing may not be performed in many laboratories because these tests involve handling live viruses, which requires high containment facilities. Several pseudotyped viruses bearing the NiV F and G proteins have been developed to obviate this requirement, and shown to be more sensitive than conventional serum neutralization assays (Wang 2012). However, further validation of the pseudotype assays, at large scale, would be required to corroborate their high sensitivity and specificity before considering them as a reliable alternative to other serological assays.

Molecular methods

Specific and reliable PCR-based methods and sequencing to identify henipaviruses are now more widely available for outbreak investigations and diagnosis, and have begun to replace serological testing (Ong 2015). A real time RT-PCR TaqMan assay for NiV was first developed in 2004, based on the N gene sequence. The sensitivity of the test was close to 1 plaque forming unit, and it was demonstrated that the assay was able to detect NiV RNA in blood specimens from infected hamsters. The assay was also shown NiV-specific since it failed to detect HeV RNA. A commercial kit based on this technology has obtained CE marking and been made available, for the detection of NiV in serum, plasma, infected animal tissue or secretion by using real time PCR systems.

Subsequently, in another study, several consensus quantitative PCRs were developed for detection of both HeV and NiV. In this study, the N gene SYBR Green assay was the most useful assay for investigation of potentially unknown henipaviruses and the P TaqMan assay was preferred when high sensitivity was required to detect infection by know strains of NiV (reviewed by Wang 2012).

Two versions of a Taqman array card have also been recently developed for simultaneous detection of more than 20 pathogens (including NiV) in cerebrospinal fluid or blood samples (Onyango 2017, Liu 2016). The assays showed good performance when compared to standard PCR, with better specificity (96-99% overall) than sensitivity (< 90% overall). The TaqMan array card could be used in field settings with different objectives: as a rapid screen in case of suspected neurological disease, for outbreak investigations or for the surveillance of specific pathogens including NiV.

Tissue culture method

Virus culture can be used for diagnosing NiV infections. Particularly in any new case or outbreak, isolation of the virus is highly desirable. Brain, lung, kidney and spleen samples should be tested. A cytopathic effect usually develops within 3 days of culture in Vero cells. Initially after low multiplicity infection of cell monolayers, the cytopathic effect is manifested by the formation of syncytia that may contain up to 20 or more nuclei. Subsequently syncytia lift from the substrate, leaving punctate holes in the cell monolayer. Identification methodologies for virus isolates include immunostaining of fixed infected cells, neutralization with specific antisera, PCR of culture supernatants, and electron microscopy (Daniels 2001).

Immunohistochemistry

Where infected animal or human tissues are available, immunohistochemistry using specific anti-henipavirus antibodies is sometimes useful to confirm the diagnosis (Ong 2015). In NiV infections there is a wide range of tissues in which viral antigen can be detected (Daniels 2001), since the primary pathology occurs in the vascular endothelium. However, this method has been more frequently reported for detection of HeV than NiV infections.

Summary and challenges

Table 3 provides an overview of the advantages and disadvantages of the different technologies used for diagnosis of NiV, and table 4 provides a summary of the techniques available in various laboratories for diagnosis of NiV infections. Despite the very narrow geographical distribution of the disease, a variety of diagnostic tools have been made available by various laboratories.

Table 3. Summary of advantages / disavantages of the main NiV assays (for diagnosing human infections)

Technique	Advantages	Disadvantages
ELISA (IgM)	May provide Nipah diagnosis if performed between 4 days and 3 months after exposure	
ELISA (IgG)	May provide Nipah diagnosis	Requires a second serum sample (convalescent serum)
Nucleic acid-based assays	Becoming the clinical diagnostic standard Performed rapidly	
Viral culture	Virus isolation important when a new case or outbreak occurs	Requires too much time to be of use in clinical setting Requires BSL4 precautions

Table 4. Overview of diagnostic tests developed in various laboratories
(adapted from Kulkarni 2013)

Technique	Assay	Laboratory
ELISA (detection of viral antigen)	Antigen-capture ELISA using antibodies produced by DNA immunization	CDC, USA
	Antigen-capture ELISA using antibodies produced by DNA immunization	Nat. Inst. Inf. Dis., Japan
	Monoclonal antibody-based antigen-capture ELISA	CDC, USA
ELISA (detection of IgM and IgG)	Solid-phase blocking ELISA	DVS, Malaysia
	Indirect ELISA based on E coli-expressed N	Chinese Nat. Diagn. Center for Exotic Animal Dis.
	Indirect IgG ELISA based on recombinant N	Institute Trop. Med., Japan
	IgM capture ELISA based on recomb. N	Institute Trop. Med., Japan
Luminex	Binding assay	CSIRO, Australia
	Receptor inhibition (blocking) assay	CSIRO, Australia
Neutralization	Plaque assay	CSIRO, Australia
Pseudotype neutralization	VSV pseudotypes expressing NiV F /G	CDC, USA
	VSV pseudotypes expressing NiV F /G	Nat. Inst. Inf. Dis., Japan
	VSV expressing secreted alkaline phosphatase pseudotyped with NiV F/G	Nat. Inst. Inf. Dis., Japan
Immunohistochemistry	Monoclonal antibody-based immunohistochemistry	Nat. Inst. of Animal Health, Japan
PCR	Real-time RT-PCR (Taqman) using primers in N gene	Institut Pasteur, France
	Real-time RT-PCR (Taqman) using primers in P gene	Inst. of Zoology, UK
	SYBR Green assay using primers in N gene	Inst. of Zoology, UK
	Duplex nested RT-PCR (bat urine specimen)	Chulalongkorn Uni. Hosp., Thailand
	Taqman array card (multiplex)	CDC, USA
Virus culture	Plaque assay	CSIRO, Australia

Many countries in the South-East Asia region did not have adequate facilities for diagnosing the virus when the first outbreaks occurred. However, Bangladesh, India and Thailand developed laboratory capacity and addressed this issue. For instance, a Nipah laboratory was set up in Bangladesh (IEDCR) for safe specimen handling and testing by ELISA to identify IgM and IgG antibodies against NiV (Rahman 2012). In India, a BSL4 laboratory at National Institute of Virology (ICMR), Pune, has prepared to diagnose NiV in the country. The OIE Reference Laboratory for Henipaviruses in Asia–Pacific region is located at Australian Animal Health Laboratory, Geelong, and the High Security Animal Disease Laboratory, in Bhopal, with BSL3 + facility caters the need for exotic animal disease diagnosis (Kulkarni 2013).

Of note, NiV diagnostic tests have to be deployed under a range of circumstances: they are involved in studies of the natural history of infections, diagnosis of the disease in pigs; in special circumstances they may facilitate international trade in known susceptible species and they are a key to the diagnosis of human infection and disease. An additional constraint is that diagnostic technologies should be appropriate to resource-limited environments (Wang 2012).

NiV diagnostic validation studies are still lacking to fully characterize the performance of available assays. In particular, assay cross-reactivity appears as a largely unaddressed topic. The antibody cross-reactivity between HeV and NiV can be expected to decrease NiV assay specificity. However, in some instances, assays providing wide coverage, across all henipaviruses, may be desirable. Surveillance studies indicated the presence of a diverse group of henipavirus or henipa-like viruses in bats at different geographic locations around the world, from Australia, Southeast Asia to China, Madagascar, and West Africa. It is highly possible that any of these bat viruses have the potential to spill-over into other mammalian hosts, including human, and cause diseases. These viruses may induce cross-reactive, but not cross-neutralizing, antibody responses against known henipaviruses (Wang 2012).

Gap analysis: Diagnostics

What are the sensitivity and specificity of current ELISA IgM assays?

Due to the high case fatality rate associated with NIV infections, and the risk of human-to-human transmission, accurate tests, with very high levels of both sensitivity and specificity are needed. The consequences of false negative or false positive assay results are indeed difficult to manage. Available data remain insufficient to determine whether available tests have adequate performance for optimal diagnosis of human NiV infections. Detection of IgM by ELISA has been most widely applied in the context of the latest outbreaks in Bangladesh. However, very limited information has been disclosed about the performance of these assays. Laboratories seem to be more concerned by a possible lack of assay specificity than sensitivity, as IgM ELISA positive results are usually reported to be confirmed by another method (Sazzad 2015, Homaira 2010, Gurley 2007).

Laboratories offering henipavirus testing pay detailed attention to quality assurance issues, but NiV disease may occur in remote locations without ready access to sophisticated laboratory facilities, and therefore reproducible diagnostic test accuracy can sometimes be challenging to deliver at the point of care (Wang 2012). Continued efforts are therefore needed to ensure better access to suitable diagnostics in all areas where NiV outbreaks are likely to occur.

Future directions for research in NiV diagnostics should include assay validation vs. international reference standards (RNA, antibody), point-of-care diagnostic development, and expansion of multiplex assays to distinguish Nipah from other diseases with similar clinical presentations.

Therapeutic interventions

Antiviral drugs

Ribavirin and chloroquine

Ribavirin is a guanosine analogue and broad spectrum nucleoside antimetabolite antiviral drug which features on the WHO Essential medicines list. An inhalation solution of ribavirin is also indicated for the treatment, in young children, of severe lower respiratory tract infections due to respiratory syncytial virus, another paramyxovirus. During the NiV outbreak in Malaysia in 1998/99, ribavirin was given empirically to treat 140 patients. The trial was not randomized. Patients who were managed prior to the availability of ribavirin or refused ribavirin were taken as controls. There were 45 deaths in the treated group (32%) and 29 in the controls (54%), corresponding to 36% reduction in mortality (Chong 2001). On Cox regression analysis, younger age and use of ribavirin were independently associated with better survival (p = 0.011 and 0.013, respectively). To our knowledge, this is the only available report on the efficacy of ribavirin in patients. In subsequent animal studies, ribavirin was found to only delay NiV disease and death (reviewed by Ong 2015, Broder 2013, Steffen 2012).

Ribavirin was also tested in combination with the antimalarial drug chloroquine. Chloroquine was indeed shown early on to block the critical proteolytic processing needed for the maturation and function of the HeV F glycoprotein (Pager 2004), and later shown to inhibit NiV infection in cell culture (Porotto 2009). However, in vivo data proved disappointing. Chloroquine did not protect hamsters when administered either individually or in combination with ribavirin (Freiberg 2010).

Other antiviral drugs

In view of the questionable efficacy of ribavirin and/or chloroquine and the severity of NiV infections in people, considerable effort has been spent in developing and exploring new therapeutic options against henipaviruses. Such research has primarily focused on targeting the fusion and entry steps of the virus infection process, as done by F glycoprotein-targeted peptide fusion inhibitors. A 36 amino acid **HR2-based fusion inhibitor** (NiV-Fc2), analogous to the approved HIV-specific therapeutic peptide enfuvirtide, has been proposed as a specific therapy against henipaviruses (Steffen 2012).

Subsequent studies focused on peptide optimization, leading to the identification of the cholesterol tagged hPIV3-based HR2-derived peptide as a promising candidate (Porotto 2010). Such cholesterol-tagged peptides could penetrate the CNS and exhibited some effective therapeutic activity against NiV infection in the hamster model. However, relatively large amounts of HR2-cholesterol peptides (2 mg/kg) were needed to achieve 60% or less survival of hamsters infected with NiV, when administered simultaneously or prior to NiV inoculation.

Nearly two decades of research on the molecular mechanisms of membrane fusion have not resulted in the identification of a lead candidate with successful proof of concept data in an animal model of NiV infection

Additional studies were conducted more recently in view of better understanding the properties underlying the peptides' potency (Mathieu 2017). The observation of direct correlation between the length of the linker, the antiviral effect of the molecule and its protease sensitivity (leading to decreased stability in vivo) illustrates the major challenges remaining to be addressed by this type of research.

Small-molecule nucleoside inhibitors have also been evaluated against NiV. Very recently, Hotard (2017) evaluated 4'-Azidocytidine (R1479), an antiviral initially developed for hepatitis C therapy, against a range of paramyxoviruses and reported similar levels of in vitro activity against henipaviruses as against flaviruses.

Other candidate drugs evaluated in vitro for their activity against henipavirus infections include cationic compounds and calcium influx inhibitors (Aguilar 2011).

Biologicals

Convalescent plasma

The recent pathogen outbreaks, such as Ebola viral disease or Middle East respiratory syndrome coronavirus, have renewed attention to convalescent plasma and immunoglobulins. In case of severe disease, when no treatment with a proven record of safety and efficacy is available, they may appear as the only available therapeutic option. However, convalescent plasma has not been investigated clinically during outbreaks of NiV infections, and research efforts are rather focused on monoclonal antibodies.

Monoclonal antibodies

Poly-IC12U has not reached 100% protection in the hamster model of NiV infection. Can it be considered a promising drug candidate?

Data from the phase 1 trial of m102.4 will help estimate its therapeutic window, and the future commercial cost of a treatment

Monoclonal antibodies targeting the surface glycoproteins of HeV have shown efficacy against both HeV and NiV as pre- and post-exposure prophylaxis in animal models, but since these antibodies must be administered before the onset of clinical signs, they are unlikely to be useful for treating symptomatic patients, while probably beneficial for post-exposure prophylaxis in potentially exposed individuals (Satterfield 2015). Presently, the only reported and most promising post-exposure therapy against NIV infection is a human monoclonal antibody known as m102.4, which was isolated from a recombinant human phage-displayed Fab library (reviewed by Broder 2013).
The m102.4 mAb has exceptionally potent neutralizing and cross-neutralizing activity against both NiV and HeV viruses and its epitope maps to the ephrin receptor binding site. Testing of m102.4 has confirmed its neutralization activity against several isolates including NiV-M and NiV-B. Effective post-exposure efficacy with m102.4 has been demonstrated in both ferrets and NHPs (AGMs) infected with either HeV or NiV. Of note, a study conducted in AGMs confirmed the higher pathogenicity and lethality of NiV-B compared to NIV-M, and showed that the therapeutic window for m102.4 was much shorter with NiV-B than NiV-M, with all animals succumbing to NiV-B infection if treated later than on days 3 and 5 post inoculation (Mire 2016).

Over the past years, eleven human subjects have been reported to receive high-dose m102.4 therapy on an emergency use basis because of high-risk exposure to HeV in Australia (10 people) or NiV in the United States (one person), and all have remained well with no associated adverse events (Broder 2013). A phase 1 clinical trial has been initiated for this product in April 2015 in Australia in a total of 40 subjects (5 groups of 8 subjects receiving 1 or 2 intravenous infusion(s) of different doses of m102.4) (https://www.anzctr.org.au/Trial/Registration/TrialReview.aspx?id=368110&isReview=true). Assessments include safety/tolerability, pharmacokinetics and immunogenicity parameters. To our knowledge, the outcome of this trial has not been disclosed yet, but the results will be essential for determining the feasibility of using such monoclonal antibody for pre- or post-exposure prophylaxis.

Host directed interventions

Immunomodulators

The innate immune response to NiV infection is thought to alter the pathogenic process that is induced, offering the option of a therapeutic approach based on immunomodulation. A derivative of synthetic polyinosinic:polycytidylic acid (poly-IC12U or Rintatolimod), an analogue of double-stranded RNA which strongly activates IFN production, has been shown effective in limiting disease and increasing survival of NiV-infected hamsters. When administered at 3 mg/kg of body weight daily from the day of infection to 10 days post-infection, prevented mortality in 5 of 6 infected animals (Georges-Courbot 2006). This drug candidate is not new. It was evaluated clinically as early as in the 1980s, and at that time associated to significant toxicity (with adverse events such as fever, arthritis, liver toxicity, thrombocytopenia, or neurotoxicity). Nevertheless, poly-IC12U underwent further clinical development for chronic fatigue syndrome, with more than 90 000 doses administered, and these trials concluded in an acceptable safety profile (Mitchell 2016). Poly-IC12U may thus hold promise for Nipah therapy.

Another strategy, targeting the activation of IRF3-dependent signalling mechanisms with small molecule agonists, has been proposed more recently by Pattabhi (2016), but so far it has not advanced beyond a very early stage of development.

Adjunctive therapies

As for other severe diseases of viral origin, aggressive supportive care may help improve patient survival. NiV infections, especially as seen in Bangladesh, are associated to respiratory disease and respiratory failure. Oxygen supplementation and eventually transfer to ICU are part of the management guidelines of this infection. Ensuring patient access to the best medical practices in this area should remain a priority.

Gap analysis: Therapeutics

Without any other currently available therapeutic options, ribavirin is still considered today as an option for treatment of NiV infections in emergency settings, but its impact on disease progression is highly questionable. Research on alternative treatments appears therefore as critical. Numerous studies have uncovered determinants important for various steps in the NiV replication cycle. While each step of the replication process represents a potential target for the development of antiviral drugs, most efforts have been focused on the mechanisms leading to productive membrane fusion. Until now, such research has not resulted in the identification of many promising candidates, and none of them has been reported successful in an animal model of NiV infection.

The most advanced alternative treatment under development is a monoclonal antibody, m102.4, which was identified by panning a large nonimmune antibody library against the HeV glycoprotein G. This monoclonal antibody was then affinity maturated, converted to IgG1 and proved highly neutralizing against NiV (Zhu 2008). It has now reached clinical phase 1 evaluation. Following high-risk NiV exposure or cases of infection in India or Bangladesh in recent years, there has been an interest in compassionate use of the m102.4 antibody, which was found difficult to orchestrate as the product was still at a preclinical stage of development. A possible strategy for access to this therapy would be to further develop, manufacture and stockpile the antibody so as to deploy it rapidly when and where another outbreak occurs (Broder 2013). However, more data from clinical studies will be required to determine what could be the indication and usage of this monoclonal antibody.

Another therapeutic approach may be based on immunomodulation, as suggested by the efficacy of poly-IC12U in the hamster model of NiV infection. However, for a better understanding of the probability of success of this approach, poly-IC12U should be evaluated in the same AGM model as used for the m102.4 antibody.

Overall, the development of therapies against NiV infections remains at a very early stage. Research efforts in this area should be encouraged, especially when considering the high case fatality rate associated to NiV infections and the risk of a large outbreak occurring in the future. One may also consider that antiviral drugs usually have the potential for broad virus coverage, so that progress made on NiV research can be expected to bring additional benefits for the management of other henipa- or paramyxovirus infections.

Vaccines

All R&D activities for NiV vaccines are in the pre-clinical stage. Many vaccine candidates including different live recombinant vaccine and subunit vaccines have been produced and tested in various animal models including hamsters, pigs, cats, ferrets and AGMs. These vaccines are based on the F and/or G glycoproteins, and essentially target the induction of NiV neutralizing antibodies, as done with other human paramyxovirus vaccines such as mumps or measles vaccines.

Despite the high level of identity between NiV-M and NiV-B, shouldn't a vaccine be based on Niv-B sequences rather than NiV-M?

Live-attenuated vaccine candidates (reassortant/recombinant)

Due to the extreme lethal nature of NiV, producing a safe, live attenuated vaccine with no potential of reversion is generally considered a difficult approach, although recombinant-derived NiV mutants have been produced that are attenuated in hamster and ferret models. A live-vectored vaccine approach has been preferred.

Vaccinia virus-derived vectors

The first vaccination and challenge experiments were carried out with NiV in the hamster model using recombinant vaccinia viruses (Guillaume 2004). NiV F and G encoding recombinant vaccinia viruses (highly attenuated NYVAC strain) were examined individually and in combination. All animals were completely protected following intraperitoneal NiV challenge, regardless of whether they were immunized with the G or F or both vaccinia virus recombinants. Of note a humoral anamnestic response was observed following virus challenge suggesting that vaccine-induced immune responses did not prevent virus replication, i.e. sterile immunity was not induced. As passive transfer of antisera from vaccinated animals also demonstrated protection, a major role of specific neutralizing antibody in protection was inferred. Subsequently, a recombinant canarypox (Alvac)-based candidate, another highly attenuated vaccinia virus vector suited to veterinary applications, was also tested successfully in a pig model of NiV infection (Weingartl 2006).

Vesicular Stomatitis Virus Vectors

The most studied vectored vaccine candidate is the VSV vector, which uses a similar strategy to that being employed in the Ebola virus vaccine candidate in current clinical trials. However, the VSV vector used has not been identical among studies (reviewed by Satterfield 2016). Three types of vaccines can be distinguished : replication-incompetent VSV pseudotypes expressing NiV G or F proteins (Lo 2013), VSV virions with F and G that can undergo a single round of replication (produced by co-infection of two VSV pseudotypes, one expressing F and one expressing G, which generates a chimeric virus pair that expresses both VSV F and G on the virus surface) (Mire 2013, Chattopadhyay 2011), and replication competent VSV recombinants, where the VSV-G is replaced in the vaccine vector by the Ebola GP so as to overcome the lack of a functional surface protein for virus entry (DeBuysscher 2014).

A study tested the protective efficacy of the replication competent VSVs expressing either N, F or G of the Malaysian strain of NiV. Following a single dose administration, the vaccine vectors expressing G and F fully protected Syrian hamsters from lethal NiV challenge, whereas the N expressing vector conferred only partial protection (DeBuysscher 2014). Another study in AGMs confirmed the protective capacity of the same recombinant virus expressing the G protein of NiV (rVSV-EBOV-GP-NiV-G) (Prescott 2015). Interestingly, in the hamster model, this candidate, when used for single-dose vaccination 1 day before challenge, reduced viral load, limited pathology and fully protected hamsters from NiV infection. The vaccine was even partially protective when administered at early time points following challenge with NiV, suggesting the potential of the vaccine in an outbreak setting or for post-exposure prophylaxis. Moreover, induction of cross-protection between NiV-B and NiV-M has been demonstrated for another VSV-vectored vaccine (single round replication) in AGMs (Mire 2013).

Hence, VSV recombinant vaccines may appear as the most promising vaccine candidates for Nipah. However, a recent toxicity study conducted in mice (Van Den Pol 2017) pointed to a significant safety concern of neurotropism for such recombinant vaccine. A combination of VSV recombinant viruses expressing both Nipah F and G (as described by Mire 2013 and Chattopadhyay 2011) was indeed found even more neurotropic than wild-type VSV after intracranial injection, evoking a rapid lethal response in the adult brain. The observation is in contrast with an earlier study that showed that both the VSV-Ebola and VSV-Lassa viruses were devoid of neurotropic actions in mice and rats, and suggests that a vaccine expressing a single NiV glycoprotein should be preferred over a combination of F and G.

Measles Virus vector

Live-attenuated measles vaccines have been used since the 1960’s worldwide, and have appeared as attractive candidates for development of vectored vaccines. In particular, measles virus induces strong cellular immunity and durable responses. A concern related to the use of a measles vector is due to the possible negative effect of pre-existing immunity in human populations on the immunogenicity of such vector vaccine. Nevertheless, the vaccine has been considered to offer the potential to elicit long-term immunity against both MV and NiV, and has been proposed as a way to reach general childhood vaccination against NiV. The pathway of clinical development for such combination vaccine remains largely unclear, and most likely would require too significant investments to appear as a feasible strategy. In any case, protection data in AGMs for this candidate have appeared suboptimal, as after 2 injections of the vaccine, animals were not protected against the brain lesions induced by NiV challenge (Yoneda 2013).

The neurotropic nature of a VSV vaccine expressing both F and G is a critical safety concern

Venezuelan Equine Encephalitis virus vector

A replicon vaccine vector system was developed from an attenuated strain of Venezuelan equine encephalitis virus (VEE). Alphavirus replicon vectors offer several potential advantages as vaccine delivery systems. They typically express heterologous genes to high levels and induce self-limiting infection. Replicons expressing HIV or cancer target antigens have been evaluated in human subjects, and some promising data generated. A VEE-vectored NiV vaccine candidate has been evaluated in mice and found to induce NiV neutralizing antibodies following a 3-dose vaccination schedule (Defang 2010). To date, the protective potential of this vaccine candidate remains unknown.

Adeno-Associated Virus

Adeno-associated viruses are probably more popular as gene-therapy vectors than vaccine platforms. Nevertheless, a number of AAV-based vaccine candidates have been shown to induce promising data in animal models. Ploquin (2013) demonstrated that a single injection of the AAV8-NiV.G vector is sufficient to protect the hamsters against lethal challenge with NiV.

Subunit vaccines

A subunit vaccine incorporating recombinant glycoprotein G has been approved as a veterinary vaccine for HeV in Australia in 2015. This vaccine is formulated using glycoprotein G with a proprietary immunostimulatory complex adjuvant. Currently, the vaccine is administered to horses by the intramuscular route as two immunizations, three to six weeks apart followed by boosting six months later. The effectiveness of this vaccine in horses suggests this approach may also be of interest in humans (Satterfield 2015). Various formulations of an experimental subunit G vaccine against Nipah have been evaluated successfully in animal models, including AGMs, confirming the potential of this type of vaccine. Some of these studies, with challenge performed up to more than a year after vaccination, demonstrated the durability of protection induced by these vaccine.

HeV is a zoonotic infection affecting horses and humans in Australia. A vaccine has been made available for horses in 2012 (Broder 2013). Horse owners in Australia are encouraged to vaccinate their horses to both reduce the risk of HeV infection, and to prevent potential transmission to humans. Vaccine uptake has been limited though, with an estimated 11-17% of horses in Australia vaccinated (Manyweathers 2017). Spill-over events of HeV in horses continue to occur.

NiV virus-like particles (VLPs) have also been obtained by co-expression of the G, F and M proteins under optimized conditions. They appeared as an alternative vaccine candidate, especially in view of their ability to induce a neutralizing antibody response in mice (Walpita 2011).

A vaccine candidate requiring multiple injections does not seem very compatible with the targeted indication for at-risk persons in the area of an ongoing outbreak

Vaccine summary

Table 5 below presents the various vaccine candidates evaluated in preclinical models.

Table 5. Nipah vaccine candidates with preclinical data (adapted from Satterfield 2015)

Candidate name/ identifier & institution	Efficacy or immunogenicity data in animal model	Developer	Reference
VV-NiV.F and/or G	100% protection in hamster model, following 2 vaccinations (1 month apart) starting 4 months before challenge	INSERM	Guillaume 2004
ALVAC-F/G*	100% protection in pig model, no evidence of clinical illness, following 2 vaccinations (14 days apart) starting 28 days before challenge	CFIA-NCFAD	Weingartl 2006
VSV-NiVM F and G	High neutralizing antibody titers induced in mice following single intranasal vaccination	Yale University	Chattopadhyay 2011
VSV-NiVB F and/or G	100% protection in ferret model, no evidence of clinical illness, following single vaccination 28 days before challenge	UTMB	Mire 2013
VSV-NiVM F or G	100% protection in hamster model, no evidence of clinical illness, following single vaccination 32 days before challenge	CDC	Lo 2014
rVSV-EBOV-GP-NiV-G	100% protection in hamster model following single-dose vaccination 1 day before challenge	RML	DeBuysscher 2014
	100% protection in AGM model following single-dose vaccination, 29 day before challenge		Prescott 2015
rMV-Ed-G	100% protection in hamster model, no evidence of clinical illness, following 2 vaccinations (21 days apart) starting 28 days before challenge	UoT	Yoneda 2013
	100% protection in AGM model, but no protection against infection (pathological changes observed in brain), following 2 vaccinations (28 days apart) starting 35 days before challenge		
V-NiVG (VEE)	High neutralizing antibody titers induced in mice following 3 vaccinations at weeks 0, 5 and 18	USU	Defang 2010
AAV-NiVM G	100% protection in hamster model, no evidence of clinical illness, following single vaccination 32 days before challenge	INSERM	Ploquin 2013
rLa-NiVG and/or rLa-NiVF**	High neutralizing antibody titers induced in pigs following 2 vaccinations (4 weeks apart)	CAAS-SKLVB	Kong 2012
HeV sG (subunit) + CpG	100% protection in ferret model, no evidence of clinical illness, following 2 vaccinations (20 days apart) 20 or 434 days before challenge	Zoetis, Inc. /USU	Pallister 2013
HeV sG (subunit) + Alum + CpG	100% protection in AGM model, no evidence of clinical illness, following 2 vaccinations (21 days apart) starting 42 days before challenge		Bossart 2012
	100% protection in cat model, no evidence of clinical illness, following 2 vaccinations (21 days apart) starting 42 days before challenge		McEachern 2008
HeV sG (subunit) + Quil A + DEAE-dextran + Montanide	100% protection in cat model, no evidence of clinical illness, following 3 vaccinations (14 days apart) starting 104 days before challenge		Mungall 2006
VLPs (F/G/M)	High neutralizing antibody titers induced in mice following 3 vaccinations at weeks 0, 2 and 4	UTMB	Walpita 2011

** Canarypox vector, suited to veterinary applications*

*** Newcastle Disease Virus vector, suited to veterinary applications*

Abbreviations: USU (Uniformed Services University of the Health Sciences); UTMB (University of Texas Medical Branch); CDC (Centers for Disease Control and Prevention); RML (Rocky Mountain Laboratories); TJU (Thomas Jefferson University); CFIA-NCFAD (Canadian Food Inspection Agency – Centre for Foreign Animal Diseases); Institut national de la santé et de la recherché médicale (INSERM); UoT (University of Tokyo); CAAS-SKLVB (Chinese Academy of Agricultural Sciences (CAAS) – State Key Laboratory of Veterinary Biotechnology (SKLVB).

Another summary of the present status of knowledge associated to the different vaccine candidates under evaluation for Nipah considers the advantages and disadvantages of these vaccines platforms, as shown in Table 6 below.

Table 6. Advantages and disadvantages of the different vaccine platforms under evaluation for Nipah (human vaccination)

Platform	Advantages	Disadvantages
Vaccinia-based vectors	Promising data in animal models of protection MVA strain well known in humans	2-dose schedule Concerns linked to anti-vector immunity
VSV-vectored vaccines	Promising data in animal models of protection Efficacy in animals vaccinated 1 day prior to challenge Platform used successfully in the context of an Ebola outbreak Single dose schedule	Neurotropism issue identified with vector expressing a combination of F and G
Measles-vectored vaccine	Promising data in animal models of protection Vector consisting of the measles vaccine strain	2-dose schedule Suboptimal protection observed in AGM model Pre-existing immunity against the vector in human populations
VEE replicon	Self-limiting infection Phase 1 clinical data available for VEE combined with HIV or prostate antigen	No protection data in NiV challenge model available 3-dose schedule
Subunit vaccine	Promising data in animal models of protection Expected safety	Need for an adjuvant, impacting perception of safety and potentially complicating clinical development Need for several injections less compatible with use in emergency setting

Gap analysis: Vaccines

As of today, no NiV vaccine candidate has advanced to a clinical phase of development. Consequently, it remains difficult today to assess the likelihood that any of these candidates will demonstrate characteristics compatible with the Target Product Profile developed by WHO in June 2017 for a Nipah vaccine (http://www.who.int/blueprint/priority-diseases/key-action/nipah/en/). Nevertheless, the probability of success of a vaccine against Nipah is expected to be very high. Other related paramyxoviruses, such as measles and mumps viruses, yield long-term immunity after natural infection, and live attenuated vaccines have been developed that have been used safely and effectively against these pathogens for decades. It has also been suggested that the likelihood of success of viral vaccines targeting viruses with average incubation periods of at least 5–7 days, as seen with NiV, is higher than that of vaccines for viruses with shorter incubation periods. In addition, various candidate vaccine platforms have demonstrated the feasibility of using one or both of the NiV glycoprotein (G) and fusion (F) protein as the antigen(s) to stimulate a protective immune response in various preclinical challenge models including hamsters, cats, ferrets, AGMs and pigs. Little or no clinical signs of disease were observed in vaccinated animals after NiV challenge, and protection against mortality often reached 100% (Satterfield 2016).

One of the most promising vaccine candidates is a VSV-G recombinant. In the hamster model, this vaccine was found protective following single-dose vaccination 1 day before challenge, suggesting the potential of this product for use in an emergency setting. However, despite encouraging efficacy data in animals, the proof of concept of such vaccine is still far from being established, as evidenced by the recent observation of a neurotropic effect with a VSV vector system expressing both NiV F and G. Another candidate of interest is a subunit vaccine containing adjuvanted recombinant G glycoprotein. The success of such vaccine candidate in experimental animal models of NiV infection and the use of Equivac HeV® as an effective subunit vaccine in horses suggest this approach may also be efficacious in humans (Satterfield 2016). However, the requirement for a multiple-dose schedule of immunization with this type of vaccine does not appear very compatible with the targeted indication for immunization of at-risk persons in the area of an ongoing NiV outbreak.

In any case, the epidemiology and sporadic nature of NiV outbreaks will make large scale clinical efficacy trials very difficult to organise, so that the pathway towards licensure for a Nipah vaccine will most likely require creative approaches. Specific opportunities, such as the procedure for Emergency Use Assessment and Listing (WHO EUAL), to facilitate access to critically needed vaccines in case of emergency are likely to be of help. In the USA, the Food And Drug Administration's Animal Rule pathway is intended to enable approval of drugs against highly lethal infections in situations where definitive human efficacy studies cannot be conducted (Satterfield 2016). In this instance, efficacy is to be demonstrated via protection in one or two experimental animal models that replicate key characteristics of the human disease and are predictive of the mechanism of protection in humans. The AGM, ferret, and hamster models are well established and accurately model human disease. However, no vaccines have been approved through this mechanism to date. And even with the Animal Rule, human clinical trials are still required for demonstrating vaccine safety.

The key issues with vaccines are delivery and costs (Hayman 2014). The question of how to finance such product development has to be raised, as a NiV vaccine would likely find use primarily in the low and middle income countries where the virus is currently endemic. In view of the current low disease incidence, a reasonable objective may be to advance the development of a vaccine candidate to early phases of clinical development, which would aim at better preparing for a potential epidemic of larger size. In parallel, it would be important to clarify expectations for a NiV vaccine. Answering questions such as "what role could a NiV vaccine play in controlling the disease? with what cost/effectiveness?" would help define the best way forward in terms of vaccine research and development.

Vector Control

The NiV outbreaks in Malaysia in 1998-1999 have been associated with infection of pigs with subsequent spread to human populations, while the outbreaks in Bangladesh resulted from direct contamination from infected fruit bats and human-to-human transmission. Theoretically, vector control efforts may target these 2 species. In any case, a transdisciplinary approach will be required to develop appropriate host management strategies that both maximise the conservation of bat populations as well as minimise the risk of disease outbreaks in domestic animals and humans (Breed 2006).

Pigs

NiV was first described following the 1998-1999 outbreaks of disease in pigs and humans in peninsular Malaysia. Over one million pigs were culled to contain the outbreak (Breed 2006), which had an enormous economic and social impact. To date, no other disease outbreak has been observed in this animal species, but following an outbreak of NiV observed in horses in 2014, the potential for new spill-over into swine can be considered as threatening. Vaccinating pigs has been proposed as a means to prevent spread to human populations, but it is also a veterinary option, aimed at protecting swine herds in the event of a new outbreak. As of today, a swine vaccine against NiV is not available, but promising results have been obtained with the canarypox vectored vaccine candidate and R&D efforts targeting the development of a veterinary vaccine against Nipah are still ongoing.

Bats

(adapted from Breed 2006)

Management of a bat-borne zoonotic disease has been previously attempted for rabies virus. Historically, population reduction was used as a control strategy for vampire bats in Latin America. The methods used at that time are now generally considered inhumane, unethical and ineffective and some of the targeted species have become endangered in their natural environment. Trap, vaccination and release programs using parenteral vaccination have been employed for rabies control of a few terrestrial wildlife species, but this approach is considered prohibitively expensive for large populations and logistically impossible for non-terrestrial species. An oral vaccine has been shown capable of inducing a protective immune response to rabies in vampire bats following oral vaccine delivery, and hence an oral vaccination approach may be plausible for other bat species. However, such program would be very ambitious. A specific vaccine would have to be developed, including a biomarker for discriminating between vaccinated and naturally infected individuals (Mackenzie 2003). Moreover, various aspects of bat ecology and behaviour would require further study before an oral vaccine, suitable bait and vaccination strategy can be deployed. The feasibility of using a NiV vaccine in wild bats for controlling outbreaks in human populations is still far from being established.

General conclusion and recommendations

This document gathers available data pertaining to NiV epidemiology, diagnostics, as well as vaccines, therapeutics and other methods for prevention and control. It identifies research and knowledge gaps which are meant to be used as a basis for discussion on the development of a NiV R&D roadmap.

Nipah is one of eleven diseases considered as in urgent need of R&D attention in the revised priority list of pathogens issued by WHO in January 2017 (http://www.who.int/blueprint/priority-diseases/en/). Since 2001, it has caused almost annual outbreaks in Bangladesh, and the infection has been associated to a case fatality rate of up to 100%. Nipah is a zoonotic disease. As its reservoir, the Pteropus bat, has a flying range that can cover huge areas, the risk of further spread of the disease is perceived as very high.

Since the first identification of the virus in 1999, significant efforts have already been devoted to development of diagnostic methods, outbreak preparedness and response as well as epidemiological surveillance. The outcome of research has been impressive as well, in terms of characterizing the virus, elucidating its mechanisms of replication, identifying strategies for development of novel therapies and conducting preclinical studies for an array of vaccine candidates.

However, more progress is still needed to offer the most adequate tools for controlling Nipah. In terms of diagnostics, validation of methods and standardization across laboratories would improve currently available tests. Moreover, it would be useful to further invest in strategies that can facilitate access of patients to suitable diagnostics in all areas where NiV outbreaks are likely to occur.

In terms of therapies, animal models have suggested that the m102.4 human monoclonal antibody can prevent NiV infection and/or disease. The antibody is being developed for human use as both a NiV and HeV.countermeasure. Clinical data are still required to define how m120.4 would be used in patients (pre- or post-exposure), and what would be the cost of a treatment. It has been suggested that pre-positioning of the product in NiV endemic areas would facilitate access to this therapy in the event of another outbreak. However, the feasibility of such stockpiling would largely depend on international cooperation and financial support (Broder 2013).

Research on alternative therapeutic candidates should also be encouraged. An advantage of antivirals and immunomodulators compared to biologicals is their expected breadth of coverage. While NiV infections are the focus of this report, therapies that would also prove efficient against other henipaviruses appear as highly desirable.

Among the different vaccine candidates tested in preclinical models, VSV recombinant viruses appear as the most promising. However, the neurotropic potential of such vaccine should be investigated in detail before the product can be advanced to a clinical phase of development. Alternative vaccine approaches may also built on the experience gained with the subunit vaccine againt HeV.

Finally, an essential strategy for controlling Nipah should focus on preventing virus transmission from bats to humans. Controlling the virus in its wild reservoir does not seem a feasible approach. However, establishing or reinforcing surveillance systems is of utmost importance to ensure that NiV outbreaks can be detected quickly and appropriate control measures promptly initiated. Also essential are the efforts on behaviour change communication interventions, so as to increase awareness on the risks associated with this virus.

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:** This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting. This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India; associated case fatality rates in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary NiV sources being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B).

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition for industry and international philanthropic public-private

partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities have very rudimentary laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials, is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regarding the feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with local government authorities in endemic and at-risk areas to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1)

determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3) determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies. More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.
3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.

4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobank of human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.

- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiV diagnostic tests for use in humans and animals that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV_M and NiV_B are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies and clinical trials as appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccines for use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV$_M$ and NiV$_B$ in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.

Commented [MGN1]: Perhaps needs to be changed to be inclusive of all NiV strains

- Guidance on use of NiV vaccines (or broader henipavirus vaccines) to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.

Commented [MGN2]: Perhaps add, "including special populations such as elderly, immune-compromised, and pregnant individuals"

- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV$_M$ and NiV$_B$, including recent strains; only a few studies demonstrating cross-protection have been performed to date.

Commented [MGN3]: All NiV strains

- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than

one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possible strategies for vaccine use.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deploy NiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluating NiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:** This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting. This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India; associated case fatality rates in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary NiV sources being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B).

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition for industry and international philanthropic public-private

partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities have very rudimentary laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials, is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regarding the feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with local government authorities in endemic and at-risk areas to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1)

determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3) determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies. More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.
3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.

4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobank of human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.

- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiV diagnostic tests for use in humans and animals that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV_M and NiV_B are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies and clinical trials as appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccines for use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines (or broader henipavirus vaccines) to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B, including recent strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than

one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.

- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possible strategies for vaccine use.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deploy NiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluating NiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

---

Hello Kris,
I found the document very inclusive of the ideas discussed at the meeting. I don't have any substantive changes to suggest for the majority of the document but had a few suggestions for the vaccine section. The document is very nicely done.
Gregg

Subject: Revised Nipah virus R&D roadmap for taskforce review and comment--please send written comments by April 25
Importance: High

Dear Nipah Virus R&D Roadmap Taskforce members:

Attached please find a revised version of the Nipah virus R&D roadmap for your review. This version incorporates comments made during the in-person consultation in early March, comments we received after the consultation, and recent literature. We also consolidated all of the cross-cutting issues near the beginning of the roadmap.

