Today, the Australian Animal Health Laboratory (AAHL) is the only OIE Henipavirus Reference Laboratory. Within the OIE network, with their priority diseases, reference laboratories are assigned to support other laboratories with training, technology transfer, and technology support. As the only reference laboratory on henipaviruses, the synergies that would otherwise be present in a larger network of henipavirus laboratories are missing. Thus, AAHL is interested in talking to other laboratories with an interest in joining an informal network of laboratories performing henipavirus diagnostics. Network activities could for example include sharing of protocols, reagents, and samples.

Serological assays for henipavirus diagnostics

Professor Anne Balkema-Buschmann – Friedrich-Loeffler-Institut (FLI)

(Presented on Day 2 of the conference)

Friedrich-Loeffler-Institut (FLI) is developing diagnostic assays for henipaviruses in Europe, far from the endemic areas, in the interest of preparing for potential epidemic and bioterrorism threats. Testing European animals that may have been exposed to henipaviruses requires previous validation of the diagnostic assays against indigenous livestock breeds. First, an indirect henipavirus ELISA assay was developed with NiV N protein expressed in *E. coli*, and the cut-off value was determined against negative samples from Canadian pigs. Furthermore, the establishment of indirect ELISAs for NiV G and HeV G, using proteins expressed in *L. tarentolae* (which closely mimics the protein glycosylation patterns seen in humans), allowed for differentiation between NiV and HeV infection: While there is still cross-reactivity between NiV and HeV in these two latter assays, the homologous virus yields a higher response. Finally, Western blot is used to confirm positive samples against plasmid-derived NiV G, using a monoclonal antibody for NiV G as positive control. The assay has now been validated for North American and European serum samples, and is available for screening and diagnostic purposes.

Working to establish a Hendra diagnostic for horse samples, an indirect ELISA was developed based on HeV G expressed in *L. tarentolae* and HeV N expressed in baculovirus-infected insect cells. Screening of 288 German negative horse sera yielded the cut-off, and assay validation was conducted in Geelong using samples with confirmed diagnosis (135 negative, 95 vaccinated, and 21 infected horse sera). The German ELISA assay compared very well with the Australian assay, having very similar cut-off values and high, comparable levels of sensitivity and specificity.

There is serological evidence of henipavirus spillover into human populations in Africa, and although the clinical relevance is unclear (there have been no detectable cases), there is a desire to establish strain-specific tools for serosurveillance. Positive sera were generated immunising fruit bats (*Rousettus aegyptiacus* and *Eidolon helvum*) hosted at the FLI with different recombinant viruses. In preparing for these infection studies, the circadian temperature baseline had already been established (body temperatures in the bats range from 34 to 41 °C depending on time of day and activity levels). Sera from vaccinated bats, when tested with ELISA or the corresponding multiplex setup (on Luminex®), again demonstrate cross-reactivity, but show the strongest response with the homologous test. FLI now continues to work on establishing multiplex assays for henipavirus differentiation in pigs, horses, and bats, as well as detecting antibodies against other relevant antigens in bats and pigs.

Establishment of an immunofluorescence assay to detect IgM antibodies to Nipah virus using HeLa cells expressing recombinant nucleoprotein

Dr. Yoshihiro Kaku – National Institute of Infectious Diseases, Tokyo

The National Institute of Infectious Diseases (NIID) started working on Nipah in response to the 2014 outbreak on the Philippines, partnering with Research Institute of Tropical Medicine (RITM), WHO, and AAHL. NIID was involved in performing serological and nucleic acid testing on the samples from three of the seventeen cases detected in the outbreak.

The ambition of NIID is to develop diagnostic methods for NiV that are available under BSL-2 conditions and use inexpensive equipment. At the time, NIID did not have an IgM detection system in place, due to the lack of positive control human serum. Instead, they embarked on developing a positive control through the immunisation of macaques (*Macaca fascicularis*), since IgM and IgG from macaques are typically cross-reactive to human IgM and IgG. The macaques were immunised with 1 mg NiV N-protein purified from baculoviruses, followed by 0.2 mg booster doses on days 15, 28, 42, and 56. Serum was collected on days 5, 7, 9, 11, 13, **15** (30 ml), 53, and **63** (whole blood), where serum from day 15 was used as positive control for IgM, and whole blood from day 63 served as positive control for IgG.

An IgM capture ELISA was designed as follows: Wells were coated with goat anti-human IgM, to which samples and positive controls containing human and macaque IgM, respectively, were added. Half of the wells were incubated with NiV-N antigen corresponding to the antigen to which the macaques had been immunised, and the other half with irrelevant antigen from baculovirus. Captured antigen was detected by rabbit anti-NiV-N serum and goat anti-rabbit IgG linked to horseradish peroxidase (HRP). The IgM assay was tested against serum collected from two immunised macaques on days 5-15, demonstrating seroconversion for one of the macaques around day 9 (which could then be used as positive control). Macaque number two failed to elicit a significant immune response to NiV-N.

An IgM indirect fluorescence antibody test (IFAT) was developed by (stably or transiently) transfecting HeLa-229 cells with plasmids containing NiV-N cDNA and blastcidin as reporter. For transient expression, the HeLa cells were trypsinised on day 4, seeded onto 14-well glass slides and fixed with acetone. For stable expression, blastcidin-expressing cells were selected, trypsinised, and mixed with mock-transfected cells in a 1:3 ratio prior to fixation, since this yields a setup better suited for distinguishing between false positive and true positive results. The IFAT was conducted by adding test serum, and subsequently Alexa Fluor 488-conjugated goat anti-human IgM, to the fixed HeLa cells. If the test serum contains anti-NiV-N IgM, the NiV-N-expressing HeLa cells will emit fluorescence.

The IgM capture ELISA proved to have a lower detection limit for anti-NiV-N IgM than the IFAT assay, yet the three patient samples received by NIID from the 2014 Philippines outbreak were all confirmed NiV positive by both assays. When testing the IgM IFAT assay against normal (uninfected) sera from The Malaysian Cohort (TMC) project, all samples were negative at a 1:100 serum dilution. The IFAT assay was also shown to be able to detect anti-NiV-N IgG, and to be cross-reactive for anti-HeV-N IgG. The IFAT antigen slides are fairly stable, and can be stored at -80 °C for several years awaiting future use. It is possible to use them directly after thawing, which makes them suitable for rapid diagnostic response in a laboratory setting.

NIID has also developed a pseudotyped VSV neutralisation assay, which is more sensitive than neutralisation assays with live NiV. The assay is suitable for both screening (in a high-throughput setting) and confirmation of infection status, and could potentially limit the need for confirmation with a second assay. NIID are happy to share the technique and reagents with other laboratories.

Session 4 Q&A

Q: Are there plans for using the mobile diagnostic system developed in India as part of prospective surveillance? Can you bring the system on a flight? What is the cost?

A: The system can be used both prospectively and in an outbreak setting. Yes, the system can be brought on the plane, but may sometimes be rejected by staff, for example due to safety concerns. The cost per test is reasonable, about 800 Indian rupies.

Q: What more can be said about the vocal groups opposing the Hendra vaccine?

A: One challenge is social media like Facebook, where people hesitant to the use of vaccines come together and share stories about horses getting sick from vaccination, and claims that the manufacturer is pushing the vaccine in regions where HeV has never been seen. A recent spillover event close to Sydney may serve to counter this view, and has caused all thoroughbred stables in the area to vaccinate their horses. A recent pro-bono legal class action has caused a number of people to come forward saying that their horse had a reaction to the vaccine. This certainly detracts from our cause of trying to save the lives of people and horses, but we have to keep offering up all the good information about the vaccine and ensure continued use.

Q: Can the HeV vaccine be used in humans?

A: The approach in Australia has been to vaccinate the horses, rather than people, and protect everyone – since the horses are the amplifying host (humans have never gotten Hendra directly from a bat). From a One Health point of view it makes sense to vaccinate the horses.

Q: How is the use of the HeV vaccine being monitored, in terms of side effects?