We would very much appreciate your written feedback/comments on this version **no later than Wednesday April 25.**

We're sending this to you as a Word doc to make editing and commenting easier. We suggest that you cc the whole group when you provide edits/comments—to ensure that you all see each other's perspectives.

Once we incorporate your additional feedback, the next step will be to post the document for public comment. We also plan to begin working on a set of measurable and achievable milestones and will start considering ways to approach the critical path analysis.

Again, we very much appreciate your ongoing support and involvement with this important project.

Warm regards,

Kris

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:** This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting. This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also ~~occurring~~ identified periodically in eastern India; associated case fatality rates during outbreaks in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropus bat species) and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary routes of human NiV ~~sources~~ infection being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely

related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_{M}) and in Bangladesh/India (NiV_{B}).

Commented [EG1]: Nearly all cases in Bangladesh have altered mental status or unconsciousness.

Commented [EG2]: Would be good to provide the year here since there could also be variation within South Asia- which paper is this specifically?

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition for industry and international philanthropic public-private

partnerships are needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities have very rudimentary laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

Commented [EG3]: True, but it is not typically clinically distinguishable from other causes of encephalitis.

- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses for livestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials, is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Commented [EG4]: In Bangladesh, the greater concern from local authorities would be in conducting the phase 1 rather than the phase 2.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regarding the feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with local government authorities in endemic and at-risk areas to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Commented [EG5]: This one is tricky. Nipah is rare. Heightened awareness about the dangers of Nipah lead to patients being turned away, particularly if hospital staff do not feel well trained and equipped to perform required PPE. Education itself will only create fear, unless we can also ensure supplies and ongoing training and support. Local clinics cannot currently diagnose anyway, but they could be trained on how to collect specimens.

Commented [EG6]: Not exactly sure what this means.

Commented [EG7]: Collaboration between local authorities and who? International public health stakeholders? NiV experts?

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, and drivers of infection in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is

essential for development and evaluation of MCMs. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3) determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between NiV$_{B}$ and NiV$_{M}$ infection, as well as differences between strains in Bangladesh, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in NiV$_{B}$ and NiV$_{M}$ pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies. More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.

3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.
4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures and outbreak detection and response. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis, outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species) appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Commented [EG8]: There are now PCR methods that take a few hours on hand held devices. They are expensive, but quick. I think that PCR based techniques could be useful, even given the realities of timeline, but they are expensive in terms of infrastructure and are not currently available in the facilities where patients seek care. Of course, these aren't as easy as rapid tests could be.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobank of human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.

- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of public health concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Commented [EG9]: And, perhaps, and estimate of how many would be sufficient to make this case. Ballpark?

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiV diagnostic tests for use in humans and animals that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.

3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.
4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.

- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV_M and NiV_B are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies and clinical trials as appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccines for use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV$_M$ and NiV$_B$ in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiV vaccines (or broader henipavirus vaccines) to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Commented [EG10]: Enhanced surveillance may be needed to test such vaccines, to have enough cases to power trials.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV$_M$ and NiV$_B$, including recent strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.

- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possible strategies for vaccine use.

Commented [EG11]: And for vaccine trials.

- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock (or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals (that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deploy NiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluating NiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV$_B$ and NiV$_M$ strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.

- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Commented [EG12]: And, improve our chances of being able to test vaccines.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

---

Kris,

Many thanks for your efforts to put this draft together. I think the draft does a great job of summarizing our conversations in London. I've included some comments and suggestions, attached.

All the best,
Emily

Subject: Revised Nipah virus R&D roadmap for taskforce review and comment--please send written comments by April 25
Importance: High

Dear Nipah Virus R&D Roadmap Taskforce members:

Attached please find a revised version of the Nipah virus R&D roadmap for your review. This version incorporates comments made during the in-person consultation in early March, comments we received after the consultation, and recent literature. We also consolidated all of the cross-cutting issues near the beginning of the roadmap.

We would very much appreciate your written feedback/comments on this version **no later than Wednesday April 25.**

We're sending this to you as a Word doc to make editing and commenting easier. We suggest that you cc the whole group when you provide edits/comments—to ensure that you all see each other's perspectives.

Once we incorporate your additional feedback, the next step will be to post the document for public comment. We also plan to begin working on a set of measurable and achievable milestones and will start considering ways to approach the critical path analysis.

Again, we very much appreciate your ongoing support and involvement with this important project.

Warm regards,

Kris

NipahResearch and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:**This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting.This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV)is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported inthese countries since May 1999.NiV infection was subsequently recognized, however,in Bangladeshin 2001 and nearly annual outbreaks have occurred in that country since, with disease also~~ occurring~~ being recognized periodically in eastern India; associated case fatality rates in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropusbatspecies)and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In theoutbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary NiV sources being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely

related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for cases. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness,cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated ~~that two distinct~~multiple strains of NiV. The strain responsible for the outbreak in Malaysia is different from the strains seen in ~~were responsible for the outbreaks in Southeast Asia (NiV$_M$) and in~~ Bangladesh/India (NiV$_B$).

Commented [SPL1]: We have isolated multiple different strains in Bangladesh.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Commented [SPL2]: I recommend spelling out this acronym, so that readers don't need to learn a new acronym to understand the article.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, respond, prevent, and control outbreaks of NiV infection(and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value propositionfor industry and international philanthropic public-private partnershipsare needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities ~~have very rudimentary~~ are primary in nature in terms of laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses forlivestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials,is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be

considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regardingthe feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with ~~local~~ government authorities in endemic ~~and at-risk areas~~countries to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturingto endemic and at-risk areas.

Commented [Mahmudur3]: It will be necessary to involve the development partners who support the countries

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed torefine, standardize, and validate relevant animal challenge models(e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in

supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3)determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between ~~NiV$_B$ and NiV$_M$ infection~~different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in ~~NiV$_B$ and NiV$_M$~~ pathogenesis among different strains of NiV that may have implications for the development of safe and effective NiV vaccines or therapies.More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hostsand pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiVMCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.

3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.
4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

~~4.~~5.

Commented [Mahmudur4]: Consider adding "Enhance disease detection capabilities through active and passive surveillance"

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform**phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV$_B$ and NiV$_M$ pathogenesisthat may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Commented [SPL5]: As noted above, I do not consider this dichotomous framing appropriate. It has been used in the literature, but I see this as erroneous. There is not a single strain of NiV$_B$, but rather multiple.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote**early communication between developers and appropriate NRAs forclarity and guidance on the regulatory aspects ofMCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacityto: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiVsurveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorizationfrom appropriate NRAs for NiVMCMs.This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify**the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Commented [SPL6]: This is a key component. The general description of research needs and capacity development, seem to me to be fairly complete, but a thoughtful consideration of priority in sequence could help direct development.

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection arenonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species)appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge forensuring diagnostic preparednessto respond tofuture outbreaks.

Commented [SPL7]: A related problem is that in many of the contexts where these patients present, etiologic diagnosis is often not pursued. We need more than an inexpensive sensitive and specific Nipah diagnostic. For this to be used clinicians need to see value in conducting the tests. Having a specific therapeutic treatment could help motivate this. A multiplex diagnostic tool that provided insight on other pathogens (especially if they were treatable) would also encourage more frequent testing.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobankof human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course,are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.

- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detectionat various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiVdiagnostic tests for use in humans and animalsthat are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiVinfectionat different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protectionagainst lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV$_{M}$ and NiV$_{B}$are needed to assess the safety, tolerability, and efficacyof m102.4 (and possibly other mAbs) for PEPand potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the mostpromising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV$_{B}$ and NiV$_{M}$, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV$_{B}$ to be shorter than for NiV$_{M}$.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer.This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies,diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Commented [SPL8]: I suspect there is differences of opinion on this. On the one hand there is observational data from the Malaysian outbreak that NiV patients who received ribavirin had lower case fatality than NIV patients who did not. The unanswered question is whether this improved survival was a result of the ribavirin or whether it was primarily a result of ribavirin being used later in the outbreak once clinicians recognized the disease and possibly implemented better supportive care. The absence of impact on animal models suggests (but does not prove) that the improvement in human survival was due to confounding rather than biological effect. Given a fixed amount of resources and the opportunity cost of identifying patients who might benefit, I personally would not be particularly enthusiastic to conduct a phase III trial of ribavirin in Nipah patients in Bangladesh.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies andclinical trialsas appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infectionthat are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV$_B$ and NiV$_M$and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop**guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccinesfor use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV_M and NiV_Bin humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiVvaccines (or broader henipavirus vaccines)to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategiesover time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B, including recent strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than

one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.

- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possiblestrategies for vaccine use.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock(or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals(that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deployNiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluatingNiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains,and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effectivemonovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve**surveillance capabilities,particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide**guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Hi Kris,

Attached are a few additional comments.

Steve

Mahmudur Rahman Wednesday, April 25, 2018 8:17 AM

Dear Kris,

Greetings from Bangladesh !!!

Hope you all are doing fine.

Please find attached herewith the "Nipah Research and Development (R&D) Roadmap" with my comments in track change mode.

Best regards,

Mahmud

Kris Moore Friday, April 13, 2018 3:19 PM

Dear Nipah Virus R&D Roadmap Taskforce members:

Attached please find a revised version of the Nipah virus R&D roadmap for your review. This version incorporates comments made during the in-person consultation in early March, comments we received after the consultation, and recent literature. We also consolidated all of the cross-cutting issues near the beginning of the roadmap.

We would very much appreciate your written feedback/comments on this version **no later than Wednesday April 25.**

We're sending this to you as a Word doc to make editing and commenting easier. We suggest that you cc the whole group when you provide edits/comments—to ensure that you all see each other's perspectives.

Once we incorporate your additional feedback, the next step will be to post the document for public comment. We also plan to begin working on a set of measurable and achievable milestones and will start considering ways to approach the critical path analysis.

Again, we very much appreciate your ongoing support and involvement with this important project.

Warm regards,

Kris

NipahResearch and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:**This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting.This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV)is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illnessin pigs andencephalitic disease in humans occurred in Malaysia and Singapore in 1998and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported inthese countries since May 1999.NiV infection was subsequently recognized, however,in Bangladeshin 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India; associated case fatality rates in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropusbatspecies)and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In theoutbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary NiV sources being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely

related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness,cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B).

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, respond, prevent, and control outbreaks of NiV infection(and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value propositionfor industry and international philanthropic public-private partnershipsare needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities ~~have very rudimentary~~ are primary in nature in terms of laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses forlivestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials,is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regardingthe feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with ~~local~~ government authorities in endemic ~~and at-risk areas~~countries to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturingto endemic and at-risk areas.

Commented [Mahmudur1]: It will be necessary to involve the development partners who support the countries

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed torefine, standardize, and validate relevant animal challenge models(e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1)

determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3)determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in NiV_B and NiV_M pathogenesisthat may have implications for the development of safe and effective NiV vaccines or therapies.More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hostsand pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiVMCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.
3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.

4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

~~4.~~5.

Commented [Mahmudur2]: Consider adding "Enhance disease detection capabilities through active and passive surveillance"

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform**phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV_{B} and NiV_{M} pathogenesisthat may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote**early communication between developers and appropriate NRAs forclarity and guidance on the regulatory aspects ofMCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacityto: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiVsurveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorizationfrom appropriate NRAs for NiVMCMs.This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify**the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection arenonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species)appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge forensuring diagnostic preparednessto respond tofuture outbreaks.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobankof human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course,are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.

- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detectionat various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiVdiagnostic tests for use in humans and animalsthat are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiVinfectionat different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protectionagainst lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV$_{M}$ and NiV$_{B}$are needed to assess the safety, tolerability, and efficacyof m102.4 (and possibly other mAbs) for PEPand potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the mostpromising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV$_{B}$ and NiV$_{M}$, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV$_{B}$ to be shorter than for NiV$_{M}$.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer.This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies,diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies andclinical trialsas appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infectionthat are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both $\mathrm{NiV_B}$ and $\mathrm{NiV_M}$and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop**guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccinesfor use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV_M and NiV_Bin humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiVvaccines (or broader henipavirus vaccines)to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategiesover time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B, including recent strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than

one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.

- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possiblestrategies for vaccine use.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock(or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals(that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deployNiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluatingNiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains,and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effectivemonovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve**surveillance capabilities,particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide**guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

---

Dear Kris,

Greetings from Bangladesh !!!

Hope you all are doing fine.

Please find attached herewith the "Nipah Research and Development (R&D) Roadmap" with my comments in track change mode.

Best regards,

Mahmud

NIPAH R&D ROADMAP DEVELOPMENT TASKFORCE

Call Date: January 9, 2018

Taskforce Members on the Call: Christopher Broder, Kaw Bing Chua, Stephen Luby, Gregg Milligan, Pierre Rollin, and Mahmudur Rahman

Taskforce Members Unable to be on the Call: Emily Gurley and Lin-Fa Wang

R&D Roadmap Technical Team: Michael Osterholm, Kristine Moore, Julie Ostrowsky, Becky Johnson, and Anje Mehr (CIDRAP)

CONFERENCE CALL SUMMARY

Topic	Key Discussion Points
R&D roadmap architecture	• The WHO generic methodology for developing R&D roadmaps for priority pathogens (draft dated Aug 30, 2017) provides the basis for developing R&D roadmaps, as part of the global R&D Blueprint initiative. • Specific resources for guiding R&D roadmap development include the 2013 Malaria vaccine technology roadmap, the 2016 MERS-CoV roadmap report in Nature Medicine, and the 2016 MERS-CoV summary roadmap. • The Nipah R&D roadmap will provide a framework for identifying the vision, underpinning strategic goals, and prioritizing research areas and activities for accelerating the collaborative development of diagnostics, therapeutic agents, and vaccines against Nipah virus (NiV). The scope of R&D for medical countermeasures (MCMs), as put forward in the WHO roadmap generic methodology, includes basic research through to late-stage development, licensure, and early use of products.
Role of taskforce (TF) members	• TF members will be actively involved in reviewing draft roadmap documents and providing feedback; participating in the March 1-2, 2018 consultation at the Wellcome Trust offices in London; and assisting with ongoing review, development, and dissemination of the Nipah R&D roadmap over the next 6 months.
Roadmap development and timeline	• The draft Nipah R&D roadmap will provide the basis for discussion at the consultation in March. • The final roadmap product may include a summarized outline format as well as a text version similar to the MERS-CoV roadmap report in Nature Medicine. • The CIDRAP technical team will distribute a revised version of the draft roadmap in mid-February 2018, prior to the consultation, along with relevant background information. • Following the consultation, the team will further revise the draft roadmap based on information obtained during the consultation and will seek additional feedback from TF members and others before posting a new draft online for public comment. After further review from WHO and other key stakeholders, the final roadmap document will be available for publication by the end of August 2018.
Feedback on draft roadmap document: *General*	• Taskforce members generally agreed with the content in the introductory section, but indicated that the section could be improved by incorporating additional critical Nipah considerations, such as a description of the virus, the zoonotic potential, and the geographic location in which NiV and Hendra virus (HeV) are found. In addition to human health implications, NiV has the potential to impact trade and travel. • Consider subcategorizing Primary Challenges to group topical elements (e.g., clinical aspects, laboratory aspects, financial constraints).
Feedback on draft roadmap document: *Cross Cutting*	• Laboratory biosafety level (BSL) is primarily an issue when working with animal models and/or neutralization assays, which require the use of a BSL4 facility. Much of the NiV work is done at a lower level (e.g., serological tests are conducted in BSL2 conditions in Bangladesh).

	• NiV and HeV have multiple appropriate animal models for human disease. African green monkeys (AGMs) best replicate human disease, and hamsters and ferrets also serve as good animal models. The current animal models may provide sufficient data for the US Food and Drug Administration (FDA) Animal Rule regulatory pathway for approval for diagnostics, therapeutics, and vaccines. However, the US FDA may require additional data on correlates of protection in the animal models as compared to humans when evaluating MCMs under the US FDA Animal Rule. • While animal models for NiV are well-developed, taskforce members expressed concern that they might not be deemed sufficient for evaluation under the US FDA Animal Rule.
Feedback on draft roadmap document: *Diagnostics*	*Primary challenges:* • Strain variability (i.e., NiV$_M$ and NiV$_B$) has not been recognized to cause problems for diagnostics or MCMs. In fact, HeV reagents have been effectively used for NiV. Strain variability should not be emphasized in the Diagnostics or Therapeutics section. *Key needs:* • Point-of-care rapid diagnostic tests (RDTs) applicable under a variety of circumstances are necessary for NiV surveillance and to ensure appropriate therapeutic distribution/use. Different use cases may be necessary, given the variety of circumstances under which NiV diagnostics may be needed. • Improved infrastructure is needed in relation to RDTs to ensure that health professionals responsible for diagnostic testing know that RDTs are available and how to use them accurately and safely. • To increase the likelihood of RDT use, consider combining NiV detection with another more-common disease for the geographic region (e.g., the strategy of developing a combined RDT for malaria and NiV was discussed). *Priority Areas/Activities:* • The ideal sample(s) are those that easy to collect. In the field, saliva and respiratory secretions have been used for diagnostic work. Urine may also be a suitable sample type for diagnostics. Research is needed to better understand the most practical sample type(s) for different situations. *Other:* • The group discussed clinical manifestations of NiV and implications for the sample type that should be collected for making the diagnosis. Of note, unpublished data show low rates of asymptomatic infection, with NiV spread generally occurring via saliva or respiratory secretions. To better direct development of diagnostics, understanding viral load in different sample types (e.g., saliva, respiratory secretions, urine) would be beneficial.
Feedback on draft roadmap document: *Therapeutics*	*Primary challenges:* • Patients typically present late in the clinical course, which decreases the likelihood of successful treatment. • BSL4 laboratories are required for high-throughput screening. *Other:* • One team has explored the effectiveness of therapeutics at point-of-fever in an animal model. • The human monoclonal antibody m102.4 has shown protection in nonhuman primates (NHPs), has been used effectively as a compassionate use therapeutic for 14 humans, and recently underwent a Phase 1 study involving 40 adults. Taskforce members discussed sharing the safety data from the Phase 1 study, which has not yet been published.
Feedback on draft roadmap document: *Vaccines*	*Primary challenges:* • Due to the fact that NiV generally occurs as small, focal outbreaks, conducting Phase 3 studies are probably unrealistic. However, Phase 1 studies are very plausible, and Phase 2 studies may be possible in endemic regions. *Key needs:* • To conduct clinical trials in the endemic regions at risk for NiV infection, additional information is needed regarding what the government (e.g., Ministry of Health)

	requirements for conducting such studies would be. Additionally, a strategy is needed to address vaccine acceptability in the at-risk population. *Other:* • Anti-vaccine sentiments in the general public are currently an issue for HeV vaccine use in horses, and are expected to be a hurdle for NiV vaccine acceptability as well. Incorporating effective communication strategies for communities that would benefit from an NiV vaccine will be paramount to vaccine success.
Other comments	• The CIDRAP Team requested that taskforce members provide written comments on the draft roadmap document by January 19, if possible. • CIDRAP staff may follow-up with certain individual members of the taskforce, as necessary.

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.
- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis

more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.

- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecologic and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Product development

- **Generate** a TPP for NiV diagnostics.

- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV_M and NiV_B strains may impact the effectiveness of developed MCMs, yet NiV_M has been used significantly more often than NiV_B in research. *(*cross cutting)*
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Knowledge gaps

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ribavirin was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional

animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.
- **Determine** the key differences between NiV_B and NiV_M that may have implications for the development of safe and effective NiV therapeutics.

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV_B and NiV_M and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.
- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.

- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.
- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.

- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.

- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Subject:	Call notes from the Nipah Roadmap Taskforce Conference Call which was held on Tuesday, January 9
Date:	Thursday, January 18, 2018 8:48:13 PM
Attachments:	Nipah Taskforce Conference Call Summary 20180109.final.doc Nipah Draft Roadmap.V5.docx
Importance:	High

Dear Nipah roadmap taskforce members:

First, I want to thank all of you who were able to participate in our conference call on Tuesday January 9. The discussion was very helpful and we very much appreciate you input.

Second, please send us any written edits or comments on the draft document as soon as possible, if you have a moment. I have attached the draft again here. We plan to revise the draft and send it on to WHO for review soon, in order to meet our current timelines. Any additional written comments you may have would be most appreciated.

Finally, I have attached meeting notes from the conference call for your records.

Again, thank you for all of your support in this important effort. We will be in contact again soon regarding next steps in preparing for the in-person March meeting in London.

Warm regards,

Mike

DRAFT V5 —NOT FOR DISTRIBUTION— January 1, 2018

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

Commented [pyr31]: Mostly Bangladesh, not seen in Malaysia. Not occurring in healthcare facilities, only at home, certainly due to lack of basic precaution

Commented [EG2]: There were a couple of suspect cases of this in Malaysia, but this has been a prominent feature of the outbreaks in India and Bangladesh.

Commented [EG3]: Cough has been more common than vomiting in the Bangladesh case series.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

Commented [pyr34]: Basic hand washing!

Commented [SPL5]: I consider this paragraph as essential framing and urge that it be retained, even as we work towards a more focused document. It is difficult, because medical countermeasures do not stand alone. They need to interface with a system that constructively deploys them. At a minimum we should strive for countermeasures that are fit for purpose for the contexts where they are needed.

Commented [EG6R5]: Complete agree with Steve on this.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.

Commented [pyr37]: Rapid test, lateral flow. Better if multivalent. A single Nipah test is unlikely to be widely used

Commented [EG8]: While this is true, even when testing is nearby, it can still take days to get back a PCR or ELISA result as these are not rapid tests as current used. Within the context of very quick progression to death, we need a bedside rapid diagnostic.

Commented [pyr39]: So far, virus quite stable, no impact on diagnostic tests. Need to be vigilant but "so far so good"

- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis

more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Commented [pyr310]: What going on in Malaysia? No data since the outbreak in 1999

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*

Commented [pyr311]: Not really a problem for diagnostic, but it is one for pathogenesis and vaccine studies

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.

Commented [pyr312]: Nipah test would be more likely used if combined with something else. In addition to increase the "market, wuld be good if it is Nipah/hendra

- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.

Commented [SPL13]: Given the wide range of Pteropus bats this needs to be defined. Clearly, we need low cost accurate diagnostics, but we also need to consider the system that needs to be in place in order to make use of the diagnostics. We risk mission creep if we include development of global surveillance as part of medical countermeasures, but there is a difference between how we would optimally deploy point of care diagnostics in Bangladesh and West Bengal, India, compared with the Philipines or Cameroon. We should consider the different needs in these different contexts, to assure that we have an approach that is fit for purpose.

Commented [EG14R13]: Agree

- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Commented [EG15]: Or, other pathogens on a differential diagnosis for humans?

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.

Commented [SPL16]: Salivary pcr is often positive in Bangladesh before antibodies are detectable.

- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.

Commented [pyr317]: On going for ELISA assays

- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Commented [SPL18]: Because this is a wildlife shed virus and these creatures live near food sources, spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh. The health care facilities that serve these communities not only have very rudimentary laboratory infrastructure, they also do not have the routine practice of using diagnostic tests to manage patients. Thus, achieving the stated strategic goals requires a much broader, deeper effort, than providing reagents and testing for proficiency at national labs.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecology~~ic~~ and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Commented [pyr319]: For Malaysia, pig surveillance could be an important surveillance project

Commented [SPL20]: Consider whether efforts to promote sharing of sequence and strains would benefit from attention.

Product development

- **Generate** a TPP for NiV diagnostics.

- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Commented [EG21]: Perhaps targeted research to identify evidence of spillover and human risk might come before investments in broader surveillance efforts.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Commented [pyr322]: Serotherapies studies in Nipah patient are past-dues

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV$_{M}$ and NiV$_{B}$ strains may impact the effectiveness of developed MCMs, yet NiV$_{M}$ has been used significantly more often than NiV$_{B}$ in research. *(*cross cutting)*

Commented [SPL23]: Moreover, if we actually had more strains we may identify more heterogeneity than is currently apparent.

- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.

Commented [EG24]: And can pose a dilemma if therapeutics prolong life and improve survival but are unable to prevent severe neurologic damage.

- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*

Commented [EG25]: Or, infection control measures which are not standard practice in many at-risk countries.

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Commented [pyr326]: Impact on pathogenesis studies and vaccine trials

Commented [pyr327]:

Commented [EG28]: Studies in animals often test usefulness of therapeutics when delivered prior to disease onset or very early during the disease course. Since humans with Nipah virus are often only detected once they are ill, the findings are less useful for understanding how the drug might work in humans.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Commented [SPL29]: Would be ideal, but, given the biology, may be much more difficult than an acute countermeasure. Might separate these into 2, so that the ideal does not become the enemy of the good.

Commented [EG30]: Patients in Malaysia were much more likely to survive than patients in Bangladesh. One hypothesis is that this is because patients in Malaysia had access to ventilator support, which is typically unavailable in Bangladesh. There may be health systems approaches that could improve survival.

Knowledge gaps

Commented [pyr331]: Anthropological studies to insure that vaccine trials are accepted

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Patients treated with Ribavirin late in the 1998-1999 NiV outbreak in Malaysia experienced 36% lower mortality than persons from earlier in the outbreak who were not treated with Ribavirin.~~was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered~~Ribaviran may be an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number

of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV$_B$ and NiV$_M$, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV$_B$ to be shorter than for NiV$_M$.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA’s Animal Rule to obtain licensing. *(*cross cutting)*

Commented [SPL32]: An important related issue is how we protect the health care workers and fellow patients in these settings. Part of this is covered in the vaccine section, but the capacity to protect health care workers and other patients is extremely limited in the contexts where we see recurrant NiV outbreaks. A clear eyed understanding of the context, and piloting approaches within these contexts is essential to develop and refine medical counter measures to that they can reduce pandemic risk. To be effective these countermeasures need to work, not only in idealized trial conditions, but in the everyday setting where high risk patients present.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Commented [EG33]: Median days from onset to death for patients in Bangladesh who die from Nipah virus is 6 days. Typically, they present unconscious on around day 3. So, there is little time to act but even less when healthcare seeking is delayed, because progression is so fast. This is a worthy goal, but the limited access to healthcare will reduce the number patients we can find in time to treat and will have an impact on field trials.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.

- **Determine** the key differences between NiV_B and NiV_M that may have implications for the development of safe and effective NiV therapeutics.
- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV_B and NiV_M and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

Commented [pyr334]: Combination vaccine for better acceptability from population and will be more useful

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore,

alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*
- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.

- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.
- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Commented [EG35]: And for the estimation of stockpiles that would be required to effectively respond to outbreaks, under various transmission assumptions.

Commented [SPL36]: I suspect that this is an easier technical problem than it is an economic problem. Only 15% of Australian horses are vaccinated against HeV. Pigs in low income countries are rarely protected against swine cholera or Japanese Encepahlitis. The incentives for livestock raisers are not well aligned for deployment as a human public health tool.

Commented [EG37R36]: Indeed, even when we offered free JE vaccine to pig raisers in northern Bangladesh, many refused due to lack of trust in the formal vet care system.

Commented [SPL38]: Should consider surge capacity to rapidly ramp up vaccine supply in case NiV is used as a bioterror agent, or we face a strain that naturally develops increased capacity for person to person transmission.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.

- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.

- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Subject: Save the Date - January 9 and 10 (depending on time zone)- WHO R&D roadmap taskforce conference call for Nipah virus
Importance: High

Dear Colleagues:

Thank you to those who provided your availability for a Nipah WHO Roadmaps taskforce conference call.

Based on majority availability, the taskforce call will be held on **Tuesday, January 9 at 7 pm CST.** The date and time for this call in the different time zones is as follows:

- PST (US): 5:00 pm (Tuesday January 9)
- MST (US): 6:00 pm (Tuesday January 9)
- CST (US): 7:00 pm (Tuesday January 9)
- EST (US): 8:00 pm (Tuesday January 9)
- GMT (London): 1:00 am (Wednesday January 10)
- CET (Geneva): 2:00 am (Wednesday January 10)
- BST (Bangladesh): 7:00 am (Wednesday January 10)
- SGT (Singapore): 9:00 am (Wednesday January 10)

Call-in information:

- Conference Code for all numbers listed below: 998-3378#
    - USA Toll Free: 866-767-9978
    - UK Toll Free: 0808 1017 535

    - Switzerland Toll Free: 0800 5537 12
    - Singapore Toll Free: 800 101 2395
- For Bangladesh, we do not have a toll free line; we will contact you separately to make logistical arrangements.
- As a BACKUP: International callers may use the following conference call information: Conference Line 205-254-8650 Conference Code: 998-3378#. However, please note that this is NOT a toll-free number.

An agenda and other meeting materials will be shared closer to the conference call date. A meeting summary will be developed and shared with the group after the call. As we anticipated, we were unable to accommodate everyone's schedules, so we apologize if you are not able to participate. If you are unable to participate, we still very much want your input, and we will look at either obtaining input via email or possibly through an individual call, if time allows.

We deeply appreciate your ongoing support and value your expertise and involvement. Please do not hesitate to contact me with any questions.

Mike

RESEARCH STRATEGY

A. BACKGROUND AND SIGNIFICANCE

A1. Henipaviruses are a critical threat to public health.

Over the past 40 years the majority of the major etiological agents of emerged or identified infectious diseases in humans have been viruses[1], and most have been zoonoses caused by RNA viruses[2]. The emergence or reemergence of pathogenic viruses are continuous threats to public health. Among these, the paramyxoviruses, which include many important human and animal pathogens, also include two emerged, zoonotic viral pathogens of importance: the henipaviruses; Hendra virus (HeV) and Nipah virus (NiV)[3,4]. Recently, a third isolate Cedar virus (CedPV) has been added to the *Henipavirus* genus[5]. Pteropid bats appear to be the major reservoir hosts for henipaviruses[6,7]. HeV and NiV have a uniquely broad host tropism capable of infecting at least 18 animal species across 6 orders of mammals, including their natural bats hosts. Among these animals, HeV and NiV can cause a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with fatality rates ranging from 40-100%[8,9]. There are no vaccines or therapeutics licensed for these viruses, highlighting an important public health unmet need.

Henipaviruses are single-stranded, negative sense, enveloped RNA viruses with two membrane anchored glycoproteins involved in virus entry, one of which mediates host cell receptor attachment (G glycoprotein) and the other, ~~is~~ a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. Both HeV and NiV use the cell surface protein ephrin-B2 as a functional entry receptor[5]. The viral G and F glycoproteins are the major antigenic targets of neutralizing Abs and also the main focus of several vaccine strategies[10]. The focus of this proposal is developing human Abs to the G protein.

NiV and HeV remain significant biothreats to humans and economically important livestock in Australia and throughout South East Asia, and there are no vaccines or antivirals approved for human use[9]. Surveillance research has detected henipavirus reactive sera and homologous RNA across a wide geographic area and in a number of bat species. Henipavirus seropositive samples have been reported in Malaysia, Indonesia, Papua New Guinea, Thailand, India, Ghana and Madagascar among both fruit and insectivorous bats and domestic pigs, suggesting that the range of NiV and/or HeV and the risk of potential outbreaks is widespread[11-22].

Further Ab discovery for HeV and NiV has been significantly hampered because of the burdensome requirements of biosafety level-4 (BSL-4) containment. However, whereas HeV and NiV are bat-borne disease-causing zoonoses, CedPV is not known to be zoonotic and has been shown to be nonpathogenic in animals susceptible to HeV and NiV disease, and resides in nature in the same bat host species as HeV[5,23]. Nucleic acid based detection studies have identified related henipavirus species, including complete genomic sequences[20,24], but HeV, NiV, and CedPV are the only virus isolates reported. We have recently rescued recombinant CedPV encoding turboGFP (rCedPV-GFP) using reverse genetics, and this platform is a new system that can be used to study henipavirus cell biology safely under BSL-2 containment. But of further significance, it is an authentic henipavirus infection and replication reporter system that is now suitable for high-throughput screening (HTS) applications for the purposes of drug discovery of potentially pan-anti-henipavirus antiviral molecules. Recently, Marsh and colleagues described the isolation of CedPV from pooled bat urine collected in Queensland, Australia[5]. CedPV is closely related to HeV and NiV, genetically and antigenically, and is the first new *Henipavirus* isolate, but the virus does not cause disease in experimental infections of mice, ferrets or guinea pigs[5].

A2. Human Abs are a feasible strategy for the prevention or treatment of henipavirus infections. There is proof-of-principle for the approach we propose here as post-exposure human monoclonal Ab (mAb) therapy (anti-NiV/HeV G glycoprotein mAb m102.4) has been examined[4,25-28]. Humanized mAb, hu5B3-1, is a potent cross-reactive anti-NiV/HeV F specific neutralizing mAb. The mAb was derived from murine 5B3 [29] which recognizes a conformational epitope in the pre-fusion form of the F glycoprotein, and binding of 5B3 prevents fusion triggering. The mAb hu5B3-1 has been shown to provide protection against NiV and HeV challenge in the ferret model when administered single dose at days 3 and 5 post virus challenge (Mire, Geisbert and Broder, unpublished). In addition, a human mAb, m102.4, recognizes the NiV/HeV G glycoprotein and is a potent cross-reactive neutralizing mAb. MAb m102.4 blocks ephrin receptor binding and the crystal structure of the mAb-G complex has been determined[27,30]. Further, m102.4 has been shown to provide post-exposure protection against NiV and HeV challenge in both the ferret[28] and nonhuman primate models[4,25,26]. m102.4 has been successfully administered to 14 individuals on emergency protocol because of HeV or NiV exposure[31], and has already completed Phase I randomized, double blind, placebo controlled study, dose escalation trial in Australia. This therapy can be~~is~~ administered within several days following lethal infection in animal challenge models. This molecule establishes the feasibility of the concept, but it is not a naturally occurring human mAb (it was derived from a library) and has ~~some~~ limitations in terms of breadth and potency. This work points the way, however, to an opportunity for a fully human broad and ultra-potent neutralizing Ab to serve as a next-generation biologic with improved properties. As shown below, we already have ~~in hand~~identified 10 new fully

Commented [LZ1]: Can we say anything about the likelihood of this continuing to advance? Is there a company developing it, or is it languishing?

human neutralizing human mAbs, including a putative lead molecule that is ultra-potent and neutralizes both HeV and NiV. In addition, ~~And~~ we have the capacity to generate many more, potentially ~~some~~ with even better activity. Development of new human mAbs for henipavirus infections is of practical utility and also will be of interest to the infectious disease, viral pathogenesis, and immunology communities. Developing and deploying a new ultrahigh-throughput Ab discovery platform capable of rapidly isolating and characterizing hundreds of members of naturally-occurring human Ab clonal lineages at a time could revolutionize the approach to therapeutic Ab science.

B. INNOVATION. We bring several innovative features of research to this proposal.

First, we will refine and deploy one of the highest yield Ab discovery platform for infectious diseases ever described. We already use what is likely the highest efficiency method for isolation of fully human mAbs to date, based on high-efficiency B cell transformation followed by formation of human hybridomas. The methodology is state-of-the-art, and it is a robust procedure in our hands, with high yields of human mAbs from donor specimens. The current yield of discovery efforts with this technology is on the order of several dozen high-affinity human mAbs from the typical 5-10 mL)?) blood specimen studied. In the current proposal, we will leverage this foundation to achieve efficiencies that are ~ two orders of magnitude higher. We will accomplish this goal by coupling the established biological cell cloning and screening procedure with next-generation immune repertoire sequencing, followed by massively parallel DNA synthesis of entire antigen-specific repertoires, using emerging synthesis technologies from Synthetic Genomics and Twist Bioscience. The goal is to isolate and characterize the largest panels of human Abs to any infectious agent ever attempted.

Commented [LZ2]: Just worried about alienating reviewers…

Second, we have a high level of expertise in the biology of henipavirus pathogens, especially HeV and NiV, and we have recombinant proteins for novel henipavirus protein targets. Our scientists have identified novel mechanisms pertaining to the pathogenesis of henipavirus infection that involve the surface G proteins (references?), and we have defined the impact of blocking attachment of viruses to cells on henipavirus virulence in large and small animal models of infection and disease (references?). We have elucidated the complex biology of these molecules, and demonstrated that their function is critical to replication and pathogenesis of these viruses (references?). Our work reveals that attachment to receptor represents a vulnerability in the viral lifecycle, ~~and therefore~~ providing~~e~~ a promising class of drug target that has not yet been fully exploited. We have already ~~have~~ established a fundamental portfolio of research in our laboratories that is focused on identifying factors and processes involved in viral replication of these pathogens and disease in their hosts. We will use this fundamental knowledge to further develop best-in-class human mAb therapeutics.

Third, there are several innovations in the present application regarding the henipavirus field. In this application, we will develop the very first cell-based HTS assay using an authentic henipavirus infection and replication reporter system based on the non-pathogenic CedPV for identifying inhibitors of henipavirus entry and replication. The basic screening protocol is based on the following two main principles: (1). Using the recombinant CedPV platform (an authentic henipavirus) all stages of virus replication are targeted in the screening assay; binding via henipavirus receptors (ephrins), membrane fusion and nucleocapsid entry, genome transcription and protein synthesis (reporter gene signal). (2). The CedPV F and G envelope glycoproteins could also be replaced within the rCedPV genome with F and G glycoproteins of HeV or NiV and replication competent chimeric viruses based on CedPV can be generated. This will allow for a HTS assay focused only HeV or NiV entry step dependent on the ephrin-B2 and B3 receptors. The proposed cell-based, HTS assay will make use of an authentic henipavirus infection and replication reporter system, which has never been done before. Thus, this assay will provide a HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. The recombinant CedPV based platform requires only BSL-2 containment, relieving the physical and economic burden of HTS screening in a high-containment environment. Because of the close phylogenic relatedness of CedPV to HeV and NiV, including the use of the same principle cell-surface receptor for entry (ephrin-B2) and replication strategies, there is good potential that identified inhibitory mAbs~~s~~ may have activity across the henipavirus genus. Indeed, this area of research is both timely and needed because there is a complete lack of any effective and approved antiviral therapeutics against henipavirus infection suitable for human use, certainly in the case of human NiV or HeV symptomatic infections.

C. APPROACH

C1. PRELIMINARY DATA

C1.1. Advanced Ab Technologies. We have developed what is arguably the highest yield system ever described for isolation of naturally-occuring human mAbs that inhibit microorganisms. The effectiveness of our pipeline can be measured by the quality of the mAbs we isolate and the rapidity with which we can develop them. For instance, we have participated as leaders in the international response to the three most recent international outbreaks of emerging infections, contributing rapid and seminal contributions to the response to these emergent events, as shown below:

Agent	Result of discovery campaign	Representative publications	Status of human mAb development for clinical testing
Ebola, Marburg	Best-in-class neutralizing human mAbs	***Cell Host Microbe*** 2018 23(1): 101 -109.e4 ***Science Translational Medicine*** 2017; 9(384). ***Nature Microbiology*** 2016; 1:16128. ***Science*** 2016; 354:350-354. ***Cell*** 2016; 164:392-405. ***Cell*** 2015; 160:904-12. ***Cell*** 2015; 160:893-903.	Abs for Ebola and Marburg have been licensed from Vanderbilt (the prime site in this application), to Mapp Bio, the commercial partner, and prepared as cGMP material. One Ab (MR191) was administered to a human in 2017 under emergency IND. BARDA invested over $30M in 2017 in the Mapp Bio program through the Emergent ADM to develop filovirus Abs, including MR191.
Zika	Best-in-class neutralizing human mAbs	***Nature*** 2016; 540:443-447. ***Nature Communications*** 2017; 8:14722.	Abs have been licensed to one biotech, and a second biotech is negotiating for exclusive rights. GMP CHO lines are being prepared by Batavia, in preparation for IND submission by Vanderbilt.
Chikungunya	Best-in-class neutralizing human mAbs	***Cell Host Microbe*** 2015; 18:86-95. ***PNAS USA*** 2015; 112:13898-903. ***Cell Reports*** 2016; 16:1326 -38. ***Science Translational Medicine*** 2017; 9:375. ***PLoS Neglected Tropical Disease*** 2017; 19;11:e0005637.	1. One set of human mAbs licensed to a big pharma, NHP studies are completed, and GMP material has been prepared for human trials. IND in preparation. 2. A second set is in manufacture as mRNA delivery for clinical trials by a large biotech.

We have already shown that we can isolate potently neutralizing Abs to HeV and NiV~~,~~ in preliminary experiments, and will continue this Ab discovery campaign in the first 2 years of this proposal. Targeting G protein of henipaviruses for mAb isolation using our hybridoma technology should be straightforward, but the yield will be uncertain until the discovery campaigns are launched in full. Typically, we have used a method based on EBV transformation followed by human hybridoma formation to isolate antimicrobial human mAbs (**Figure 2**).

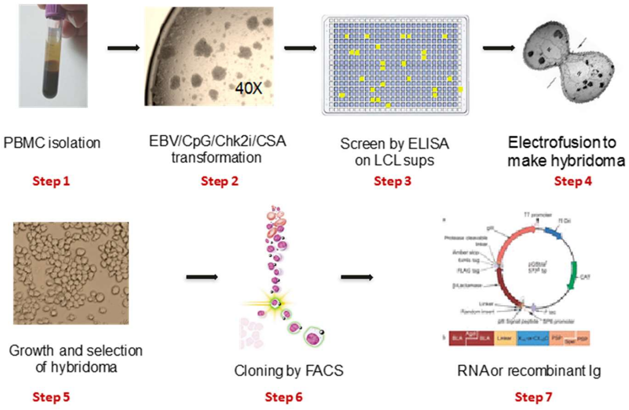

Figure 2. General workflow for generation of human mAbs by hybridoma.

The hybridoma process uses electrofusion of B cell lines with myeloma cells to create hybrids at high-efficiency[32]. This process has enabled us to isolate Abs to a vast array of human viruses. There are many advantages of this system. First, since the protocol uses human memory B cells, the timing after infection is not critical, and unlike mAbs derived from immunization related technologies, isolated mAbs are from a successful human immune response to the pathogen. In fact, we have isolated high potency neutralizing Abs to viruses ≥ 60 years after exposure to 1918 influenza[33,34] after several decades following infection with dengue virus acquired during foreign travel[35-39]. This protocol has been optimized to isolate high potency naturally-occurring Abs, but we also have a number of other techniques that can be used.

Alternative approaches to mAb development. We also have developed or deployed about a dozen additional methods for isolation of human mAbs. We will use each of our memory B cell techniques here. We also

Formatted: Font: (Default) Arial, Bold, Condensed by 0.05 pt

Commented [LZ3]: Maybe do not include if the likely source of B cells was a vaccine exposure…

pioneered and used single-cell sorting of antigen-specific B cells to isolate virus-specific mAbs as early as the late 1990s[40]. This approach can be performed by sorting antigen-specific cells, followed by isolation of Ab variable genes and expression as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. The advantage of this approach is that it can be quite quick, and also uses memory cells, so the timing of blood collection after infection is not critical. However, the challenge of this approach is to obtain a conformationally correct protective antigen for sorting. Sorting with an antigen that does not recapitulate the presentation of the antigen on the surface of the virion leads to sorting of B cells secreting Abs that are not of the right specificity or potency. The Crowe laboratory (Vanderbilt) and the Broder laboratory (USUHS) have prepared and validated the recombinant G protein antigens for this approach. One variation of the technique that we will explore is generation of small Ab variable gene libraries from oligoclonal antigen-specific EBV transformed B cell lines. We can express these gene libraries on the surface of yeast, and then select individual yeast clones for binding to the G protein of interest, using flow cytometric sorting. We have experience with this procedure for successful isolation of human Abs, which is particularly successful when the libraries are small due to enrichment for antigen-specific variable genes, accomplished by prescreening for B cell lines as we described above. This multi-pronged approach will give us "more shots on goal" from a technical standpoint, a risk mitigation strategy.

Figure 3. Large-scale collection of human PBMCs from henipavirus immune donor. A) Leukopack. Approximately 40 billion human PBMCs were collected from an immune Australian immune donor by leukoapheresis (ungloved hand is that of the donor, who observed laboratory processing). **B.** Further purification of PBMCs by dozens of density gradients. **C.** Large team required to rapidly process billions of cells. **D.** Hundreds of cryovials of immune donor cells were cryopreserved, enabling repetitive antibody discovery campaigns.

C1.2. Generation of human mAbs that neutralize henipaviruses.

We already have demonstrated the feasibility of the Ab discovery work for henipaviruses, and identified a potential lead Ab, HENV-26. We identified an Australian equine veterinary professional who had ~~had~~ an inadvertent exposure to the HeV equine vaccine (Equivac HeV), a product produced by Zoetis. The vaccine contains a non-infectious G protein component of the virus. We later determined that this individual's serum contains high levels of HeV and NiV neutralizing Abs. The subject flew to Vanderbilt where we obtained ~40 billion PBMCs by leukoapheresis, yielding hundreds of cryovials with millions of cells each (**Figure 3**).

Formatted: Underline

Human mAbs with high potency. In preliminary experiments with one 10 million cell aliquot of these cells, we made a panel of 10 human mAbs that bound to recombinant HeV G protein. All of the Abs neutralized HeV (**Figure 4A**), with one that was designated HENV-26 being especially potent. This mAb exhibited nearly 100% neutralization activity even at 390 ng/mL Its IC_{50} value is therefore very low. We need to do additional BSL4 experiments with further dilution to determine the final IC_{50}. This finding suggests that HeV is remarkably susceptible to neutralization, when the right naturally occurring human IgG clone is identified.

Human mAbs with breadth for both HeV *and* NiV. We also found that 5 of the 10 Abs also neutralized NiV, with HENV-26 again being the most potent, with near complete neutralization measured still at 195 ng/mL (**Figure 4B**). It is interesting that the activity is apparently even higher for the HENV-26 mAb isolated from a HeV G exposed person. This finding does suggest that NiV also is remarkably susceptible

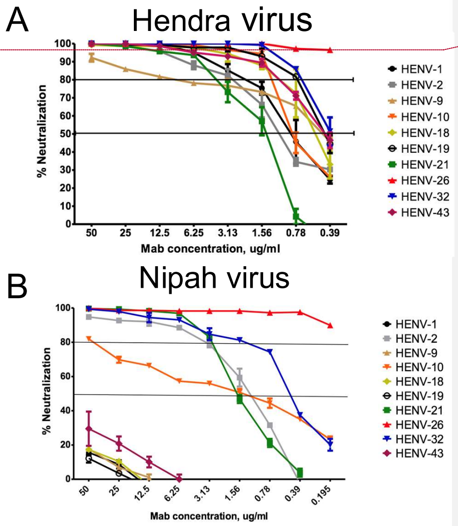

Figure 4. Percent neutralization of henipaviruses mediated by each of 10 new human mAbs, tested in a dilution series (high to low concentration of mAb left to right). **A.** Hendra virus. **B.** Nipah virus Bangladesh

to neutralization, when the right B cell clone is selected.

We performed competition-binding assays on an Octet biolayer interferometry instrument and demonstrated that the panel of 10 mAbs has members that recognize at least 4 different major antigenic sites (**Figure 5; next page**).

Finally, we obtained a crystal structure of the ultra-potent HENV-26 Fab in complex with HeV G protein (**Figure 6).** The structure reveals that this mAb binds to the receptor binding site on HeV G, thus its mechanism of action is to block receptor binding. However, close inspection of the structure in comparison with that of the receptor bound to G revealed that the Ab and the receptor use different critical contact residues to engage the receptor **(Fig 6B**).

Commented [LZ4]: Worth addressing escape mutants some where? If binding the receptor binding domain, escape is less likely; anything known about mutation rate in these viruses?

Figure 5. Competition binding experiments reveal the ten new human mAbs, each of which is neutralizing, fall into 4 competition-binding groups, suggesting they recognize diverse major antigenic sites. Hendra G protein was used to coat an Octet biosensor tip, then a mAb was interacted (to determine 100% binding level). Then we measured binding of a second mAb. Reduction of binding (from 100%) of the 2nd in the presence of the 1st was considered full (black), intermediate (grey) or no (white) competition.

These experiments, while preliminary in nature and performed using a single vial of donor cells (with hundreds more available), clearly demonstrates the high ~~feasibility~~ probability of obtaining a large number of broad and potent henipavirus neutralizing Abs. In addition,~~And~~, the HENV-26 already identified is a very promising lead for further development, even if no additional Abs are obtained in future screens. We will use our nextgen sequencing techniques to identify somatic variants of HENV-26 for recombinant expression and determine if any exhib~~v~~it~~s~~ an increase in inhibitory activity. Also, our industrial partner, Mapp, will begin manufacturability assessments at the start of the work using HENV-26. At the beginning of the proposal (prior to new Ab discovery campaigns) we can combine mAbs from each of the other competition-binding groups (*i.e.*, mAbs to other antigenic sites) to see if any cocktail achieves a cooperative or synergistic effect. Monotherapy (with a broad and ultra-potent mAb like HENV-26) is simpler from a manufacturing and regulatory perspective. But cocktails sometimes exhibit cooperative effects and they are more likely to resist viral escape.

Figure 6. Crystal structure of the complex of Hendra G protein and human mAb HENV-26 reveals this potent antibody blocks receptor engagement. Left) The Hendra virus G protein is shown in green, the Fab light chain in yellow, the Fab heavy chain variable domain in magenta and the Fab heavy chain CH1 domain in cyan. For comparison, the receptor structure is shown in grey color in the position was found in the complex of receptor and Hendra G protein. **Center**) Close-up view of the antibody and ephrin-B2 receptor reveals the antibody blocks receptor binding, but the residues on Hendra G protein with which the antibody and receptor interact differ greatly. **Right**) Hendra G protein surface showing binding sites of ephrin B2 and Fab HENV-26. Residues interacting with both HENV-26 and ephrin B2 are shown in green, with only HENV-26 shown in blue, with only ephrin B2 in yellow.

The goal of the proposed discovery efforts here is to identify the most potent neutralizing mAbs possible, with the greatest breadth against henipaviruses possible. Given the excellent potency of HENV-26, the cross-neutralization of NiV and HeV, and the known mechanism of action, HENV-26 appears optimal as a lead candidate. However, we may be able to find a clone with an even better profile. We will conduct discovery campaigns for about 18 months, then choose a lead by the end of Year 2 ~~years~~. Even finding additional clones with the identical specificity, mode of action, potency and breadth would help us when we transition the project to product development and manufacturing. Mapp will perform manufacturing assessments on lead compounds, as discussed in detail below. Having more clones to work with at that stage enhances the likelihood of finding a clone with desirable biologic activity *and* manufacturability.

C2. SPECIFIC AIMS

Specific Aim 1. Isolation of human mAbs from patients previously infected with henipavirus or exposed to henipavirus vaccine antigens

Rationale: We have several powerful B cell technologies that can be brought to bear on this project. The principal approach is to generate human hybridomas from circulating B cells using an electrofusion technique we developed under a previous NIH Bioengineering grant. This approach is the highest efficiency technique for isolating human clones with naturally-matched heavy and light chain genes ever reported. Using this approach, we have generated thousands of virus-specific B cell lines and mAbs to RSV[41-49], MPV[49-51], rotavirus[40,52-59], norovirus[60,61], influenza NA H1/2/3/5/7 and NA9[33,34,62-70], dengue viruses[35-39,71-76], Zika virus[60,77], hepatitis C virus[78], HIV[79-83], chikungunya virus[76,84-87], Ebola viruses[88-91], Marburg virus[92-94], poxviruses[95], *S. aureus*[96] and many others (unpublished). The method is efficient enough~~, for example,~~ that we were able to generate human hybridomas to the 1918 H1N1 pandemic influenza virus from ~ 100-year-old survivors, in whom the average frequency of B cells specific for that early 20th century HA was only 1 in 4 x 10^6 cells (or 0.000025%)[33].

Commented [LZ5]: Off-putting to reviewers?

PBMC samples from human subjects with henipavirus immunity. Fortunately, we have an ongoing donor identification and sample acquisition program in the Vanderbilt Vaccine Center, which obtains serum, plasma and peripheral blood mononuclear cells (PBMC) for isolation and cryopreservation. These materials are processed and stored in a de-identified manner in the Vanderbilt Vaccine Center Biorepository, which is a de-identified sample archive. The acquisition of samples does not use federal funds, as this is an institutionally supported service. The use of these materials by VVC investigators is *Not Human Subjects Research* category activity. The current proposal does not propose to support acquisition of new human subjects. Nevertheless, we are aware that the program is enrolling a survivor of natural HeV infection in early 2018. If that occurs, we would obtain some of those de-identified cells for use in the current proposal if funded. If any NiV immune subject materials are deposited in the Biorepository, we also would request use of those.

Recombinant HeV and NiV glycoproteins. The Crowe laboratory produced the soluble forms of HeV and NiV G proteins that were used in the preliminary Ab screens shown above. The proteins bind to human Abs in human immune serum, and they facilitated isolation of ultra-potent neutralizing antib~~v~~odies already, validating their utility in the proposed work. The Broder laboratory also has extensive experience in the development and characterization of human cell line expressed soluble, oligomeric forms of viral envelope glycoproteins which have been used in a variety of applications in vaccine development, viral entry mechanisms and receptor discovery, and as antigens in biosurveillance [8,9,97-106]. Specifically, we have prepared the NiV and HeV soluble tetrameric G glycoproteins (sG), as well as other henipavirus sG (Kumasi, Cedar, Mojang) that are available to perform various human mAb selections, including multiple antigen selections to identify cross-reactive, pan-henipavirus G mAbs.

Cell isolation and fusion: The specific technique is as follows. We will use cells isolated from cryopreserved PBMCs with Ficoll-Hypaque following an established density gradient method. Transforming EBV (substrain B95.8), and the TLR agonist CpG ODN 2006 (2.5 μg/mL; Invivogen), 10 μM of Chk2 inhibitor II (Sigma C3742), and 1 μg/mL cyclosporine A (Sigma) will be used to stimulate human lymphocytes for transformation. Cells are plated in 384-well tissue culture plates and monitored visually for transformation.

Screening for virus-specific Ab lines: Supernatants from wells containing EBV-transformed lymphoblastoid cell lines (LCL) will be screened for binding activity in several ELISAs against the recombinant G proteins described above. Up to 10 antigens can be used in each screen, facilitating the search for pan-henipavirus mAbs. Positive wells in any of these assays will be selected for cell fusion. EBV-transformed LCLs do secrete human Abs, but these lines are quite unstable and difficult to clone biologically. LCLs secreting antigen-specific Abs will be fused with HMMA 2.5 myeloma cells to form human hybridomas, which are much more stable. The system used is a programmable electrofusion source (BTX). The fusion volume is 500 μL. HMMA2.5 myeloma cells and EBV-transformed human B cells are washed with RPMI-1640 and cytofusion medium. Large volume fusion chambers are commercially available and interface well with this unit. The key to the fusion is bringing the two cell types into close physical contact using dielectrophoresis in a low-voltage AC field (in which cells developed a dipole, essentially becoming like little magnets stuck together in long linear chains). After fusion, cells will be allowed to recover in the fusion electrode for 30 min, harvested, and then washed with medium prior to plating for selection. **Hybridoma selection and cloning:** After fusion, fused cells are seeded into 384-well plates in complete medium containing HAT and ouabain. After five days of culture, cells are fed by removing 100 µL of the culture medium and adding an equal volume of fresh medium containing hypoxanthine/thymidine or HT. We use a series of STEMCELL Technologies media for these procedures, most importantly the ClonaCell®-HY Medium E for growth and expansion. After initial screening for human Ig production by ELISA, the hybridoma cells from positive wells are expanded into 96- and then 24-well plates and cultured in complete medium, and then hybridoma cells are seeded in 96-well plates at 0.3 cell-per-well density. Finally, we single-cell sort the lines on a FACSAria III flow cytometer or with a ClonePix.

Ab sequences: After clonal hybridomas are obtained that secrete mAbs, we will determine the genetic basis for development of high-potency Abs to henipaviruses by sequence analysis and interpretation of Ab variable gene regions from HeV G protein-reactive human mAbs. **Prioritization scheme:** We are likely to isolate very large numbers of mAbs from these samples. If we isolate hundreds (or more likely thousands), we can retain the mAbs but we will not be able to perform complete characterization of all of these mAbs in the scale of this application. We will use several criteria to determine the highest priority clones to study. First, we will focus on Abs that neutralize with high potency (<0.1 µg/mL IC_{50}). Second, if there is still a large number, we will perform competitive binding assays by ELISA, Wasatch SPR and Octet biosensors to determine groups of mAbs with a similar binding pattern. We will make sure to characterize mAbs from each competition group, and within those groups, focus the most effort on the mAbs with the highest inhibitory potency. Third, we will focus on clones that neutralize both HeV and NiV, or, when identified, on pan-henipavirus clones. **Nextgen library preparation and sequencing:** PBMCs isolated from subjects ~~also~~ will also either be sequenced directly or enriched for specific B cell populations of interest such as antigen-specific memory B cells. We will extract total RNA and construct bulk B cell libraries as previously described. Sequencing will be performed according to standard Illumina 2 x 250 amplicon sequencing protocols that are well-established in the Crowe laboratory. In some cases, we will perform single-cell sequencing according to the 10X Genomics Single Cell VDJ B cell protocol and sequencing on an Illumina HiSeq 2500 to capture heavy-chain and light-chain linked information. Finally, we will perform an alternate single-cell approach in which single B cell are sequestered into water-in-oil emersions using a Dolomite µencapsulator system and full-length V_H or V_L sequences are physically linked via overlap extension PCR in the final form of a single-chain fragment variable region (scFv). These scFv libraries will be sequenced on a PacBio Sequel sequencing platform and used in a yeast display assay to test for additional functionality aspects. Following collection of raw data, we will analyze heavy and light chain variable region sequences using the proprietary PyIR software that we developed for large-scale immune repertoire studies. These differing approaches eliminate common bottlenecks related to B cell repertoire sequencing.

Recombinant Ab cloning and expression: Following sequencing of clones from hybridomas, yeast display, or repertoire studies, we will synthesize heavy and light chain variable region sequences of interest to the project for recombinant cloning and expression and downstream functional assays. Due to the potentially large number of interesting Ab sequences we are likely to discover, we will perform high-throughput synthesis of Ab genes using our 3 BioXP synthesizers (Synthetic Genomics) and Twist Bio custom synthesis, which can provide unrivaled scalability and throughput for synthesizing DNA at a high-quality level and low associated cost. Twist Bio and SGI DNA offer DNA synthesis services with the ability to produce large, small, and complex DNA constructs using the Gibson assembly method and error correction technology. Using in-house SGI DNA BioXP 3200 DNA synthesizers, we are able to synthesize and clone up to 1,400 genes between 300bp and 1.8 kbp in length per week at a cost of $0.11/base. Alternatively, for larger scale gene synthesis efforts Twist Bio has the capacity to synthesize and clone up to 10,000 genes between 300 and 3.2 kb in length per month at a cost of $0.09/base. Following synthesis, Ab genes will be Gibson-cloned in a 96-well format using a gateway-based Ig cloning platform to allow for rapid recombinant subcloning between different Fc variant expression vectors that are well established with the Crowe laboratory (70 Fc variant expression vectors are available). This high-throughput and modular recombinant Ab system allows for not only rapid expression of Ab genes of interest, but also rapid functional testing of different Fc-mediated Ab effects. This entire recombinant Ab cloning platform can be scaled from a low-throughput and manual-based preparation to a high-throughput and automated preparation on Tecan liquid handlers in the Crowe laboratory.

Commented [LZ6]: Might want to elaborate here – the hamster model could potentially be used to dissect the importance of effector function activity for in vivo protection…

Parallelized micro-scale Ab expression: We achieved a recent expansion in capabilities for micro-scale Ab expression and purification. Methods are now in place to express Abs either as hybridomas or recombinantly in a CHO cell transient transfection system across a broad range of scales from 96-well plates to multi-liter bioreactors. The lower volume end of this range allows parallelized expression of 100s to 1,000s of lead Abs, which will feed into the automated Ab purification on our Tecan automation platforms. This approach will allow early-stage assays to identify leads definitively that can then be iteratively produced, purified, and screened across our wide range of volume options (6-well plates, small volume shake flasks, large-volume shake flasks, and bioreactors). This approach will allow us to broadly screen entire panels of purified Abs at micro-scales, and then specifically tailor our time and reagent investment to prioritization of the clone. **Ab preparations:** Hybridoma cell lines will be adapted to serum-free medium. Supernatants of high-density cultures will be produced in CELLine Devices (BD Biosciences). Purified and concentrated preparations of each of the Abs will be prepared by FPLC using protein G resin on an AKTA followed by buffer exchange using ultracentrifugal filter devices, followed by quantitative ELISAs to define concentration.

Potential Pitfalls and Alternative Approaches. There are a number of technical challenges in the work that we propose. First, the frequency of human B cells in human subjects with immunity to viruses is uncertain. The occurrence of such circulating cells could be rare in some individuals. Therefore, our method must be capable of isolating rare B cell clones in a comprehensive manner. This risk is mitigated however because we have identified a donor with high frequency of HeV and NiV cross reactive B cells, and we have billions of PBMCs stored in the VVC Repository. We also will address this challenge in several experimental ways. First, our Ab discovery platform will incorporate not only state-of-the-art antigen-specific B cell isolations, but also, we will couple this with comprehensive sequencing of all Ab genes in the donor specimen. This repertoire sequencing approach will define billions of Ab variable gene sequences (likely reduced to about 20 million circulating clonotypes), allowing us to examine the entire lineage of somatic variants for any Ab isolated. This information is fascinating in terms of shining a light on the extreme diversity of the human immune response. However, in this proposal, we will turn that data into actionable information for the first time by large-scale synthesis of entire antigen-specific immune repertoires. To our knowledge, no group has ever attempted to synthesize Ab gene repertoires of the scale, much less expressed and characterized every member of a clonal lineage in this way for hundreds of lineages. This massive and comprehensive survey of Ab specificity and function in individuals with recent infection should allow us to identify the optimal functional members amongst large clonal lineages. This approach should allow us to find the rarest of clones with high therapeutic potential. In the past, contemplating such a large-scale Ab discovery campaign was unthinkable. However, the high-efficiency technique that we propose, using biological isolation coupled with next-generation sequencing and high-throughput gene synthesis and expression, makes such a survey possible.

The purification of membrane proteins can pose challenges that can affect the ability to prepare relevant microbial antigens. We have significant experience in purification of these surface proteins and have confidence in our ability to purify these proteins using our established protocols.

Commented [LZ7]: Perhaps delete? You've already established that you and Chris can make the proteins.

***In vitro* functional screens to test human Ab efficacy and specificity:** Once candidate Abs are identified, they will be screened using *in vitro* assays to identify the most functional molecules. We will target henipavirus G proteins, as described above. First, Abs generated against HeV and other viruses will be evaluated for the ability to neutralize HeV and NiV. Initially, we will use *wt* viruses, in the BSL4 laboratories at UTMB, but in the first year of the proposed studies we also will test using BSL2 surrogate virus systems developed by the Broder laboratory (described below). Abs will be used alone or in combination to determine the most effective cocktails that inhibit virus replication. With Abs that block the receptor binding domain (such as the HENV-26 mAb described in preliminary data above) we expect to achieve near complete blockade of henipavirus attachment to receptor. Considering that attachment is required for viral replication, these mAbs will represent powerful therapeutics to protect against infection by henipaviruses. The most active Ab and Ab combinations will be advanced to *in vivo* protection studies to define their therapeutic efficacy.

Cedar virus-based neutralization assay development: The ability to carry-out serum neutralization tests (SNTs) against infectious NiV or HeV is challenging because of the requirements for BSL-4 containment. The development of a robust surrogate assay for NiV and HeV SNTs that could be conducted at BSL-2 lab conditions would be a significant advancement for this proposed project but also to the henipavirus research field as a whole. Cedar virus (CedPV) was isolated from pooled bat urine collected in Queensland, Australia and is the only other authentic henipavirus isolate to date[5]. CedPV is closely related to HeV and NiV, genetically and antigenically. The Broder lab has been studying the functional characteristics and cellular receptor use profile of CedPV and its interactions with host cells of varied species. A reverse genetics system has recently been established for CedPV and this platform represents a new system which can be exploited in the present application that can be used safely under BSL-2 containment. ***Rationale:*** An authentic henipavirus CedPV-based neutralization assay will provide a long-term henipavirus neutralization testing platform that will alleviate the requirement for costly high-containment BSL-4 testing against NiV and HeV. This assay will facilitate the extensive combination (multiple mAbs) neutralization testing *in vitro* to identify the most potent antiviral combinations of mAbs, prior to conducting initial testing *in vivo* in hamsters. ***Innovation:*** The difficulties faced in the quantitation and assessment of vaccine-induced neutralizing Ab responses to NiV/HeV are significant owing to the requirements of BSL-4 containment for use of infectious virus. Typically, all SNT assays using mAbs or polyclonal sera derived from animals, humans, or from experimental vaccine protocols are carried using infectious wild-type NiV and/HeV isolates. A classical plaque reduction neutralization test (PRNT) to evaluate neutralizing polyclonal sera or mAbs (Abs reactive to the NiV/HeV G and F envelope glycoproteins) is wildly used, and PRNT titers will give an indication of protective immunity. PRNT using live NiV has been developed [107]. However, for NiV and HeV, PRNT assays must be performed in BSL-4 containment and takes 5–7 days to complete. Alternatives to assessing neutralization of NiV/HeV by Abs have been explored such as recombinant VSV-based pseudotyped reporter-gene virions bearing NiV or HeV F and G [108], however this assay is not as sensitive as the PRNT using authentic NiV. Other reporter virus platforms using VSV and HIV-1 have described as well but again, consistent production of quality pseudotyped virus stocks is difficult and neither have offered real improvements over the classical PRNT with infectious NiV and/or HeV[109,110]. Finally, because of the known details of NiV and HeV host cell infection process and receptor use, cell-free systems have also been explored. Bossart *et al*.,[111] developed a Luminex-based NiV/HeV sG and ephrin receptor Ab blocking assay, and although in general it can assess relative potency of neutralizing Abs as a surrogate assay, it cannot assess all types of neutralizing Abs reactive to G. Indeed, the ephrin-B2/B3 receptor binding site on G is only one of 7 known virus neutralizing determinants (Broder *et al*, unpublished). The innovation here is two-fold: First, we propose here a cell-based SNT that will make use of an authentic henipavirus infection and replication reporter system (a replication competent, reporter gene-encoding CedPV) which has never been done before. Second, the recombinant CedPV-based platform requires only BSL-2 containment, relieving the cost and technical challenges of the high-containment environment when high numbers of samples are to be tested. ***Approach:*** *Develop, characterize and adapt a rCedPV luciferase reporter virus for use in SNT*. Here, we will develop the very first cell-based, authentic henipavirus infection, replication and reporter system based on the non-pathogenic CedPV. We will rescue a second pair of rCedPV chimeras, bearing the HeV and NiV F and G glycoproteins, as reporter viruses encoding luciferase. These novel viruses will serve as authentic replication competent henipaviruses with the same tropism and biology of HeV and NiV but that can be grown and employed in virus infection assays outside of BSL-4 containment. We will provide these reagents to the Geisbert lab to characterize and compare them to wild-type NiV and HeV in cell-based infection tropism and growth kinetics assays and validate their use as surrogates in neutralization assays. The novelty of our approach is that the virus reporter system is an authentic henipavirus and one that may be used in the BSL-2 setting. ***Experimental Methods and Design:*** Generation of plasmids and rescue of recombinant viruses: We have already constructed a recombinant CedPV antigenome clone by synthesis of several large segments of the genome into pOLTV5[112] between a T7 RNA promoter and hepatitis delta virus (HDV) ribozyme. The pOLTV5 vector was similarly used for cloning and expression of recombinant HeV[113] and methods similar to those used in the rescue of recombinant NiV[114]. The first reporter virus chosen was using Turbo-GFP, and the GFP gene was modified to be flanked by the CedPV intragenic P stop and M start sequences conforming to the “rule of six”. As with recombinant HeV[113] the GFP gene was inserted between the P and M genes to maintain the levels of N and P transcripts. Helper plasmids for the N, P, and L genes from CedPV were also prepared (pCMV). To generate recombinant CedPV, pCMV CedPV N, pCMV CedPV P, pCMV CedPV L, and pOLTV5 full-length rCedPV-GFP anti-genome plasmid were mixed with Lipofectamine LTX (Invitrogen) in OptiMEM, and used to transfect 5 x 10^5 BSR-T7 cells. At day 4, GFP was observed in BSR-T7 cells transfected with the rCedPV-GFP antigenome and N, P, and L helper plasmids. Non-adherent BSR-T7 cells and culture supernatant were collected and freeze-thawed 3-times. Vero cells at a density of 1 x 10^6 cells/well in 6-well plates were inoculated with the freeze-thaw supernatant. Maximal GFP signal and syncytia were observed after 6 days, supernatant was clarified by centrifugation and 300µL of supernatant was passaged to fresh 1 x 10^6 Vero cells in 6-well plates. Within 24h, GFP signal and syncytia were observed. At 3 days, maximal GFP signal was observed and supernatant was passaged on fresh Vero cells (75 cm^2 flasks) for amplification of rCedPV-GFP. We also plan to increase the efficiency of CedPV rescue, and the pOLTV5-CedPV vector has been modified to express a 5′ HDV ribozyme site anterior to the CedPV 3′ leader sequence[115]. With this modified anti-genome two additional recombinant viruses have already been made; a CedPV void of any reporter gene but retaining the introduced restriction site (rCedPV+6) which is our wild-type CedPV, and luciferase encoding virus. We chose nanoluciferase (NanoLuc) a newly developed small luciferase reporter (brightest bioluminescence reported to date), which is a small luciferase subunit (19 kDa) from the deep-sea shrimp *Oplophorus gracilirostris*[116]. The rCedPV-GFP virus and wild-type rCedPV are amplified in Vero cells, and typically 8 T-75 cm^2 flasks, after 4 days in culture yield viral stocks of 1 x 10^8

pfu/mL in ~3 mL after purification and resuspension and can be stored aliquoted at -80ºC. We have also determined that CedPV exhibits a remarkably broader ephrin receptor usage profile, and cells bearing CedPV G and F can also mediate fusion with cells expressing ephrin-B1 and the glycosylphosphatidylinositol (GPI) anchored ephrin-A proteins; ephrin-A1, A2 and A5. Shown in **Figure 7** is the CedPV F and G cell fusion obtained with all B and A class ephrins.

Figure 7. <u>CedPV (CeV) glycoprotein-mediated fusion with a panel of A-type and B-type ephrin-expressing cells.</u> Target cells were prepared by transfecting a panel of ephrin expression plasmids into HeLa USU cells infected with vCB21R(Laz-reporter vaccinia virus) and allowed to fuse with CedPV F+G expressing HeLa USU effector cells infected with vTF7.3 (T7-polymerase reporter vaccine virus. Fusion is quantitated as the rate of β-galactosidase activity[117]. CedPV mediated fusion with cells expressing ephrins-A1, -A2, -A5, -B1, and -B2.

CedPV cell fusion also correlates with CedPV G glycoprotein binding to ephrins and this data has been confirmed by surface plasmon resonance experiments with soluble ephrins and CedPV soluble G. (C. Navaratnarajah, R. Cattaneo, and C. Broder, data not shown).

<u>*Generation of rCedPV Chimeras*</u>: The Broder lab was the first to show the unique functional similarities between NiV and HeV G and F glycoproteins by demonstrating that they are the only paramyxoviruses that can bi-directionally functionally complement heterotypically[118] perhaps owing to their aa identity (~83% and 89% for G and F). Our new data with CedPV has provided a breakthrough in finally distinguishing between a functional vs. non-functional F-G interaction. The CedPV-F is only 42% and 43% identical with HeV-F and NiV-F respectively; and CedPV-G is 29% and 30% identical with HeV-G and NiV-G. Performing F and G co-expression and fusion assays using combinations of CedPV, HeV and NiV (**Figure 8**) has provided some very important observations. Ephrin-B2 and -B3 negative HeLa-USU cells are negative for CedPV fusion, as are ephrin-B3 bearing Hela-B3 cells. Fusion does occur with 293T and ephrin-B2 bearing HeLa-B2 cells. Thus, CedPV-F has heterotypic function with both HeV-G and NiV-G, but CedPV-G has heterotypic function with only HeV-F and not NiV-F and correlates with ephrin use. Of significance, these data support the hypothesis that we will be able to construct and generate novel rCedPV isolates using our reverse genetics system, whereby the F and G genes within the rCedPV genome maybe removed and replaced by with NiV F and G or HeV F and G. These new reporter gene encoding authentic henipaviruses that may be used under BSL-2 containment and they will be the ideal tools in establishing a robust SNT assay to assess virus neutralizing Ab responses in HeV-sG vaccinated subjects. Experiments on the generation and manipulation of the non-pathogenic rCedPVs, including the proposed development of novel chimeric viruses using the NiV and HeV F and G glycoproteins, have been approved by the Institutional Biosafety Committee (IBC). The chimeric viruses will in fact be loss-of-function recombinant viruses because of the reduced ephrin receptor use profiles between CedPV and either NiV or HeV.

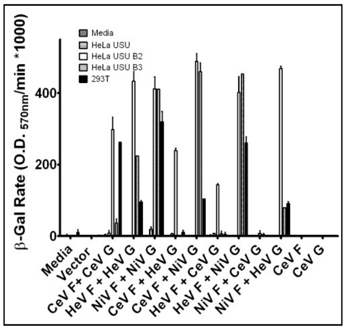

Figure 8. <u>CedPV mediated cell fusion and heterotypic mixing with HeV and NiV.</u> Various target cell populations are shown in the legend.

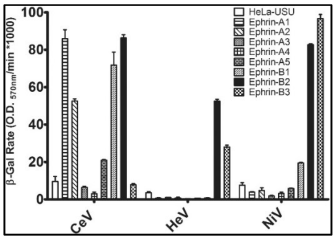
<u>Characterization of the recombinant CedPV viruses:</u> We expect the reporter gene encoding virus will not be hindered in any way based on the amplification results and titer of rCedPV-GFP, but we will analyze the replication kinetics of rCedPV-Luc and also compare those results to wild-type rCedPV (no reporter gene). Each virus will be used in experiments to determine receptor tropism and compared to the CedPV cell fusion assays using CedPV F and G expression as done with HeV and NiV[105,117-119]. <u>*Expected Results and Data Analysis:*</u> Based on the preliminary data in hand, we do not expect any unforeseen difficulties in generating the novel rCedPV/NiV-HeV chimeric viruses. We expect that all recombinant viruses will have an infection profile identical to the cell-cell fusion assays using recombinant expressed F and G from CedPV, NiV and HeV. Because we have rescued the GFP-encoding CedPV, we do not anticipate any unexpected limitations in recusing the rCedPV chimeras encoding NiV or HeV F and G. Based on the replication results with rCedPV-GFP, we expect that large amounts of reporter virus stocks can be prepared, providing a consistent source of material for conducting the number of SNT assays expected to be carried out.



<u>**Specific Aim 2: Develop immuno-therapeutics for the treatment of henipavirus infections.**</u>

Rationale: In Specific Aim 1 we will isolate human mAbs targeting conserved G protein domains. Experiments in Aim 2 will evaluate the therapeutic value of these Abs in animal models of viral infection. The goal is to create broadly reactive Abs that both inhibit viral replication, while simultaneously promoting immune-mediated clearance. Considering the conservation of the selected target across henipavirus strains, mAbs developed through this campaign have the potential to be valuable for treatment of a variety of diseases.

***In vivo* protective effect of Abs against invasive infection caused by henipaviruses:** This project will employ golden Syrian hamsters as the small animal model of NiV and HeV disease since they develop late stage lesions similar to those in humans and because they are more suitable than other small animals for screening large numbers of MAbs. Using hamsters will allow us to select optimal MAb formulations and regimens prior to efficacy testing in NHPs. African Green Monkeys (AGMs) are the gold standard animal models for henipaviruses and can provide a model of ~~immunogenicity and~~ efficacy that has ~~some~~ predictive value for therapeutic interventions. The AGM model was developed by Dr. Geisbert for HeV and NiV infection [2, 3]. The AGM model results in neurological disease and severe respiratory pathology along with generalized vasculitis that provides an accurate reflection of what is observed in henipavirus-infected humans [1-3]. The model yields a consistent lethal infection and disease with low dose challenge (less than 5000 pfu for Nipah virus, Bangladesh strain) given by the intratracheal (i.t) and/or intranasal (i.n.) route (TW Geisbert, unpublished data). The virus spreads rapidly within 3-4 days and the infection is established in multiple organ systems. Animals develop a severe ARDS-like disease, associated with copious amounts of sanginous fluid and froth. Death usually occurs within 7-9 days after infection. Evidence of endothelial syncytia are prominent in most of the tissues and vasculitis is systemic. Virus can be found in virtually every organ system at the time of death in the AGM, and most infected AGMs show evidence of henipavirus-induced neurological disease with congestion of the brain and evidence of meningeal hemorrhage and edema. The cynomolgus macaque model is not useful for demonstrating the effectiveness of therapeutic interventions or vaccines because the virus is not lethal in cynomolgus macaques when given by the combined i.n. and i.t. routes at a dose that is lethal in AGMs (TW Geisbert, unpublished data) and animals universally recover. Therefore, AGMs will be used as the NHP species of choice for the proposed research.

The Geisbert laboratory will test the *in vivo* efficacy of human mAbs using the ~~(~~Syrian golden hamster (*Mesocricetus auratus*) and AGM primate model of infection. This laboratory is one of the most experienced groups in the world in the use of animal models of henipavirus infection. Once Abs are demonstrated to recognize and block virus attachment to receptor, or other functions in the life cycle, they will be assessed for protection in the appropriate infection model. Varying concentrations of specific Abs, used alone or in combination, as well as control Abs will be tested in Syrian golden hamsters aged 5 to 8 weeks of age, weighing 50-150 grams with equal numbers of males and females. The total number of animals that will be used over the course of these studies is 240. Once the number of candidate mAbs/mAb cocktails is reduced to x from the hamster testing, ~~The lead mAbs also~~they will be tested in African green monkeys (*Chlorocebus aethiops*) using adult animals 3 to 12 years of age, weighing 2.5-9 kg, and using equal numbers of males and females. The total number of monkeys that will be used over the course of these studies is 36. Animals will be obtained from a commercial vendor. In years 1 and 2 of the project, hamsters will be exposed to HeV or NiV by the intranasal (i.n.) administration of up to 1 x 10^6 pfu of virus and treated at various times or with varying doses after henipavirus exposure by i.p. administration of mAbs to establish the therapeutic window and dose response,, respectively. In years 3 to 5, work will focus on assessing the protective efficacy of the most promising mAbs identified from the hamster studies. African green monkeys (AGMs) will be challenged by the intratracheal (i.t.) and/or i.n. routes using up to 1 x 10^6 PFU of HeV or NiV and treated at various times after exposure by intravenous (i.v.) administration of mAbs. Blood collection will be done as described in Section 3 of the Vertebrate Animals document.

Manufacturability. To augment the measures of biological activity, we will design and execute a manufacturability assessment (MA) study with desired product quality attributes and ensure the lead molecule(s) demonstrate adequate expression, process yield, processing and storage stability. We will continue to refine the Target Product Profile (TPP; see Product Development Strategy) since some components of the MA study design will be dependent on the TPP. This will allow us to focus on the most critical biophysical properties for the indication, route of administration and target concentration resulting in an optimized MA study design to rank the candidate molecules. We will take a tiered approach to maximize the use of resources and material. The first step, *in-silico* assessment of potential liabilities will include identifying unpaired Cys and exposed Trp/Met in variable regions and either re-engineer or de-prioritize, accordingly. Expression levels will be evaluated using Octet RED96 (Pall) with Protein A/anti-Fc biosensors. The top 10-20 candidates will then be subjected to protein A elution and low pH hold steps to evaluate the propensity to aggregate by SEC, form fragments by CE-SDS, intact mass by LC-MS and total yield by UV spectroscopy. Candidates will be ranked based on purity assessed by the methods mentioned above and the total yield. The

Formatted: Font: (Default) Arial

top 3-5 candidates that result will then be subjected to biophysical analysis determined by the TPP. For example, thermal stability will be evaluated by pH ranging studies (pH 5 – 8) in 2 platform buffers and if target concentration is ≥ 50 mg/mL, viscosity and solubility as a function of pH will be investigated to determine the optimal pH range. The top 2-3 candidates will be advanced with the chosen formulation buffers into stress assessments such as accelerated temperature at 40ºC for 4 weeks, 3X Freeze-Thaw and Agitation studies with and without surfactants. Readouts will be aggregation, fragmentation, particulate formation and protein concentration. Evaluation of binding to GP will be included. At this stage, charge heterogeneity and glycosylation analysis of the top candidates will be performed in chosen formulation buffers. Detailed biophysical profiling with material from the final host cell platform and process conditions will be performed later during development to understand the behavior of representative material for scale up and manufacturing.