A: The monitoring is ensured by the APVMA, and all reports of adverse events are sent to them. The manufacturer has a role in facilitating this, and in following up on the reports. According to the vaccine company, adverse events linked to the use of vaccine have been minimal.

Q: Annual booster doses of the HeV vaccine seems a bit excessive. Is there any evidence to support this?

A: With the documentation available, 12-month boosters are still recommended. With more data, one may be able to reduce the number and frequency of boosters.

SESSION 5 – Pathogenesis and animal models

Chair: Dr. Amy Shurtleff, CEPI

Development of a nonhuman primate model for Nipah virus infection that accurately reflects human disease

Dr. Mike Holbrook – NIAID, NIH

NIAID works to develop a non-human primate model that accurately recapitulates human disease to aid in the development of medical countermeasures to Nipah virus infection. While, historically, such an animal model would have been designed to be uniformly lethal, NIAID seeks to develop a model that is more true to NiV infection in humans. Specifically, they wish to replicate the clinical hallmarks of Nipah disease: 1) Acute Respiratory Distress Syndrome (ARDS), as evidenced by "ground glass" opacities of lung computed tomography (CT) scan or X-ray; 2) late-onset encephalitis, manifesting as focal hyper-intense lesions or confluent cortical involvement on brain MRI scans; 3) widespread vasculitis, especially of highly vascular organs such as the spleen. At the NIAID integrated research facility, one has been able to study the impact of exposure to different-sized particle aerosols with NiV in animals, using clinical imaging to assess the disease progression in lungs and brain, and immunological tests to evaluate immune responses. These are the only facilities in the world to allow for advanced clinical imaging of live animals kept at BSL-4.

Currently, NiV-M and NiV-B particles about 12 µm in size are used to infect wild-caught Caribbean origin African green monkeys (AGM) at a dose of about 500 plaque-forming units (pfu) per monkey. Surprisingly, infecting with NiV-M or NiV-B results in widely different disease progression, where NiV-M causes extended disease with about 30 % survival, and NiV-B leads to rapidly progressing disease with about 50 % survival. Quantification of RNA in blood, nasal swabs, and cerebrospinal fluid (CSF) demonstrates viral shedding during the acute phase of disease, as well as penetration of NiV-M across the blood-brain barrier (BBB) into the central nervous system (CNS). Seroconversion is detected in only some of the animals, starting around day 10 post infection. Neither seroconversion nor the presence of neutralising antibodies seem to be reliably protective. While antibodies may limit respiratory disease, no effect has been found on the progression of neurological disease.

A number of different coagulation assays point to a link between acute-phase disease progression and the development of haemorrhagic disorders: 1) Reduced platelet levels, as well as increased partial thromboplastin time (PTT) and thrombocytopenia suggest onset of disseminated intravascular coagulation (DIC); 2) Elevated fibrinogen suggests severe DIC; 3) Elevated von Willebrand factor (vWF) is indictive of vasculitis. Brain imaging is conducted regularly on live, infected animals (CT throughout infection, MRI from day 15 since it requires anaesthesia), and later guides the acquisition of brain biopsies that allow for confirmation of encephalitis. Detection of circulating cytokine levels may serve to corroborate the inflammatory status of the animal, though clinically predictive patterns have not yet been identified. Lung infiltration of NiV-B has been demonstrated to severely affect lung capacity.

The AGM model results in the development of neurological disease several weeks after exposure, and requires survival of the acute respiratory phase of the disease. The animals respond differently to infection, as would be expected in the human population: Some show no clinical evidence, some are infected with clinical manifestations but survive, and some succumb to the infection. When delivered to the oropharynx and upper respiratory tract, NiV-M causes less respiratory disease than NiV-B. Haemorrhage and coagulopathy seems to be a critical aspect of Nipah disease. Neurological disease results from vasculitis (microinfarcts) or inflammation (encephalitis) rather than virus specifically targeting neural tissue, and this occurs even in the presence of NiV neutralising antibodies.

Some points to consider: 1) NiV infection may initially present as a mild to moderate respiratory infection, progressing to neurologic disease in some cases if unrecognised or untreated; 2) Serological and nucleic-acid based diagnostic tools complement each other, and should be used in combination, with whole blood and nasal swabs as suitable sources of viral RNA; 3) Therapeutic approaches focusing on vasculitis/DIC should be developed; 4) Continued development of the NHP model for NiV infection will aid in understanding the disease and in developing clinical countermeasures.

Advances in non-human primate models of henipavirus disease: refinement of routes and the importance of species selection

Dr. Robert Cross, University of Texas Medical Branch (UTMB)

In the AGM model, NiV infection by the intratracheal or intratracheal + oral route results in disease characterised by thrombocytopenia, leukopenia, neutrophilia, generalised vasculitis (lung and brain), hypoalbuminemia, pulmonary distress, and (often) neurological symptoms. NiV-B has proven more potent than NiV-M, and consistently kills the monkey in 9-10 days. Respiratory disease has a rapid onset around day 8-10, showing up on X-ray shortly before the animal needs to be euthanised. Neuronal and endothelial deposition of viral antigens causes the characteristic brain lesions. Circulating viral genome may be detected from day 7 post infection in this model.

Whereas the intratracheal route may have its uses, it is labour-intensive and cumbersome to use. Therefore, an intranasal NiV exposure AGM model has been developed using the mucosal atomization device MAD Nasal™ from LMA®. Using doses of 2,000 and 20,000 pfu, the intranasal model was uniformly lethal, with time to death of about 9-10 days. Vasculitis and viral depositions in the spleen may be one reason why a protective immune response to the infection is not established and the animals succumb. Nipah is a vascular disease, and wherever endothelial cells are present, viral replication may occur. Thus, viral RNA is found in blood as well as in most tissues examined. Cytokine profiling indicates no systemic inflammation until late in the disease.

While the AGM model is uniformly lethal, another model has been developed using cynomolgus monkeys (CM) and administration of NiV-M, NiV-B, or HeV intratrachially (5.0×10^5 pfu). This model has pathologies consistent with human infection and other animal models, yet the animal survives. While circulating virus may be detected from day 5 or 6 – with peak viremia around day 7 – spleen, lung, and brain tissues are minimally affected. One reason for this may be stronger immune responses to henipaviruses in CM, as detected by considerable titres of serum neutralising antibodies and high circulating levels of the chemokines MCP-1 and IL-6. A differential gene expression microarray analysis showed characteristic differences between AGM (fatal infection) and CM, and this is hoped to help clarify the mechanisms underlying CM survival. Furthermore, while reagents for phenotyping of immune cells are lacking for use in AGM, digital cell quantitation based on results from the microarray analysis has allowed the *in silico* identification of B cells and Th1 cells as possible key cell populations in survival of AGM infected by NiV. In contrast, mast cells and NK cells may play a detrimental role in the pathogenesis of Nipah infection.

Oronasal challenge of ferrets with henipaviruses

Dr. Glenn Marsh, CSIRO, Australian Animal Health Laboratory (AAHL)

Over the past 15 years, AAHL has developed a ferret model for Nipah infection that closely mimics the human disease. When infected with NiV-B, the ferrets experience predominantly respiratory disease, whereas with NiV-M the disease has more of a neurological character. Clinical endpoints are typically reached day 6-9. As with the non-human primate models, terminal animals experience a drastic drop in platelets (causing haemorrhaging) and circulating lymphocytes. The model has been extensively used for the assessment of clinical countermeasures like the HeV sG equine vaccine, monoclonal antibody m102.4, peptides, and repurposed medications.

Significant differences are seen between NiV-B and NiV-M, in animal models as well as in humans. NiV-M is the result of a single spillover event with bat-to-pig and pig-to-human transmission, yet no human-to-human transmission. NiV-B, on the other hand, has seen multiple spillovers over the last years, with bat-to-human and human-to-human transmission. The question is whether the epidemiological differences are a result of distinct viral properties, or if environmental and host factors also play a role. Notably, different NiV-B isolates used in animal testing may have different properties, as well. The strain used by AAHL was isolated from an outbreak in Rajbiri in 2004, where human-to-human transmission was not a major source of infection (other strains have not been available to them).