Generation of the CHO line. CHO cells are the standard of choice for manufacturing complex biomolecules like IgG fusion proteins for therapeutic purposes. Due to its robust nature and track record as a proven host for biologics manufacturing, there is substantial infrastructure within the US to assure GMP production of CHO material at virtually any scale. **Figure 9** shows Mapp's approach to producing the material to be used in the later stages of the proposal as well as the CHO cell line to support advanced development of the product. The sequence of the lead mAb(s) will be optimized *in silico* for expression in CHO cells and synthesized by DNA2.0. The synthesized sequences will be inserted into DNA2.0's IP-free plasmid DNA expression vector for stable integration in CHO (CHOZN®; Sigma; fucosylated N-glycans) or Mapp's CHOK1-AF (afucosylated N-glycans) host cell line depending upon the preliminary results. Following transfection of the CHO host with the mAb vectors, stable pools will be generated. Following selection, the pools will be fractionated into mini-pools for analysis using a Molecular Devices Clonepix™ 2 automated high-throughput colony picker in use at Mapp. Approximately 100 high expressing single-cell clones will be selected using the ClonePix 2 system, expanded, and screened for production by ELISA. Productive subclones will be screened and a Research Cell Bank (RCB) for up to 5 of the best subclones will be created. The RCBs will be tested for Mycoplasma, sterility, and relevant viruses. These banks will contain several vials of each subclone and safely stored under appropriate conditions.

Figure 9. Strategy for production of mAbs and generation of stable CHO cell lines.

Production of mAbs. Mapp will perform early manufacturing using the polyclonal mini-pools in advance of a clonal cell line in order to develop the manufacturing process and prepare for production of material to support IND-enabling NHP testing and GLP tissue cross reactivity (TCR) testing. MAbs for the NHP and TCR study will be generated using the clonal cell lines identified. Manufacturability is critical to the success of any potential biotherapeutic. Therefore, to ensure the cell lines and product meet the requirements necessary for a successful clinical campaign, Mapp will employ commonly accepted industry practices for evaluating and selecting a CHO cell line suitable for this task. Polyclonal mini-pools and clonal cell lines will be subjected to a standard platform fed-batch process for determination of the cell line most suitable for manufacturing purposes. Cells will be grown in shake flasks or larger systems (*e.g.*, Wave bioreactor; 50L) as appropriate. Supernatant from the bioreactors will be harvested via filtration and subsequently processed using a 2-step purification process. The first chromatography step will be Protein-A affinity. The subsequent chromatography step will likely be an ion exchange step similar to the current platform process in use at Mapp (Q-sepharose). Bulk drug substance will be formulated and stored at an appropriate temperature for future use. The resulting product will be tested using a set of assays typical for mAbs as well as those specific to the NiV/HeV mAbs. Research-grade material for use in biochemical characterization and *in vivo* efficacy testing will be generated from polyclonal pools of transfectants; material to support future toxicology studies will be generated from the clinical cell line using bioreactor and/or shake-flask vessels.

Evaluation of cross-reactivity to human tissues under Good Laboratory Practices (GLP). These studies are conducted by Charles River Laboratories in accordance with FDA guidelines in compliance with GLP regulations. Biotinylated mAb will be incubated with frozen normal human-tissue specimens (all major organs, including adrenal, brain, eye, kidney, bone marrow, liver, lung) for measurement of cross-reactivity. Tissues from three adults and one neonate donor are used and Synagis® (MedImmune) serves as a control mAb. All slides are examined and scored by a board-certified veterinary pathologist.

Commented [LZ8]: Jim, not in our budget…you can say that Mapp will be responsible for funding this activity here or in the budget justification

Submission of pre-IND to FDA (Final Milestone). Upon conclusion of the work effort, a pre-IND will be submitted to the FDA. This regulatory filing will outline the data accumulated to date including the *in vitro* and *in vivo* efficacy data. In addition, our proposed pharmacology/toxicology studies and Phase 1 clinical safety trial design will be presented. The purpose of this submission is to solicit feedback on the current set of data as well as the future plans to best prepare a future IND submission to support the Phase 1 trial.

Potential Pitfalls and Alternative Approaches. We do not anticipate any challenges with the viral G protein binding assays, virus neutralizing assays or hamster infection models as we have considerable experience in each of these techniques and these assays are established in our laboratory. The studies described above aim to generate human Abs that recognize important viral protein epitopes expressed on the surface of the virus during infection. Production of high concentrations of human Abs can be challenging for some clones. We have described the approach above to enhance manufacturability of the Abs. Also, we anticipate having hundreds of mAbs from which to choose, with similar potency and mechanism of action, but diverse expression profiles. We will focus on development of ultra-potent neutralizing Abs that produce well in CHO cells early in the process.

Commented [LZ9]: Perhaps something about PK not being a problem? i.e. mAbs have a long half-life and the course of disease is short,,,

This is a little cleaned up compared the version i sent earlier.
If you haven't started, use this to edit
Its getting big so i zipped it
It you need to , you can just send edited pieces back, or share a dropbox or something

Subject: Re: nipah

I'm kinda hurting bad on this. I made the mistake/choice/blessing of taking ~ 8 days off at the end of the year, and have been completely underwater ever since. I still want to submit this, but it's going to be a scramble. A lot (but not all) of the admin stuff is done. But the science is still in shambles. I need to put it together over the next day.

What I need, or could benefit from, from you guys:
TOM

1. Select agent section, since there is Hendra and Nipah
2. Biosafety section
3. Vertebrate Animals section

4. Any basic (even extended) text or old grant sections on "HeV and NiV are xxx viruses", "bad for you", and "neut test is done by x, with these strains: yy", "animal models are . . . "

Larry

1. Anything you would do for characterizing manufacturability or development of the lead mabs, for the science section
2. A "product development plan section" on human mAbs for these viruses. Kinda boilerplate, which i am guessing you have already

DRAFT V5 —NOT FOR DISTRIBUTION— January 1, 2018

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

Clinical aspects:

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Quality, quantity, types and timing of collection of clinical samples can greatly affect the accuracy of laboratory test results.

Laboratory aspects:

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Various types of test methods/platforms are required to cover testing at different phases of Nipah virus infections. As diagnostic capabilities and resources are often inadequate in endemic

Formatted: Font: Italic

Formatted: Font: Italic

Formatted: No bullets or numbering

Formatted: Font: Not Italic

and at risk areas, test platforms/types to be developed for these areas need to be cheap, simple to perform and require minimum instrumentation.

Virus aspects:

Formatted: Indent: Left: 0.5", No bullets or numbering

Formatted: Font: Italic

Formatted: No bullets or numbering

- As Nipah virus is PC4 virus, ~~D~~diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.
- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Financial constraints:

Formatted: Indent: Left: 0.5", No bullets or numbering

Formatted: Font: Italic

Formatted: No bullets or numbering

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- ~~High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*~~

Key needs

- A WHO clinical guideline on early diagnosis and management of Nipah virus infection need to be developed to guide clinicians/epidemiologists on early detection of cases (based on clinical and epidemiological data), samples collection/transport and management of cases.
- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.

- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids such as saliva, urine and respiratory fluid, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids such as saliva, urine and respiratory fluid, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecologic and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV_M and NiV_B strains may impact the effectiveness of developed MCMs, yet NiV_M has been used significantly more often than NiV_B in research. *(*cross cutting)*
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*
- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.

- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Knowledge gaps

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ribavirin was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and

identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.
- **Determine** the key differences between NiV_B and NiV_M that may have implications for the development of safe and effective NiV therapeutics.
- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV_B and NiV_M and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*
- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.
- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.

- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.

- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.
- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis

more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.

- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecologic and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Product development

- **Generate** a TPP for NiV diagnostics.

- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV_M and NiV_B strains may impact the effectiveness of developed MCMs, yet NiV_M has been used significantly more often than NiV_B in research. *(*cross cutting)*
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Knowledge gaps

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV_B and NiV_M infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ribavirin was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional

animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.
- **Determine** the key differences between NiV_B and NiV_M that may have implications for the development of safe and effective NiV therapeutics.

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV_B and NiV_M and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.
- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.

- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.
- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.
- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.

- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.

- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

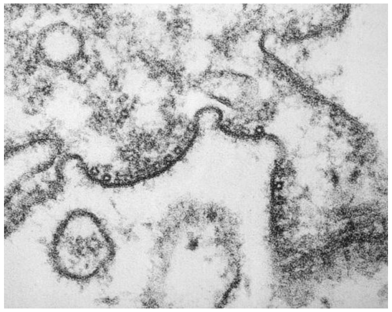
Nipah Virus R&D Roadmap Development Taskforce Conference Call

January 9/10, 2018



Agenda

1. Welcome and roll call
2. R&D roadmap architecture
3. Role of roadmap taskforce members
4. Roadmap development and timeline
5. Discussion of draft R&D roadmap for Nipah virus
6. Next steps

World Health Organization

Developing and Implementing R&D Roadmaps *for priority pathogens with epidemic potential*

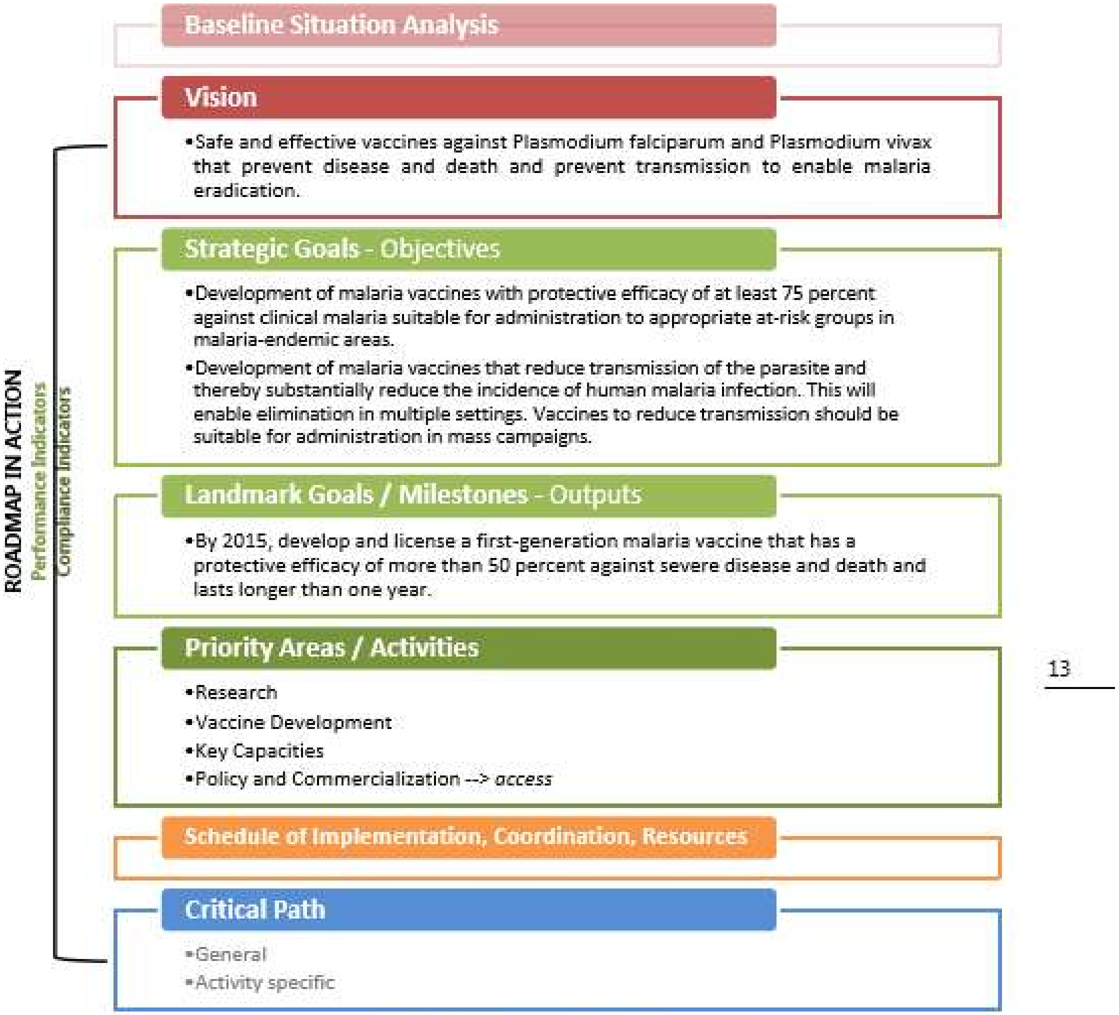
A generic methodology

R&D BLUEPRINT

Working Draft, version 30 August 2017

WHO | R&D Blueprint | Geneva, 30 August 2017

Example of Roadmap Architecture: Malaria Vaccine



Baseline Situation Analysis

Vision

- Safe and effective vaccines against Plasmodium falciparum and Plasmodium vivax that prevent disease and death and prevent transmission to enable malaria eradication.

Strategic Goals - Objectives

- Development of malaria vaccines with protective efficacy of at least 75 percent against clinical malaria suitable for administration to appropriate at-risk groups in malaria-endemic areas.
- Development of malaria vaccines that reduce transmission of the parasite and thereby substantially reduce the incidence of human malaria infection. This will enable elimination in multiple settings. Vaccines to reduce transmission should be suitable for administration in mass campaigns.

Landmark Goals / Milestones - Outputs

- By 2015, develop and license a first-generation malaria vaccine that has a protective efficacy of more than 50 percent against severe disease and death and lasts longer than one year.

Priority Areas / Activities

- Research
- Vaccine Development
- Key Capacities
- Policy and Commercialization --> *access*

Schedule of Implementation, Coordination, Resources

Critical Path

- General
- Activity specific

COMMENTARY

A roadmap for MERS-CoV research and product development: report from a World Health Organization consultation

Kayvon Modjarrad, Vasee S Moorthy, Peter Ben Embarek, Maria Van Kerkhove, Jerome Kim & Marie-Paule Kieny

As part of the World Health Organization (WHO) R&D Blueprint initiative, leading stakeholders on Middle East respiratory syndrome coronavirus (MERS-CoV) convened to agree on strategic public-health goals and global priority research activities that are needed to combat MERS-CoV.

The emergence and persistence of MERS-CoV as a cause of severe respiratory disease 10 years after the outbreak of severe acute respiratory syndrome coronavirus (SARS-CoV) highlights the need for the rapid development of effective interventions against highly pathogenic human coronaviruses. As MERS-CoV grows in global importance—causing disease and death in more than 1,700 and 600 people, respectively, across 27 countries[1]—research and print for emergency R&D to prevent, or at least mitigate, the impact of infectious-disease outbreaks. MERS-CoV is one of eight pathogens prioritized in the WHO blueprint (http://www.who.int/medicines/ebola-treatment/WHO-list-of-top-emerging-diseases/en/), and it was selected as a case study to demonstrate how accelerated basic and applied research, as well as product development, could be better supported and coordinated. The WHO therefore scientific community that dromedary camels are the main animal reservoir and source of zoonotic transmission to human populations[3]. However, the dynamics of transmission events from dromedaries to humans and between humans are poorly understood. Although studies have demonstrated that individuals with close and frequent contact (i.e., occupationally exposed) with dromedaries are at much higher risk for MERS-CoV infection than the general population[4], it remains

Supplemental note to commentary:

A Roadmap for Research and Product Development against Middle East Respiratory Syndrome-Coronavirus (MERS-CoV)

Background on Technology Roadmaps

Technology roadmaps have been successfully used in several sectors where large-scale, collaborative efforts are required to deliver outcomes related to innovation including product development. In all such processes, it is critical to understand and articulate the goals and markets for innovative products. High-level priority objectives are identified, followed by agreement on specific activities to reach the objectives. It is critical to map baseline knowledge gaps and then develop a strategic plan to address those deficiencies. This also requires an assessment of capacity needs that can support these activities. Project management and implementation structures are subsequently established to pursue agreed activities to reach the goals. An example of this process can be found in the WHO Malaria Vaccine Technology Roadmap.

Introduction

The Scientific Advisory Group convened by WHO to advise the Blueprint included MERS CoV as one of the disease priorities, and this document was prepared for MERS as a prototype. It represents the results of a consultation process facilitated by WHO, working with international stakeholders, to develop a MERS-CoV Research and Product Development Technology Roadmap.

Middle East Respiratory Syndrome-Coronavirus (MERS-CoV) is an emerging pathogen of growing importance. As of May 2016, MERS-CoV has been confirmed as cause of severe acute respiratory disease in 1728 people, resulting in 624 deaths. The high case fatality rate, growing geographic

Nipah Virus Taskforce Members

- Christopher Broder
- Kaw Bing Chua
- Emily Gurley
- Stephen Luby
- Gregg Milligan
- Mahmudur Rahman
- Pierre Rollin
- Lin-Fa Wang

Role of Taskforce Members

- Contribute to the initial development of the draft roadmap outline (via early document review and a conference call prior to the in-person consultation).
- Participate in the in-person consultation (if available): March 1-2, 2018.
- Review subsequent roadmap drafts and provide ongoing input.
- Provide assistance with dissemination of the roadmaps.

Timeline for Nipah Virus Roadmap Development

Pre-consultation conference call with TF members to review draft outline	January 9/10
Obtain written feedback from TF members on outline (if feasible)	By January 19
Revise outline and send out to SMEs who will be participating in the in-person consultation	Mid-February
Hold in-person SME consultation on Nipah roadmap	March 1-2
Incorporate feedback from SMEs and create new draft (text format)	March/April
Seek additional input from TF members on the new version	April

Timeline for Nipah Virus Roadmap Development (cont.)

Post draft roadmap online for public comment	April/May*
Incorporate feedback, adjudicate comments, and create final draft	May*
Send final draft to TF members for review (if necessary)	June*
Continue to review and revise final draft with input from WHO and others	July/August*
Publish final roadmap document	Late August
Begin dissemination process	September

*Tentative

Considerations for Roadmap Review

- Organizational approach
- Level of detail
- Questions
  - Are the right issues covered?
  - What is missing?
  - Is anything inaccurate?
  - What should be removed?
  - Other comments, questions, or concerns

Discussion of Draft Roadmap Outline

- **Diagnostics**
  - Background: primary challenges, key needs, knowledge gaps
  - Strategic goals
  - Priority activities
    - Research
    - Product development
    - Key capacities
    - Policy and commercialization

Thank you!!!!

A roadmap for MERS-CoV research and product development: report from a World Health Organization consultation

Kayvon Modjarrad, Vasee S Moorthy, Peter Ben Embarek, Maria Van Kerkhove, Jerome Kim & Marie-Paule Kieny

As part of the World Health Organization (WHO) R&D Blueprint initiative, leading stakeholders on Middle East respiratory syndrome coronavirus (MERS-CoV) convened to agree on strategic public-health goals and global priority research activities that are needed to combat MERS-CoV.

The emergence and persistence of MERS-CoV as a cause of severe respiratory disease 10 years after the outbreak of severe acute respiratory syndrome coronavirus (SARS-CoV) highlights the need for the rapid development of effective interventions against highly pathogenic human coronaviruses. As MERS-CoV grows in global importance—causing disease and death in more than 1,700 and 600 people, respectively, across 27 countries[1]—research and development (R&D) efforts to design diagnostic, prophylactic and therapeutic products are gaining momentum. In the aftermath of the 2014–16 Ebola epidemic in West Africa and the current Zika virus outbreak, it has become clear that more strategic investments are needed in the early development of diagnostics, therapeutics and preventives against pathogens of pandemic potential[2]. The ultimate goal is to reduce delays between the identification of a public-health emergency and the deployment of effective medical interventions that will save lives and minimize socioeconomic disruption. Toward this objective, the WHO is developing a blueprint for emergency R&D to prevent, or at least mitigate, the impact of infectious-disease outbreaks. MERS-CoV is one of eight pathogens prioritized in the WHO blueprint (http://www.who.int/medicines/ebola-treatment/WHO-list-of-top-emerging-diseases/en/), and it was selected as a case study to demonstrate how accelerated basic and applied research, as well as product development, could be better supported and coordinated. The WHO therefore convened a consultation of leading experts (**Supplementary Note 1**) on 10–11 December 2015 to develop a roadmap for MERS-CoV activities as part of the blueprint agenda.

Baseline assessment and epidemiology

The WHO's assistant director-general for health systems and innovation, Marie-Paule Kieny, opened the consultation by framing the meeting in the context of the broader blueprint for R&D preparedness and emergency response for known priority pathogens. The first author of this report then presented a landscape analysis of MERS-CoV diagnostics, preventives and therapeutics, highlighting the major gaps and advances in ongoing research and product-development activities. This baseline analysis summarized a report that was written for the consultation and that can be accessed on the WHO website (http://www.who.int/csr/research-and-development/mers-landscape.pdf?ua=1). After these overviews, a series of presentations described current knowledge about MERS-CoV epidemiology.

There is already broad consensus within the scientific community that dromedary camels are the main animal reservoir and source of zoonotic transmission to human populations[3]. However, the dynamics of transmission events from dromedaries to humans and between humans are poorly understood. Although studies have demonstrated that individuals with close and frequent contact (i.e., occupationally exposed) with dromedaries are at much higher risk for MERS-CoV infection than the general population[4], it remains unclear what routes of exposure mediate viral transmission most efficiently. Since the recognized introduction and entrenchment of MERS-CoV in human populations, the majority of MERS-CoV outbreaks have occurred in the nosocomial setting[5]. Although surveillance programs, observational studies and enhanced infection-control systems are now being prioritized and implemented throughout the Middle East, there is still wide variability across the region in the reach of surveillance efforts, the depth of case investigations and adherence to infection-control protocols. Improvements in these efforts will require political will, coordination across multiple sectors within countries at highest risk for future outbreaks, more streamlined communication, engagement with affected communities and cross-validation of diagnostics already in use and in development.

Diagnostic-assay development and standardization

During the early stages of infection, MERS-CoV cannot be clinically distinguished from other types of respiratory infections. Thus,

as the current case definition of MERS-CoV infection is based on laboratory confirmation[6], the development and harmonization of sensitive, specific and easily administered diagnostic assays are crucial to the success of surveillance systems, epidemiologic studies and efficacy assessments in clinical trials. One of the principal challenges of developing useful diagnostic assays is that they are dependent on high levels of virus replication and thus cannot detect infection until several days after viral exposure. During this time, the individual is infectious and poses great risk to others. Speaking to these issues, several participants surveyed the diagnostics in use and commented on their current utility and future viability for both clinical and research purposes.

Nucleic acid–amplification tests (NAATs) are currently the gold standard of MERS-CoV diagnostic platforms[7]. Although these tests have become substantially easier to implement, their performance is still dependent on specimen quality and technician training, because environmental contamination can easily confound accurate interpretation of results. Serologic assays—such as those based on immunofluorescence, immunochromatography, enzyme-linked immunosorbence and live-virus or pseudovirus neutralization—vary in their performance characteristics, but provide benefits over NAATs in the form of easier implementation and more functionally relevant readouts[8]. The performance of any assay, particularly with respect to MERS-CoV, depends on when it is administered during the natural history of disease. A more detailed understanding of the key features of the clinical course of MERS-CoV infection is, therefore, needed to inform the optimization of existing assays and the development of next-generation diagnostics. It was generally agreed that, even in the absence of these data, there is an urgent need for rapid, point-of-care diagnostics for both human and animal populations. The suggestion was made to develop commercially available—or at least adequately validated—simple, dipstick immunochromatographic assays that are suitable for use on livestock and humans (before confirmatory testing of positive results in humans). It was also recommended that more-advanced diagnostics, such as real-time reverse-transcriptase polymerase chain reaction (rRT–PCR) assays, be developed as part of a multivalent respiratory panel. There is also a need for more coordinated efforts to sequence circulating viruses and to correlate those data with phenotypic outcomes, such as viral fitness, virulence and structure–function relationships of the surface Spike (S) and other MERS-CoV proteins. There was a general call for the development of commercial tests and quality assurance of existing assays, although some of this work has already been started[7]. The validation of diagnostic tests will be essential for the execution and interpretation of epidemiologic studies that can better define viral reservoirs, transmission dynamics and correlates of protection.

Therapeutics

There are currently no licensed treatments for MERS-CoV. The discovery of antivirals for MERS-CoV has been limited to the repurposing of compounds already licensed or in development for other diseases. Some of the experimental treatments used sporadically during this outbreak are the same as those used for SARS-CoV. As in the SARS-CoV epidemic, however, the use of treatments such as ribavirin, interferons and corticosteroids have yielded little to no clinical benefit, despite showing efficacy in nonhuman primates (NHPs)[9]. High-throughput screens of large libraries have uncovered pharmaceutical agents across several classes that inhibit MERS-CoV replication *in vitro* and a few that improve survival in marmoset models[10]. Investigational agents are also being repurposed from other infectious diseases, such as Ebola virus disease, for potential use against MERS-CoV. Data were presented on the antiviral furthest along in development: GS-5734, an adenine analog that incorporates into viral RNA to disrupt replication. It has been shown to protect NHPs from Ebola virus disease and is now advancing through a phase 1 dose-escalation trial[11]. So far, its activity against MERS-CoV has been tested only in cell lines.

Antibodies, both monoclonal and polyclonal, have eclipsed antivirals as the focus of MERS-CoV therapeutic R&D. Initially, convalescent plasma administration, which had been used in other emerging infection outbreaks, was seen as a potentially expeditious and effective means of post-exposure prophylaxis in the setting of cluster outbreaks[12]. A regional protocol was developed, but ultimately could not be implemented, owing to a lack of sufficient convalescent donors[13]. Meanwhile, a different formulation of polyclonal antibodies, derived from a transchromosomal humanized bovine model, has been moving forward in development. Both prophylactic and therapeutic use of this polyclonal preparation significantly reduces viral lung titers in mice that were intranasally transduced with adenoviral vectors that expressed the human MERS-CoV cognate protein receptor, DPP4 (ref. 14). However, it was noted by several experts that therapeutic studies conducted thus far in animals may not be relevant to human outbreaks, given that products are administered only hours after challenge, probably before symptoms in humans would appear.

Among products being researched for pre- or post-exposure prophylaxis, monoclonal antibodies (mAbs) targeting the receptor-binding domain (RBD) of S are furthest

Table 2 MERS-CoV vaccine candidates in development. There are five general vaccine platforms in development for MERS-CoV. At the time of this report, all candidates are still in different preclinical stages of development.

Vaccine platform	Institution	Product	Stage of preclinical development			Stage of clinical development

along in the product-development pipeline[15] (**Table 1**), some of which were presented at the meeting. Although representatives from each of the groups developing MERS-CoV mAbs presented data on the origin, potency, breadth and animal efficacy of their respective mAbs, some common themes emerged from the session as a whole and from the discussion that followed. Because most of the antibodies that have been developed target the RBD, there is a potential for viral escape from any one mAb. Thus, there should be greater efforts to (i) monitor circulating strains to assess viral evolution; (ii) define and measure phenotypic correlates of viral sequences; (iii) investigate the use of combination mAbs or polyclonal sera to overcome the potential emergence of therapeutic resistance; and (iv) study the serum of human survivors to better understand the response to natural infection and to develop reference reagents.

Vaccines

The global will to develop a coronavirus vaccine faded in the aftermath of the SARS-CoV pandemic, but has since gained renewed momentum in the face of the current MERS-CoV outbreak. This session started with a broad overview of vaccine-development pipelines and stressed that most vaccines fail to advance beyond phase 1 testing because of a lack of interest from funders and limited industrial support. In the realm of emerging infectious diseases with suspected or known pandemic potential, governmental agencies and nongovernmental organizations might have a key role in the development of interventions against diseases that do not provide a strong incentive for private-sector investments, but that are still relevant to public health and global security.

There are currently a dozen vaccine candidates in preclinical development (**Table 2**). Seven of the groups presented their products at the meeting. All developers are basing their immunogen designs on the S surface glycoprotein, the primary target for neutralizing antibodies during natural MERS-CoV infection[16]. Multiple platforms can be used to produce S, including but not limited to those presented at the meeting, such as live-attenuated viruses, DNA vectors, protein subunits and viral vectors (i.e., adenovirus, modified vaccinia virus Ankara and measles virus)[17]. Several of the products presented have demonstrated protection in at least one animal model. Although most of the vaccine candidates in the pipeline are being developed for human use, two of the vaccines have been tested in camels, which, if effective, would interrupt transmission of the virus to humans. A successful example of this "OneHealth" strategy—in which human, animal and environmental concerns are all considered—was described for the vaccine against Hendra virus in horses[18]. One of the lessons learned from the Hendra experience is that preclinical development and animal-model testing in relevant smaller animal models should be extensive before efficacy trials are commenced in larger-animal target populations, such as horses, or in the case of MERS-CoV, dromedary camels. Downselection of vaccine candidates in smaller animals increases the likelihood of success in large animals, which is crucial because the costs are much higher and logistical challenges much greater in the latter models. An additional lesson to take from previous experiences with animal vaccines for human health is to engage affected populations and educate them on the potential benefits and risks of a vaccine for their animals (i.e., camels) and communities.

One of the difficulties facing the development of effective vaccines for MERS-CoV is the absence of an animal model that recapitulates the pathogenesis and natural history of severe human disease. Two presentations and a robust discussion centered on this limitation in the field. Several mouse models that are transgenic for the human DPP4 protein receptor have now been developed[19]. Despite their manifestation of clinical disease, data from these transgenic mice might need to be supplemented with that of other, larger animal models for clinical advancement and ultimate licensing. Semi-permissive NHPs have been used as an animal surrogate in vaccine-efficacy testing thus far[20], but it is not clear whether either the rhesus or marmoset NHP models will serve as an accurate proxy for human disease, given that knowledge of the human pathology of MERS-CoV infection is limited to a single autopsy[21]. The development of more relevant animal models requires parallel investigation and elucidation of the virus's pathogenesis in humans. Additionally, there is some concern that a vaccine developed against a new coronavirus may induce antibody-dependent enhancement of infectivity and eosinophilic pulmonary infiltrates, as was observed among mice vaccinated with a virus-like particle (VLP) or killed–inactivated SARS-CoV vaccine[22]. However, none of the vaccines currently being developed for MERS-CoV includes the VLP or killed-inactivated platforms.

The roadmap for MERS-CoV R&D (**Supplementary Note 2**) will focus on vaccines that are indicated for populations and purposes of priority to the WHO perspective. Three broad indications for vaccination were discussed. The first two indications are for human use. They include a single-dose vaccine to be deployed for individuals at acute risk during outbreaks and a two-dose vaccine to induce durable protection for those at continual risk, such as camel handlers and health-care workers. The third vaccine indication proposed is for dromedaries, particularly juvenile camels, which pose a greater risk than older camels of transmitting virus to humans. The endpoint for a veterinary vaccine is likely to be the reduction or prevention of viral shedding, rather than sterilizing immunity. Despite the great potential for a camel vaccine to interrupt the epidemic, there has been a gap in funding for the development of a camel vaccine from conventional sources that support veterinary vaccines. One reason may be that a MERS-CoV vaccine for camels would be used differently than conventional veterinary vaccines. Usually, animals are vaccinated to prevent illness and death within veterinary populations. In the case of a MERS-CoV camel vaccine campaign, however, the primary intent is to prevent infection and disease in human populations. It will be important to shore up funds for a camel vaccination option, as this may be the fastest developmental and regulatory route toward licensing a product that can prevent human MERS-CoV infections and deaths.

Drafting a research and product development roadmap for MERS-CoV

R&D roadmaps have been used successfully in many sectors in which large-scale, collaborative efforts are required to deliver outcomes related to the innovation and development of new products. In all such processes, it is essential to start by clearly articulating and understanding the goals and markets for these products. High-level priority areas are first identified, after which an agreement on specific activities is decided. It is also crucial to first map out the baseline knowledge gaps and then to develop a strategic plan to address those deficiencies. This also requires an assessment of capacity needs that can support these activities. Project management and implementation structures are subsequently established to pursue agreed-upon activities to reach these goals. An example of this process can be found in the WHO Malaria Vaccine Technology Roadmap, which has culminated in a first-generation malaria vaccine and catalyzed the development of second-generation products (http://www.who.int/immunization/topics/malaria/vaccine_roadmap/en/).

At the meeting, four strategic goals were agreed upon in principle. The first is to establish a surveillance network of coronavirus laboratories as an early warning system to identify circulating species and strains in animal populations, new outbreaks in human populations and emerging strains in all populations. The second is to acquire a better understanding of MERS-CoV pathogenesis, natural history and veterinary and human epidemiology. The third is to develop, manufacture, test, license and use improved diagnostics, preventives and therapeutics that enable the interruption of transmission between humans and from dromedary camels to humans. The fourth, and perhaps most important, is for the global donor community to establish a mechanism that provides a line-of-sight for manufacturers from preclinical proof-of-concept studies to post-licensing procurement of MERS-CoV products, by initiating a public-health financial model for emerging pathogens prioritized by the WHO blueprint process.

Priority activities to be pursued through the MERS-CoV roadmap

A series of activities was prioritized and divided into the following categories: (i) basic, translational, epidemiological and social research; (ii) cross-cutting product development that includes refining more relevant animal models, developing reference reagents and designing tools and methods for rational prioritization between products; (iii) improved diagnostics; (iv) therapeutics, mAbs and polyclonal-antibody preparations; (v) vaccines for humans and camels; (vi) capacity development; and (vii) policy and commercialization. These will be further developed in consultation with potential funding stakeholders such as the Biomedical Advanced Research and Development Authority (BARDA), the US National Institutes of Health (NIH), the Wellcome Trust, the European Commission and the International Vaccine Initiative, among others, and with the broader MERS-CoV research community, to include public-health officials, manufacturers, regulators and product-development partnerships. The draft roadmap was posted for public consultation on WHO's website throughout the month of February 2016 and was finalized in May 2016 (http://www.who.int/csr/research-and-development/roadmap-consultation/en/).

Summary

The 2014 Ebola epidemic in West Africa revealed both great potential and pernicious deficiencies within existing mechanisms for rapid medical-product development and deployment. In the aftermath of the epidemic, global health communities coalesced around the realization that a multifaceted plan was required to respond quickly and efficiently to the next outbreak. The WHO is currently developing an R&D blueprint by which such preparation and response can follow, highlighting MERS-CoV as a case study. Although global coordination has resulted in the maturation of the preclinical pipeline for novel interventions for MERS-CoV, products will have to be developed along faster than normal timelines, with greater investments by multiple agencies for development, manufacturing and preclinical and clinical testing, as well as preparations for timely efficacy testing in affected populations if the incidence of disease rises sharply. As the global community takes lessons from the recent Ebola crisis, applies them to the current Zika virus outbreak and prepares for the potential of another regional epidemic or broader pandemic, stakeholders in research and product development on emerging pathogens must set out a sound strategy now for where to best target their investments in anticipation of future outbreaks. The current consultation is a first step toward that end, having opened a forum for global dialogue between public-health agencies, scientists, product developers and funders to engage in joint planning of MERS-CoV R&D activities.

Note: Supplementary Information and Source Data files are available in the online version of the paper.

A Roadmap for Research and Product Development against Middle East Respiratory Syndrome-Coronavirus (MERS-CoV)

Background on Technology Roadmaps

Technology roadmaps have been successfully used in several sectors where large-scale, collaborative efforts are required to deliver outcomes related to innovation including product development. In all such processes, it is critical to understand and articulate the goals and markets for innovative products. High-level priority objectives are identified, followed by agreement on specific activities to reach the objectives. It is critical to map baseline knowledge gaps and then develop a strategic plan to address those deficiencies. This also requires an assessment of capacity needs that can support these activities. Project management and implementation structures are subsequently established to pursue agreed activities to reach the goals. An example of this process can be found in the WHO Malaria Vaccine Technology Roadmap.

Introduction

The Scientific Advisory Group convened by WHO to advise the Blueprint included MERS CoV as one of the disease priorities, and this document was prepared for MERS as a prototype. It represents the results of a consultation process facilitated by WHO, working with international stakeholders, to develop a MERS-CoV Research and Product Development Technology Roadmap.

Middle East Respiratory Syndrome-Coronavirus (MERS-CoV) is an emerging pathogen of growing importance. As of May 2016, MERS-CoV has been confirmed as cause of severe acute respiratory disease in 1728 people, resulting in 624 deaths. The high case fatality rate, growing geographic distribution, and poorly defined epidemiology have created an urgent need for applied research and product development in order to better characterise epidemiology, diagnose, treat and prevent transmission and disease related to MERS-CoV.

Since the identification of MERS-CoV in the Kingdom of Saudi Arabia in 2012, human cases have been confirmed in 27 countries, including a large outbreak in the Republic of Korea. It is generally believed that dromedary camels are the intermediate animal reservoir; a high prevalence of MERS binding or inhibitory antibodies has been reported in camels across the Middle East, North Africa, and in sub-Saharan Africa. Outbreak investigation reports are strongly suggestive of a link between contact with camels and human cases of MERS-CoV. However many gaps remain in understanding of epidemiology and transmission of MERS-CoV.

Strategic Goals

- A strengthened network of laboratories able to act as an early warning system for emerging highly pathogenic viruses with the potential to cause public health emergencies
- Stimulate basic research for better understanding of the MERS-CoV pathogen, pathogenesis, immunity, epidemiology, transmission including the intermediate animal reservoir as well as person to person transmission
- Development, testing, manufacturing, licensure and use for improved diagnostics, therapeutics and preventives, including preventives for dromedary camels.

- ***Enabling environment strategic goal***: Establish line of sight for manufacturers from pre-clinical proof-of-concept to procurement of MERS products once licensed, by establishing public health-oriented financing model for MERS products, and other products for emerging pathogens prioritized by WHO blueprint process

Priority Areas

Research

- **Acquire** understanding of naturally acquired immunity, and immunity acquired through vaccination
- **Explore** social and cultural questions related to camel vaccination in most affected countries
- **Develop** an immune correlate of protection during pre-clinical and clinical efficacy trials
- **Urgently define** and address epidemiological, biological, behavioural and environmental knowledge gaps related to the definitive host, the intermediate animal reservoir, transmission to humans, person to person transmission, and characterisation of target groups for deployment of preventives
- **Characterise** pathogen diversity of MERS-CoV isolates in different outbreaks as basis for diagnostics, therapeutics and preventives development
- **Model** possible progression of outbreaks of MERS-CoV in various countries, and model impact of alternate approaches to vaccination in camels and humans
- **Research** improved infection control strategies, including appropriate models for triage in healthcare facilities

Cross-Cutting Product Development Related Priority Areas

- **Improved** animal models more representative of human disease for evaluation of different classes of products, including an animal model for enhanced disease. It is expected that animal model data evaluating enhanced disease will be available before licensure of MERS products
- **Develop and endorse** an international standard panel of calibration reagents to allow for comparability between different operators, labs, and assays, for nucleic acid, binding antibody and inhibitory assays
- **Prioritization** for potential products through use of **Target Product Profiles**, head-to-head testing and use of comparable assays with reference reagents

Diagnostic

- **Develop** quality assured, point of care diagnostics for MERS-CoV.
- ***Preferred diagnostic goal***: Multivalent MERS-CoV point of care diagnostic as part of a panel, including RSV, influenza, and other respiratory infections.

Treatment

- **Develop** quality assured therapeutics with acceptable safety and proven efficacy against MERS-CoV in those at high risk of mortality without treatment
- **Pursue evaluations of GMP grade therapeutics in parallel** on an urgent basis with at least 2 products to be tested during 2016

  - **Phase 1 selection based on pre-clinical proof of concept data, time of GMP availability and regulatory/ethics approvals**
  - **Timings for Phase 1 start, and go/no go to Phase 2-3 is critical factor in decision-making**
  - **Proceed** into phase 2-3 evaluations in MERS affected countries and patients, once supportive phase 1 data is available.
- **Assess** the most effective approaches for supportive care, including for low technology settings.

Preventive

- Human vaccine 1: **Develop and license** single dose MERS-CoV vaccine suitable for reactive use in outbreak settings with rapid onset of immunity
- Human vaccine 2: **Develop and license** two dose vaccine with durable protection for administration to those at high ongoing risk of MERS-CoV such as healthcare workers, and those working with potentially infected animals
  - At least 2 different MERS vaccine approaches to be tested in Phase 1 during 2016, with contingency planning to proceed to Phase 2-3 if Phase 1 data supportive
- Dromedary camel vaccine: **Develop and license** a vaccine suitable for administration to camels to prevent transmission of MERS-CoV from animal reservoir to humans
  - Note that recombinant viral vectors and DNA vaccines are already licensed and in use as veterinary vaccines
  - Evaluation in camels of promising approaches to be conducted during 2016

Key capacities

- **Support** regulatory and ethics capacity strengthening in MERS-CoV most affected countries for oversight of clinical trials
- **Build** GCP Clinical Trial Capacity for product evaluation
- **Establish and coordinate** GCLP Laboratory Testing Capacity for product evaluation

Policy and commercialization

- **Define** scale-up needs and **develop** GMP Manufacturing capacity to meet these needs
- **Develop and encourage** responsible stewardship and support for MERS-CoV research and product development and implementation through appropriate project management and investment strategies (supported by Target Product Profiles vetted by key stakeholders).
- **Establish regulatory pathways** for MERS-CoV products
- **Secure** financing for procurement and deployment of MERS-CoV products once available
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring

The Stakeholders Group for the WHO Blueprint

Starting in 2015, WHO convened a group of key stakeholders in R&D preparedness for emergencies. These include the following funding agencies: BARDA, NIAID, IVI, Wellcome Trust, European Commission Directorate-General Research & Innovation, the GLOPID-R network of funders coordinated via the European Commission and the Bill and Melinda Gates Foundation. It is envisaged that this group will meet by teleconference on a regular basis with WHO to review gaps in key activities at the global level, minimize unhelpful overlaps, and stimulate priority activities to maintain momentum. The roadmap can also be updated at the annual meetings if necessary. Other stakeholders include public health agencies particularly in affected countries, academia, the biotech sector, industry, regulators and ethics committees amongst others. A mechanism will be developed to implement the MERS R&D Roadmap by agreeing which activities should be carried out by the different stakeholders.

Subject: Agenda and materials for the Nipah WHO R&D Roadmap Taskforce conference call to be held on Tuesday, January 9 or Wednesday January 10, depending on time zone
Importance: High

Dear Colleagues:

I am writing to remind you of our Nipah Roadmap Taskforce conference call **on Tuesday, January 9 at 5:00 pm PST, 7:00 pm CST, 8:00 pm EST, and Wednesday, January 10 at 1:00 am GMT, 2:00 am CET, 7:00 am BST, and 9:00 am SGT.**

Each of you should have received a calendar invite with the call-in information and I have repeated that information below:

- Conference code: 998-3378#
    - USA Toll Free: 866-767-9978
    - UK Toll Free: 0808 1017 535
    - Switzerland Toll Free: 0800 5537 12
    - Singapore Toll Free: 800 101 2395
- For Bangladesh, we do not have a toll free line; we will contact you separately to make logistical arrangements.
- As a BACKUP: International callers may use the following conference call information: Conference Line 205-254-8650 Conference Code: 998-3378#. However, please note that this is NOT a toll-free number.

This email includes the following attachments:

- The Nipah draft roadmap outline. **Please review this document before the call** because most of our call will be devoted to discussing the document. Also, we would very much appreciate any written edits or comments that you have on the document, particularly if you are not able to participate in the call. In order to keep to our development timeline, we need to receive any written comments from you no later than Friday, **January 19.** Please send comments directly to kamoore@umn.edu.
- A short slide deck for our call on Tuesday.
- Supplemental materials on the MERS-CoV Roadmap as examples, including a Nature Medicine article on that Roadmap and an outline of the roadmap, similar to the outline we have developed for the Nipah Roadmap.

The agenda for the call is as follows (most of the time will be devoted to discussing the draft Nipah Roadmap outline):

1. Welcome and roll call
2. R&D roadmap architecture
3. Role of roadmap taskforce members
4. Roadmap development and timeline
5. Discussion of draft R&D roadmap for Nipah
6. Next steps

Thank you again for agreeing to be part of this important work. We look forward to speaking with you next week and to receiving your comments on the draft Roadmap outline by January 19.

Warm regards,

Mike

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

Commented [EG1]: There were a couple of suspect cases of this in Malaysia, but this has been a prominent feature of the outbreaks in India and Bangladesh.

Commented [EG2]: Cough has been more common than vomiting in the Bangladesh case series.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

Commented [SPL3]: I consider this paragraph as essential framing and urge that it be retained, even as we work towards a more focused document. It is difficult, because medical countermeasures do not stand alone. They need to interface with a system that constructively deploys them. At a minimum we should strive for countermeasures that are fit for purpose for the contexts where they are needed.

Commented [EG4R3]: Complete agree with Steve on this.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.
- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis

Commented [EG5]: While this is true, even when testing is nearby, it can still take days to get back a PCR or ELISA result as these are not rapid tests as current used. Within the context of very quick progression to death, we need a bedside rapid diagnostic.

more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.

Commented [SPL6]: Given the wide range of Pteropus bats this needs to be defined. Clearly, we need low cost accurate diagnostics, but we also need to consider the system that needs to be in place in order to make use of the diagnostics. We risk mission creep if we include development of global surveillance as part of medical countermeasures, but there is a difference between how we would optimally deploy point of care diagnostics in Bangladesh and West Bengal, India, compared with the Philipines or Cameroon. We should consider the different needs in these different contexts, to assure that we have an approach that is fit for purpose.

Commented [EG7R6]: Agree

Commented [EG8]: Or, other pathogens on a differential diagnosis for humans?

Commented [SPL9]: Salivary pcr is often positive in Bangladesh before antibodies are detectable.

- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Commented [SPL10]: Because this is a wildlife shed virus and these creatures live near food sources, spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh. The health care facilities that serve these communities not only have very rudimentary laboratory infrastructure, they also do not have the routine practice of using diagnostic tests to manage patients. Thus, achieving the stated strategic goals requires a much broader, deeper effort, than providing reagents and testing for proficiency at national labs.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecology~~ic~~ and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Commented [SPL11]: Consider whether efforts to promote sharing of sequence and strains would benefit from attention.

Product development

- **Generate** a TPP for NiV diagnostics.

- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Commented [EG12]: Perhaps targeted research to identify evidence of spillover and human risk might come before investments in broader surveillance efforts.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV_M and NiV_B strains may impact the effectiveness of developed MCMs, yet NiV_M has been used significantly more often than NiV_B in research. *(*cross cutting)*
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*

Commented [SPL13]: Moreover, if we actually had more strains we may identify more heterogeneity than is currently apparent.

Commented [EG14]: And can pose a dilemma if therapeutics prolong life and improve survival but are unable to prevent severe neurologic damage.

Commented [EG15]: Or, infection control measures which are not standard practice in many at-risk countries.

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Commented [EG16]: Studies in animals often test usefulness of therapeutics when delivered prior to disease onset or very early during the disease course. Since humans with Nipah virus are often only detected once they are ill, the findings are less useful for understanding how the drug might work in humans.

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.

Commented [SPL17]: Would be ideal, but, given the biology, may be much more difficult than an acute countermeasure. Might separate these into 2, so that the ideal does not become the enemy of the good.

Commented [EG18]: Patients in Malaysia were much more likely to survive than patients in Bangladesh. One hypothesis is that this is because patients in Malaysia had access to ventilator support, which is typically unavailable in Bangladesh. There may be health systems approaches that could improve survival.

- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Knowledge gaps

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV$_B$ and NiV$_M$ infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Patients treated with Ribavirin late in the 1998-1999 NiV outbreak in Malaysia experienced 36% lower mortality than persons from earlier in the outbreak who were not treated with Ribavirin.~~was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered~~Ribaviran may be an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number

of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV$_B$ and NiV$_M$, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV$_B$ to be shorter than for NiV$_M$.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*

Commented [SPL19]: An important related issue is how we protect the health care workers and fellow patients in these settings. Part of this is covered in the vaccine section, but the capacity to protect health care workers and other patients is extremely limited in the contexts where we see recurrant NiV outbreaks. A clear eyed understanding of the context, and piloting approaches within these contexts is essential to develop and refine medical counter measures to that they can reduce pandemic risk. To be effective these countermeasures need to work, not only in idealized trial conditions, but in the everyday setting where high risk patients present.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Commented [EG20]: Median days from onset to death for patients in Bangladesh who die from Nipah virus is 6 days. Typically, they present unconscious on around day 3. So, there is little time to act but even less when healthcare seeking is delayed, because progression is so fast. This is a worthy goal, but the limited access to healthcare will reduce the number patients we can find in time to treat and will have an impact on field trials.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.

- **Determine** the key differences between NiV$_B$ and NiV$_M$ that may have implications for the development of safe and effective NiV therapeutics.
- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV$_B$ and NiV$_M$ and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV$_B$ and NiV$_M$ and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore,

alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.

- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.
- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Commented [EG21]: And for the estimation of stockpiles that would be required to effectively respond to outbreaks, under various transmission assumptions.

Commented [SPL22]: I suspect that this is an easier technical problem than it is an economic problem. Only 15% of Australian horses are vaccinated against HeV. Pigs in low income countries are rarely protected against swine cholera or Japanese Encepahlitis. The incentives for livestock raisers are not well aligned for deployment as a human public health tool.

Commented [EG23R22]: Indeed, even when we offered free JE vaccine to pig raisers in northern Bangladesh, many refused due to lack of trust in the formal vet care system.

Commented [SPL24]: Should consider surge capacity to rapidly ramp up vaccine supply in case NiV is used as a bioterror agent, or we face a strain that naturally develops increased capacity for person to person transmission.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.

- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Mike and colleagues,

I very much look forward to working with you all on this endeavor.

I will be on a flight to Dhaka during the call, so unable to participate. I'll look forward to hearing the updates.

I've attached a few comments to the draft that Steve sent.

All the best,
Emily

Subject: Re: Agenda and materials for the Nipah WHO R&D Roadmap Taskforce conference call to be held on Tuesday, January 9 or Wednesday January 10, depending on time zone

Mike,

Thanks so much for moving this forward. I am looking forward to the call.

I will be in Bangladesh, but I should be able to connect.

Attached are some comments on the roadmap outline.

Steve

Michael Osterholm

Thursday, January 04, 2018 8:50 AM

Dear Colleagues:

I am writing to remind you of our Nipah Roadmap Taskforce conference call **on Tuesday, January 9 at 5:00 pm PST, 7:00 pm CST, 8:00 pm EST, and Wednesday, January 10 at 1:00 am GMT, 2:00 am CET, 7:00 am BST, and 9:00 am SGT.**

Each of you should have received a calendar invite with the call-in information and I have repeated that information below:

- Conference code: 998-3378#
  - USA Toll Free: 866-767-9978
  - UK Toll Free: 0808 1017 535
  - Switzerland Toll Free: 0800 5537 12
  - Singapore Toll Free: 800 101 2395
- For Bangladesh, we do not have a toll free line; we will contact you separately to make logistical arrangements.
- As a BACKUP: International callers may use the following conference call information: Conference Line 205-254-8650 Conference Code: 998-3378#. However, please note that this is NOT a toll-free number.

This email includes the following attachments:

- The Nipah draft roadmap outline. **Please review this document before the call** because most of our call will be devoted to discussing the document. Also, we would very much appreciate any written edits or comments that you have on the document, particularly if you are not able to participate in the call. In order to keep to our development timeline, we need to receive any written comments from you no later than Friday, **January 19.** Please send comments directly to kamoore@umn.edu.
- A short slide deck for our call on Tuesday.
- Supplemental materials on the MERS-CoV Roadmap as examples, including a Nature Medicine article on that Roadmap and an outline of the roadmap, similar to the outline we have developed for the Nipah Roadmap.

The agenda for the call is as follows (most of the time will be devoted to discussing the draft Nipah Roadmap outline):

1. Welcome and roll call
2. R&D roadmap architecture

3. Role of roadmap taskforce members
4. Roadmap development and timeline
5. Discussion of draft R&D roadmap for Nipah
6. Next steps

Thank you again for agreeing to be part of this important work. We look forward to speaking with you next week and to receiving your comments on the draft Roadmap outline by January 19.

Warm regards,

Mike

DRAFT V5 —NOT FOR DISTRIBUTION— January 1, 2018

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, outlining the underpinning strategic goals, and prioritizing research areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus (NiV) infection.

*(**Note:** The content below is organized into the three main categories for R&D of MCMs [diagnostics, therapeutics, and vaccines] to allow reviewers an opportunity to follow the lines of thinking for each category. Some issues are cross cutting and apply to more than one category. As this draft is refined, the content may be reorganized to create one over all roadmap and to group cross-cutting issues together. In addition, this document is relatively detailed to ensure that the most important issues are identified and discussed. As the document evolves, certain items may be "rolled up" into a smaller number of broader issues, strategic goals, and primary activities.)*

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak occurred in pigs and humans in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized in Bangladesh in 2001 and nearly annual outbreaks have occurred in that country since, with disease also occurring periodically in eastern India. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the natural reservoir for NiV (Pteropus bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, and Ghana. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and human-to-human NiV transmission. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a role, with human consumption of bat-contaminated raw date palm sap serving as the primary NiV source. In humans, NiV infection has neurological and respiratory syndromes, with fever, headache, dizziness, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and/or relapsing encephalitis, and survivors may experience long-term neurological deficits. Genomic sequencing has demonstrated that two distinct strains of NiV were responsible for the outbreaks in Southeast Asia (NiV_M) and in Bangladesh/India (NiV_B). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). To date, HeV disease has been confined to Australia. An outbreak of an unidentified Henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2015.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and

timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's initial list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no medical countermeasures [MCMs] exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of medical countermeasures to prevent and control LF outbreaks and endemic disease.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment, effective community engagement, and workforce development and training in at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

Commented [SPL1]: I consider this paragraph as essential framing and urge that it be retained, even as we work towards a more focused document. It is difficult, because medical countermeasures do not stand alone. They need to interface with a system that constructively deploys them. At a minimum we should strive for countermeasures that are fit for purpose for the contexts where they are needed.

VISION

Robust MCMs to detect, prevent, and control outbreaks of NiV (and other closely related henipaviruses) that are available and readily deployable for use when needed. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific and the diagnosis often is not suspected at the time of presentation. Additionally, latent disease can occur long after initial infection. Both of these factors can hinder accurate diagnosis.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- NiV appears to have the potential for strain heterogeneity and antigenic variability, which could potentially influence accuracy of diagnostic testing over time.
- The natural reservoir for NiV is fruit bats of the Pteropus genus, which have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis

more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.

- Pteropus bat species also appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- High-level biocontainment requirements may pose an impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Diagnostic preparedness to detect HeV and other emergent henipaviruses in humans and animals as they arise.
- Proficiency testing, to monitor reproducibility and performance of NiV diagnostic assays in the field.
- Enhanced laboratory infrastructure in at-risk areas, with a particular focus on improving regional and national laboratory capacity for case and outbreak confirmation.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the DIVA test.
- Long-term need: multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or additional high-consequence pathogens.

Commented [SPL2]: Given the wide range of Pteropus bats this needs to be defined. Clearly, we need low cost accurate diagnostics, but we also need to consider the system that needs to be in place in order to make use of the diagnostics. We risk mission creep if we include development of global surveillance as part of medical countermeasures, but there is a difference between how we would optimally deploy point of care diagnostics in Bangladesh and West Bengal, India, compared with the Philipines or Cameroon. We should consider the different needs in these different contexts, to assure that we have an approach that is fit for purpose.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, and limits of detection) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs).
- Additional validation data are needed to assess performance characteristics of NiV diagnostic assays against the various strains of NiV.

Commented [SPL3]: Salivary pcr is often positive in Bangladesh before antibodies are detectable.

- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor antigenic changes over time that may impact diagnostic testing and the epidemiologic and clinical features of disease.
- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats. *(*cross cutting)*

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detection at various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Promote the development and assessment of affordable, highly sensitive and specific, point-of-care diagnostic tests for use in humans and animals that have minimal requirements for biosafety precautions and staff training and that can detect NiV and other related henipaviruses.
3. Strengthen laboratory infrastructure and capacity in the endemic and at-risk areas to improve early diagnostic capabilities.

Commented [SPL4]: Because this is a wildlife shed virus and these creatures live near food sources, spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh. The health care facilities that serve these communities not only have very rudimentary laboratory infrastructure, they also do not have the routine practice of using diagnostic tests to manage patients. Thus, achieving the stated strategic goals requires a much broader, deeper effort, than providing reagents and testing for proficiency at national labs.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and develop appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Expand research** to further understand the ecologic and epidemiology of NiV and other henipaviruses in human and animal populations over time, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to research** development of serologic tests to distinguish vaccinated from infected animals, if henipavirus vaccines are to be widely used in livestock populations.

Commented [SPL5]: Consider whether efforts to promote sharing of sequence and strains would benefit from attention.

Product development

- **Generate** a TPP for NiV diagnostics.

- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other high-consequence pathogens in humans and animals.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure for detection of NiV in endemic and at-risk areas, particularly in support of enhanced national and regional diagnostic capabilities.
- **Improve surveillance capacity** to: (1) better define the incidence of disease in NiV-endemic areas and (2) promote surveillance in non-endemic areas to enhance detection of emergent NiV disease or disease caused by other related henipaviruses.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV point-of-care diagnostics.
- **Ensure** access to regulatory review and authorization of NiV diagnostic assays.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostic products to endemic and at risk areas.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV disease occurs in relatively small outbreak settings, the low incidence of disease poses a major challenge for conducting phase 3 clinical trials; therefore, alternative regulatory pathways will need to be considered for licensure of vaccines or therapeutics. *(*cross cutting)*
- Differences between the NiV$_M$ and NiV$_B$ strains may impact the effectiveness of developed MCMs, yet NiV$_M$ has been used significantly more often than NiV$_B$ in research. *(*cross cutting)*

Commented [SPL6]: Moreover, if we actually had more strains we may identify more heterogeneity than is currently apparent.

- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier and can access the brain and spinal cord to inhibit viral replication. This is particularly important for preventing late-onset CNS disease.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons. In addition, the healthcare systems in endemic areas are not able to rapidly identify contacts most likely to benefit from PEP. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat both acute and chronic (relapsing) NiV infection to improve survival and decrease associated morbidity and long-term disability.

Commented [SPL7]: Would be ideal, but, given the biology, may be much more difficult than an acute countermeasure. Might separate these into 2, so that the ideal does not become the enemy of the good.

- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock. *(*cross cutting)*

Knowledge gaps

- Additional information is needed on the immunology and pathogenesis of NiV in order to develop appropriate treatment options. This includes evaluating the pathophysiologic differences between NiV$_B$ and NiV$_M$ infection, determining the mechanisms of late-onset and relapsing NiV encephalitis, identifying factors influencing the development of permanent neurological sequela, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Patients treated with Ribavirin late in the 1998-1999 NiV outbreak in Malaysia experienced 36% lower mortality than persons from earlier in the outbreak who were not treated with Ribavirin.~~was found to reduce mortality by 36% in the 1998-1999 NiV outbreak in Malaysia and is considered~~Ribaviran may be an option for treatment of NiV infection. However, animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided as a compassionate use for a small number

of individuals exposed to HeV-infected horses. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials are needed to assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.

- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV_B and NiV_M, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV_B to be shorter than for NiV_M.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the type of exposures that warrant such intervention and the most appropriate agents to administer.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of individual components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform supportive care and best-practice guidelines.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), such as determining the most appropriate lethal NiV dose for MCM development and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*

Commented [SPL8]: An important related issue is how we protect the health care workers and fellow patients in these settings. Part of this is covered in the vaccine section, but the capacity to protect health care workers and other patients is extremely limited in the contexts where we see recurrant NiV outbreaks. A clear eyed understanding of the context, and piloting approaches within these contexts is essential to develop and refine medical counter measures to that they can reduce pandemic risk. To be effective these countermeasures need to work, not only in idealized trial conditions, but in the everyday setting where high risk patients present.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection and ensure that therapies are prepositioned in endemic areas for use as needed.
2. Stimulate basic research for better understanding of NiV pathogenesis and the immune response to infection.
3. Strengthen clinical and laboratory infrastructure in endemic and at-risk areas to promote early diagnosis of NiV cases so that effective treatment and PEP can be rapidly administered.
4. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Conduct** basic science research on the immunology and pathogenesis of NiV infections to inform development of new therapeutic agents.

- **Determine** the key differences between NiV_B and NiV_M that may have implications for the development of safe and effective NiV therapeutics.
- **Continue to research** the safety, tolerability, and efficacy of investigational therapies for NiV infection, including animal studies and clinical trials as appropriate and feasible.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infection that are active against both NiV_B and NiV_M and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and NiV_M and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Refine, standardize, and validate** animal challenge models for future assessment of promising therapeutic candidates.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV therapeutics.
- **Support** plans for licensure/registration, adequate manufacturing, and subsequent distribution of safe and effective therapies to endemic areas and to other at-risk areas on an as-needed basis for outbreak control.
- **Secure** financing for procurement and deployment of NiV therapeutics for outbreak control once treatment agents are available.
- **Develop** treatment and PEP guidance as new therapies demonstrate safety and efficacy.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Because NiV occurs as relatively small, focal outbreaks, the low incidence of infection poses a major challenge for conducting phase 3 clinical trials for efficacy demonstration; therefore,

alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics. *(*cross cutting)*

- High-level biocontainment requirements pose a significant impediment to development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions. *(*cross cutting)*
- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in the under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value proposition is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. *(*cross cutting)*
- The absence of improved diagnostic assays for timely diagnosis of infection creates a challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control, once vaccines are available for use. *(*cross cutting)*
- While ferrets, Syrian hamsters, and INFO KO mice are well-established animal models for NiV research applicable to humans, African green monkeys (AGMs) are regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure involving alternative regulatory pathways. Costs, space requirements (particularly in BLS-4 containment facilities), and ethical concerns constrain the use of AGMs. *(*cross cutting)*

Key needs

- Safe and effective PEP (either vaccines or therapeutic agents) to prevent infection following exposure to NiV and guidance on their use. Such countermeasures are important tools to protect healthcare workers, family caregivers, and livestock workers. *(*cross cutting)*
- Nipah vaccines that can protect against both NiV_M and NiV_B in humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks. Research tools, such as standardized neutralization assays, to compare immunogenicity of different vaccines.
- Enhanced surveillance capacity to provide more accurate information on the current incidence and geographic distribution of NiV in endemic and at-risk areas in order to refine potential vaccination strategies, particularly over time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- The mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis are unknown. Further research to better understand viral clearance has important implications for development of vaccines and therapeutics.
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B; only a few studies demonstrating cross-protection have been performed to date.

- Further research is needed to determine durability and safety profiles of candidate vaccines, such as VSV recombinants, where concerns regarding potential neurotropism have been raised.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoestis).
- The identification of specific correlates of protection and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines and in simulating various epidemiologic scenarios that may impact strategies for vaccine use.
- Additional research is needed to refine, standardize, and validate relevant animal challenge models for NiV infection in humans (e.g., INFAR KO mouse, ferret, Syrian hamster, and AGM models), including determining the most appropriate NiV dose for MCM development (Johnston 2015) and identifying the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain licensing. *(*cross cutting)*
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. Currently, one HeV vaccine is available for horses. Ongoing research into developing NiV/HeV vaccines for livestock is needed to further assess the merit of this potential control strategy.
- If evidence at some point supports the need for a broader, population-based vaccination strategy, additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.

Commented [SPL9]: I suspect that this is an easier technical problem than it is an economic problem. Only 15% of Australian horses are vaccinated against HeV. Pigs in low income countries are rarely protected against swine cholera or Japanese Encepahlitis. The incentives for livestock raisers are not well aligned for deployment as a human public health tool.

Commented [SPL10]: Should consider surge capacity to rapidly ramp up vaccine supply in case NiV is used as a bioterror agent, or we face a strain that naturally develops increased capacity for person to person transmission.

Strategic Goals

1. Develop, evaluate, and license NiV vaccines for use in humans and potentially livestock, primarily for reactive/outbreak use in endemic and at-risk areas.
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Ensure that post-approval pharmacovigilance is in place to support product deployment and monitoring.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection.

- **Determine** the key differences between NiV_B and NiV_M pathogenesis that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains, and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research efforts and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Generate** research tools (e.g., standardized neutralization assays) to compare immunogenicity of different vaccines.
- **Complete preclinical evaluation** of promising candidate NiV vaccines for safety, immunogenicity, efficacy, correlates of protection, and durability.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effective monovalent NiV vaccines for humans and livestock, primarily for reactive use during outbreaks.

- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.

Key capacities

- **Refine and validate** relevant animal challenge models for NiV infection.
- **Improve** surveillance capabilities, particularly in rural areas of resource-limited settings, to assess the true burden and incidence of NiV disease, which may in turn, inform vaccination strategies.
- **Ensure** post-approval pharmacovigilance and effectiveness evaluations occur to support product deployment and monitoring.

Policy and commercialization

- **Establish** a sustainable value proposition for NiV vaccines.
- **Ensure** access to regulatory review and authorization of NiV vaccines, particularly if non-traditional pathways are needed for licensure.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.
- **Provide** ongoing assessment to inform development and maintenance of NiV vaccine stockpiles over time; mathematical modelling may be used to contribute to this assessment.
- **Continue** to provide guidance on vaccination strategies for various target populations and epidemiologic scenarios, once vaccines are available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Subject: Re: Agenda and materials for the Nipah WHO R&D Roadmap Taskforce conference call to be held on Tuesday, January 9 or Wednesday January 10, depending on time zone
Date: Saturday, January 6, 2018 4:49:10 AM
Attachments: Nipah Draft Roadmap.V5 sl.docx

Mike,

Thanks so much for moving this forward. I am looking forward to the call.

I will be in Bangladesh, but I should be able to connect.

Attached are some comments on the roadmap outline.

Steve

Michael Osterholm Thursday, January 04, 2018 8:50 AM

Dear Colleagues:

ï¿½

I am writing to remind you of our Nipah Roadmap Taskforce conference call **on Tuesday, January 9 at 5:00 pm PST, 7:00 pm CST, 8:00 pm EST, and Wednesday, January 10 at 1:00 am GMT, 2:00 am CET, 7:00 am BST, and 9:00 am SGT.**

ï¿½

Each of you should have received a calendar invite with the call-in information and I have repeated that information below:

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->Conference code: 998-3378#

<!--[if !supportLists]-->oï¿½ï¿½ <!--[endif]-->USA Toll Free: 866-767-9978

<!--[if !supportLists]-->oï¿½ï¿½ <!--[endif]-->UK Toll Free: 0808 1017 535

<!--[if !supportLists]-->oï¿½ï¿½ <!--[endif]-->Switzerland Toll Free: 0800 5537 12

<!--[if !supportLists]-->oï¿½ï¿½ <!--[endif]-->Singapore Toll Free: 800 101 2395

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->For Bangladesh, we do not have a toll free line; we will contact you separately to make logistical arrangements.

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->As a BACKUP: International callers may use the following conference call information: Conference Line 205-254-8650 Conference Code: 998-3378#. However, please note that this is NOT a toll-free number.

ï¿½

This email includes the following attachments:

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->The Nipah draft roadmap outline. **Please review this document before the call** because most of our call will be devoted to discussing the document. Also, we would very much appreciate any written edits or comments that you have on the document, particularly if you are not able to participate in the call. In order to keep to our development timeline, we need to receive any written comments from you no later than Friday, **January 19.** Please send comments directly to kamoore@umn.edu.

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->A short slide deck for our call on Tuesday.

<!--[if !supportLists]-->ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ï¿½ <!--[endif]-->Supplemental materials on the MERS-CoV Roadmap as examples, including a Nature Medicine article on that Roadmap and an outline of the roadmap, similar to the outline we have developed for the Nipah Roadmap.

ï¿½

The agenda for the call is as follows (most of the time will be devoted to discussing the draft Nipah Roadmap outline):

1. Welcome and roll call
2. R&D roadmap architecture
3. Role of roadmap taskforce members
4. Roadmap development and timeline
5. Discussion of draft R&D roadmap for Nipah
6. Next steps

ï¿½

Thank you again for agreeing to be part of this important work. We look forward to speaking with you next week and to receiving your comments on the draft Roadmap outline by January 19.

ï¿½

Warm regards,

ï¿½

Mike

Science Program Review
February 08 - 10, 2017

CBEP
Cooperative Biological Engagement Program

Defense Threat Reduction Agency
United States of America

DEPARTMENT OF DEFENSE
COOPERATIVE THREAT REDUCTION PROGRAM

DEFENSE THREAT REDUCTION AGENCY
8725 JOHN J. KINGMAN ROAD, STOP 6201
FORT BELVOIR, VA 22060-6201

Dear Colleagues,

Welcome to the 9th Science Program Review of the U.S. Defense Threat Reduction Agency's Cooperative Biological Engagement Program (DTRA CBEP). The CBEP carries out its mission by collaborating with partner countries and the international community to minimize the threat of deliberate, accidental and natural infectious disease outbreaks through enhanced biosecurity, biosafety, and biosurveillance measures. Cooperative Biological Research (CBR) is an integral element of the threat reduction mission by supporting and informing operational biosurveillance, enhancing global health security, and establishing and fostering sustainable research partnerships. CBEP's achievements rely on successful collaboration with partner-country scientists, and we thank you for your dedication and cooperation in our shared efforts to better understand the biological threats that face our world today.

We have in attendance nearly 120 researchers from over 30 countries representing 70 CBR projects, and this three-day event will feature briefings by CBEP partner-country scientists and collaborators conducting CBEP-funded research. We look forward to engaging with researchers from around the globe and evaluating the spectrum of CBEP research activities, in order to strengthen the quality of projects supported by the program and ensure that current efforts meet research priorities and objectives.

A significant benefit of the CBEP Science Review is networking amongst fellow scientists. During the next few days, you will have the opportunity to meet with scientific and program colleagues from CBEP partner nations, the U.S. Department of Defense, other U.S. Government stakeholders, and international and U.S. program partners. With such a broad range of scientific expertise present, we hope that this environment will create new networks among subject matter experts and facilitate new partnerships within the scientific community.

Again, I want to thank you for your participation in this 2017 CBEP Science Program Review. I hope that you will enjoy your experience and find opportunities to expand your collaborative research network.

Lance Brooks
Division Chief
Cooperative Biological Engagement
Program, J3CTB

Table of Contents

CBEP Mission

The Defense Threat Reduction Agency's Cooperative Biological Engagement Program is the Department of Defense’s premier biological nonproliferation division protecting the United States and its allies from especially dangerous pathogens by collaborating with partner countries and the international community to minimize the threat of deliberate, accidental, and natural infectious disease outbreaks through enhanced biosafety, security, and surveillance measures.

The Defense Threat Reduction Agency's Cooperative Biological Engagement Program utilizes Science Diplomacy to promote scientific and technical collaborations among partner nations and the international community in [the disciplines of] biological safety, security and surveillance to build constructive and sustainable international partnerships that address threats posed to health security from deliberate, accidental, and natural infectious disease outbreaks.

General Information

- Posters may be displayed on the available poster boards in the Foyer area. An informal networking and poster session will be held following the “Doing Science in Difficult Places” session.
    - Posters displayed in the Foyer area must be removed by 1:00 PM on Friday, February 10, 2017. Posters that are not removed by this time will not be kept by DTRA.
- A designated Prayer Room is available next to the Registration area in the Dogwood Room. Please see attendants at the Registration desk for additional information.
- If temporary luggage storage is required, please see the hotel Front Desk.
- Meeting space is available during the event for collaborative discussions. Please see the Registration desk for more information.
- Please see the Registration Desk for any questions or concerns during the event.

Acknowledgments

The following individuals were instrumental in the development and implementation of this event.

CBEP Science Program Review Steering Committee

Dr. Carl Newman
Chief Scientist, Cooperative Biological Engagement Program (CBEP)

Dr. Martha Stokes
Southeast Asia Science Manager, CBEP

Dr. Mary Lancaster
Africa Science Manager, CBEP

Contractor Support Steering Committee Members:

- Dr. Jarrad Marles
- Ms. Nicki Aleman
- Dr. Ayanna Flegler
- Dr. Dawn Defenbaugh
- Dr. Michael Patterson
- Dr. Elizabeth Waligora

Special Thank You to those who helped organize this event:

- Dr. Jeanne Fair
- Dr. Gavin Braunstein
- Mr. Andrew Kotila
- Dr. Mariam Lekveishvili
- Ms. Natalie Might
- Mr. Jeffrey Russin
- Mrs. Karla Somera
- Ms. Audrey Speer
- Ms. Danielle Wilbur

Science Program Review Panel

CBEP would like to acknowledge the following individuals for serving on the Review Panel for the 2017 CBEP Science Program Review. The Review Panel is comprised of experts with varied backgrounds in a broad range of scientific disciplines and expertise in public health security and program implementation. The Review Panel will provide CBEP with an external technical and programmatic evaluation of the CBEP-sponsored research portfolios to identify strengths and weaknesses in CBEP research engagements, along with recommendations for improving how the portfolios are designed and implemented.

Jessica Appler, PhD, is the Associate Director, Portfolio Development for the Biomedical Advanced Research and Development Authority (BARDA) Modeling and Visualization Hub within BARDA's Division of Analytic Decision Support at the U.S. Department of Health and Human Services (HHS). She oversees the development of a portfolio focused on assessing the public health and medical consequences for chemical, biological, radiological, and nuclear (CBRN) incidents, emerging infectious diseases, and pandemic influenza events. Prior to joining HHS, she was at the Deputy Undersecretary of the Army for Test and Evaluation CBRN Defense Division, where her portfolio included oversight of CBRN test and evaluation programs, as well as the testing and standards development for the Transport Isolation Systems during the 2014-2015 West African Ebola crisis. Previously, she was a member of the Chemical and Biological Defense Division of Department of Homeland Security's Science and Technology Directorate, where she provided subject matter expertise and strategic vision for existing and planned biosurveillance programs. She was part of the interagency team that identified critical needs and gaps across the government in biological detection and diagnostic technology for the National Biosurveillance Science & Technology Roadmap. Dr. Appler earned her Ph.D. in Neurobiology from Harvard University, and her B.S. in biochemistry from the University of Southern California.

Hillary H. Carter, PhD, is the Director for Countering Biological Threats on the National Security Council (NSC) staff. Dr. Carter's portfolio includes the Global Health Security Agenda, domestic and international biosecurity issues, implementation of the President's Strategy for Countering Biological Threats, biological threat reduction, and policies related to Dual Use Research of Concern. Dr. Carter is also an adjunct Professor at the George Washington University where she lectures on Global Health Diplomacy. Prior to joining NSC staff, Dr. Carter was the Senior Advisor for Biosecurity and a Team Chief in the Office of Cooperative Threat Reduction (CTR) at the U.S. Department of State. In this role, Dr. Carter led CTR's special project and management teams to develop policy and implement programs to combat global biological, chemical, and nuclear threats. Prior to this role, Dr. Carter served as the Acting Deputy Team Chief for the Biosecurity Engagement Program where she oversaw health security programs to reduce global biological risks. Dr. Carter received a Ph.D. in Cell and Developmental Biology from Vanderbilt University, where she studied intracellular transport during early development. Dr. Carter holds a B.S. in Neuroscience with a minor in Spanish from Vanderbilt University.

Marco De Nardi, DVM, has 15 years working experience in the field of animal health and epidemiology in both developed and less developed countries. He received a Degree in Veterinary Medicine (DVM) from Bologna University (IT) in 2002 and a MSc degree in Veterinary Epidemiology from the Royal Veterinary College and the London School of Hygiene and Tropical Medicine, UK in 2008. He is currently enrolled in the residency training (Population Medicine) of the European College of Veterinary Public Health. Following his DVM he practiced as a veterinary clinician in dairy farms in Italy. He then worked as a veterinary consultant and project coordinator for international organizations (non-governmental organizations and the Food and Agriculture Organization (FAO)) in East Africa from 2004 to 2007. In 2009-2013, he worked on research and capacity building programs at the "World Organization for Animal Health (OIE) and FAO Reference Laboratory for Avian Influenza" and the "FAO Reference Centre for Rabies" at Istituto Zooprofilattico Sperimentale delle Venezie (IZSVe) in Italy. In 2011, he coordinated the European Food Safety Authority (EFSA)-funded project "Flurisk," assessing the pandemic risk posed by animal influenza viruses.

In 2013 he joined the private veterinary consultancy company SAFOSO (www.safoso.com), where he is responsible for the development and implementation of consultancy, research projects and capacity building programs in the area of risk assessment, surveillance, veterinary epidemiology, animal health and food safety. As a SAFOSO consultant he worked in different projects in Europe, U.S., Ukraine, Armenia, Georgia, Kazakhstan, Mongolia and Vietnam.

Sam Howerton, **PhD**, is as a Senior Executive at the National Science Foundation. Hearing the call to service in 2001, he escaped the bounds of a traditional scientific career by seeking out organizations undergoing change. He oversaw the development of new drugs, negotiated new international agreements, and provided entrepreneurs training on transforming their ideas into business ventures.

With a healthy appetite for risk, Sam is known for his 'first unto the breach' leadership and willingness to try most any food.

Possessed of a strong imagination and an inquisitive mind, he earned a Ph.D. in Chemistry-Environmental Toxicology and completed Air War College. Sam's most important job is raising his sons to be good Southern gentlemen.

Paul Keim, **PhD**, is the executive director of The Pathogen and Microbiome Institute, which uses genomic tools for understanding infectious diseases and the microbiome. This is a joint institute between TGen and Northern Arizona University, where Dr. Keim holds the Cowden Endowed Chair in Microbiology. His work has employed genetic and genomic analyses for understanding bacterial pathogen population structure and evolution for more than 30 years. Linking populations to their ecology has also been a critical part of his program. His laboratory served as the evidence repository and genetic analysis lab for the Federal Bureau of Investigation during the 2001 anthrax-letter investigation. He has been a leader in the field of microbial forensics which uses evolutionary analysis to understand close relationships among pathogen isolates. This work was foundational for his pursuit in public health investigations and the development of novel clinical diagnostic tests. He is an elected fellow of both the American Association for the Advancement of Science and the American Academy for Microbiology. The National Institutes of Health appointed him to the National Science Advisory Board for Biosecurity in 2004 and served as its chairman for two years. He has published over 400 scientific research articles that have been cited over 20,000 times.

Jennifer Nuzzo, DrPh, SM, is a Senior Associate at the Johns Hopkins Center for Health Security (formerly the University of Pittsburgh Medical Center for Health Security), Visiting Faculty in the Department of Environmental Health and Engineering and Associate in the Department of Epidemiology at the Johns Hopkins Bloomberg School of Public Health. An epidemiologist by training, her work focuses on international and domestic biosurveillance, infectious disease diagnostics, and disease mitigation strategies. She also has worked on issues related to the Affordable Care Act, tuberculosis control, foodborne outbreaks, and water security. Dr. Nuzzo is an Associate Editor of the peer-reviewed journal *Health Security* (formerly *Biosecurity and Bioterrorism*).

In addition to her work at the Center, Dr. Nuzzo has advised national governments and nonprofit organizations. She has served as a consultant to the National Biosurveillance Advisory Subcommittee, as a member of the US Environmental Protection Agency's National Drinking Water Advisory Council (NDWAC), and as a member of the NDWAC's Water Security Working Group. She has also served as a project advisor for the American Water Works Association Research Foundation (now called the Water Research Foundation), a primary funding organization for drinking water research in the United States. She has also been consulted on pandemic planning efforts in the Republic of Indonesia and Taiwan.

Dr. Nuzzo received a Doctor of Public Health degree (DrPH) in epidemiology from the Johns Hopkins Bloomberg School of Public Health, an SM in environmental health from Harvard University, and a BS in environmental sciences from Rutgers University.

Martina Siwek, **PhD**, a native of the Czech Republic, obtained a Bachelor of Arts (BA) in Biological Science from Goucher College and a Doctorate of Philosophy in Molecular Microbiology and Immunology from the Johns Hopkins Bloomberg School of Public Health. She has extensive research experience in HIV vaccine research and human immunity and infectious diseases, especially viral pathogens. Dr. Siwek has worked in support of the Department of Defense since 2010. She started at the Joint Program Executive Office (JPEO) as the Technical Director for the Critical Reagents Program (CRP) and as a subject matter expert in infectious diseases and especially dangerous pathogens. Dr. Siwek eventually transitioned to serving as the Liaison Officer coordinating various inter- and intra-agency efforts and organizations, including the Armed Forces Health Surveillance Branch (AFHSB), the Centers for Disease Control and Prevention (CDC), the Defense Threat Reduction Agency (DTRA), and many others. She assumed her role as the Chief Scientist for the Global Emerging Infections Surveillance (GEIS) Section at the AFHSB in 2014. There she provides scientific guidance and oversight for emerging infectious disease surveillance projects conducted by or in conjunction with US military research laboratories in continental United States (CONUS) as well as outside of the continental United States (OCONUS) settings.