Comparing NiV-B and NiV-M in the ferret model, NiV-B was demonstrated to be more infectious by a factor of about 100 (5 pfu needed to infect two out of two animals, whereas the corresponding dose for NiV-M was 500 pfu). The pathology of infection, however, is comparable for the two strains, with onset of symptoms day 5-6 and euthanasia day 7-9. As in other models, gross pathology of NiV infection in ferrets involves visible haemorrhaging on the surface of the lungs and other organs. One difference between NiV-B and NiV-M in ferrets is the higher viral load and, hence, higher oral and nasal shedding, of virus in NiV-B infection. However, this shedding is not sufficient to cause transmission of virus to other animals through regular contact, suggesting that transmission requires direct transfer of bodily fluids, and that aerosol transmission occurs rarely if at all. This suggests that preventing close contact with infected individuals is likely to be an effective measure against human-to-human transmission.

Nipah virus pathogenesis in experimentally infected swine

Dr. Brad Pickering – Canadian Food Inspection Agency (CFIA), Winnipeg

During the first Nipah outbreak in Malaysia, close to a million pigs were culled, and the financial repercussions led to a high interest in studying NiV infection in pigs. There has since not been a single outbreak, outside of the Philippines, involving pigs as an intermediary host. Pigs remain, however, an interesting model for the study of NiV infection – especially given their potential to cause new epidemics. Although clinical signs of NiV infection in pigs include acute febrile illness with respiratory and neurological symptoms, as well as increased salivation and nasal discharge, the infection is often asymptomatic and may result in sudden death. During the Malaysia outbreak, the incidence of infection within affected farms was 100 %, with 1-5 % mortality. The disease would typically last for about 2 weeks on each farm, providing ample opportunity for spillover into humans.

A NiV-M infection model in swine used at CFIA involves the oronasal or nasal inoculation of 10^5 pfu per animal, resulting in relatively mild infection with some clinical signs such as laboured breathing and sometimes CNS involvement. Viral shedding peaks between days 3 and 5, allowing for detection in oral and nasal swabs. Through a nasal lavage it is possible to detect viral shedding as early as 2 days post infection (DPI). In spite of few symptoms, the animal's organs may be severely affected by the infection, with enlargement and bleeding. Oronasal infection typically spreads through local lymph nodes, lungs, and nose, and into the brain via cranial nerves (specific to pigs).

It is important to understand whether NiV-B may also infect pigs, as a potential mode of spillover into humans. Thus, Canada's National Centre for Foreign Animal Disease (NCFAD) has obtained a recombinant NiV-B (rNiV-B) isolate for comparisons with NiV-M *in vitro* and *in vivo*. The kinetics of virus replication was tested in three different cell lines and the two viral strains were found to be comparable in all cell lines. When used to infect piglets (who were indeed susceptible), at 2.5×10^5 pfu, rNiV-B caused oral shedding from day 2 post infection (as assessed on a community basis by cotton ropes hanging in the pen, which the pigs would chew on). One difference between NiV-M and rNiV-B is that the latter also sheds rectally at detectable levels, from 1 to 10 DPI.

Furthermore, only low-level antibody responses were induced after oronasal infection with rNiV-B, and titres of neutralising antibodies were low. Thus, detection of circulating antibodies may not be an option for diagnosis of potential NiV-B infection in swine, and emphasis should be put on active surveillance and ensuring diagnostic capability of veterinary laboratories in at-risk regions.

Session 5 Q&A

Q: The differences in pathology seen between NiV-B and NiV-M infections are intriguing. Has the same been seen in humans?

A: More data is needed to assess this.

Q: In the NiV-B AGM model, the lungs of the animals were gravely affected in the acute phase (example shown from diseased animal at day 8). Was this consistent for all animals, and did respiratory disease occur at a later stage with NiV-M?

A: It was pretty consistent in the animals infected with NiV-B that succumbed to the infection, and typically occurred around day 8-10. NiV-M infection given by inhalation of large particles did not result in respiratory disease.

Q: Were the infected ferrets displaying respiratory symptoms, such as coughing, sneezing?

A: Yes, coughing and sneezing did occur in some of the animals. In others, the neurological symptoms were more prominent.

Q: Were cohabiting ferrets able to interact physically?

A: Yes, the ferrets are typically housed in pairs, and for transmission studies three ferrets are housed in the same cage. They will often curl up in a corner of the cage, and thus enjoy close interactions. This is true even for sick animals, in general. With other pathogens than NiV, transmission is frequently seen under these conditions.

Q: Could airflow between cages in the BSL-4 facilities contribute to transmission?

A: Yes, with easily transmissible pathogens, transmission has been observed across cages due to the forced airflow of BSL-4 facilities. One tends to try and avoid this through careful positioning of the cages.

Q: Will the swine model be used for transmission studies?

A: Yes, once the plans for expanding the facilities have been completed, transmission studies will be conducted.

Q: The swine model is one of few non-fatal NiV animal models. Could this be used to investigate a potential role of "immune amnesia" in NiV infection, akin to what has been described for measles?

A: Some work is being done on the actual immune cells, including infected cells. This will be published soon.

Q: Could the lack of neutralising antibodies induced by rNiV-B be linked to the age of the animals (piglets) used?

A: Yes, age is definitely a factor regarding the development of immunity in pigs. Piglets are used in the interest of ease of handling in a BSL-4 context. The use of a recombinant strain could potentially be a factor, though not necessarily.

Q: Have you looked at blood gas oxygenation as an endpoint in the pig model?

A: No, but more chemistry and blood work will be included in future studies.

Day 2

SESSION 6 – Transmission/Case management

Chair: Dr. Pierre Formenty, WHO

Person-to-person transmission of Nipah virus

Dr. Emily Gurley, Johns Hopkins Bloomberg School of Public Health

The first studies of human-to-human transmission of NiV were published in 2001 and 2002, with inconclusive results (data from healthcare workers in Malaysia and Singapore). In 2004, the first study to conclude with human-to-human NiV transmission, with data from two outbreaks in Bangladesh, was published. The conclusion was further corroborated by studies in India and Bangladesh (published in 2006 and 2007, respectively). In the latter studies, so-called superspreaders were identified, which served as the source of infection for a large number of individuals. Importantly, the 2007 publication observed that contacts who washed their hands were at reduced risk of infection. In contrast, a publication from 2010 suggested that transmission of NiV could also happen in the absence of close contact. Moreover, a case-report from 2012 of a woman who had presented with late-onset Nipah encephalitis 11 years after the initial outbreak in Malaysia, questioned the original conclusion that the Malaysia outbreak did not involve human-to-human transmission. A 2013 report also demonstrated transmission from a dead person. With the publication in 2015 of the first henipavirus outbreak in the Philippines, one began to realise that the "emergence" of Nipah and related diseases was linked to human-to-human transmission, which causes outbreaks big enough to be detected even in the absence of active surveillance. The outbreak in Kerala in 2018 was a surprise, with Nipah emerging far from previous outbreaks, yet again the outbreak was caused by a hospitalised superspreader.

Key questions concerning human-to-human transmission are: 1) When and where does transmission occur?; 2) Which patients are more likely to transmit to someone else?; 3) Which contacts are most likely to be infected?; 4) What mechanisms are the most important drivers of transmission? Models trying to describe human-to-human transmission consider 1) the availability of infected (and infectious) individuals; 2) the availability of susceptible individuals; and 3) the ways these individuals interact. Whether a patient is infectious depends on the level of viral shedding, clinical symptoms that may help spread the virus (such as coughing and sneezing), and the infectiousness of the virus, which can vary from strain to strain. When it comes to NiV susceptibility, all humans are susceptible to infection. The nature of human interactions, which are often affected by the disease itself in terms of seeking healthcare and receiving visitors, is an important driver for transmission. Population density and duration of illness are other factors influencing the risk of transmission through contact.

Importantly, the route of transmission affects the progression of Nipah disease. Patients infected through date palm sap have more rapid onset of disease and a higher mortality (~90 % vs. ~50 %) than patients infected through human-to-human contact. The latter are also more likely to be diagnosed before death. This has broad-reaching implications for identification, containment, and resolution of outbreaks.