Program Agenda

Wednesday, February 8, 2017		
Time	**Session**	**Notes**
1:30 PM - 2:00 PM	**CBEP EUCOM Overview**	Overview Briefs by DTRA/CBEP for Review Panel (Note: **Closed Session** for US Government Personnel and Review Panelists only)
2:00 PM - 2:30 PM	**CBEP AFRICOM Overview**	
2:30 PM - 3:00 PM	**CBEP CENTCOM Overview**	
3:00 PM - 3:30 PM	**CBEP PACOM Overview**	
3:30 PM - 4:00 PM	**Coffee Break**	Open to all Attendees
4:00 PM - 5:00 PM	**Session 1: Special Presentation** **"Doing Science in Difficult Places"**	Open to all Attendees
5:00 PM - 6:30 PM	**Poster Session & Networking Event**	Open to all Attendees

Thursday, February 9, 2017

Time	Speaker	Country	Project
8:30 AM - 8:50 AM	**Opening Remarks**		
8:50 AM - 10:10 AM	**Session 2: Chiroptera (Bats) - Important Reservoirs Hosts of Emerging Viruses**		
	Olival, Sidamonidze, & Al-Hmoud	Georgia & Jordan	(BAA) Understanding the Risk of Bat-Borne Zoonotic Disease Emergence in Western Asia
	Smith	Cambodia	(BAA) Investigating the Risk of Human Disease from Parasites of Small Mammals and Bats
	Kityo	Uganda	(Call) Arthropod-borne Viruses Associated with the Chiroptera of Uganda: Isolation and Characterization
	Mendenhall	India	(BAA) Bat Harvesting in India: Detection, Characterization and Mitigation of Emerging Infectious Disease Risk
	Ekiri	Tanzania	(BAA) Evaluating Zoonotic Viral Sharing Among Bats, Primates and People in High Risk Transmission Interface in Southern Tanzania.
10:10 AM-10:30 AM	**Coffee Break**		
10:30 AM-11:40 AM	**Session 3: Epidemiology & Biosurveillance - Group 1**		
	Chanturia	Georgia	GG-19: Epidemiology and Ecology of Human Tularemia in Georgia
	Jacobs	Azerbaijan	TAP-10: Ecological and Epidemiological Study of *Yersinia pestis* and *Francisella tularensis* in the Northern Part of Azerbaijan Regions of Gusar and Khachmaz
	Kilonzo	Tanzania	(BAA) One Health Approach to Brucellosis and Rift Valley Fever Surveillance in Tanzania
	Bhengsri	Thailand	(Call) Acute Febrile Illness Study Among Patients in Nakhon Phanom and Tak Province, Thailand
	Orynbayev	Kazakhstan	TAP-8: Especially Dangerous Pathogen Differential/Rule-Out Elimination Assays & Modeling (EDP-DREAM) of the Saiga Antelope Mortality

Thursday, February 9, 2017 (Continued)

Time	Speaker	Country	Project
11:40 AM-12:30 PM	**Session 4: Viral Pathogens of Security Concern**		
	Babuadze	Georgia	(Call) Assessing the Seroprevalence and Genetic Diversity of CCHFV and Hantaviruses in Georgia
	Eyangoh	Cameroon	Epidemiology of Emerging Viruses
	Karesh & Van Vuren	South Africa	(BAA) Understanding Rift Valley Fever in South Africa.
	Epstein	Malaysia	(BAA) Biosurveillance for Henipaviruses and Filoviruses at the Agricultural Animal-Human Interface in Malaysia
12:30 PM - 1:30 PM	**Lunch**		
1:30 PM - 2:20 PM	**Session 5: Community Outreach to Combat African Swine Fever**		
	De Nardi	Implementer	ASF Public Outreach Project Overview
	Niazyan	Armenia	TAP-A1: Community Outreach to Support Understanding of ASF Ecology and Epidemiology in Eastern Europe: Training and Implementation for Methods and Strategies for Control and Prevention
	Ninidze	Georgia	TAP-9: Community Outreach to Support Understanding of ASF Ecology and Epidemiology in Eastern Europe: Training and Implementation for Methods and Strategies for Control and Prevention
	Datsenko	Ukraine	TAP-4: Community Outreach to Support Understanding of African Swine Fever (ASF) Ecology and Epidemiology in Eastern Europe

Thursday, February 9, 2017 (Continued)

Time	Speaker	Country	Project
2:20 PM - 3:20 PM	**Session 6: Transboundary Animal Diseases**		
	Dung	Vietnam	(Call) Foot-and-Mouth Disease Virus Surveillance and Ecology in Vietnam
	Okoth	Kenya	(BAA) Whole Genome Sequencing of African Swine Fever Virus in Kenya.
	Nevolko	Ukraine	TAP-6: Analysis of the Threat of Spread of African Swine Fever and Classical Swine Fever in Wild Boar Populations in Ukraine: Improving Diagnosis, Surveillance, and Prevention
	Mwiine	Uganda	UG-2: Research and Development of Countermeasures to Support the Control of FMDV in Uganda
	Filatov	Ukraine	(USDA ARS) African Swine Fever Threat Reduction Through Surveillance in Ukraine
3:20 PM - 3:40 PM	**Coffee Break**		
3:40 PM - 5:00 PM	**Session 7: Bacterial Pathogens of Security Concern - Group 1**		
	Motin & Shikhaliyeva	Georgia & Azerbaijan	(BAA) Molecular Epidemiology and Ecology of *Yersinia* spp. in the Transboundary Plague Endemic Territory in Georgia and Azerbaijan
	Sansyzbayev	Kazakhstan	KZ-31: Effect of *Rickettsia* spp. upon Fitness of *Yersinia pestis* in Fleas that Vector Plague in the Republic of Kazakhstan
	Tarasov	Ukraine	UP-2: Development of the Epidemiological Forecasting System for Zoonotic Diseases Employing GIS Technology
	Solomonia	Georgia	GG-23: Creation of Sustainable Immunodiagnostics
	Avetisyan	Armenia	AM-1: Medical/Biological Mapping of Tularemia Natural Foci and Epidemiology using GIS in Armenia
5:00 PM - 5:10 PM	**Break**		

Thursday, February 9, 2017 (Continued)

Time	Speaker	Country	Project
5:00 PM - 6:20 PM	**Session 8: Avian Transmissible Diseases**		
	Goraychuk	Ukraine	(USDA ARS) Genomic, Epidemiological, and Biological Characterization of Newcastle Disease Virus Isolates from Ukraine
	Ateya	Kenya	(Call) Newcastle Disease: Surveillance, Molecular Epidemiology, and Control of NDV in Kenya
	Strochkov	Kazakhstan	TAP-11: Molecular Characterization and Complete Genome Sequence of Newcastle Disease Virus Isolated in Kazakhstan
	Muzyka	Ukraine	UP-4: Risk Assessment of Selected Especially Dangerous Pathogens Potentially Carried By Migratory Birds Over Ukraine
	Kapur	India	(BAA) Detection and Molecular Epidemiologic Analysis of Especially Dangerous Pathogens in Backyard Poultry, Commercial Broilers and Waterfowl in India
6:20 PM - 6:30 PM	**Day 1 Wrap-up**		

Friday, February 10, 2017

Time	Speaker	Country	Project
8:30 AM - 8:40 AM	**Opening Remarks**		
8:40 AM - 10:20 AM	**Session 9: Bacterial Pathogens of Security Concern - Group 2**		
	Chanturia	Georgia	(BAA) Characterization of NCDC Strain Repository by Next Generation Sequencing (NGS)
	Shah	Pakistan	(BAA) High Resolution Chemical Characterization of *Yersinia pestis* Cells Within Soil Matrices: Implications for Understanding Natural Foci and Telluric Reservoirs of Plague
	Bitek	Kenya	(CDC IACRO) Estimating Incidence and Socio-economic Impact of Brucellosis in Humans and Animals in Kajiado County, Kenya
	Sidamonidze	Georgia	TAP-10: Molecular Epidemiology of *B. anthracis* and *Brucella* spp. in Turkey and Georgia
	Malania	Georgia	GG-27: Regional Study of the Ecology of Anthrax Foci in Georgia and Azerbaijan
	Ismayilova	Azerbaijan	AJ TAP-11: Regional Study of the Ecology of Anthrax Foci in Georgia and Azerbaijan
	Zimmerman	Lao PDR	Environmental Surveillance of *Bukholderia pseudomallei*, Pilot Study in Lao PDR
	Limmathurotsakul	Thailand	Melioidosis Regional Coordination Network
10:20 AM- 10:40 AM	**Coffee Break**		
10:40 AM - 12:00 PM	**Session 10: Emerging Infectious Diseases**		
	Reynolds	Georgia	(Call) Enhancing Capacity for Case Detection and Diagnosis of Febrile Zoonotic-related Cutaneous Lesions in Georgia
	Gulbani	Georgia	(BAA) Enhancing Capacity for Case Detection and Diagnosis of Febrile Zoonotic-related Cutaneous Lesions in Georgia
	Abubakar	Malaysia	(Call) Multi-Year Prospective Cohort Study to Evaluation the Risk Potential of MERS-CoV
	Orynbayev	Kazakhstan	KZ-33: Middle East Respiratory Syndrome Coronavirus (MERS-CoV): Surveillance for Distribution and Prevalence in Kazakhstan
	Buza	Tanzania	(BAA) Global Health, Emerging Infectious Diseases and Food Safety Implications of Bushmeat in Tanzania
	Sam	Malaysia	(BAA) Etiology of Severe Acute Respiratory Infections in Kuala Lumpur, Malaysia

Friday, February 10, 2017 (Continued)

Time	Speaker	Country	Project
12:00 PM - 1:00 PM	**Lunch**		
1:00 PM - 2:40 PM	**Session 11: Epidemiology & Biosurveillance - Group 2**		
	Ragan	Armenia	AM-4: One Health Surveillance for Brucellosis in Armenia
	Byarugaba	Uganda	(BAA) Acute Febrile Illness in Uganda.
	Mammadov	Azerbaijan	(Call) Infectious Etiologies of Acute Febrile Illness Among Members of the Azerbaijan Military
	Gulbani	Georgia	GG-20: Prevalence, Epidemiological Surveillance, and Laboratory Analysis of *Coxiella burnetii* in Georgia
	Sandybayev	Kazakhstan	KZ-32: Prevalence of *Brucella* Species and Bluetongue Virus Serotypes Among Domestic Livestock or Ruminants in Southern Kazakhstan
	Avetisyan	Armenia	TAP-H1: Identification of Etiology, Clinical Outcomes, Incidence, and Epidemiological Patterns of Hospitalized Febrile Patients in Armenia
	Burjanadze	Georgia	GG-21: Human Disease Epidemiology and Surveillance of Especially Dangerous Pathogens in Georgia
	Godbold	Armenia	AM-3: The Epidemiological Status of African Swine Fever in Domestic Swine Herds in the Tavush Marz Region, Republic of Armenia
2:40 PM - 2:50 PM	**Break**		
2:50 PM - 3:30 PM	**Session 12: Arthropods and Arboviruses**		
	Ismayilova	Azerbaijan	AJ TAP-13: Investigation of Mosquito and Tick-Borne Arboviruses in Southeastern Azerbaijan
	Sukhaishvili	Georgia	TAP-12: Analysis of Previously Identified *Rickettsia* Positive Georgian Ticks by Multi-locus Sequence Typing
	Khan	Pakistan	(BAA) The Role of Arboviruses as a Cause of Undifferentiated Febrile Illness in Sind, Pakistan
3:30 PM - 3:50 PM	**Closing Remarks**		

Presentation Summaries

February 8, 2017

Session 1

Doing Science in Difficult Places

PRESENTERS: Valerie DeThomas (CRDF)/ Jeffrey Skowera (CRDF)/ Robert Esler (CRDF)/ Matthew Bouton (Univ. of Michigan)/ Amir Abdulmawjood (Univ. of Veterinary Medicine Hannover – Germany)

Since 1995, CRDF Global has worked in over 40 countries using science to address priority issues in support of U.S. and foreign government agencies, foundations, and private sector organizations. Many of these countries may be considered difficult places to work due to past or ongoing war or other conflicts, political or economic instability, resource constraints, or significant differences in research capabilities, scientific norms and practices.

Application of tailored programming approaches, genuine commitment to understanding the environments in which partner country scientists operate, and flexibility form the foundation for effective science collaboration in difficult places. Ultimately, scientists are eager to engage and work together in search of solutions to the world’s problems.

In 2013-2016, CRDF Global’s work with scientists and researchers from Iraq and Afghanistan in support of CBEP included a research grant competition, science fellowships and network building and exposure programs. CRDF Global’s ability to meet program objectives required building trust and rapport with Iraqi and Afghan participants, regular communication, engagement of all necessary stakeholders, adaptability, flexibility, and creative solutions. The programs’ success is, in large part, attributed to participation of scientists in the U.S., Germany, Italy, India, Australia, Switzerland, Jordan and Malaysia, who hosted Iraqi and Afghan researchers at their labs for trainings, lab tours, exposure visits and fellowships.

Presentation Summaries

February 9, 2017

Session 2: Chiroptera (Bats) – Important Reservoir Hosts of Emerging Viruses

Understanding the Risk of Bat-Borne Zoonotic Disease Emergence in Western Asia

PRESENTERS: Kevin Olival/Ketevan Sidamonidze/Nisreen Al-Hmoud

COUNTRY: United States/Georgia/Jordan

Bats are natural reservoir hosts to several emerging viruses with pandemic potential, including Ebola, Marburg, Nipah, and SARS and MERS-coronaviruses, but current research on the distribution of bats, diversity of their viruses, and potential for zoonotic disease emergence in Western Asia is severely limited. To fill this gap and contribute to biological threat reduction, we propose a hypothesis-driven One Health research project focused on characterizing bat coronavirus diversity and the risk of bat-borne zoonotic disease emergence. This will include extensive non-lethal field sampling of bats, screening and characterization of viruses from bat specimens with two regional partner laboratories currently operating within the region, the Lugar Center in Georgia and RSS in Jordan, and modeling emerging disease risk by combining viral data with host, geographic, and ecological data. Data for risk modeling will be collated across a larger region than our field sampling will allow through the creation of a collaborative Western Asia Bat Research Network (WAB-Net) – including key researchers and public health representatives from >12 countries. Research activities will be strengthened via laboratory exchanges and annual data sharing and capacity building workshops. This integrated, multi-disciplinary approach presents a coordinated strategy to advance scientific knowledge around transboundary zoonotic disease emergence risk in Western Asia to inform early detection, diagnosis, and response to support the Global Health Security Agenda and CBEP goals.

Investigating the Risk of Human Disease from Parasites of Small Mammals and Bats

PRESENTER: Gavin Smith

COUNTRY: Cambodia

Emerging and re-emerging infectious diseases pose a significant public health challenge globally, with severe economic, social, and health consequences. It is estimated that the SARS outbreak alone cost over $50 billion dollars in lost global economic activity. The frequency of epidemics caused by newly emerging and re-emerging pathogens and the likelihood of rapid global spread have increased dramatically in recent decades, with Southeast Asia considered a hot spot for future emergence events. Small mammals and bats play an important role in the maintenance and transmission of select agents that infect humans such as *Brucella* species, coronaviruses, filoviruses, henipaviruses, hantaviruses/bunyaviruses, plague, rabies (lyssaviruses) and *Rickettsia* species. The global distribution of several species of small mammals and bats, in addition to the ever-increasing interface between humans and wildlife, ensures that cross-species transmission events will continue to occur, often with devastating effects. By proactively sampling animal populations in Cambodia to discern circulating parasitic genotypes and screening human sera for evidence of exposure, we can determine which parasites have human pathogenic potential. A standardized trapping regimen will allow us to understand which ecological and environmental variables are associated with host and parasite presence-absence, facilitating the creation of ecological niche maps and models to determine risk and inform future surveillance efforts across Southeast Asia.

Arthropod-Borne Viruses Associated with the Chiroptera of Uganda: Isolation and Characterization

PRESENTER: Robert Kityo

COUNTRY: Uganda

This project aimed to achieve a better understanding of bats, their ecology and their potential roles in virus ecology. This has been done through graduate training and research, training in field techniques of capture and processing of bats for virus detection and characterization, and a compilation of reference calls of micro-chiropteran bats for Uganda. Field biosurveillance training was held with participants from NADDEC, UVRI and Makerere University at Zika forest. A graduate student was recruited and completed an ecological study on bats in the Kaptum cave. We conducted bat surveys from around Uganda and have collected voucher calls from 28 microchiropteran bats from over 10 localities in Uganda.

From our graduate student's research, we now know there are 6 bat species (*Nycteris thebaica, Rhinolophus landeri, Rhinolophus hildebrandtii, Hipposideros caffer, Hipposideros ruber,* and *Myotis bocagei*) in Kaptum cave. Although they may mix up, these seem to have preferred roosting corners in the cave defined by slight differences in temperature and relative humidity.

Besides Kaptum Cave, we have documented the existence of many other caves around the country with bats. These caves are frequently visited by local people for various reasons. This could inevitably expose such members of the local communities to aerosols in the caves. Collectively, this project has advanced our knowledge of bat ecology in Uganda and enhanced collaborative research between US and Ugandan institutions which will promote cooperation during future biosurveillance and outbreak events.

Bat Harvesting in India: Detection, Characterization and Mitigation of Emerging Infectious Diseases Risk

PRESENTER: Ian Mendenhall

COUNTRY: India

Emerging infectious diseases pose a continual risk for humans, imparting major health and economic challenges. It is estimated that greater than 70% of these diseases originate in wildlife, which demonstrates the importance of understanding the diversity of parasites that circulate in animals. Bats are important reservoirs of several medically important viruses that have high case fatality rates, including rabies/lyssaviruses, the henipaviruses, SARS-like coronaviruses, and Ebola virus and the related filoviruses. India is one of the most biologically diverse countries in the world, however there are currently few reports of viruses detected in bats. Outbreaks will often begin from point source origins, as phylogenetic data from the recent Ebola outbreak in West Africa indicates. Therefore, studying specific interfaces where humans are exposed more frequently due to their proximity and heightened interactions with wildlife can provide critical information on exposure. Bat harvesting is a common practice across India, as concentrated efforts can yield high numbers of bats. This contact and processing of bushmeat is an opportune place for cross-species transmission to occur. By sampling the bat populations where harvesting occurs before, during and after the trapping, we can determine if bat harvests increase the shedding of viruses and what medically important viruses are circulating in these bat populations. This will allow us to generate risk models and understand which species may be natural virus reservoirs in India.

Evaluating Zoonotic Viral Sharing Among Bats, Primates, and People in a High-risk Transmission Interface in Southern Tanzania (VISHA Project)

PRESENTER: Abel Ekiri

COUNTRY: Tanzania

Through project partners, including Metabiota, University of California Davis, Sokoine University of Agriculture, and the Ifakara Health Institute, we are evaluating: 1) the risk of zoonotic virus transmission among bats, non-human primates (NHP), and people sharing a forest interface with high human-wildlife contact in Southern Tanzania; 2) the impact of bat and primate community composition on virus diversity; and 3) exposure to zoonotic viruses in high-risk human populations living at the forest interface. By investigating cross-species viral sharing at this high-risk interface, our team will increase the understanding of pathogen emergence risk and transmission between human and wildlife hosts, strengthen Tanzanian surveillance and diagnostic capacity for pathogens of pandemic and biosecurity concern, and identify key intervention points to reduce local viral spillover from wildlife into human populations. The VISHA project team is investigating the epidemiology of known and novel zoonotic viruses (including filoviruses) in bats, NHPs, and humans by: 1) characterizing forest field sites; 2) collecting bat and NHP specimens during wet and dry seasons; 3) collecting specimens from high-risk human groups near forest areas during wet and dry seasons; 4) testing wildlife and human specimens for potential zoonotic viral pathogens using virus family-level RT-PCR; 5) performing phylogenetic and other genomic analyses on all detected viruses; 6) identifying risk factors for human exposure to bat and NHP viral pathogens using spatial analyses and epidemiologic modeling; and 7) training Tanzanian scientists in surveillance, molecular diagnostics, genomic analyses, and field and laboratory biosecurity practices.

Epidemiology and Ecology of Tularemia in Georgia

PRESENTER: Gvantsa Chanturia

COUNTRY: Georgia

Our study investigated the epidemiology of human and animal tularemia in Georgia. The project included (1) the study of seroprevalence of tularemia among individuals living in geographic areas with tularemia, and healthy individuals; and (2) estimate risk factors for seropositive humans and animals. We also established active surveillance for human tularemia clinical cases with the goal of increasing the efficiency and tularemia diagnostic capability. Isolates from human cases (900 volunteers) for comparison to both current environmental and historical isolates (National Center for Disease Control and Public Health). From an environmental prevalence emphasis, we will establish active surveillance for *F. tularensis* in the environment, including a study of small rodents and associated vectors and identification of the sources of outbreaks among humans. Field sampling for active surveillance for *F. tularensis* in the environment included small rodents and associated vectors, linking with human cases and seroprevalence study among the population living in foci area. More than 60,000 vectors were collected and pooled into 6,000 collections. All strains were isolated, evaluated, and monitor patterns of antimicrobial resistance. A bacteriophage component of this project examined isolated *F. tularensis* strains by genomic sequencing, proteomics analysis (Ilia State University), and phage discovery (the Eliava Institute). Geographic information systems and genetic algorithm for rule-set production were used for pathogenic distribution. Ecological niche models were created for ectoparasite species and primary rodent vectors. Consistent differences were found by the expression of some proteins between the isolates. Real-Time PCR and Western immunoblotting further validated these differences.

Ecological and Epidemiological Study of *Yersinia pestis* and *Francisella tularensis* in the Northern Part of Azerbaijan Regions of Gusar and Khachmaz

PRESENTER: Jolanta Jacobs

COUNTRY: Azerbaijan

Robust surveillance of *Y. pestis* and *F. tularensis* was once carried out routinely, however since the collapse of the Soviet Union little funding has been allocated to such efforts, and thus almost no data are available on the current distribution of plague and tularemia foci and vectors in Azerbaijan.

TAP-10 project proposes to conduct surveillance of ectoparasite vectors of plague and tularemia in northern Azerbaijan, in an area with a historical presence of those diseases and located near known natural foci of plague and tularemia.

The project started in April 2015 and is being implemented by Khachmaz Anti-Plague Division (APD). Sample collection (arthropods: fleas and ticks) field activities were carried out over six months in spring, summer, and autumn of 2015. Sample collection was completed in total of 13 villages of Gusar and Khachmaz regions in September 2015. Collected ticks and fleas were sorted, counted, identified, pooled, homogenized and their nucleic acids were extracted. The extracted nucleic acid samples have been tested by PCR (Bio-Rad 96 instrument) for two targets for each of the pathogens. 8,216 ticks and 154 fleas have been counted, identified, and sorted. 1,269 tick pools and 55 flea pools have been created and homogenized and their DNA extracted. Primer and probe sets were optimized and testing is ongoing.

A One Health Approach to Brucellosis and Rift Valley Fever Surveillance in Tanzania

PRESENTER: Chris Kilonzo

COUNTRY: Tanzania

Our One Health team, including partners from Metabiota, the University of California, Davis, Sokoine University of Agriculture, and Ifakara Health Institute is utilizing a transdisciplinary approach to investigate the epidemiology and genomic diversity of the zoonotic pathogens Rift Valley fever virus (RVFV) and *Brucella* in south-central Tanzania. The primary objectives of the project are to evaluate the influence of risk factors such as animal contact and climatic conditions on increased RVFV and *Brucella* infection among livestock, wildlife, and humans, and to enhance in-country capacity for RVF and brucellosis surveillance, prevention, and control. To attain these goals, the team is engaged in: 1) characterization of sites with historical RVFV and *Brucella* activity in humans and animals that represent diverse climatic and animal density variables; 2) concurrent pathogen surveillance for acute and convalescent infections among humans, livestock, conspecific wildlife, and RVFV mosquito vectors to elucidate key disease transmission pathways, 3) identification of climatic conditions and temporal patterns that increase disease risk among vector and host species; 4) characterization of the RVFV and *Brucella* spp. diversity detected in mosquitos, animals, and humans; 5) identification of potential cryptic wildlife maintenance hosts using serologic evidence of prior infection, or in the case of RVFV by using blood-meal analysis of recently fed virus-infected mosquitoes, and 6) the development of integrated models to predict geographic areas of increased pathogen maintenance and transmission to identify locations for targeted intervention strategies and enhanced disease surveillance.

Acute Febrile Illness Study among Patients in Nakhon Phanom and Tak Province, Thailand

PRESENTER: Saithip Bhengsri

COUNTRY: Thailand

There are many causes of acute febrile illness (AFI) including various emerging infectious diseases in Southeast Asia and Thailand. Such diseases can be difficult to differentiate by clinical signs and symptoms, leading to misdiagnosis and possibly serious consequences for patient care. Therefore, laboratory testing is necessary to establish an accurate diagnosis. The objectives of this study are to: 1) describe the etiologies for patients hospitalized with AFI, 2) estimate incidence of specific pathogens and monitor trends over time, 3) evaluate the performance of rapid diagnostic tests (RDTs), and 4) assess laboratory diagnostic accuracy based on specimen types and testing methods for disease surveillance and outbreak identification. The study is being conducted in two Thai border provinces, Nakhon Phanom in the northwest and Tak in the east. The project is divided into 3 phases: pilot, surveillance and research phase. In the pilot phase, demographic data, clinical information and routine laboratory results will be collected from eligible patients. During the surveillance phase, patients hospitalized with undifferentiated fever will be tested for bacteremia and dengue. If dengue is not diagnosed, samples will be tested for chikungunya, *Leptospira*, *Rickettsia* species, *O. tsutsugamushi*, and Zika virus. During the research phase, new RDTs for *B. pseudomallei*, *O. tsutsugamushi*, Zika and chikungunya viruses will be evaluated. Additional testing will be performed on an expanded range of bacterial and viral pathogens. This project will provide an increased spectrum of pathogen detection, improve the timeliness of pathogen characterization, and assess promising new advanced diagnostic tests for surveillance and clinical management in the region.

Differential Diagnostics Performed by Eliminating Especially Dangerous Pathogens and Simulation (EDP-DREAM) in Cases of Saiga Antelope Mortality

PRESNTER: Mukhit Orynbayev

COUNTRY: Kazakhstan

Though several large die-offs in saiga antelope (*Saiga tatarica*) herds in Kazakhstan have been reported in the past decade, the intensity, and absolute threat to the species of the ongoing die-off in the Kostanay oblast of Kazakhstan is unprecedented. The loss of reproductive females and calves represents long-term impacts on herd recovery and may indicate an eminent threat to regional livestock health. Reports have suggested the saiga die-off may be related to pollution or plant toxins, yet it is unclear how such toxicity would result in 100% mortality of nursing calves. Such a rapid die-off could be explained by viral (or viral/bacterial) infection. Even though Foot and Mouth Disease Virus (FMDV) has been reported in saiga, relatively few viruses result in 100% mortality, particularly in calves. However, FMDV could potentially play a role in a multiple pathogen infection. This study will implement a differential diagnostic work flow to diagnose anthrax and other Especially Dangerous Pathogens (EDPs) that may be involved in the saiga die-off. The project will use high resolution GPS collar data from animals at-large during the die-off. The first field expedition began in September 2016, and experts from the lead KZ partner, the Research Institute for Biological Safety Problems (RIBSP), pursued saiga individuals of Ural population in West Kazakhstan and Atyrau Oblasts to take samples and fit them with collars. Fifty-four individuals were captured from the Ural population: fifty-two individuals in West Kazakhstan oblast, and two individuals in Atyrau Oblast. During the field expedition, the five available animal collars were placed on animals and found to provide a stable signal. All samples have been delivered to RIBSP and are being stored at the BSL-3 laboratory. Currently materials and reagents are bring procured. Dr. Jason Blackburn from University of Florida is the collaborator for the study.

Assessing the Seroprevalence and Genetic Diversity of CCHFV and Hantaviruses in Georgia

PRESENTER: Giorgi Babuadze

COUNTRY: Georgia

The proposed collaborative research project will assess the seroprevalence and genetic diversity of highly pathogenic bunyaviruses circulating in Georgia to include Crimean-Congo hemorrhagic fever virus (CCHFV) and hantaviruses causing hemorrhagic fever with renal syndrome (HFRS), such as Puumala (PUUV), Dobrava (DOBV), or Seoul (SEOV) viruses. Specific aims of the project are to: (1) Determine the prevalence and serological diversity of CCHFV and hantaviruses in patient populations using samples collected from previously funded CBEP projects, human samples (GG-21) and environmental samples (GG-19); (2) Establish multiplexed immunological and molecular diagnostic assays for detecting circulating strains of pathogenic bunyaviruses, and provide suitable training for sustainment of these assays and capabilities within Georgia; (3) Initiate active surveillance for CCHFV, and hantaviruses in the environment to include small rodents and ticks; (4) Identify and characterize the genetic diversity of CCHFV and hantaviruses detected in rodents and ticks; (5) Establish a DNA barcode reference library for local tick species, to facilitate future identification and incrimination of tick-borne disease in Georgia.

These studies will provide a baseline assessment of the potential for future outbreaks of CCHF and HFRS in this region. Rodent and tick samples will be tested by ELISA and RT-PCR for evidence of CCHFV or hantavirus infections. Selected samples will be sent to the USAMRIID for virus-specific neutralization tests in BSL-3 or BSL-4 containment laboratories.

Epidemiology of Emerging Viruses in Cameroon

PRESNTER: Sara Eyangoh

COUNTRY: Cameroon

The geographical and socio-cultural diversity of Cameroon makes it vulnerable to many emerging tropical viral infections like, Ebola, Zika, Dengue, Lassa, etc. While some studies have been done on the epidemiology of some of these viruses, these dispersed studies remain insufficient as a basis for the implementation of effective public health measures in this regard. Our objective was to assess the circulation of certain emerging viruses in the Cameroonian population in order to make recommendations to strengthen their surveillance and reinforce the rapid detection of any eventual epidemic.

In this respect, different samples were collected from 6 sites of Cameroon in different regions. These samples were serum/whole blood from 1500 blood donors, blood/oral swabs from 500 febrile patients susceptible of carrying a potential viral infection, and samples from bats to look for potential viral reservoirs. Collection of samples is complete, but analysis is ongoing at French Arbovirus National Reference Centre (Marseille, France). Preliminary data are available from blood donors. All donor blood samples were analyzed by ELISA. Positive samples underwent seroneutralisation analysis, RT-PCR (for DENV) and serotyping and phylogeny subsequently. Blood donor sample preliminary ELISA positive results were as follows: WNV(61.6%),TBE(39,9%), DENV(56,9% with 7.6% positive on RT-PCR, serotyping in progress), TOSV(7%), RIFTV(0%), ZIKV(10,4%).

Our definitive findings hope to build a framework upon which public health decisions can be made to increase preparedness for an eventual epidemic of an emerging viral infection and improve laboratory detection capabilities at the national level.

Understanding Rift Valley Fever in the Republic of South Africa

PRESENTERS: Billy Karesh & Petrus Van Vuren

COUNTRY: South Africa

Rift Valley fever virus (RVFV) is a vector-borne pathogen causing significant livestock, wildlife and human morbidity and mortality, and results in significant economic damages and food security concerns. RVFV has spread from Africa to the Arabian Peninsula, has the potential to spread to the Americas, and is considered a potential bioweapon. In South Africa, we have a multi-disciplinary team working to correlate environmental factors with vector succession and abundance, understand the role herd immunity may play in the occurrence of outbreaks and characterize the risk to people working in high-risk occupations. Initial analyses indicate that there are several vegetation and soil characteristics associated with locations of animal cases of RVF during the 2010-2011 outbreak. The baseline seroprevalence (representing herd immunity) in livestock have been established and experiments are running to understand how this may change. In people, the seroprevalence against RVFV is 0.1. Each year we hold national-level and local stakeholders' meetings to disseminate the data to national and provincial departments of agriculture, health and wildlife, as well as to farmers and workers, animal production groups and the weather service. Through this collaborative, One Health approach the project has become more robust and has strong support locally. The resultant data represents a significant step toward improving prediction of outbreaks and understanding how RVFV might spread, what effect climate change may have on the virus, how vaccination strategies may affect the risk of an epizootic and the risk of translocation to naïve countries, such as the United States.

Biosurveillance for Henipaviruses and Filoviruses at the Agricultural Animal-Human Interface in Malaysia

PRESENTER: Jonathan Epstein

COUNTRY: Malaysia

The henipaviruses and filoviruses include Hendra virus (HeV) and Nipah virus (NiV), and several species of Ebola (EBOV) and Marburg virus (MARV), respectively, which are highly pathogenic viruses and select agents capable of causing public health emergencies of international concern. Bats are recognized as reservoirs for both henipa- and filoviruses, and zoonotic transmission of these viruses from bats to humans via domestic animals has occurred in Southeast Asia. The full diversity of henipa- and filoviruses in bats and their potential to infect livestock and people is unknown. This project will enhance early detection and surveillance capacity in Malaysia by: 1) transferring Luminex-based technology with validated reagents to detect IgG antibodies against henipa- and filoviruses to Government of Malaysia partner labs in wildlife, livestock and human health sectors; 2) training laboratory personnel to develop and utilize Luminex-based assays to identify exposure to henipa- and filoviruses; 3) conduct biological surveillance in wildlife (esp. bats), livestock and people around indigenous communities that hunt wildlife and on farms in Peninsular Malaysia, where there are high levels of contact among people and animals. Based on building local capacity for hypothesis driven research and improved use of technology, this project will help characterize the distribution and spillover potential from bats of henipa- and filoviruses in Peninsular Malaysia. Activities will be coordinated with and complimentary to the USAID Emerging Pandemic Threats: PREDICT program and surveillance data will be shared with the Govt. of Malaysia (GoM). The proposed project is closely aligned with the aims of the Cooperative Biological Engagement Program in that it will support biosurveillance and capability building, engages partner-country scientists, and promotes a One-Health approach to threat reduction.

Session 5: Community Outreach to Combat African Swine Fever

ASF Public Outreach Project Overview

PRESENTER: Marco De Nardi

The Defense Threat Reduction Agency (DTRA) sponsored a four-country regional public outreach project to combat African Swine Fever (ASF). The primary objective of the project was to develop a comprehensive and sustainable regional network of knowledge, expertise, and know-how for the control and prevention of ASF emerging events through a joint-effort based Threat Agent Detection and Response (TADR) Activity Project (TAP) that combines four countries (Armenia, Georgia, Kazakhstan, and Ukraine) in a common activity-based Science plan. To achieve this goal, delegates from each country worked with project implementers to identify gaps in knowledge, legislative framework, and outbreak preparedness. As a pathogen of high bioterrorism potential, veterinary health importance, and/or responsible for major economic instability, it is of critical importance that ASF-threatened and ASF-affected countries have appropriate infrastructure to accurately and rapidly identify and report ASF activity and types to international veterinary health agencies, as well as provide follow-up concerning the spread of the virus. This project sought to identify key human resources and veterinary health systems in order to initiate implementation of solutions to address recognized gaps, thereby enhancing the capacity by which to mitigate the risk of ASF. The project used a “train-the-trainer” approach to successfully reach over 10,000 farmers, veterinarians, pig traders, rangers, and hunters among others, teaching the signs and symptoms to identify ASF along with the proper reporting measures. This project was the first four-country public outreach project sponsored by DTRA and is considered a monumental success due to the large numbers reached. The project also improved collaboration among regional partners with the hopes of additional similar outreach efforts on other pathogens and diseases of public health importance in the years to come.

Community Outreach to Support Understanding of ASF Ecology and Epidemiology in Eastern Europe: Training and Implementation for Methods and Strategies for Control and Prevention

PRESENTER: Lyudmila Niazyan

COUNTRY: Armenia

African swine fever (ASF) is a highly contagious viral disease of swine populations that can have significant economic consequence. It was successfully eradicated from most of the Eurasian continent almost 30 years ago, but was re-introduced in Georgia in 2007. Since then ASF has spread widely affecting swine in Georgia, Azerbaijan, Armenia, Ukraine, and Russia.

The primary goal of this project was to develop a comprehensive and sustainable regional network of expertise for the control and prevention of ASF through a joint-effort-based project combining four countries: Armenia, Georgia, Kazakhstan, and Ukraine. The project aims to identify and then educate persons working in the pig production chain (e.g., pig keepers, butchers, community veterinarians) to recognize clinical and epidemiological patterns of ASF. The training will allow these workers to understand (1) common routes of exposure, (2) preventative measures, (3) how to recognize clinical signs, (4) the importance of reporting to veterinary authorities, and (5) how to respond to suspected ASF cases.

In Armenia, a Knowledge and Attitude survey was implemented through veterinary authorities to assess the knowledge of the chosen target groups in ASF. For the public outreach campaign ten inspectors and ten epidemiologists were selected to train target groups, but due to the short time just 301/603 veterinarians, 1000/2412 farmers and 100/2670 hunters have been trained to date (Map 1). An additional 1000 farmers were subsequently educated by community vets during their routine work after the public outreach campaign ended. Over the course of the project and its aftermath, 3000 booklets and 150 posters were distributed and 2401 total persons informed.

This project facilitated the development of a sustainable capacity to implement outreach campaigns for future disease outbreaks in the region. Countries receiving training were taught how to run an outreach campaign including how to identify the target audience, how to produce effective educational materials, and how to effectively distribute those materials.

Community Outreach to Support Understanding of ASF Ecology and Epidemiology in Eastern Europe: Training and Implementation for Methods and Strategies for Control and Prevention

PRESENTER: Lena Ninidze

COUNTRY: Georgia

In 2007, Georgia was affected by a nationwide outbreak of African swine fever (ASF), and outbreaks were simultaneously reported in three different locations across the country. Monitoring ASFV in Eastern European countries is a top priority for the U.S. Defense Threat Reduction Agency (DTRA). The primary objective of the project was to develop a comprehensive and sustainable regional network of expertise for the control and prevention of ASF events through a collaborative project that united four countries (Armenia, Georgia, Kazakhstan, and Ukraine). Gaps in knowledge, legislative framework, and outbreak preparedness in the partner countries were identified. Additionally, this project contributed to long-term sustainability by conducting outreach campaigns for future disease outbreaks. Georgian directors were taught to lead and implement outreach campaigns, including how to identify target audiences (e.g. local farmers, veterinarians, and members of the pork industry) and efficiently create and disseminate educational materials. Over 450 veterinarians and farmers were trained, and 20,000 educational materials were distributed. Pre and post ASF campaign tests were developed to track progress; post-test scores were 16% higher than pre-test scores, which indicates that the outreach program was successful. Regional and state veterinarians, along with government agencies will be responsible for measuring the long-term success of these programs through laboratory results, monthly disease reports, and veterinarian updates. The number of ASF outbreaks are an indicator of the long-term success of the outreach program.

Community Outreach to Support Understanding of African Swine Fever (ASF) Ecology and Epidemiology in Eastern Europe

PRESENTER: Roman Datsenko

COUNTRY: Armenia

In 2015, the State Scientific and Research Institute of Laboratory Diagnostics and Veterinary and Sanitary Expertise (SSRILDVSE) and Institute of Veterinary Medicine (IVM) of the National Academy of Agrarian Sciences took part in an ASF outreach activity implemented within the Defense Threat Reduction Agency (DTRA) Cooperative Biological Engagement Program (CBEP) in Ukraine. The project aimed at establishing a regional alliance between Armenia, Georgia, Kazakhstan, and Ukraine to exchange experience, raise awareness, and provide education on ASF. Specialists from SSRILDVSE and IVM were trained as trainers before implementing their own outreach program in Ukraine. During in-country workshops and 14 training sessions in 14 Oblasts of Ukraine, veterinarians from 307 rayons, 531 epizootologists of state regional veterinary administrations and 4482 veterinary doctors of district animal hospitals were educated in the country. Additionally, information materials (flyer and poster) were developed. They included information about the clinical and epidemiological patterns of ASF, common sources and routes of exposure, preventative measures, how to recognize symptoms, and how to respond to suspected ASF cases. 100,000 flyers were printed and distributed among farmers and populations, as well as 1,500 posters for veterinarians in 24 Oblasts. Due to these efforts, necessary information was brought to the attention of veterinary doctors at district animal hospitals who communicate directly with farmers and persons that work with swine. This project demonstrated an approach for conducting and applying a public outreach program in Ukraine that can be used to raise awareness and help mitigate future outbreaks of ASF and other diseases.

Foot-and-Mouth Disease Virus Surveillance and Ecology in Vietnam

PRESENTER: Do Huu Dung

COUNTRY: Vietnam

The purpose of this project is to improve understanding of the epidemiology of foot-and-mouth disease virus (FMDV) in the Vietnamese setting using state of the art tools for genetic characterization of the virus in this endemic context. The intended goal is to mitigate the impact of this disease on local agriculture and improve preparedness for potential disease incursions in the US homeland with awareness of emerging virus strains.

Foot-and-mouth disease (FMD) is a contagious viral disease of domestic and wild cloven-hoofed animals, most notably cattle, pigs, sheep, buffalo and goats. Despite recent successes in controlling the disease in Europe and some parts of South America, FMD remains one of the most important infectious diseases of livestock due to the potential impact of an outbreak on trade in animals and animal products.

The project is currently operating in the second year of the (expected) four year period of performance. Five of the seven defined project objectives are either completed or well-underway. Two objectives are still in the planning phase. Current and ongoing activities in the field consist of passive surveillance of all FMDV outbreaks reported to the Vietnam Department of Animal Health and active surveillance of healthy livestock in six provinces spanning northern, central and southern Vietnam.

This collaborative endeavor has already resulted in two published, peer-reviewed scientific papers and two more papers have been submitted for peer review. Specific accomplishments achieved within the project include 1) genetic characterization of over 160 novel strains of FMDV, 2) enhanced understanding of risk factors for FMDV infection, 3) unique analyses of movement of FMDV strains across regions of Vietnam, and 4) improved understanding of the role of asymptomatic carriers in FMD epidemiology in Vietnam.

Whole Genome Sequencing of African Swine Fever Virus in Kenya

PRESENTER: Edward Okoth

COUNTRY: Kenya

African swine fever (ASF) is a lethal disease of domestic pigs caused by a large DNA virus. In endemic areas ASF virus (ASFV) circulates in asymptomatic wild pigs and ticks and can remain stable in pork products for several months. ASF is endemic to Africa and was restricted only to that continent until 1957. Since then it has spread to Europe, Latin America and Asia. It is currently endemic in Russia and the Caucasus. There is a real risk of accidental or deliberate introduction of ASF to the United States of America (US), which would be devastating to the US $1.25 billion/year pig industry. There are at present no control measures other than test and slaughter. The objective of the proposed research is to determine the genome sequences of at least 60 ASFV isolates, selected so as to include as many as possible of the major genotypes for which genome sequences are currently lacking. These will be made available to veterinary and biosecurity authorities in the US and endemic countries through GenBank. This knowledge will enable more precise identification of the source of future ASF outbreaks, both within and outside Africa. It will also underpin development of future ASF control tools including diagnostic products and vaccines. The project will build ASFV research and surveillance capacity in Africa to support future disease control efforts.

Analysis of the Threat of Spread of African Swine Fever and Classical Swine Fever in Wild Boar Populations in Ukraine: Improving Diagnosis, Surveillance, and Prevention

PRESENTER: Oleg Nevolko

COUNTRY: Ukraine

Listed as high priority pathogens by the World Organization for Animal Health (OIE), African swine fever virus (ASFV) and classical swine fever virus (CSFV) cause epizootically and economically significant animal diseases. Since 2012, the number of reported ASF outbreaks in Ukraine has increased, with 148 confirmed ASF incidents registered in 18 Oblasts of Ukraine (households - 123; wild boar populations – 24; infected object - 1) including 91 in 2016 (84 in the households and 7 in wild boar population). In order to strengthen the accuracy and effectiveness of ASF/CSF diagnostics in the country and to provide Ukrainian scientists with the ability and infrastructure to quickly and accurately monitor ASF and CSF movement, DTRA supported TAP-6 project that commenced on 1 September 2016. The aims of this project are (1) to analyze the distribution of ASFV and CSFV among wild boar populations inhabiting regions of Ukraine, which border the Russian Federation, Belarus, and Poland, and (2) to evaluate the risk of transmission to domestic pigs in the country. In addition to ELISA and PCR, monitoring targeted wild boar populations in Ukraine for ASF and CSF will be accomplished by using genomic-based biosurveillance methods and trainings on real-time PCR, molecular analysis, phylogenetic analysis, and complex sequence data analysis. This will provide an improved scientific basis to optimize current interventions and develop new tools and strategies to reduce the risk of ASFV transmission to domestic pigs. These biosurveillance efforts will facilitate development of ASF and CSF control strategies, which will contribute to limiting the spread of both infectious agents.

Research and Development of Countermeasures to Support the Control of Foot and Mouth Disease Virus (FMDV) in Uganda

PRESENTER: Frank Mwiine

COUNTRY: Uganda

Foot and Mouth Disease (FMD) virus causes an acute and the most contagious vesicular disease of livestock. The causative agent is a virus of the *Aphthovirus* genus in the *Picornaviridae* family. This disease in endemic in Uganda. Here, we report on a cross-sectional surveillance study designed to monitor and isolate FMDV serotype(s) circulating in the country divided into four regions: Northern, Western, Central and Eastern. A total of 38 representative districts from all the regions of Uganda were selected where 10,321 cattle sera and 1,300 oral-pharyngeal fluid samples were collected. All sera were analysed by the presence of antibodies directed against the virus non-structural proteins (NSP) using commercially-available kits at Makerere University. In addition, all oral-pharyngeal fluid samples were tested by rRT-PCR and virus isolation (VI) tissue culture followed by virus capsid sequencing to determine the FMDV serotypes by ARS, USDA at Plum Island Animal Disease Center. From samples collected during 2014-2015, thirty two percent of the serum samples were positive towards NSP antibodies. FMDV serotype O was isolated from Northern and Eastern regions while serotype SAT 2 was isolated from Western region of Uganda during samples collected in 2014. However, FMDV serotype SAT 1 (from the same region) and O were isolated in oral-pharyngeal fluid samples collected in 2015. The phylogenetic analysis of the P1 sequences for the viruses isolated in relation to geographical distribution of FMDV serotypes isolated during 2014-2015 in Uganda will be discussed. This information is of great importance for the improvement of disease control strategies and for vaccine strain selection for Uganda in the future.

African Swine Fever Threat Reduction Through Surveillance in Ukraine: Surveillance of Potential Arthropod Vectors

PRESENTER: Sergiy Filatov

COUNTRY: Ukraine

African swine fever (ASF) is a high-consequence viral disease threatening the pig industry in Western Europe. In its native range, ASF virus (ASFV) is transmitted to pigs and maintained in Nature by soft ticks. Eastern European nations, including Ukraine, are considered to be endemic with ASF outbreaks occurring in pigs and wild boar. However, the factors underlying ASF westward expansion and reoccurrence on the affected territories remain to be fully understood.

Because certain soft tick species of the genus *Ornithodoros* can serve as biological vectors and reservoirs of ASFV, our research group focused on the development and implementation of vector surveillance in selected regions of Ukraine to establish methods that could be scaled up to the national level. The surveys conducted updated known soft tick distribution patterns. Field samples were identified morphologically as *Ornithodoros verrucosus*, and live specimens used to establish a laboratory colony of this suspected ASFV vector at the NSC IECVM. The *O. verrucosus* colony is a valuable resource to assess the risk of soft tick involvement in the epidemiology of ASF in Eastern Europe.

Ukrainian scientists developed research capacity in soft tick biology, collection methods, rearing and colonization techniques, and vector-host-pathogen interactions at USDA-ARS locations, and collaborating universities in Texas. Results of the project were presented at five scientific national and international conferences, summarized in a book published in Ukrainian and English, and two research papers published in international peer-reviewed journals.

Molecular Epidemiology and Ecology of *Yersinia* spp in the Transboundary Plague Endemic Territory in Georgia and Azerbaijan

PRESENTER: Vladimir Motin & Sheyda Shikhaliyeva

COUNTRY: United States, Georgia, and Azerbaijan

Plague has been known in Caucasus region for many centuries, with the reports in Georgia dated back to the XI century and in Azerbaijan to VII century. The absence of recent reports can be partially explained by reduced surveillance, but also by the possibility of existence of atypical strains of *Y. pestis*, which can be missed by the testing laboratory due to presence of non-culturable strains as well as an absence of some genetic loci which would render the use of common molecular markers ineffective. The investigations of natural foci of plague in both Georgia and Azerbaijan have resulted in numerous cases of isolation of *Yersinia* species other than *Y. pestis*. The exchange of genetic material between *Yersinia* strains can challenge the detection of the strains of *Y. pestis*. We hypothesize that: 1) diverse *Yersinia* species, including *Y. pestis* and *Y. pseudotuberculosis* coexist; 2) *Yersinia* diversification is driven by host ecology; 3) *Yersinia* diversification is driven by exchange of genes within rodent populations; and 4) novel genetic methodology can improve identification of *Yersinia* species. To test these hypotheses, we propose: 1) ecological surveys targeting rodent populations in the transboundary focus located in both Georgia and Azerbaijan; 2) development of culturing and PCR-based procedures for detection of multiple strains of *Yersinia*; 3) molecular screening of the collected rodent and ectoparasite samples; 4) comparative analysis of genomes of obtained strains of *Yersinia spp*; 5) spatial analysis of distribution of strains of *Yersinia spp.* This project will result in enhancement of the plague biosurveillance capacities in the endemic regions of Georgia and Azerbaijan. This will be the first comprehensive project investigating and modeling plague foci in the South Caucasian region, which will foster improvements in national and international public health, surveillance, and biodefense efforts. This project will not overlap with national surveillance efforts.

Effect of *Rickettsia* spp. upon Fitness of *Yersinia pestis* in Fleas that Vector Plague in the Republic of Kazakhstan

PRESENTER: Yerlan Sansyzbayev

COUNTRY: Kazakhstan

The goal of this study is to strengthen surveillance of important flea-borne human infectious diseases (plague and rickettsioses) in the context of vertebrate reservoirs, invertebrate vectors (e.g. ectoparasites), and infectious disease agents. Plague and certain rickettsiae are flea-borne diseases that share similar characteristics in disease symptoms, case definitions, and association with co-infections. These data will be very important to health authorities and government agencies in Kazakhstan and the US, where they will support important DTRA objectives including: enabling a partner country to detect/identify/report disease outbreak (naturally occurring or intentional) and providing a system that is sustainable by that partner country's budget and infrastructure. From a public health standpoint, it is important to know which vertebrate species are reservoirs for particular infectious agent(s) and if they are infested with ectoparasites. The Kazakh Science Center for Quarantine & Zoonotic Diseases (KSCQZD) is the lead institute in the implementation of the project, while the anti-plague stations will be involved in providing samples for research. This project will study the effect of flea-borne rickettsial infections upon the fitness of *Yersinia pestis* (causative agent of plague) within plague vector fleas obtained from small mammals in various environmental settings of Kazakhstan. Specifically, the study hypothesizes that in austere environments, rickettsiae and *Y. pestis* will compete for limited resources within the invertebrate host, allowing one species to out compete the other.

Development of the Epidemiological Forecasting System for Zoonotic Diseases Employing GIS Technology

PRESENTER: Oleksandr Tarasov

COUNTRY: Ukraine

The project was a multi-year study focused on surveillance, mapping, and modeling the spatio-temporal and ecological patterns of *Francisella tularensis* and *Bacillus anthracis* in Ukraine. Collaborative efforts of researchers from the institutes of the Ministry of Health of Ukraine and National Academy of Agrarian Sciences of Ukraine included:

- analyses of historical tularemia and anthrax data sets;
- active surveillance for *Francisella tularensis* in small mammals and ticks and validated integration of these collections with appropriate culture and PCR-based analyses at the laboratory;
- surveillance and environmental sampling for *Bacillus anthracis*, with the integration of appropriate PCR-based detection assays in the laboratory;
- serological (ELISA) tests of sera sampled from wild boars;
- forecast pathogen outbreak using advanced spatial analyses, analyses with Geographic Information Systems (GIS) and Remote Sensing (RS) approaches to define the geographic extent of the pathogens and landscape dynamics that effect those distributions.

Throughout the period of performance, databases related to the epidemiological situation of tularemia and anthrax in Ukraine and geospatial data were developed and analyzed and areas historically at risk were determined for each disease. Ukrainians obtained extensive training in a variety of GIS and spatial analytical techniques, as well as research support at the sites and at the University of Florida. GIS and laboratory capacity at UCDCM and IVM were established. The GIS sector at IVM is now capable of sustaining basic GIS data development. Much of the work from the UP-2 project has been or will be published in the peer-reviewed literature.

Creation of Sustainable Immunodiagnostics

PRESENTER: Revaz Solomonia

COUNTRY: Georgia

The primary goal of this project was to provide Georgian scientists with critical educational tools that will help detect biological threats using immunological assays developed within their own laboratories. This included training on developing and validating immunoassays for proteins and antibodies (monoclonal [mAbs] and polyclonal). The project also provided the tools necessary to develop novel diagnostic measures against new or re-emerging biological threats. Antigenic material from *Francisella tularensis* and *Brucella* species (both endemic in Georgia) were used for the development of antibodies and subsequently for immunoassay development and testing. Collaborators from the Naval Medical Research Center (NMRC), helped develop and validate antigen production, antibody production and purification, ELISA development, optimization, and validation. Polyclonal antibodies and mAbs were raised against *F. tularensis* and *Brucella* spp. whole cell extracts. Antibodies of interest were selected by affinity, and were purified; corresponding ELISA procedures were optimized and validated. In addition, the antibodies were characterized by Western immunoblotting. Antibodies protein targets were examined on polyacrylamide gels, in-gel digestion, and liquid chromatography-mass spectrometry. Using this approach, chaperone protein DnaK and GroEL/ES from *F. tularensis* were identified as a candidate targets of MAB 3.2 and MAB 8.2. As a result, this project yielded a comprehensive suite of protocols that can be used by Georgian scientists to develop assays and scale up production of reagents for commercial production and distribution.

Medical/Biological Mapping of Tularemia Natural Foci Cases, Reservoirs, and Vectors Using GIS in Armenia

PRESENTER: Lilit Avetisyan

COUNTRY: Armenia

Background: Past studies have reported over 95% of Armenia is endemic for tularemia. The development of a Geographic Information System (GIS) database and mapping system will provide a tool for tularemia data management and introduce a sustainable technology for continued surveillance in Armenia.

Methods: A retrospective study using the archives of NCDCP centers across Armenia. For GIS data processing we used the ArcGIS 10.1. The extensions Spatial Analyst and Geostatistical Analyst from ArcView GIS were utilized to process data.

Results: In the period 1981-2012, tularemia epizootics were recorded in 27 of the 38 administrative regions of Armenia. These cases involved five species of rodents, one type of insectivore, ticks of the *Ixodidae* and *Gamasidae* genera, and three species of flea. The optimal habitat was characterized by middle mountain steppe landscape zone at 2,065 to 2,407 meters above sea level, receiving 600-800 mm yearly precipitation, and moderate climates with short cool summer and cold winters or dry warm summers with cold winters. A total of 266 human cases of tularemia were recorded in Armenia from 1996-2012. GIS mapping showed that 199 tularemia human cases were registered in the steppe vegetation zone, 224 cases- in a zone with moderate, relatively dry warm summers and cold winters (1400-2300m), 206 cases in a middle mountain steppe zone.

Discussion: The developed model showed an association ($p < 0.05$) between number of human cases and the number of epizootic sites, number of isolates, and percent of samples with positive cultures. The analysis conducted using GIS methodology delineated the risk zones with a high probability of tularemia occurrence. Identification of high-risk areas will serve public health officials in focusing surveillance efforts.

Genomic, Epidemiological, and Biological Characterization of Newcastle Disease Virus Isolates from Ukraine

PRESENTER: Iryna Goraychuk

COUNTRY: Ukraine

The genetic diversity of Newcastle Disease virus (NDV) in Ukraine was studied for the first time. Newcastle disease (ND) is caused by the virulent forms of this virus that affects a wide range of wild and domestic bird species. At least 15 genotypes cause periodic large-scale outbreaks with extensive morbidity and mortality in avian species worldwide.

We conducted passive surveillance in poultry and active surveillance in wild birds in the Southern-Eastern territories of Ukraine and bordering regions with Russia. These studies characterized viral distribution and identification of predominant circulating strains from 1967 to 2016, including the characterization of repository viruses. Genotype identification and pathotype of NDV were determined by direct sequencing of the complete F-gene and full genome using next-generation sequencing. Based on the sequence of the fusion protein cleavage site a more precise pathotyping in eggs and chickens was conducted using isolates that represent the most typical isolates of each of the geno-groups.

Migratory birds in Ukraine are part of east-to-west and north-to-south migration routes. The phylogenetic study allowed to determine the relationship of Ukrainian isolates with other viruses from Eastern Europe, Asia and Africa and a better understanding the transcontinental movement of NDV.

In addition, training programs on standard operation procedures for BSL3 laboratories, biosecurity and biosafety practices were implemented for Ukrainian scientists. Results from this collaboration were presented at three conferences and summarized in six publications in an international journal.

Newcastle Disease: Surveillance, Molecular Epidemiology, and Control of NDV in Kenya

PRESENTER: Leonard Ateya

COUNTRY: Kenya

Although Newcastle disease (ND) is a notifiable disease in Kenya, the disease is under-reported. Current ND control measures include vaccinations after hatching and outbreaks. Currently, there is no active surveillance for ND. Project objectives are to: (1) improve ND surveillance, detection, and diagnosis and reporting of pandemics and (re-) emerging pathogens; (2) facilitate & improve collaborative research amongst Kenyan institutions employing modern methods; and (3) characterize NDV strains, assess ND socio-economic impacts and identify risk factors contributing to NDV spread in Kenya. The project hypothesis is that virulent NDV reservoirs are asymptomatically maintained in wild birds and pet avian species that reside in the proximity of domestic poultry. Samples will be collected in four agro-ecological zones: (1) Zone II (tropical highlands) with poultry markets and where poultry is culturally significant; (2) Zone III (Kenyan food basket with crop-livestock farming system); (3) Zone IV (part of seasonal wild bird migratory and poultry trade routes); and (4) Zone V (free-range small-scale poultry farming). Sampling will be mainly on case-based and passive and active response surveillance. Positive samples identified by antigen detection, hemagglutination of allantoic fluids, or RT-PCR will be used to characterize and define viral strains circulating in Kenya. Ten-year (2005-2015) historical data on ND incidence and outbreaks have been analyzed and used to validate the project's sampling sites. Some of the sites have been visited and samples collected. Four MSc students, the key players in transfer of acquired technologies, have been recruited.

Molecular Characterization and Complete Genome Sequence of Newcastle Disease Virus Isolated in Kazakhstan

PRESENTER: Vitalyi Strochkov

COUNTRY: Kazakhstan

Newcastle disease virus (NDV) is a highly contagious viral infection of birds, characterized by pneumonia, encephalitis, multi-site hemorrhages and destruction of internal organs. It is considered one of the two most devastating diseases in poultry and wild birds, similar to avian influenza. Since Kazakhstan is on the main pathways of transcontinental migratory routes of many wild birds, genomic analysis of circulating NDV strains in Kazakhstan can potentially provide insights to its genetic evolution and add insight to pathogenic characteristics. Only limited studies on the genetic variability of NDV strains in Kazakhstan have been conducted. The project aims to perform full genome sequencing of five (5) isolates, conduct phylogenic analysis, and develop correlation between genotypic features and pathogenicity of five isolates from chicken flocks of previous outbreak during a one-year period. The team will retrieve full genome sequence of representative isolates from open source genomic sequence repository (GenBank), design primer sets for sequencing, and conduct sequencing using the ABI 3130xl platform at the Research Institute for Biological Safety Problems (RIBSP). Bioinformatic analysis will be performed to determine phylogenetic placement of these isolates among those in Genbank, and analyze the likelihood of introduction to and spread from Kazakhstan. The sequence data will be deposited to the National Center for Biotechnology Information (NCBI) database.

Risk Assessment of Selected Especially Dangerous Pathogens Potentially Carried By Migratory Birds over Ukraine

PRESENTER: Denys Muzyka

COUNTRY: Ukraine

Highly pathogenic avian influenza (HPAI) and Newcastle disease viruses (NDV) cause serious diseases in domestic and wild birds, and also pose additional risk due to the potential for spillover into human populations. Monitoring of orthomyxoviruses and paramyxoviruses conducted by NSC IECVM in 2010-2015 within the USDA/ARS projects revealed 168 avian influenza virus (AIV) and ND viruses, 23 antigenic combinations, and new serotypes (APMV-13). The extreme variability of AIV can lead to new genetic variants of the virus with pandemic potential that could damage people. The geographical position, natural conditions, large amount of birds and several transcontinental migration routes contribute to the re-emergence of those pathogens that was confirmed by outbreaks of HPAIV H5N1 and NDV in 2005-2008 and HPAIV H5N8 in poultry in 2016-2017. Commencing on December 1, 2016 the project aims to survey areas of Ukraine for AIV and NDV that may be harbored by wild birds associated with major northern and southern migratory flyways in the country. The project will assess the ecologic, epizootic, and epidemiologic risk of disease transmission. Bird observations, viral detection data, and Geographic Information System will be used to analyze and predict the anthropogenic impact on viral prevalence and type. The project will support local capacity building through enhancement of diagnostic capability, data management and analysis, and reporting. The project supports a One Health approach through linkage of researchers from the Institutes of the Ministry of Health, National Academy of Agrarian Sciences, and State Service for Food Safety and Consumer Protection of Ukraine.

Detection and Molecular Epidemiologic Analysis of Especially Dangerous Pathogens in Backyard Poultry, Commercial Broilers and Waterfowl in India

PRESENTER: Vivek Kapur

COUNTRY: India

Emerging and re-emerging respiratory diseases in poultry, especially velogenic viscerotropic Newcastle disease (vvNDV) and highly pathogenic avian influenza (HPAI), present a major threat to animal and public health worldwide, particularly in rapidly developing nations such as India. The core viral pathogens of human and animal concern involved in Respiratory Disease Complex of poultry have not been studied. To fill this knowledge gap, we propose to test three hypotheses. **Hypothesis 1.** The respiratory tract viromes from commercial and backyard flocks (herein referred to as domestic poultry) and waterfowl in Haryana, Odisha and Kerala are a potential source of especially dangerous pathogens (EDPs); **Hypothesis 2.** Molecular genotyping approaches will identify host- and region-specific fingerprint profiles of select agents including vvNDV and HPAI; **Hypothesis 3.** Next generation sequencing will help identify nucleic acid signatures of novel / emerging viruses in domestic poultry and waterfowl. The overall goal of this project is to discover novel viruses and enable the development of genomics-based strain-typing capability of EDPs and emerging viral pathogens from avian sources in academic research settings in India. Molecular epidemiologic analysis and comparative metagenomics investigation of respiratory viromes of domestic poultry and migratory birds, using a comprehensive and statistically robust stratified random sampling approach, will provide a strong foundation for the development of evidence-based approaches for implementing sustainable measures to control EDP. This investigation will also help generate data and tools, build sustainable capabilities, and enhance domestic and international academic partnerships critical to characterizing the zoonotic pathogens associated with domestic poultry and waterfowl in India.

Session 9: Bacterial Pathogens of Security Concern – Group 2

Characterization of NCDC Strain Repository by Next Generation Sequencing

PRESENTER: Gvantsa Chanturia

COUNTRY: Georgia

The three year project was launched in March 2016. It is a collaborative effort of the Los Alamos National Laboratory (LANL), NM, USA and National Center for Disease Control and Public Health of Georgia (NCDC), Tbilisi, Georgia. LANL has been working alongside the Georgia National Center for Disease Control and Public Health (NCDC) Genome Center Facility at the R. G. Lugar Center for Public Heath Research in developing Next Generation Sequencing (NGS) and analytic capabilities. The proposed project leverages the technical capabilities at both institutes to complete sequencing and characterization of the especially dangerous pathogens stored in the freezer archive at the NCDC. Up to 100 isolates of *Yersinia pestis, Bacillus anthracis, Brucella spp*., and *Francisella tularensis* from the NCDC pathogens collections will be selected for draft sequencing on the Illumina MiSeq. The draft genomes will be comparatively analyzed against strains from worldwide databases, SNPs will be discovered and subjected to phylogenetic analysis.

During the past year, ten *Brucella spp*. and twelve *F. tularensis* were have been sequenced. *F. tularensis* strains were processed for genome assembly and phylogenetic analysis on CLC-Bio, EDGE and PHAME software. Two draft genome announcement manuscripts have been drafted. A two week training for one bioinformatician from the NCDC team was held at LANL in November 2016. The sequencing of the rest of the samples is in process at NCDC. Ten isolates will be chosen to forward to LANL for PacBio sequencing. NCDC staff, as well as students involved in the project, will exercise their sequencing and bioinformatics skills on the samples and data from this project. Additional skills will be acquired through advanced training on data generated by this project. Completion of this research project will provide novel genomic characterization of the NCDC's extensive pathogen archive, cement the collaborative network between the NCDC and US collaborators, and ensure the NCDC's ability to utilize advanced sequencing technologies as independent researchers.

High Resolution Chemical Characterization of *Yersinia pestis* Cells within Soil Matrices: Implications for Understanding Natural Foci and Telluric Reservoirs of Plague

PRESENTER: Muhammad Reza Shah

COUNTRY: Pakistan

The persistence of *Yersinia pestis* in soil matrices suggests a novel, yet completely uncharacterized, environmental reservoir for plague organisms. This has critical implications for understanding natural plague foci,non-traditional transmission routes between hostsand its changing risks for humans, and finally, the detection of *Y. pestis* in environmental samples.To address this challenge, we have constructed a multidisciplinary project to examine the chemical and physical response of *Y. pestis* cells after exposure to soil habitats. The project includes high-resolution, single cell analytics to characterize the metabolism, surface chemistry, and structural changes in individual *Y. pestis* cells within this unique growth environment. Results from this work will increase basic understanding of pathogen ecology and the molecular mechanisms by which*Y. pestis* functions in environmental reservoirs outside of traditional transmission vectors.

This project is a collaboration between Virginia Commonwealth University (Richmond, VA, USA) and the HEJ Research Institute of Chemistry at the University of Karachi (Karachi, Pakistan). VCU is leading culturing efforts and surface characterization of *Y. pestis* cells using a range of high resolution microscopy and mass spectrometry techniques and the University of Karachi is developing novel techniques for chemical analysis of cell surfaces and in situ assays with nanoparticle-based probes. Training in Biosafety practices and microbiological characterization will facilitate collaborative pathogen research and build new capabilities at the University of Karachi that will complement its existing analytical strengths and create a new center in Pakistan capable of identifying unknown bacterial samples and conducting basic research on endemic pathogens.

Estimating Incidence and Socio-economic Impact of Brucellosis in Humans and Animals in Kajiado County, Kenya

PRESENTER: Austine Bitek

COUNTRY: Kenya

Brucellosis is a common bacterial zoonotic infection, but there is limited data on burden of the disease in Kenya for humans and animals. To generate data to inform prevention and control strategies, we conducted a longitudinal study to determine incidence of brucellosis in humans and animals and estimate its socio-economic impact at the household level among a pastoralist community in Kajiado.

All households and their livestock in four sub-locations in Kajiado County were enrolled for follow-up for 12 months from 2015 to 2016. A subset of their livestock were recruited in to the study after screening for *Brucella* using RBPT, and sera was collected every four months and tested for *Brucella* IgG antibodies using ELISA. Incidence in humans was calculated from the number who were determined to be acutely ill with brucellosis from among those who presented at study health facilities, while incidence in livestock was the number of livestock that sero-converted for brucella antibodies between two sampling points. To calculate economic losses, direct losses in livestock were calculated using parameters derived from the incidence study and literature, and the results were analyzed in an analytical economic model.

801 households with a total of 4,729 humans and their 5,746 livestock were recruited in the study. Of the household members enrolled, 52% (n=2475) were males. The mean household (HH) size was 6 persons (range 1 – 19). Average HH income over a 3 months period was $ 820 (range $100 - $ 16,000). Overall incidence rate of brucellosis in livestock on ELISA sero-positivity between the first and the second visit was 0.0076 (8/1,000) cases per animal; 3 months at-risk equivalent to 0.0304 (30 animals per 1,000 animal-year at risk). Total direct losses due to brucellosis in livestock was estimated to be KES 6.6 Million (USD 66,000). The losses due to abortion accounted for 54% of the total losses in livestock. Estimated out of pocket expenditures incurred by HHs was $12.2 per human case (range $2 -$100). This study reports a high burden of brucellosis in humans in a pastoral community in Kajiado with substantial economic losses arising from brucella infection in livestock at the household level.

Lugar Center Regional Integration: Kafkas University Partnering for Molecular Epidemiology *of Bacillus anthracis* and *Brucella* species in Turkey

PRESENTER: Ketevan Sidamonidze

COUNTRY: Georgia

It is vital that effective collaborative links are built between the National Center for Disease Control and Public Health (NCDC), Richard G. Lugar Center for Public Health and institutions in neighboring countries to tackle shared common bacterial threats. Kafkas University's veterinary school, located in the northeastern Turkish city of Kars, serves a primarily agricultural region adjacent to the Georgian/Turkish border; diseases including anthrax and brucellosis, are endemic in these regions. Molecular typing tools were outdated at Kafkas. A study using the high-resolution molecular tools available at NCDC Lugar Center on common bacterial strains (*Bacillus anthracis* and *Brucella* spp.) on both sides of the border was developed. To achieve this aim, a team at the Lugar Center supported by WRAIR provided training to researchers from Kafkas University in the use of the state-of-the-art capabilities available at the Center. The project consisted of three main technical elements: bacterial DNA extraction; molecular analysis of *B. anthracis*; and molecular analysis of *Brucella* spp. Overall, 60 bacterial isolates including *B. anthracis* (n=30) and *Brucella* spp. (n=30) from Turkey were analyzed at the Lugar Center using multiple locus variable number tandem repeat analysis (MLVA) and single nucleotide polymorphisms SNP. MLVA and SNP typing results show genetic homogeneity of Georgian and Turkish *B. anthracis* strains, which may be caused by migration of the pathogens across the Georgia-Turkey border over time. This study also resulted in successful capacity-building efforts for pathogen typing for the Turkish researchers from Kafkas University.

Regional Study of the Ecology of Anthrax Foci in Georgia and Azerbaijan

PRESENTER: Lile Malania

COUNTRY: Azerbaijan

Anthrax is a livestock-borne zoonotic disease that is endemic in the South Caucasus region. It is hypothesized that both human and environmental factors affect the migration of *Bacillus anthracis* strains across borders and throughout regions. This study evaluates the following: (1) identify regional foci and spatial risk factors of anthrax to improve surveillance and documentation of the disease; (2) assess the genetic relationships of environmental *B. anthracis* isolates to better understand the organism's ability to persist in the environment and to allow for improved epidemiologic "trace-back" of human and livestock infections; and 3) collaborate on regional issues related to the control and management of a re-emerging infectious disease by sharing local/regional predictions of risk and molecular profiles of the pathogen. Collaborators from both Georgia and Azerbaijan have collected and tested soil samples for the presence of *B anthracis.* Positive samples were molecularly characterized and were examined using multilocus variable number tandem repeat analysis (MLVA), as well as global and regional single nucleotide polymorphisms (SNPs), including a well-established Georgian SNP typing panel. Spatial genetic pattern analysis and risk factor mapping were conducted using geographic information system. In turn, this regional collaboration will provide the potential for the cooperative development of strategies for the control and trans-boundary management of this disease.

Regional Study of the Ecology of Anthrax Foci in Georgia and Azerbaijan

PRESENTER: Rita Ismayilova

COUNTRY: Azerbaijan

Anthrax is a livestock-borne zoonotic disease that is endemic in the South Caucasus region. Not much is known about the regional epidemiology of this pathogen nor the transboundary factors related to its persistence. The aim of this collaborative (Azerbaijan and Georgia) effort was to ascertain both human and environmental factors that may affect migration of *Bacillus anthracis* strains across borders and through regions. There are seven Azerbaijan rayons (Gazakh, Agstafa, Tovuz, Samukh, Gakh, Zagatala, and Balakan) bordering Georgia with recurring cases of both human and animal anthrax; from those, 30 villages were selected for sample collection. Samples were to be collected from known animal burial sites and areas of previous contamination, as evidenced by livestock outbreaks or human case records. Organisms isolated from the collected soil samples were to be characterized by biochemical methods (Gram stain, motility, Trypticase Soya Broth) and then by gamma phage. The nucleic acids extracted from presumptive positive samples were to be tested by PCR using Amplisense kits on BioRad.

A total of 804 soil samples have been collected from five rayons Nov 2015 - Sept 2016. From the 768 processed, over 200 samples exhibited colony morphology suggestive of *B. anthracis*; 10 were deemed positive by gamma phage. DNA extractions from 60 presumptives (by biochemistry and gamma phage) have been sent to Georgia Lugar Center for genotyping in April 2016 and were negative for *B. anthracis*. The samples should be retested by Tetracore PCR kit.

Environmental Surveillance of *Burkholderia pseudomallei,* Pilot Study in Lao PDR

PRESENTER: Rosalie Zimmerman

COUNTRY: Lao PDR

The environmental bacterium *Burkholderia pseudomallei* (*Bp)* is the causative agent of melioidosis and a Tier 1 Select Agent. *Bp* is endemic in tropical soils and has been found in surface waters. To investigate the distribution of this pathogen in Lao PDR, its occurrence in rivers, and associated environmental factors, we studied 23 rivers (including the Mekong) in the South, Center and North of the country, applying culture-based methods and a specific quantitative real-time PCR assay to water filters and streambed sediments. Geochemical measurements included turbidity, a proxy for suspended sediment load which was measured on-site using a turbidity meter and confirmed in the laboratory by dry weight measurements. *Bp* was present in 9% of the rivers in the dry season. In contrast, we found *Bp* in the water of 57% of the rivers in the rainy season, 35% of them with associated *Bp*-positive sediments. Turbidity correlated positively with *Bp* presence (p=0.01). All *Bp* positive rivers were situated in the South and Center of the country. Our preliminary results provide evidence for a heterogeneous spatial and temporal distribution of *Bp* in Lao PDR. The seasonal dynamics and predominant occurrence of *Bp* in particle-rich water and the lower yield in sediments suggest that *Bp* is washed out with eroded soil during periods of heavy rainfall and transported by rivers. These findings will contribute to improved *Bp* risk modelling and health management strategies. Further laboratory and statistical analyses, including additional geochemical factors, and land-cover data analyses using geographic information systems, are in progress.

Melioidosis Research Coordination Network

PRESENTER: Direk Limmathurotsakul

COUNTRY: Thailand

Melioidosis is caused by *Burkholderia pseudomallei,* a Tier 1 select agent and an environmental bacterium commonly found in tropical countries. It is estimated that 89,000 deaths were caused by melioidosis per year worldwide. However, melioidosis remains under-reported due to its diverse clinical manifestation, incapacity of bacterial isolation and identification in low-resource settings, and limitation of national notifiable diseases surveillance systems in low and middle-income countries (LMICs). The unawareness of the disease becomes problematic for policy makers, clinicians and researchers in many LMICs because melioidosis is not perceived as a threat.

To solve the problems, the Melioidosis Research Coordination Network (RCN) was developed. The RCN aims (1) to make data of total number of culture-confirmed melioidosis cases and deaths worldwide openly available for policy makers, clinicians, funders and researchers worldwide, and (2) to support connections and communications among those stakeholders.

The RCN working group will call for information from clinicians and researchers at any hospitals or institutions worldwide for the total number of culture-confirmed melioidosis cases and deaths they observed yearly from 2012 to 2016. We will curate and make those data openly available on www.melioidosis.info. The system will be quite similar to PROMED but better curation and better supports from funders and melioidosis research community. The RCN will make the information of data contributors clearly available so that funders and other researchers know where they can fund melioidosis research and find collaborators, respectively. The RCN will also make information about potential support from contributors available, including bacterial identification and biosafety support.

Enhancing Capacity for Case Detection and Diagnosis of Febrile Zoonotic-related Cutaneous Lesions in Georgia

PRESENTER: Mary Reynolds

COUNTRY: Georgia

In the summer of 2013 an outbreak of febrile rash illness in herders in the Akhmeta region of Georgia was linked to a novel *Orthopoxvirus* (OPXV). The unique genetic profile of this emerging zoonotic disease made it difficult to identify using the existing molecular assays for OPXV species. Two other OPXV isolates have been identified in Georgia. One was found in 1986 in a rodent in the southeastern part of the country; the other was recently identified by the National Center for Disease Control and Public Health of Georgia (NCDC) and the Centers for Disease Control and Prevention (CDC) Poxvirus laboratory in a retrospective analysis of a suspected anthrax case that occurred in 2010. Activities undertaken by CDC Headquarters in conjunction with the CDC South Caucasus Office are part of a collaborative effort comprising three complementary proposals. The goal of these combined efforts is to: 1) identify the geographic distribution and natural hosts of the known virus, 2) determine if any other such viruses occur in this region, 3) investigate the impact of OPXV infection on dairy production and to at-risk individuals, and 4) increase in-country capacity to detect, identify, and respond to future outbreaks. Activities are approached through a One Health framework, promoting timely, actionable communication among in-country counterparts representing the animal and human health sectors.

Enhancing Capacity for Case Detection and Diagnosis of Febrile Zoonotic-related Cutaneous Lesions in Georgia

PRESENTER: Ana Gulbani

COUNTRY: Georgia

The discovery of a new *Orthopoxvirus* demonstrates the need for poxvirus detection and diagnosis capacity in Georgia (country). Human illness caused by this virus has implications for differential diagnosis of cutaneous lesion-producing zoonotic infections, principally anthrax. Simultaneously, animal infection may impact agricultural productivity and food safety. Therefore, accurate detection and case diagnosis is important for both humans and domestic animals. In collaboration with the CDC Atlanta, we are working to enhance capacity to detect, diagnose and report *Orthopoxvirus* infections. Health-care workers will be trained to recognize zoonotic-related cutaneous lesions to detect human cases; NCDC personnel will be trained to collect clinical specimens from patients with such lesions and from the rodents; NFA and regional veterinarians will be trained to recognize lesions associated with orthopoxviruses among domestic and wild animals as well as field collection of pertinent animal specimens. Emphasis will be placed on field and laboratory biosafety. Additionally, CDC Atlanta Poxvirus Team members will provide training for animal (LMA) and human sample (NCDC) processing with rapid qPCR-based diagnostic tests and serologic assays for case diagnosis. Retrospective case diagnosis is needed as testing by rapid qPCR on anthrax-negative samples has already identified an orthopox positive sample, thus warranting further investigation on stored samples. New assays will be developed and assessed for detecting any new orthopoxvirus variants in humans, rodents, domestic and wild animals found in Georgia. Activities will result in improved capacity for efficient identification of emerging orthopoxviruses, as well as biosurveillance capacity for orthopoxviruses in human and animal populations.

Multi-Year Prospective Cohort Study to Evaluate the Risk Potential of MERS-CoV

PRESENTER: Sazaly Abubakar

COUNTRY: Malaysia

Since its first appearance in 2012, the Middle East respiratory syndrome coronavirus (MERS-CoV) has emerged as a serious public health threat of global concern. As of December 2016, the World Health Organization has been notified of 1,879 laboratory confirmed cases and the case fatality rate is estimated at 35%. Beyond its high fatality rate, significant concern lies in the potential for MERS-CoV to spread beyond the Middle East, as was recently witnessed in the South Korea. In collaboration with the Ministry of Health Malaysia (MoHM) and the Malaysia Hajj Pilgrims Fund Board (MHPFB), a multi-year cohort of pilgrims departing for Hajj from Malaysia has been established to assess the risk that MERS-CoV infection poses to travellers to the Middle East. Pre- and post-pilgrimage blood specimens were collected for serologic analysis to estimate MERS-CoV exposure rates, while survey data will be used to stratify the risk of exposure by factors such as age, gender, geographic regions visited during the pilgrimage. For the 2016 Hajj cohort, a total of 568 participants were enrolled and 367 (65%) submitted to post-pilgrimage blood draws and data collection upon their return from the Hajj. To date, paired blood samples (pre- and post- pilgrimage) from 318 participants have been analyzed by ELISA for the presence of IgG antibodies to MERS-CoV. Preliminary findings suggest at least three individuals showed increases in MERS-CoV specific IgG titers post-Hajj. Confirmatory microneutralization assay is ongoing and planning has started for the 2017 Hajj cohort studies.