The basic reproduction number (R 0) of Nipah infection, defined as the average number of people one infected person will infect in a susceptible population over the course of infection, has been as low as about 0.2 during the last decade. For a larger outbreak to occur, an R 0 close to or higher than 1 is required. There is substantial variation in the viral strains spilling over from bats to humans every year, and a low R 0 indicates that the spillover viruses have been less suitable for human-to-human transmission. A case-contact study in Bangladesh (published 2019) identified male adults with breathing difficulties to be the primary source of human-to-human transmission of NiV. This is an important clue for safe case management. In total, 9 % of cases (22 out of 248) were shown to transmit NiV to contacts. Highest at risk for human-to-human transmission were family caregivers, individuals with prolonged exposure (> 12 hours) to a case, and individuals who came into contact with a patient's body fluids. All of the transmitters died from the infection, and the number of contacts (physical or fluid) went up in the later stages of the disease, increasing the risk of transmission. Notably, only 4 of the 22 transmitters were admitted to a surveillance hospital, representing a serious limitation for surveillance.

A systematic review of 133 henipavirus transmission studies (52 human and 81 animal studies) revealed that the proportions of transmitters were comparable in Bangladesh, India, and the Philippines (9 %, 10 %, and 12 %, respectively). The patterns of human-to-human transmission were consistent across countries; adult males with respiratory symptoms being the primary source of infection, and family members being primarily affected. While representing only a tenth of the individuals infected, transmitters were shown to be an important determinant for the size of an outbreak. Published data on viral shedding was only available for 37 patients, in which shedding was documented in oral/nasal swabs as well as in urine, but only during acute infection. Viral shedding in semen was documented in one Indian case, for at least 25 days after the onset of disease. Not a single human study has so far documented circulating viral loads.

Patient management & infection control practices

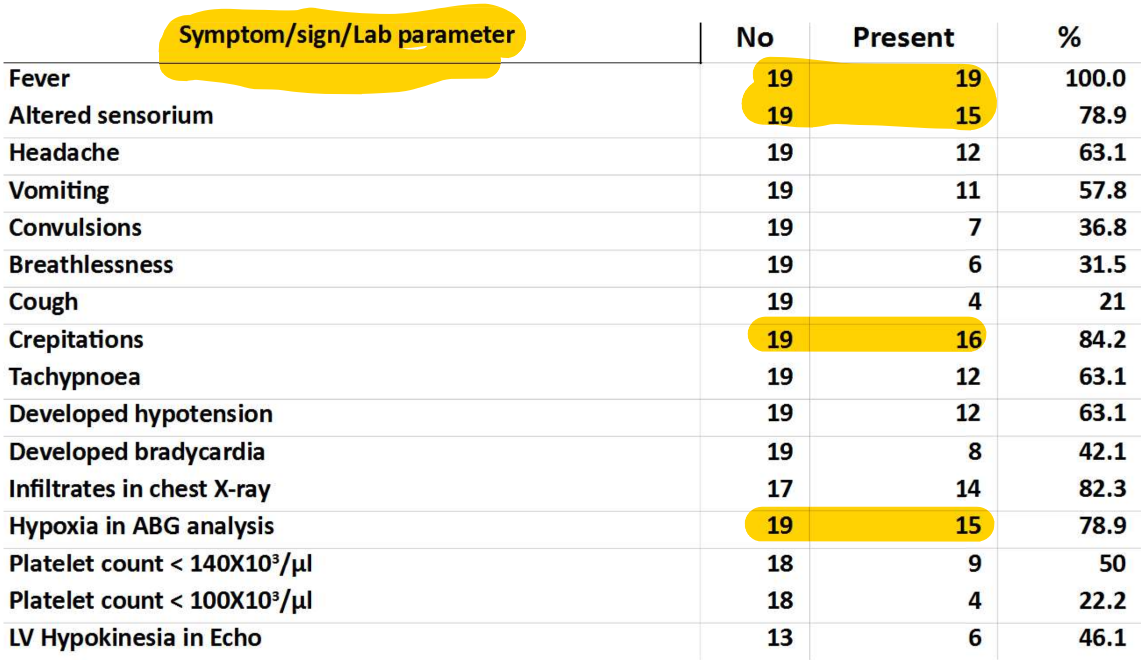
Dr. Chandni Sajeevan – Government Medical College Kerala

The Kerala outbreak in 2018 seemed to start on May 17 with a 32-year old female presenting to a private hospital with ARDS and myocarditis. The day after, lab results showed the presence of a potentially dangerous virus, and on May 20 the Indian National Institute of Virology (NIV) officially declared the NiV outbreak. Later on, it became clear that there had been another case in Kerala of viral encephalitis with ARDS on May 5, a 26-year old male. He died the same day as he arrived at the hospital. The clinical profile of NiV in the Kerala outbreak often included myocarditis in addition to encephalitis and ARDS, an interesting new observation.

The response to the outbreak was immediate, both on the hospital and public health levels. Outbreaks are not unusual in Kerala, and plans for action in the face of an outbreak already existed. Seven steps were deemed critical for controlling the NiV outbreak: 1) Maintain strict infection control practices (ICPs); 2) Ensure proper use of PPE; 3) Follow appropriate house-keeping practices; 4) Monitor staff health (no sick people at work); 5) Implement strict visitor policy; 6) Ensure safe collection and handling of samples; 7) Strict adherence to protocol for handling deceased individuals. A successful response requires preparations based on continuous learning and committing to the necessary practice changes during an outbreak.

During an outbreak, individuals presenting to the hospital with fever are triaged and, if matching the Nipah case definition, are put in isolation. Seriously ill patients are managed by the intensive care unit (ICU). *Suspected* NiV cases are individuals from an area known to be affected by an outbreak, who has encephalitis, ARDS, or myocarditis. A *probable* case is a suspected, now deceased (before diagnosis could be made) individual who had been in contact with what is assumed (or confirmed) to be an infected individual. A *confirmed* case is a suspected case with laboratory confirmation of NiV infection, by way of real-time RT-PCR.

In the 2018 Kerala outbreak, there was one index case and 18 confirmed cases (12 male, 7 female), as well as 4 probable cases (3 male, 1 female). Of the former, two patients survived, one who had typical symptoms and one with only mild disease (flu-like symptoms). All cases had fever, and in two instances the decision to isolate the patient was based solely on the fever and contact history. Altered sensorium was observed in 15 of the 19 cases at presentation (see Figure 9 for more details).



Symptom/sign/Lab parameter	No	Present	%
Fever	19	19	100.0
Altered sensorium	19	15	78.9
Headache	19	12	63.1
Vomiting	19	11	57.8
Convulsions	19	7	36.8
Breathlessness	19	6	31.5
Cough	19	4	21
Crepitations	19	16	84.2
Tachypnoea	19	12	63.1
Developed hypotension	19	12	63.1
Developed bradycardia	19	8	42.1
Infiltrates in chest X-ray	17	14	82.3
Hypoxia in ABG analysis	19	15	78.9
Platelet count < 140X10^3/µl	18	9	50
Platelet count < 100X10^3/µl	18	4	22.2
LV Hypokinesia in Echo	13	6	46.1

Figure 9: Symptoms of Nipah cases at time of presentation (Kerala, 2018; Dr. Sajeevan)

After the 2018 outbreak, a number of challenges were identified and addressed, including the need for 1) early diagnosis of suspected cases; 2) contact management; 3) uniform standard of care; 4) safe and dignified burials; 5) resolving psychosocial problems; 6) long-term follow-up of survivors. When the second spillover in Kerala happened in May 2019, response plans were implemented within 24-48 hours, perhaps as a result of the experiences from 2018. Implementation included training, setting up an isolation facility, contact tracing, and establishing a point of care laboratory.

A case-control study of henipavirus outbreak, Philippines, 2014

Dr. Paola Katrina Ching, Dr. Jose N. Rodriguez Memorial Hospital, Philippines

The 2014 henipavirus outbreak in the Philippines was the first in this country and affected two villages in the southern province of Sultan Kudarat. It was first reported as a possible case of food-borne illness from the consumption of horse meat, on April 1. Among 128 residents who had eaten horse meat, initially four individuals were reported to have gotten sick with CNS symptoms and died. Later in April it became clear that two potentially related syndromes had been identified: 1) Food poisoning; 2) Febrile illness with CNS symptoms. These were both linked to the consumption of horse meat from sick, injured, or deceased animals. The Philippines Field Epidemiology Training Program (FETP) conducted an investigation, and identified an outbreak of a human, fatal encephalitis syndrome that had resulted in 79 cases, causing 9 deaths. The causative agent was not identified, but JE, Chikungunya, and dengue were suspected. As a precautionary measure, consumption of meat from sick or dead horses was banned, and animal handlers and health care workers (HCW) were advised to follow protocols on infection control. On May 12, the Philippine Government requested WHO's assistance for further outbreak investigation.

In a joint mission starting May 22, Philippine health officials and WHO conducted a detailed outbreak investigation, with the objectives of confirming the aetiology of the outbreak and ensuring containment. Cases were now serologically confirmed, and defined as any person from Sultan Kudarat positive for henipavirus antibodies. Hence, there were 17 confirmed henipavirus cases in the outbreak (16 males, 1 female), of which 11 had acute encephalitis syndrome (AES). The rest had milder disease characterised by meningitis (n = 1) or influenza-like illness (ILI; n = 5). All of the cases had headache and fever, plus a range of other classical symptoms including difficulty of breathing, coughing, vomiting, and altered sensorium. Case onset lasted from March 10 to May 23, 2014. The incubation period ranged from 3 to 27 days (median for AES: 15 days; median for ILI/meningitis: 10 days). CFR was 83 % among cases with AES. For ten of the cases, transmission was linked to consumption of horse meat, whereas five cases had been in contact with sick humans. For two of the cases, transmission was likely to have been caused by contact with a sick horse and/or a sick human. The two AES survivors had long-term sequelae, whereas the other survivors did not experience sequelae.

In the two villages, 11 horses had died, and four cats had died after eating horse meat. It was found that horses were often tethered day and night, in forests where bats roosted. Potential food sources for flying foxes were available. Eighty percent of the horses had neurological symptoms, and four died of AES within 12 hours after initial onset of symptoms. In a case-control study, infected individuals were 20 times more likely than controls to have taken care of a sick horse, and 64 times more likely to have taken care of a sick person. NiV RNA found in the Philippine outbreak had 99 % sequence homology to NiV isolates from Malaysia. However, it was not possible to isolate the replicating virus. While flying foxes were not formally confirmed to serve as reservoir in this outbreak, it remains likely that flying foxes infected the horses, which in turn infected humans that later resulted in human-to-human transmission. Since the outbreak, measures have been taken to improve nationwide readiness and surveillance of AES, yet there have been no new cases.

Lessons learned from pathology and disease course: Malaysia

Professor Kum Thong Wong, University of Malaya

Acute henipavirus infection is a multi-organ infection caused by dual pathogenetic mechanisms; 1) vasculopathy (endothelial infection, vasculitis, thrombosis, microinfarction); and 2) parenchymal cell infection (infection of organ cells). Viremia is thought to result in vascular infection, which causes vasculitis leading to thrombosis. Thrombosis, in turn, leads to vascular occlusion and microinfarction, damaging the endothelium and allowing the virus to escape and infect the parenchymal cells of the CNS, lungs, kidneys, and other organs.

Relapsing and late-onset henipavirus infections seem to be confined to the CNS, and are not accompanied by the vasculopathy of acute-phase infection. Both NiV and HeV have been demonstrated to cause relapsing or late-onset infection, resulting in inflammation and confluent (geographical) lesions of the brain – as opposed to the necrotic plaques seen in acute infection. In late-onset henipavirus infection (seen to affect 3.4 % of cases), the patient does not experience encephalitis in the acute phase – instead, encephalitis occurs weeks, months, or years later. In relapsing henipavirus infection (observed in 7.5 % of cases), the encephalitis experienced during the acute phase recurs at a later time.

Viremia has never been documented for henipavirus infection, though it is believed that viremia is a prerequisite to account for the ability of the virus to affect multiple organs. One hypothesis explaining the differences seen between acute and relapsing/late-onset encephalitis, is that the viral foci observed in acute encephalitis are disseminated by viremia, whereas relapsing/late-onset encephalitis involves the recurrence of infection from residual foci. In some cases, the confluent lesions typical for relapsing/late-onset infection is seen very early, even in the acute phase. More clinical and animal model data (ideally in an animal model for relapsing/late-onset infection, which has not yet been developed) is necessary to address the mechanisms behind the observed differences in pathogenesis between cases. Possible factors influencing the development of relapsing/late-onset encephalitis include 1) viral dose; 2) pathogen virulence and mutations during the infection (as seen with measles, which along with NiV and HeV is a paramyxovirus); 3) host immunosuppression (also seen with measles).

Session 6 Q&A

Q: Could the reduced mortality of NiV upon human-to-human transmission indicate that the virus is attenuated upon replication in humans?

A: There is no data to support this. Another relevant factor is the dose of virus given through the different routes of transmission.

Q: Is there any evidence of "barking coughing" in superspreaders of NiV, as there has been for superspreaders of measles virus?

A: Not too much is known about the superspreaders of NiV, who often do not present themselves at hospitals, though all of the transmitters have respiratory symptoms. The superspreader from the Kerala outbreak did have a prolonged cough.

Q: What protective measures were available for HCW during the first Kerala outbreak?

A: The HCW had access to gloves and masks, but it is not clear to what extent the measures were adhered to. Two HCW got infected, of which one died (the nurse who cared for the index case, who vomited and was very ill).

Q: In the Philippine henipavirus outbreak, there were five dogs identified with antibodies against NiV. Were you able to eliminate the possibility of anyone being infected by these dogs, who had been infected?

A: All the identified cases had been in contact either with a sick horse or a sick person, as revealed through interviews. Contact with dogs did not come up as a likely source of transmission.

Q: What have been the measures implemented for bat surveillance on the Philippines, and what has been found, so far?

A: In 2014, 144 bats were sampled, of which six were positive for NiV antibodies. Whether subsequent surveys in bats have been conducted is not clear.

C: Prof. Wong mentioned a lack of data in animal models concerning variations in CNS tropism among the different NiV strains. In ferrets, there are no apparent differences between NiV-B and NiV-M. However, some differences have been observed between wild-type and W- or CW knockout animals.

A: Thanks. To get the full picture, it is recommended to do pathology on complete sections of the brain, not just fragments.

C: Autopsies have so far not been available in Bangladesh, but could be instructive for improving our understanding of CNS-involvement in Nipah disease, as well as for the development of therapeutics.

A: Yes.

Q: Are there any pathological similarities between the rare subacute sclerosing panencephalitis (SSPE) following measles infection and relapsing/late-onset encephalitis in henipavirus infection?

A: SSPE typically occurs 6-7 years after measles infection, in a slow process where the brain shrinks and the patient eventually dies. In contrast, cases with relapsing/late-onset encephalitis typically survive. Neurons are the target for both viruses, but the progress is slower in SSPE.

SESSION 7 – Epidemiological needs for clinical trials

Chair: Dr. Jakob Cramer, CEPI

Approaches to demonstrate the effectiveness of Nipah vaccines

Dr. Marie-Pierre Preziosi, WHO R&D Blueprint (on behalf of Ana María Restrepo, WHO R&D Blueprint)

There are several pathways for bringing a new vaccine to licensure: 1) *Traditional approval* (the gold standard), based on a randomised controlled trial (RCT) with clinical endpoint or accepted correlate of protection; 2) *Accelerated approval* for therapeutics with considerable benefit over existing therapies (breakthrough status, based on preliminary clinical data) that are also considered PRIority MEdicines (PRIME); 3) *Animal rule* (only U.S. Food and Drug Administration [FDA]), or the somewhat corresponding *Exceptional circumstances* (EMA), where approval is based on animal studies due to inability to conduct clinical trials for serious or life-threatening conditions; 4) *WHO emergency use listing (EUL)*, which is a time-limited approval for use during public health emergencies of international concern (PHEIC), based on basic clinical safety data and/or immunogenicity data. In addition, there is a separate procedure for immune markers, provided they are reasonably likely to predict protection against disease. As indicated, the amount of evidence required for each pathway varies, and data missing at the time of licensure must be provided in a timely fashion post licensure.