Middle East Respiratory Syndrome Coronavirus (MERS-CoV): Surveillance for Distribution and Prevalence in Kazakhstan

PRESENTER: Mukhit Orynbayev

COUNTRY: Kazakhstan

Middle East Respiratory Syndrome (MERS) is a viral respiratory illness caused by a recently identified zoonotic coronavirus, MERS-CoV, which is transmitted from camels to humans. The southern border regions of Kazakhstan contain more than 150,000 camels, which creates the potential for endemic circulation of the virus. Bats have also been associated with presence of the MERS-CoV, and there are 24 species of bats which may carry related coronaviruses. Due to camel trade with MERS-CoV endemic areas, the project hypothesizes that MERS-CoV is likely present in the Kazakhstani camel population. One of the objectives is to determine the sero-prevalence and epidemiology of MERS-CoV in adult and juvenile camels in seven regions of Kazakhstan to verify the prediction that camel populations in Kazakhstan have been exposed to and generated antibodies against MERS-CoV. Also, the MERS-CoV genetic diversity in camels across Kazakhstan will be determined as will the identity of coronaviruses in Kazakh bats. The project has been approved by DTRA and kick-off was held on 14 October 2016. The lead institute for the study, KZ's Research Institute for Biological Safety Problems (RIBSP), has submitted paperwork requesting permit from Ministry of Agriculture for sample collection for the study. RIBSP also reported that they have a small group of pre-existing samples from camels and bats in storage that may be of use to the project. RIBSP is currently seeking to identify the location of camel farms that have interaction with camels from the Middle East. Drs. Ian Mendenhall and Gavin Smith from Duke-NUS Medical School are collaborators for the study. Currently materials and reagents are being procured.

Global Health, Emerging Infectious Diseases, and Food Safety Implications of Bushmeat Consumption In Tanzania

PRESENTER: Joram Buza

COUNTRY: Tanzania

“Bushmeat”, the meat and organs derived from wildlife species, is a major source of protein in many parts of Africa, and is often hunted illegally and transported to markets in unsanitary conditions, thereby representing an important conduit for the transmission of zoonotic pathogens. Despite considerable evidence that select agents, including *Bacillus anthracis*, *Brucella* and *Coxiella,* are frequently found in animals harvested for consumption in Tanzania, their distribution in bushmeat and the related human health risks are not known. To fill this critical knowledge gap, we have initiated a program to map the distribution of especially dangerous pathogens in bushmeat from three major ecosystems in Tanzania (Serengeti, Ruaha-Rungwa, Selous-Mikumi) during wet and dry seasons to capture spatial and seasonal variation in pathogen prevalence.

Preliminary PCR based-analyses of more than 500 fresh and dried bushmeat samples collected from 25 villages in the Western Serengeti revealed nucleic acid signatures of *Bacillus anthracis* and *Brucella* species in bushmeat. Further, host species identification with PCR sequencing of the *cytochrome B* gene suggests initial misclassification by bushmeat traders in a significant fraction (~ 40%) of the samples. Together with 16S rDNA based microbiome profiling, our preliminary investigations reveal the presence of major zoonotic pathogens, in bushmeat in Tanzania, and provide an opportunity to discover novel emerging pathogens. In the long-term, our research is positioned to provide a rational basis for defining and mitigating the public health risk associated with the harvesting, trade, and consumption of bushmeat in Tanzania.

Etiology of Severe Acute Respiratory Infections in Kuala Lumpur, Malaysia

PRESENTER: Jamal I-Ching Sam

COUNTRY: Malaysia

The epidemiology of severe acute respiratory infections (SARI) in adults in Asia is relatively understudied, but of critical global importance. This is because of the potential emergence from this region of rare/new pathogens posing a pandemic threat or a danger as potential weapons of mass destruction. Malaysia, situated in Southeast Asia, a known hotspot for emerging diseases, has had previous imported human cases of SARS-CoV, MERS-CoV, and H7N9, and H5N1 in birds. Melioidosis, caused by *Burkholderia pseudomallei*, is also endemic in Malaysia. Kuala Lumpur, the capital, is a major travel hub for immigrants and tourists. We hypothesize that potential biological threats do cause SARI in Malaysia, but that these remain largely undiagnosed due to lack of awareness and laboratory diagnostic capacity. Therefore, we propose to study the etiology of SARI in adults admitted to a teaching hospital in Kuala Lumpur over 3 years. We will establish a comprehensive panel of molecular assays to detect respiratory viruses and bacterial select agents, supplementing existing diagnostics for bacteria and mycology. This will enable our centre to detect sporadic cases and outbreaks of respiratory agents which are potential global threats. We propose a workshop for biosafety practices in diagnostic microbiology laboratories, and a practical workshop to teach these newly established assays to other laboratories in the country, thereby enhancing national capacity to safely diagnose these agents, and contribute to threat reduction. In addition, a number of samples testing negative to known viral agents will be analysed by next-generation sequencing for potential viral pathogen discovery.

One Health Surveillance for Brucellosis in Armenia

PRESENTER: Valerie Ragan

COUNTRY: Armenia

Brucellosis is a highly infectious zoonotic disease caused by bacteria of the genus *Brucella*. It is reported to be the most common zoonotic disease worldwide. The disease causes abortion, infertility and reduction in milk production in animals and a serious, recurring febrile condition in man which may become chronic and may affect any organ of the body. Successful treatment of the chronic form is very difficult. No effective treatment for brucellosis in animals has been described. The incidence of brucellosis in humans in unknown, but is suspected to be between 10 and 25 times larger than indicated by the number of cases reported to public health agencies.

Prevalence of brucellosis in humans and animals in Armenia and neighboring countries is known to be significant. However, due to the fact that comprehensive surveillance for the disease is lacking in both the human and animal populations, and the lack of shared data between human and animal health authorities, little can be said with certainty about how widespread the disease is in either population.

A “One Health Surveillance for Brucellosis in Armenia” project has just been initiated whose objective is to strengthen coordination and collaboration between the Ministry of Health and the Ministry of Agriculture during epidemiological and outbreak investigations of brucellosis, and increase the understanding of the disease burden in Armenia. A project outcome will be a draft document outlining a comprehensive surveillance and control system for brucellosis in Armenia.

Acute Febrile Illness in Uganda

PRESENTER: Denis Byarugaba

COUNTRY: Uganda

Acute febrile illness (AFI) causes significant morbidity and mortality in the tropical countries including Uganda. While part of it is caused by malaria and other common treatable infections, a significant part is caused by unknown agents. VHFs have particularly occurred recently with more frequency in Uganda and the region. This study is undertaking systematic investigations to determine the occurrence of the select agents and other previously unknown highly pathogenic pathogens with potential for causing pandemic threats. The work leverages upon existing field and laboratory research capabilities within Makerere University Walter Reed Project (MUWRP) in the country. The project does sampling from already existing sentinel surveillance sites. We collect and test at least 26 samples from AFI patients per month from at least five geographically diverse hospital sentinel sites (Gulu, Mulago, Jinja, Bwera and Bombo Hospitals). In addition, disease vector distribution and mapping is being undertaken through vector collection and identification and climate data analysis for ecological niche modeling and risk assessment. The study is expected to generate data that contributes to create in-country capabilities for more robust systems for early detection and prediction of outbreaks and rapid response and to define risk factors and vector distributions important for long-term surveillance, early detection and rapid response, and intervention strategies in contribution to global biological threat reduction.

Infectious Etiologies of Acute Febrile Illness in the Azerbaijan Military

PRESENTER: Surkhay Mammadov

COUNTRY: Azerbaijan

Mortality rate attributable to infectious and parasitic diseases in Azerbaijan is 16.4 deaths per 100,000 population. After the collapse of Soviet Union, healthcare and public health deterioration created severe gaps in accessibility and allowed for emergence/re-emergence of infectious diseases. Epidemiological information about infectious syndromes in Azerbaijan is very limited, compounded by the lack of appropriate diagnostic assays and febrile illness knowledge, precipitating unconfirmed clinical diagnoses for most febrile illnesses. Infectious etiologies of acute febrile illness (AFI) among Azerbaijan military members have not been studied, thus causative etiologies are unknown. In the proposed study serum samples from patients with undifferentiated febrile syndrome will be tested for *Brucella* spp., Dengue, WNV, *F. tularensis*, rickettsia, Q fever, hantaviruses, CCHF and TBE using standard ELISA assays. Positive or indeterminate ELISA results will be confirmed using PCR or IFA. All laboratory analyses will be done at the Epidemiological Monitoring Station of the Ministry of Defense in Baku City. Most etiologies to be targeted are considered potential biological weapon agents. Identification of these along with incidence and probable transmission pathway will significantly increase preparedness of the Azerbaijan military medical system, develop sustainable biological agent detection capabilities, and contribute health surveillance data for Ministry of Defense (MoD) force health protection policy. This study will significantly improve laboratory skills for diagnosis to improve clinical management of AFI. In addition, findings will improve the capability to differentiate between infections with similar nonspecific clinical syndromes that are not currently diagnosed or are presumably underreported among military personnel in Azerbaijan.

Prevalence, Epidemiological Surveillance, and Laboratory Analysis of *Coxiella burnetii* in Georgia

PRESENTER: Ana Gulbani

COUNTRY: Georgia

Q fever is a zoonotic bacterial disease resulting from infection by the bacteria *Coxiella burnetii*. The goal of this study is to (1) investigate the seroprevalence of *C. burnetii* among exposed cattle and small ruminants across Georgia, (2) establish active surveillance and detection of cases of Q fever across Georgia, (3) collect isolates from veterinary cases, (4) implement and evaluate new diagnostic methods, and (5) study *C. burnetii* using GIS and DNA sequencing and genotyping. Samples were collected from nine regions by the National Food Agency (NFA) of the Ministry of Agriculture (MoA): 16,343 blood, 15,269 serum, 3,970 milk, and 5,156 swab samples were collected from these animals. Samples were tested by immunofluorescent assay (IFA), polymerase chain reaction (PCR), and bacteriology to detect *C. burnetii*. For IFA, 8,688 samples were tested: 218 were Phase I positive and 42 Phase I susceptive samples; and for Phase II 40 samples were positive, and 34 susceptive. In total, 1,311 samples were tested on ELISA: 1,218 were negatives, 76 positives, and 17 susceptive. We have tested 10,310 PCR samples and seven were positive. Bacteriological tests were performed on serologically positive/ susceptive samples, and PCR positive samples (n=340). Currently, we have isolated two cultures (confirmed by PCR). Due to the amount of sample processing, the project has been extended, and research is going.

Prevalence of *Brucella* Species and Bluetongue Virus Serotypes among Domestic Livestock or Ruminants in Southern Kazakhstan

PRESENTER: Nurlan Sandybayev

COUNTRY: Kazakhstan

Brucellosis and Bluetongue (BT) are high consequence infectious diseases that affect domestic animals in Kazakhstan and worldwide. *Brucella* spp. and an array of Bluetongue virus (BTV) serotypes are considered endemic in Southern Kazakhstan where the largest concentration of cattle, sheep and goat herds in the country are located. Southern Kazakhstan is thought to be at high risk for these two diseases. The project will determine the prevalence of circulating *Brucella* spp. and BTV serotypes over a period of two years in domestic cattle, sheep and goat holdings in Southern Kazakhstan. A disease survey is the first step to link distribution of brucellosis and bluetongue with potential risk factors. The project has been approved by DTRA and kick-off was held on 14 October 2016. The lead KZ partner, the Research Institute for Biological Safety Problems (RIBSP), has submitted paperwork requesting permit from Ministry of Agriculture for sample collection for the study. RIBSP has reported the BSL-3 laboratory has been validated and BSL-3 staff and KZ-32 participants received BSL-3 facility training. RIBSP has developed 13 SOPs focused on sample collection and transport which are currently being reviewed by the collaborators. RIBSP is working closely with collaborators and CBEP’s BTRIC (CH2M) to prioritize items for procurement of laboratory supplies. Dr. Risatti (University of Connecticut), Drs. Elzer and Hagius (Louisiana State University Agricultural Center) are collaborators for the study.

Identification of Etiology, Clinical Outcomes, Incidence, and Epidemiological Patterns of Hospitalized Febrile Patients in Armenia

PRESENTER: Lilit Avetisyan

COUNTRY: Armenia

Background: Hospitalized patients with fever represent a diagnostic challenge for physicians. Scant information is available on identification of etiology, clinical outcomes, and epidemiological patterns of hospitalized patients with fever in “Nork” Infectious Clinical Hospital. The goal of this study was to describe the most common causes, with a focus on zoonotic and arboviral infections.

Methods: Medical records of hospitalized patients with fever were retrospectively reviewed in 2014. Data were abstracted from medical charts of adults (≥ 18 years) with a fever (≥ 38°C), who were hospitalized (for ≥ 24 hours) in 2010–2012.

Results: Of the 600 patients whose charts were analyzed, 76% were from Yerevan and 51% were male; the mean age was 35.5 (± 16) years. Livestock exposure was recorded in 5% of charts. Consumption of undercooked meat and unpasteurized dairy products were reported in 11% and 8% of charts, respectively. The most common signs or symptoms reported were fatigue (97%), diarrhea (56%), nausea/vomiting (54%), shaking (52%), and abdominal pain (46%). The mean duration of hospitalization was 5.5 days. The most common physical examination findings reported were: pallor (64%), abdominal tenderness (52%), pharyngeal injection (43%), and lymphadenopathy (35%). Twenty-four percent of patients received antibiotics prior to hospital admission. Intestinal infections of known (30%) and unknown (21%) etiology were the most frequently reported final medical diagnoses, followed by diseases of the respiratory system (11%), infectious mononucleosis (9.5%), chickenpox (8.3%), brucellosis (8.3%), viral hepatitis (3.2%), and erysipelas (1.5%).

Conclusions: Half of the patients were diagnosed with enteric infections, nearly half of these had no clear etiologic agent. Brucellosis was the most frequently reported zoonotic disease. Solitary cases of anthrax, leptospirosis, FUO, imported malaria, rickettsiosis, and rat-bite fever were also reported. Further prospective studies are required to identify risk factors associated with febrile illnesses, as well as to estimate the burden of selected arthropod-borne and zoonotic infections.

Human Disease Epidemiology and Surveillance of Especially Dangerous Pathogens in Georgia

PRESENTER: Irma Burjanadze

COUNTRY: Georgia

Especially Dangerous Pathogens (EDPs), or select agents, represent a major concern for global public health. These highly pathogenic agents have the potential to be weaponized. Our project was designed to expand on the successes of the Cooperative Biological Engagement Program Collaborative Biological Research and TADR surveillance efforts, and examine the human disease incidence and prevalence of pathogens of public health and biodefense in Georgia. This project has three aims: (1) to study the epidemiology and clinical manifestations of selected pathogens among patients with undifferentiated fever and hemorrhagic fever/septic shock; (2) study the seroprevalence of selected pathogens in humans in Georgia; and (3) implement and evaluate diagnostic methods for selected pathogens and monitor patterns of antimicrobial resistance in identified bacterial infections. Laboratory surveillance for acute undifferentiated febrile illness (AUFI) was established in three major Georgian hospitals by the National Center for Disease Control and Public Health in collaboration with the U.S. Navy Medical Research Unit-3 and USAMRIID. Pathogens that are studied in the seroprevalence protocol include *Bacillus anthracis*, *Brucella* species, Crimean-Congo hemorrhagic fever virus, *Coxiella burnetii*, *Francisella tularensis*, Hantavirus, *Rickettsia* species, and tick-borne encephalitis virus. Furthermore, several other pathogens were tested to develop a comprehensive differential diagnostic algorithm and antibody prevalence of similar diseases. In patients treated at participating hospitals with an undifferentiated febrile illness were tested and involved in the developing process for a comprehensive diagnostic algorithm. Currently, 98.9% of seroprevalence tests and 69.4% of febrile studies are completed. These are preliminary results of screening trial; confirmatory testing continues.

The Epidemiological Status of African Swine Fever in Domestic Swine Herds in the Tavush Marz Region, Republic of Armenia

PRESENTER: Gene Godbold

COUNTRY: Armenia

The factors associated with the spread and persistence of African Swine Fever (ASF) in the Caucasus Region remain to be fully identified. It is assumed that large naïve domestic, free-ranging, and wild pig populations are critical to disease transmission and maintenance. Nonetheless, nine years since its epidemic introduction in the region in 2007, the virus that causes ASF is still circulating suggesting that an endemic cycle is established where contact between free ranging domestic pigs, wild pigs, and probably native *Ornithodoros* ticks serve as reservoirs. Thus, research is required to gather information on the epidemiological status of ASF in the Caucasus Region focusing on understanding modes of ASFV spread and persistence in the area

An active surveillance program was established in Armenia to determine the epidemiological status of ASF focusing on an area at high risk, Tavush marz. This region was the first to report the presence of ASF in Armenia in 2007 and 2010-2011. It is the main terrestrial point of entry for traffic into Armenia and it shares a border with Georgia where the disease was introduced. Most pigs in Tavush are kept in backyard operations and allowed to free-forage, providing contact with wild pigs and ticks.

A total of 1,506 pigs were sampled from small-scale farms clustered in 30 communities across the marz. Samples were taken from the sera, complete blood, and nasal swabs tested by ELISA, IPA, and qPCR. Fifty nine ticks were collected, but the *Ornithodoros* was not found among them. All samples were negative for ASFV and ASFV antibodies suggesting that AFSV is not circulating in the sampled population.

Since sporadic ASFV outbreaks in domestic pigs have continued to occur in the Caucasus, the capacity for long-term environmental survival should be investigated. Further research is required on the epidemiological status of ASF in ticks and swine populations deemed at high risk for ASF.

Investigation of Mosquito and Tick-Borne Arboviruses in Southeastern Azerbaijan

PRESENTER: Rita Ismayilova

COUNTRY: Azerbaijan

Twelve different arboviruses were identified between 1967 and 1980 in humans and animals in Azerbaijan. Despite the known presence of arboviruses, very little vector-borne pathogen research has been conducted within Azerbaijan since then. TAP-13 project is designed to identify selected arboviruses and their arthropod vectors in southeastern Azerbaijan (Lankaran, Masalli and Gizil-Aghaj State Reserve). The aim of the project was to facilitate the development of effective strategies for the biosurveillance, control, and mitigation of four arboviral pathogens (CCHF, TBE, Sindbis and WNV) and their arthropod vectors.

The project was initiated in August 2016 and is being implemented at Lankaran Anti-Plague Division (APD) with mentorship of the Republican Anti-Plague Station (RAPS). The UK Public Health collaborators provided two PCR trainings in Lankaran APD (November and April, 2016). Arthropods were collected from three regions in October 2015, April and May, 2016 using cloth dragging and livestock collection of ticks, as well as mosquito collection using CDC-light and BG-sentinel traps. Coordinates were recorded via GPS.

Out of 1,777 collected ticks, 1,606 ticks have been counted, identified, and sorted. 590 tick pools have been prepared; 46 pools have been homogenized, extracted, and tested for TBE, Tamdy and West Nile viruses, and all were negative. Out of 5,217 collected mosquitoes, 1,152 have been counted, identified, and sorted. 96 pools have been prepared. 37 mosquito pools were tested for West Nile and Sindbis viruses, and all were negative.

The project was temporarily halted, but will resume February 2017.

Analysis of Previously Identified *Rickettsia* Positive Georgian Ticks by Multi-locus Sequence Typing

PRESENTER: Roena Sukhiashvili

COUNTRY: Georgia

Preliminary studies have shown the presence of three spotted fever group *rickettsiae* (SFGR) species among ticks in Georgia: *R. aeschlimanii, R. raoultii*, and *R. slovaca*. The identity and prevalence of other *Rickettsia* species in ticks have not been determined. The overall goal of this project was to improve the surveillance of tick-borne pathogens in Georgia in the context of rickettsial diseases. This project used the Rickettsia-positive tick samples collected in Georgia from GG TAP-4 project. All tick samples were previously entered into a database, and pertinent sample information and GPS location data were recorded. The tick DNA preparations from the tick samples were tested using multi-locus sequence typing (MLST) to identify which Rickettsia species were present. Tick samples were not collected from the field; only tick DNA preparations already tested for Rickettsia were utilized. Overall, nine species were found among 12 different tick species from five different genera: *Ixodes, Hyalomma, Haemaphysalis, Dermacentor,* and *Rhipicephalus*. Geographical distribution maps of *Rickettsia* –infected ticks that were developed in eight regions eastern and western Georgia showed that the most common *Rickettsia* species were: *R. raoultii*, *R. slovaca*-also, *R. aeschlimannii*, and *R. monacensis*. For the first time the SFGR species *R. massiliae, R. monacensis*, *R. conorii* subsp. *conorii*, *R. hoogstraalii, R. helvetica* and *Ca. R. barbariae* were detected in ticks from Georgia. High prevalence and wide distribution of *Rickettsia* species among ticks make rickettsiosis a potential public health problem in Georgia.

The Role of Arboviruses as a Cause of Undifferentiated Febrile Illness in Sindh, Pakistan

PRESENTER: Erum Khan

COUNTRY: Pakistan

The objective of this study was to develop training in arboviral diagnostics and surveillance, to determine the burden of mosquito-borne viruses that can be used as biological agents of warfare. The Pakistani collaborators then trained other public health practitioners in Pakistan to expand arboviral diagnostics and surveillance capabilities. We recorded the presence of several co-circulating arboviruses in Pakistan. Our data show that a significant percentage of patients presenting with undifferentiated fever are afflicted with at least one arbovirus with 14.2% of patients infected with dengue or West Nile virus, 3% with chikungunya virus, and 10.7% with Japanese encephalitis virus. Diagnostic techniques developed through this project helped in the early diagnosis of Chikungunya during the Nov-Dec 2016 outbreak in Karachi. We published one paper disseminating preliminary project data and are currently drafting several more papers for publication in the coming year. Additionally, based on data from this project, a team member was awarded a 12-month Fellowship in One-Health by the National Academy of Science for 2016-2017.

During the next reporting period, we will complete validation via PRNT for all samples. In light of the global outbreak of Zika virus, we will screen our samples for Zika virus. We will present data at several conferences this year.

Event Logistics and Local Information

Venue Information

2017 Science Program Review Meeting Site

Hilton Alexandria Mark Center
5000 Seminary Road
Alexandria, Virginia 22311
(703) 845-1010

Hilton Alexandria Mark Center Shuttle Services

National Airport/Pentagon City Mall & Metro

The Hilton Alexandria Mark Center offers a complimentary shuttle service seven days a week from 6:00 AM to 10:30 PM.

The vans depart from the front of the Hotel on the hour and half hour (i.e. 6:00 AM, 6:30 AM, 7:00 AM, 7:30 AM) with the last departure at 10:00 PM.

The shuttle arrives at Pentagon City Mall/Metro (Blue and Yellow Lines) at approximately 10 minutes and 40 minutes after the hour. The shuttle then continues on to Ronald Reagan Washington National Airport and returns to the hotel.

The last pick up at Pentagon City is at approximately 10:40 PM and the last van arrives to the airport at approximately 20 minutes and 50 minutes after the hour.

Ronald Reagan Washington National Airport pick-up occurs on the arrival level at the “Hotel Shuttle” pick up locations in Terminal A, Terminal B (Door 5) and Terminal C (Door 9). Our last pick up at Ronald Reagan Washington National Airport is at approximately 10:50 PM. Please make sure to mention the shuttle to the Hilton Alexandria Mark Center, as there are several Hilton Hotels in the area.

King Street Shuttle

The Hilton Alexandria Mark Center offers a complimentary shuttle service Monday through Friday that departs from the front of the hotel each hour from 3:15 PM to 9:15 PM. This shuttle is direct to the King Street Metro station in Old Town Alexandria. Last pickup from Old Town Alexandria back to the hotel is at 9:30 PM.

The drop off is the location to board the Old Town Alexandria complimentary trolley service that runs the length of King Street from the King Street Metro station to the Waterfront.

COOPERATIVE BIOLOGICAL ENGAGEMENT PROGRAM

PROGRAM MISSION

The Cooperative Biological Engagement Program (CBEP) recognizes the danger to U.S. and global health security posed by the risk of outbreaks of dangerous infectious diseases. Whether natural or manmade, disease outbreaks pose a risk to the global community. CBEP strives to address this risk by promoting best practices in biological safety and security, improving partner countries' capacities to safely and rapidly detect and report dangerous infections, and establishing and enhancing international research partnerships.

PROGRAM OBJECTIVES

1. *Secure and consolidate collections* of especially dangerous pathogens (EDPs) and their associated research at a minimum number of secure facilities
2. Enhance partner country/region's capability to prevent the sale, theft, diversion, or accidental release of biological weapons (BW)-related materials, technology, and expertise *by improving biological safety and security standards*
3. Enhance partner country/region's capability to *detect, diagnose, and report* endemic and epidemic, man-made or natural EDPs, bio-terror attacks, and potential pandemics
4. Ensure the developed capabilities are designed to be *sustainable*
5. Facilitate engagement of partner country/region's scientific and technical personnel in *research areas of interest* to both the partner country/region and the United States
6. *Eliminate any BW-related infrastructure* and technologies encountered

CORE PROGRAM AREAS

Two core program areas contribute to CBEP mission success: Biosafety and Biosecurity, and Biosurveillance.

BIOSAFETY AND BIOSECURITY

Strengthen biosafety and biosecurity standards and practices. CBEP activities improve the capability of global partners to handle, store, and account for EDPs safely and securely in accordance with U.S. and international standards, guidelines, and best practices.

Objectives

- Assess existing biosafety and biosecurity capabilities for facilities, procedures, and personnel involved with EDPs
- Provide sustainable solutions to increase biosafety and consolidate and secure pathogens, to include: facility upgrades, engineering controls, training and mentorship, and personal protective equipment
- Facilitate collaborative development of country-specific biosafety and biosecurity standards and guidelines that are sustainable and promote international scientific cooperation

BIOSURVEILLANCE

Enhance Country Disease Surveillance, Detection, Diagnostics, and Reporting Capacity. CBEP works with partner countries across human and clinical, veterinary, epidemiological, and laboratory communities to enhance partner country disease surveillance, detection, diagnostics, and reporting capabilities related to EDPs.

Objectives

- Develop disease surveillance and diagnostic laboratory networks at the national, regional, and district levels to facilitate near real-time reporting of outbreak data to national authorities
- Survey suspicious disease outbreaks, analyze epidemics, and collect disease reports from veterinarians, clinicians, and epidemiologists
- Aid partner capability to comply with the World Health Organization's International Health Regulations and World Organization for Animal Health's reporting guidelines

PROGRAM ENABLERS

CBEP-sponsored research is an important enabling tool. CBEP funds and conducts research that involves partner-country scientists and directly advances strategic policy objectives.

RESEARCH

Facilitate strategic research partnerships. CBEP establishes international research partnerships and engages scientists to enhance epidemiological and diagnostic capacities related to EDPs. Engagement focuses on research areas of interest to both the partner country and the United States.

Objectives

- Prevent the proliferation of dual-use expertise
- Increase transparency and encourage high standards of openness, ethics, and conduct
- Integrate scientists and institutes into the international scientific community
- Improve partner's understanding of endemic and emerging diseases
- Share unique pathogen strains/data with the scientific community for joint research

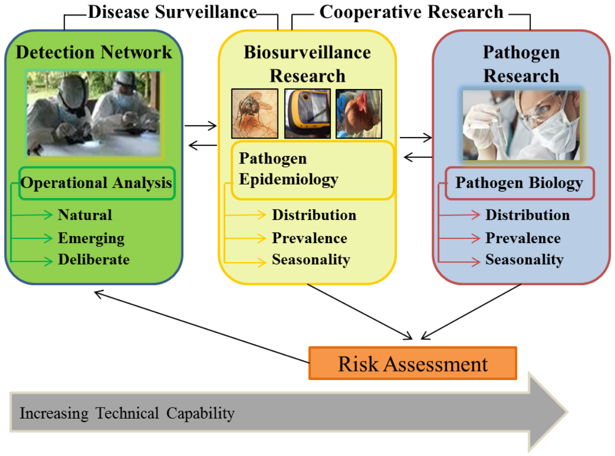
Applying for Research Funding from the Cooperative Biological Engagement Program

RESEARCH PROGRAM MISSION AND VISION:

The Cooperative Biological Engagement Program (CBEP) seeks to use cooperative international research partnerships to support its mission to reduce the threat to the U.S. and to global health security from the spread of pathogens of security concern, which includes U.S. Biological Select Agents and pathogens of pandemic potential, emerging, and reemerging infectious diseases. CBEP aims to establish and maintain these partnerships to inform and enhance operational biosurveillance systems, enhance global health security, and foster safe, secure, and sustainable bioscience capability with partner countries.

COOPERATIVE BIOLOGICAL RESEARCH

The CBEP uses Cooperative Biological Research (CBR) projects to support, enhance, and inform biosurveillance (BSV) and biosafety and biosecurity (BS&S) capabilities that reduce the threat of pathogens of security concern, while sustainably addressing infectious disease priorities of the CBEP and its partner countries.



RESEARCH FIELDS AND PRIORITIES

CBR supports and informs operational biosurveillance through an improved understanding of pathogens and their risk to global health security. In order to remain relevant, agile, and sustainable, the scope of the CBEP's research priorities include:

1. Understanding the ecology and epidemiology of pathogens of security concern
2. Differentiating pathogens of security concern

RESEARCH GOALS

The CBEP is committed to fair and open competition of research topics that enhance biosurveillance, mutually benefit the U.S. and global partner institutes, and achieve the goals outlined below:

1. Support biosurveillance and biosafety and security (BS&S) capability building efforts
2. Engage partner country scientists in ethical hypothesis-driven research resulting in high-quality data and active participation in professional societies
3. Foster sustainable partnerships with key national and international stakeholders, as well as advance partner country sustainment of global health security and one-health initiatives.

PROJECT SCOPE

The CBEP is most likely to fund projects demonstrating:

- Clear relationships to pathogens of security concern
- Links to the CBEP's threat reduction mission
- Support of BS&S and BSV capabilities
- Alignment with the CBEP and partner country priorities
- Use of sustainable techniques for partner countries in appropriate facilities
- Ethical, Hypothesis-Driven research aims

Projects focusing on or likely to result in Dual Use Research of Concern (DURC) will not be supported. Additionally, the CBEP research objectives do not include diagnostic assay development, medical countermeasures, or research focused on non-infectious diseases.

APPLYING FOR FUNDING

Research projects supported by the CBEP must align with the CBEP's mission and vision and are expected to produce results suitable for scientific publication. The CBEP welcomes research funding applications from the following domestic and foreign entities:

- Academic institutions, NGOs, industry, foreign laboratories, and private sector members through the Broad Agency Announcement (BAA)
- U.S. government partners and federally funded Research and Development Centers through the Government Service Call (Call).

ROADMAP FOR APPLICATIONS

Submitting your proposal to the BAA or the Call involves three key steps: Pre-coordination, Phase I, and Phase II. Note, each step has its own rules and requirements. A summary of each step is provided as follows:

1. Pre-coordination: This phase involves discussion and coordination between proposal offerors and the CBEP Country/Regional Manager and/or a Science Manager to ensure the proposed work is within the CBEP scope and meets CBEP priorities. Abstracts are to be emailed to the appropriate administrative email listed below. The abstract must be reviewed favorably by the CBEP prior to continuing on to a Phase I white paper. Prior to the official white paper request from CBEP, direct contact and communication is allowed. Following an invitation to submit a Phase 1 white paper, all communications must be conducted through the appropriate administrative email address listed below.
2. Phase I: Upload the Phase 1 submission with application package to www.grants.gov (BAA) or www.dtrasubmission.net (Call). Following favorable review by the CBEP, a Phase II full proposal may be requested.
3. Phase II: If invited to submit a full proposal, develop the proposal incorporating any comments from the Phase I debrief summary. Submit completed Phase II information and attachments to www.grants.gov or www.dtrasubmission.net as appropriate. Applicants must complete additional appropriate documents for BS&S review as well as documentation if research involves human or animal use.

More detailed instructions and requirements can be found through the solicitation links at www.grants.gov.

WHERE TO APPLY

For abstract submission to the BAA (HDTRA1-14-24-FRCWMD-BAA) or Service Call (HDTRA1-12-17-FRCWMD-Call) please use: HDTRA1-FRCWMD-TA6@mail.mil

For administrative questions for the BAA, please use: HDTRA1-FRCWMD-A@mail.mil

For administrative questions for the Service Call , please use: HDTRA1-FRCWMD-C@mail.mil

Navigating the Defense Threat Reduction Agency and United States Strategic Command Center for Combating Weapons of Mass Destruction Cooperative Biological Engagement Program Proposal Submission Process

Thank you for your interest in working with the Defense Threat Reduction Agency and United States Strategic Command Center for Combating Weapons of Mass Destruction's (DTRA/SCC-WMD) Cooperative Biological Engagement Program (CBEP). CBEP often works with universities, U.S. Government agencies, non-profit organizations, foreign laboratory equivalent entities, and many other organizations to implement the biological threat reduction mission through research projects.

This correspondence is intended to assist offerors in applying for DTRA/SCC-WMD CBEP funding. Information contained herein is intended to supplement, not replace, official documents including:

- DTRA/SCC-WMD's Broad Agency Announcement (BAA): HDTRA1-14-24-FRCWMD-BAA (*BAA*)
- DTRA/SCC-WMD's Government Service Call (Call): HDTRA1-12-17-FRCWMD-Call (*Call*)

These documents can be found through the solicitation links at www.dtrasubmission.net/portal/.

CBEP recommends all offerors read the applicable official document, but frequent references and citations are provided below in red to facilitate understanding of the process. Information here will help offerors answer specific questions and ease the initial stages of project/proposal development and application submission.

Frequently Asked Questions:

Question One: *Is my project appropriate for the BAA or the Call?*

The BAA and the Call both enable the same types of projects; the differentiating factor is the applying entity.

Eligible applicants under the BAA include: accredited degree-granting colleges, universities, and academic institutions; industrial and commercial entities, including small businesses with a portfolio predominantly in research; non-government organizations; not-for-profit entities with a portfolio predominantly in research; and foreign government laboratories. *BAA Section 3, pp 12- 13.*

Eligible applicants under the Call include: Federal laboratories to include Department of Defense (DoD), Department of Energy (National Labs), Department of Homeland Security (National Biodefense Analysis and Countermeasures Center, Plum Island Animal Disease Center), Health and Human Services (Centers for Disease Control and Prevention, National Institutes of Health), and U.S. Department of Agriculture (Agriculture Research Service, Animal Plant and Health Inspection Service); and DoD sponsored Federally Funded Research and Development Centers as specified in

Defense Federal Acquisition Regulation Supplement 235.017-1 and Federal Acquisition Regulation 35.017-1. *Call Section 4, pp 9.*

Question Two: *Is my project appropriate for Thrust Area 6?*

Thrust Area 6 (TA6) is intended to receive exploratory basic and applied research project abstracts, white papers, and proposals. Projects that are hypothesis driven and involve data generation in a laboratory or field environment are considered research projects and are applicable to TA6. This also includes projects that plan to display or present an analysis of data in a peer-reviewed publication or presentation. *BAA Section 1.5.6, pp 7-9; Call Section 2.1.6, pp 5-7.*

Question Three: *How can I ensure my proposal is aligned with CBEP's mission?*

At its highest level, CBEP strives to address the risk of outbreaks of dangerous infectious diseases by promoting biological safety and security, improving partner country capacity to detect and report dangerous diseases, and establishing and enhancing international research partnerships. The contribution to threat reduction is critically important to a successful white paper/proposal. Applicants have the opportunity, and are encouraged, to reach out to CBEP and coordinate project scope through submission of an abstract or concept note before applying to the BAA or Call. *BAA Section 1.5.6, pp 7-9, Section 4.2.1, pp 14; Call Section 2.1.6, pp 5-7, Section 9.2, pp 27.*

Understanding the process:

Question Four: *How long should I expect the review and award process to take?*

Receiving an award through the BAA or Service Call requires a number of key steps. Each step involves a number of factors that can influence the timeline from initial submission to award. Generally, the average length of time between an official white paper submission and project award is 12 months for both BAA and Service Call submissions. Factors influencing the process include: internal review processes, external interagency review processes, offeror submission of revised proposal documents, and contract/grant award processes. The specific timelines and deadlines for submission of documents related to each application phase will be provided in the official correspondence during the submission process.

Question Five: *What is the application process?*

Submitting your proposal to the BAA or the Service Call involves three key steps: Pre-coordination, Phase I, and Phase II. Note each step has its own rules and requirements. A summary of each step is provided in the chart on the following page.

	Thrust Area 6
Pre-Coordination	• Initiate direct communication with the Regional/Country Lead and Science Manager to determine project viability and align proposed research scope with CBEP's objectives. o *BAA Section 1.5.6, pp 7-9* o *Call Section 2.1.6, pp 5-7* • Develop an abstract of the research project and submit in the body of an email to HDTRA1-FRCWMD-TA6@mail.mil. o *BAA Section 4.2.1, pp 14; Section 7, pg 37* o *Call Section 5.1, pp 9; Section 9.2, pg 27* • Abstract must be reviewed favorably by CBEP prior to the submission of the Phase I white paper. Applicant must receive an invitation to continue on to Phase I white paper. o *BAA Section 4.2.1, pp 14-15* o *Call Section 5.1, pp 9*
Phase I – **Pre-Application White Paper**	• Please note, following an invitation to submit a Phase I pre-application white paper (white paper), communications must be conducted via the appropriate administrative email address: o *BAA: HDTRA1-FRCWMD-A@mail.mil* o *Call: HDTRA1-FRCWMD-C@mail.mil* • Develop a Phase I white paper. o *BAA Section 4.2.4, pp 14-16* o *Call Section 5.1.4, pp 10; 5.3, pp 11-12* • BAA only o Register at www.grants.gov. o Submit a completed application to www.grants.gov. o *BAA Section 4.2.4, pp 14-16* • Call only o Ensure to register with the DTRA/SCC-WMD submission website www.dtrasubmission.net. o Submit the completed application to www.dtrasubmission.net. o *Call Section 5.1-5.2, pp 9-11*
Phase II – **Full Proposal**	• Upon receipt of an invitation for a Phase II full proposal, develop a proposal and incorporate any comments from DTRA/SCC-WMD's Phase I debrief summary. o *BAA Section 4.2.6., pp 16-22* o *Call Section 5.5, pp 12-18* • All proposals involving infectious or potentially infectious materials must include a completed and signed Protocol Risk Assessment Tool (PRAT). The purpose of this form is to ensure laboratory work sponsored by CBEP is conducted safely, securely, and responsibly. The PRAT should be completed and signed by the Principal Investigator. A blank form is available via the www.dtrasubmission.net Document and Template library. • All TA6 research Phase II proposals (BAA and Call) that involve human or animal use must provide Institutional Review Board (IRB) and/or Institutional Animal Care and Use Committee (IACUC) protocols and provide provisional protocol numbers as well as IRB/IACUC point of contact information. No human/animal is permitted until BOTH the institutional review and U.S. Department of Defense approval authorities grant approval. DTRA/SCC-WMD sends all proposals through its internal Research Oversight Board and an interagency review to ensure use of best practices and a safe and secure research environment for all participants. Awardees will be notified via email when permission to begin human/animal work has been granted. This process may increase the timeline between Phase II review, funding approval, and project start. • Submit completed Phase II information including all attachments to www.grants.gov (BAA), or www.dtrasubmission.net (Call), as applicable and instructed in BAA and Call instructions. Note that Protocol Risk Assessment Tool attachments must be emailed to HDTRA1-FRCWMD-A@mail.mil (BAA) or HDTRA1-FRCWMD-C@mail.mil (Call) and NOT attached to the www.grants.gov (BAA) or www.dtrasubmission.net (Call) submission. o *BAA Section 4.2.6, pp 22* o *Call Section 5.5.3, pp 17*

Hi David,
Thanks for arranging everything and taking the time to meet with us and provide an overview of the work you've been doing.

Attached are the updated tri-fold brochures that I handed out yesterday. I'm also attaching the Roadmap document Jarrad mentioned and the book of abstracts from the 2017 CBEP Science Program Review. The abstracts will give you an idea of the kinds of projects we currently have underway.

If you or any of your colleagues have questions, feel free to give any of us a shout and we can get the inquiry sent on to the right folks.

Cheers,
Mary