WHO R&D Blueprint works to ensure a systematic approach to accelerated development of vaccines (Vx), therapeutics (Tx), and diagnostics (Dx), including the development of a baseline situation analysis (BSA), an R&D roadmap, TPPs, as well as trial designs for therapeutics and vaccines. For Nipah, this work is well underway, with trial designs already established. The main challenge for a Nipah vaccine trial is sample size, since outbreaks occur irregularly – as is true for all EIDs. The advantage of Nipah is that outbreaks do occur relatively frequently, with some regularity for example in Bangladesh. The TPP for a NiV vaccine includes two distinct use cases: 1) Preventing disease in a non-emergency setting through vaccination of populations living in endemic areas, as well as HCW; 2) Protection of individuals at risk in the area of an ongoing outbreak. In a population, everyone should be considered for vaccination, including pregnant and lactating women. End points to be considered for a vaccine trial include laboratory-confirmed Nipah clinical illness as the primary end point, as well as death and infection as secondary end points. Individual randomisation should be done within each study site. All study participants should be screened for seropositivity before vaccination, to allow for exclusion or stratification of seropositive individuals. If included and stratified, differences between groups of individuals with or without a history of NiV infection could serve to inform the design of an immune correlate of risk and/or surrogate of protection. The development of a correlate of protection, as noted in the TPP, requires availability of validated and standardised immunogenicity assays. Both neutralising antibodies and cell-mediated immunity appear to have a role in preventing NiV infection. Correlates of protection may vary across vaccine platforms.

In the absence of RCTs, observational studies such as case-control studies can provide valuable evidence. Suitable controls could be test negative (without circulating evidence of Nipah infection) or standard, matched controls from the same communities. This requires a population with high but partial vaccine coverage (< 90 %). An alternative approach would be to design a one arm study with a prospective cohort of unvaccinated individuals. Such a design involves challenges in terms of selecting comparator, choosing statistical methods, as well as adjusting for key confounders, but could provide additional evidence. Obviously, a highly effective vaccine will yield more robust results, regardless of the design. Furthermore, one powerful approach could be to conduct studies (observational studies or RCTs) across several outbreaks with a standardised protocol and blinding until the data monitoring committee deems the results of the trial to be conclusive and motions to end the trial for safety, efficacy, or futility reasons. In such a setting, care must be taken with α–spending (the overall probability of error), blinding for analysis, and comparability of risk in clusters as more are added to the trial.

Resolving epidemiological uncertainties to inform development of Nipah countermeasures

Professor Steve Luby, Stanford University

Some epidemiologic uncertainties remain for Nipah, which must be addressed before we can progress to licensure of therapeutics and vaccines. There are about a dozen promising therapeutics in the pipeline for treating NiV infection, but to test just one of them will require a clinical RCT with 132 Nipah patients (based on the assumptions of improving the survival seen in India and Bangladesh from 25 % to 50 %, as well as having 80 % power and 95 % two-sided confidence). Over the last 18 years, India and Bangladesh have seen 377 Nipah cases. In order to reach 128 study participants, all of the cases in the past eight years would need to be included, with no dropouts. Thus, it will only be feasible to test one therapeutic or one package of therapeutics for Nipah, and the question is how to select the most promising candidate(s) for testing.

Or, perhaps, are there undetected Nipah cases that could improve the situation? In Bangladesh, most of the cases from 2007 to 2014 were detected near the surveillance hospitals, which are typically situated in urban areas where people do not consume date palm sap. Correcting for health care utilisation among patients with symptoms of meningo-encephalitis, it was estimated that 48 % of the outbreaks were left undetected. Resolving this epidemiological uncertainty, through improved surveillance and access to rapid diagnostics, could help improve the power of Nipah clinical trials. Another prerequisite for clinical testing is clinical trial capacity in endemic, under-resourced settings.

How much can we shorten the time between outbreak detection and enrolment? This will be a critical parameter in terms of identifying cases. One challenge (in Bangladesh, which probably has the best NiV surveillance system in the world) is that epidemiologists are usually called in only at the end of an outbreak, when most of the cases have already died or recovered. This precludes enrolment in a clinical trial. Multiple strategies for early detection and enrolment could be tested.

Is it possible to test Nipah vaccine efficacy in humans? Applying the ring vaccination trial design that was successfully used for testing a vaccine against Ebola, with immediate and delayed vaccination of contacts of cases, would require 516 years with the NiV incidence observed over the past 15 years. Thus, in the absence of a large NiV outbreak, this strategy will not work for Nipah. Using a cluster randomised RCT design measuring prevention of spillover infections and onwards transmission will reduce time and allow for vaccination beforehand, yet a study including the entire population of the Faridpur and Rajbari districts of Bangladesh (who see the most Nipah cases; 3 million people) would still take 81 years to accumulate a sufficient number of cases and reach conclusive results. In contrast, a case-control study with vaccination of the same population and recruitment of 10 matched controls whenever a case is identified would require only 7 years to be completed (provided 70 % vaccine coverage). Such a study is within the realm of the possible, and would yield data on the effectiveness of a vaccine (case-control efficacy estimates of other vaccines have generally aligned with RCTs). Notably, a study like this is easier to implement with a single dose vaccine, and increasing case identification would improve power.

Some years have shown higher spillover rates than others. Understanding the reasons for this could improve our ability to model future outbreaks and design successful clinical trials for therapeutics and vaccines. Variations in viral shedding from bats, temperature, and ecological stress have all been suggested to impact spillover rates. Another epidemiological uncertainty that is worth resolving, is the apparent decrease in spillovers in Bangladesh during the past few years, correlating with fewer people in Bangladesh consuming date palm sap (in accordance with guidelines from the public health authorities). Is the number of cases actually declining, and how will this affect future clinical trials? The conclusion is that it should be possible to clinically test one therapeutic regimen and one vaccine against Nipah, though the international community will need to come together to decide on which candidates to advance towards clinical evaluation.

Practical issues in advancing human testing of Nipah vaccines in Bangladesh

Dr. K Zaman, icddr,b

With its five study sites across Bangladesh, icddr,b has been involved in about 85 clinical trials, of which many have been vaccine trials (phases I-IV). The first trial involving a Nipah vaccine could conceivably be designed as a randomised phase I/II placebo-controlled trial, assessing the safety and immunogenicity of the vaccine in healthy adults and children at different doses/dosing schedules, and potentially providing some preliminary information on vaccine efficacy. Such a trial could involve about 100 participants and last for about 36 months (provided enough cases).

The Directorate General of Drug Administration (DGDA) is the national regulatory body responsible for approving new therapies for use in Bangladesh. Their objective is to ensure easy access to safe, effective, and good-quality therapeutics/vaccines at affordable prices, as well as rational and safe use of these. Moreover, they have an interest in facilitating domestic production and export, and of implementing effective surveillance systems for post-licensure follow-up. A Nipah vaccine trial at icddr,b will require approval from the icddr,b institutional review board (IRB), consisting of the Research Review Committee (RRC) and Ethical Review Committee (ERC). The study will also have to be approved by DGDA, based on the provision of 1) project summary including a summary of formerly obtained preclinical and clinical data; 2) ERC-approved study protocol; 3) IRB approval; 4) the investigator's brochure, compiling information about the vaccine from preclinical and other clinical trials; 5) informed consent form (ICF); 6) sponsor agreement; 7) good manufacturing practice (GMP) certificate for the manufacturer. Vaccine import will require the presentation of a proforma invoice, as well as the DGDA approval letter, the investigator's brochure, and the IRB approval letter.

Issues that need to be considered in relation to the development and testing of a new vaccine include: 1) Establishing preclinical and clinical study protocols; 2) Selecting study sites; 3) Implementing a Data and Safety Monitoring Board (DSMB); 4) Selecting a clinical research organisation (CRO, of which there are about 8 in Bangladesh); 5) Obtaining a clinical trial agreement (CTA) as well as material transfer agreements (MTAs); 6) Maintaining cold chain for vaccine- and sample shipping and storage; 7) Obtaining permission from the Ministry of Commerce for vaccine import. Other challenges pertaining to the conduct of a clinical trial include 1) rapid identification and enrolment of eligible participants; 2) completion of follow-up on a highly mobile study population; 3) effective management of adverse events.

Epidemiologic preparedness for Nipah vaccine/therapeutic trials

Dr. Tarun Bhatnagar, National Institute of Epidemiology, ICMR

Improving epidemiologic preparedness for Nipah trials involves 1) defining the geographic area where transmissions may occur; 2) defining the population at risk; 3) gaining a better understanding of the risk factors involved in Nipah transmission; 4) improving surveillance for rapid detection of cases; 5) understanding the natural history of disease. Important parameters for assessing the risk of Nipah transmission and guiding surveillance include 1) the distribution of fruit bats; 2) evidence of NiV infection in bats; 3) previous outbreaks of NiV; 4) high-risk behaviour in humans. Fruit bats are found all over India, and Nipah outbreaks have been seen in the North East (West Bengal) and in the South West (Kerala). Thus, a systematic, nationwide surveillance system could be necessary to be able to rapidly detect the next outbreak. With risk modelling (using information about the habitats and movements of the known NiV reservoir bats), some areas have been defined that have a higher risk of spillover, and such models may serve to guide surveillance and ensure more efficient use of available resources. A strategy for identifying Nipah outbreaks that have previously gone undetected could be the testing of archived samples from AES patients with unknown aetiology. Identifying previously unknown outbreaks would help to raise awareness about the need for improved surveillance, and could shed more light on the natural history of Nipah.

Consumption of contaminated date palm sap is a known risk factor for NiV infection, and a proposed survey plans to find the frequency of date palm sap consumption among rural residents of the six

West Bengal districts bordering Bangladesh. In addition, the number of *Pteropus medius* bat roosts near rural residents will be determined. Understanding the different behaviours that may influence the risk of Nipah transmission in different geographic regions is of importance. Outbreaks may occur in clinical settings (like in the 2001 Siliguri outbreak where 66 individuals were infected) or in family settings (like in Kerala, 2018, with 12 infected individuals). The clinical features of infection may vary from outbreak to outbreak. By the time an outbreak is detected, human-to-human transmission to secondary cases have often occurred, and it may be too late for clinical intervention with therapeutics or vaccines.

Surveillance could be facility-based or community-based, targeting different populations. Event-based surveillance for identifying Nipah cases often targets events of AES (primarily due to JE), but (in Bangladesh and India, at least) overlooks ARDS. In addition, at least two suspected cases are required to warrant further investigation. This means that many cases are likely to be left undetected. One future approach for India could be to establish sentinel sites for NiV detection in high-risk areas, and detect outbreaks through clustering of cases of AES or ARDS that occur in close geographical proximity and within a timespan of 21 days, where an algorithm serves to select samples from possible NiV cases for laboratory testing. The testing can be conducted by the > 75 laboratories in the Department of Health Research (DHR) / Indian Council of Medical Research (ICMR) Virus Research and Diagnostic Laboratory (VRDL) network.

Respiratory illness surveillance was set up in India in 2016-2018 as part of the Global Health Security Agenda (GHSA), with nine participating laboratories across the country. This system could potentially be used for identification of Nipah cases among the many patients with respiratory symptoms who are never properly diagnosed (50-80 %, depending on age group). In addition to the public healthcare system, private institutions and hospitals should be involved in the work of identifying cases and clusters, sharing the same protocols for surveillance and sample referral. Based on learnings from Bangladesh, contacts are now classified into two categories: 1) Has had contact with body fluid (blood, urine, saliva) from confirmed/probable case; 2) Has spent time in close proximity of a confirmed/probable case for ≥ 12 hrs. This allows for active surveillance and management (including isolation) of high-risk contacts, and passive surveillance of low-risk contacts. Screening contacts for NiV may identify individuals with subclinical infections: 3 of 279 close contacts from the 2018 Kerala outbreak had subclinical infection, though this has not been seen in Bangladesh.

Current epidemiological status of Nipah virus encephalitis in Malaysia in the context of vaccine/therapeutic trials

Professor Tan Chong Tin, University of Malaya

The 1998-1999 Nipah outbreak in Malaysia lasted for 8 months, spreading from the Perak district to Negeri Sembilan and Selangor districts by way of transportation of sick pigs between pig farms. The pigs were the primary source of transmission to humans, but at least one patient had been infected by his dog. Cats, horses, and goats were also infected, and could potentially have served as a source of infection to humans (it has later been shown that horses were the source of infection in the 2014 Nipah outbreak in the Philippines). Since 1999, there has not been another outbreak involving pig farms in Malaysia, partly due to increased awareness by pig farmers not to have fruit trees in close proximity to the pig sties. However, the swine industry in Asia is huge, and another outbreak may just be waiting to happen. Other livestock, such as goat, may also pose a risk. Goats represent a major Asian industry, are susceptible to NiV infection, and are herbivorous scavengers. Whether the infection of goats involves the lungs remains unknown – this could aid transmission to humans. Consumption of date palm sap is known to be a risk factor of NiV infection, and this cultural habit is found in and around Bangladesh.

The risk of direct NiV infection from bats to human is low. However, in a seroprevalence study in Malaysia, more than 10 % of the participants tested positive for antibodies against NiV. Among the 110 members of the Malaysian households affected by the 1998-1999 outbreak, 27 % had symptomatic infection and 8 % had subclinical infection with positive serology. Of the asymptomatic subjects, 16 % were found to have brain abnormalities by MRI. Relapsing encephalitis was seen in 9 % of the cases. In total, there are more than 100 Nipah survivors in Bangladesh, and the survivors experiencing relapsing disease could be suitable for participation in clinical trials for Nipah therapeutics.

Despite the absence of reported Nipah outbreaks in Malaysia for the past 20 years, transmissions may have occurred that were not detected. Cases of NiV encephalitis may have gone undetected, in Malaysia as well as in other countries of Southeast Asia. Populations at risk are those exposed to bats and other susceptible animals, as well as those consuming date palm sap. Ribavirin and other therapeutics may have a role in the management of Nipah disease. In a clinical trial with 190 patients, the 140 who received ribavirin had a 36 % reduced mortality compared to controls.

Session 7 Q&A

Q: Has the WHO R&D Blueprint considered recommending certain data formats in accumulated clinical trials to allow for aggregation of data across studies?

A: Yes, this is certainly part of the master protocol. There should be standard operating procedures (SOPs) in place to allow for similar collection and processing of data across sites.

Q: A master protocol will be extremely challenging to implement, as it involves many sites. What would you say are the ethical aspects of conducting long-term RCTs for Nipah?

A: This applies to all of the EIDs, and the best guarantee of ethical conduct is a well-designed clinical trial. A solid data monitoring committee and governance structure, with well-defined plans for study reviews (including triggers), is a prerequisite – as is the involvement of national authorities and close collaboration across sites. One good example was the testing of therapeutics against Ebola.

Q: Does WHO support each of the pathways outlined, in terms of prequalification?

A: Discussions with regulators in WHO R&D Blueprint indicate that the traditional pathway to licensure, which includes an individual RCT, is the preferred pathway. WHO believes that this is possible, also for therapies targeting EIDs.

Q: Bangladesh has a very high vaccine coverage in general. If the vaccine coverage of a NiV vaccine for clinical testing exceeds 90 %, will the clinical trial still succeed?

A: No, for a case-control study of a NiV vaccine to succeed, vaccine coverage needs to be below 90 %. However, mass vaccinating people of all ages in a clinical trial is expected to yield less coverage than the ordinary child vaccination programmes.

Q: What would happen if the NiV vaccine had 70 % vaccine efficacy instead of 90 %?

A: A poorer vaccine efficacy would require a larger trial for evaluating the vaccine, and in planning the trial you could play around with a number of factors like this. However, the main point was to discuss the feasibility of the different study designs, where the case-control design is perhaps the only one that will yield sufficient data within a feasible time frame.

C: In Bangladesh, people are willing to take a vaccine once they have seen evidence of the disease and/or effects of the vaccine.

A: There is not a simple technical response to this, but we need to understand how an outbreak is experienced by the population, in terms of fear and other emotions, and consider how this affects vaccination rates. Reaching out to the community in a good way is what will enable us to reach 70 % vaccine coverage in an outbreak setting.

C: Perhaps one should not be so pessimistic in terms of sample size, consider the success we had with bringing an Ebola vaccine to licensure. Focusing on the alternative licensure pathways, with licensure based on immunogenicity data and limited clinical data, could be more constructive.

A: This was not to pre-empt the choice of licensure pathway. Large-scale vaccination trials would provide protection, insights, and safety data, even if being part of the post-marketing follow-up.

C: Comment from U.S. FDA: Seeking licensure through the animal rule (probably more straightforward than the accelerated rule), while planning for a large-scale clinical study as part of post-marketing follow-up would be recommended.

A: That would be brilliant. There could also be a conversation between innovators and authorities on a way forward.

C: New data could change the presumptions used in sample-size modelling, so far.

A: The modelling is indicative of a potential for realising larger sample sizes, but requires field trials.

C: You never know how an outbreak develops, as seen with Ebola. It would be good to plan for alternative scenarios, where a trial spans several outbreaks given that a single one of them is not large enough to reach a conclusion. Also, experience with Ebola has taught us that improving the overall standard of care is important for acceptance in the communities affected by the outbreak and the trial. A Nipah trial should also include measures to improve the standard of care.

A: Yes, there is a need for trust in the communities, and people need to feel that when they seek healthcare they benefit from it.

Q: To FDA: If doing the alternative pathway and relying on safety data for licensure, what sample size would be required?

A: Safety data will depend on a variety of factors. There will need to be safety data from the population where a vaccine or therapeutic will be used, but these could be substantiated by global data. In general, a considerable amount of safety data is required, for licensure as well as for informing confirmatory studies post licensure.

C: Dr. Zaman's presentation on vaccine testing in Bangladesh did not mention the need for permission to use genetically modified organisms (GMOs). There may be different implications for using replication competent versus replication incompetent organisms.

A: Ok, more information about this is welcome.

Q: Phase II efficacy testing of a NiV vaccine will have to be conducted in Bangladesh or another Nipah endemic location. Are there any preferences for the location of a phase I safety trial, which could also be conducted in the country of manufacturing of the vaccine since it only involves healthy volunteers?

A: Either way works, no strong preferences.

Q: In terms of feasibility, a phase II trial would be the only opportunity for a randomised Nipah vaccine trial, though there may be ethical issues with giving placebo to at-risk individuals. Is it worth spending time on considering randomisation just for phase II?

A: Yes, randomisation is valuable since it is not known how effective the vaccine will be. Also, ethical considerations are less poignant while the efficacy of the vaccine is unknown.

Q: Were anthropologists involved in the investigations of the 2018 Kerala outbreak? If so, at what stage? What role may anthropologists have in Nipah surveillance?

A: The epidemiologists were called in late in the outbreak, after the last case had been identified. In a subsequent case-control study, an anthropologist was engaged to talk to family members and neighbours to gain a better understanding of the index case, who had been to the jungle, and his pet rabbit and dog were dead. He also enjoyed eating fruits, etc. These are valuable insights. In a comprehensive surveillance system including risk assessments, anthropological support may be included, but the plans for such a system in India have not yet been finalised.

Q: Prof. Tin, given your experience and the fact that we may only have one shot at a trial for a Nipah intervention, do you have a preference for a vaccine or a therapeutic?

A: There are pros and cons to both, therapeutics having the disadvantage that onset of therapy may be delayed, and too late to save the patient, while mass vaccination may be difficult to achieve in real life. Vaccination of targeted high-risk groups could be one way of mitigating the issue, but I would rather not conclude one way or another.

SESSION 8 – Progress and challenges in vaccine development

Chair: Melanie Saville, CEPI

Nipah vaccines: Overview

Dr. Eun-Chung Park, NIAID/NIH

Vaccines against NiV typically target glycoprotein (G) or fusion protein (F), found on the surface of the virus, which are both involved in cellular entry. Viral strains used in vaccine research include HeV, NiV-M, and NiV-B. Vaccine evaluation is conducted in a wide range of NiV-susceptible animals, including mice, hamsters, ferrets, cats, pigs, ponies, and AGM. Different vaccine platforms exist, including subunit vaccines (mostly variants of sG), nucleic acid-based vaccines, passive transfer (monoclonal or polyclonal antibodies), and numerous viral vectors. In addition to the human vaccines, there have also been made vaccines for immunisation of intermediate host animals, primarily tested in pigs.

Protection with a single dose of vaccine is very important for the ability to curb an outbreak. A number of vaccines have been tested pre-clinically with a single dose, with good results in different animal models. The degree of variability in viral sequence may be of importance to the vaccine's efficacy, since challenge with a homologous viral strain (the same NiV strain as was used in the vaccine) yields the highest level of protection.

Two important challenges in NiV vaccine development are 1) difficulty of comparing the vaccines with respect to efficacy, since results are obtained using different study protocols (dose, schedule, route of administration, route of challenge), different strains of challenge virus (NiV-B, NiV-M, HeV), and different types of animals (*e.g.*, hamster, ferret, AGM); 2) correlates of protection remain unknown. Important gaps include 1) lack of a therapeutic vaccine; 2) little is known about the T-cell response; 3) lack of vaccine targeting T-cell immunity; 4) unknown durability of protection; 5) lack of tailored adjuvants; 6) incomplete cold chain (alternatively, stability issues in the absence of cold chain).

Ending with a question to the audience: Should a bat vaccine be considered to control NiV transmission? Bats constitute the reservoir, not only of NiV but also other viruses causing disease in humans. Preventing viral shedding from bats could prevent human disease.

A subunit vaccine (HeV-sG-V) to protect against Nipah and Hendra disease

Dr. Rong Xu, Profectus BioSciences

The Profectus subunit vaccine (HeV-sG-V) is a HeV sG vaccine adjuvanted with alum. It has been marketed in Australia as a vaccine for horses (Zoetis Equivac® HeV) since 2012, and a human vaccine has now completed pre-clinical development. The pre-clinical studies that have been conducted include three rabbit immunogenicity studies, four proof-of-concept (POC) challenge studies in ferrets (one study) and AGM (three studies), and one good laboratory practice (GLP) rabbit toxicology study. Based on the data from these studies, CEPI awarded $25 million to Profectus BioSciences, Emergent BioSolutions, and PATH in May 2018, for the development of a NiV vaccine within 5 years. This work shall include 1) manufacture of the vaccine and evaluation in phase I and II clinical trials; 2) conduct of non-clinical correlate of protection studies to support licensure under the animal rule; 3) stockpiling of up to 100,000 vaccine doses for emergency use.

The vaccine substance is to be manufactured by Emergent BioSolutions, whereas the vaccine product will be manufactured by the Infectious Disease Research Institute (IDRI). GMP manufacture of vaccine substance and product for the clinical trials were completed in June and October 2019, respectively. Certificates of analysis (CoA) for the clinical trial material (CTM) to be used in the investigational new drug (IND) submission were obtained in December 2019.

Three clinical trials have been planned: 1) Phase I adult trial (U.S., $n = 192$) to assess safety and tolerability (primary endpoint), as well as immunogenicity (secondary endpoint) of the vaccine, at one and two doses of escalating dosages (10, 30, and 100 µg); 2) Phase II adult trial (endemic area, $n = 600$) to confirm safety and immunogenicity of the dose and dosing regimen selected after phase I, as well as assessing the value and timing of a booster dose; 3) Phase I/II paediatric trial (endemic area, $n = 300$) to assess safety and immunogenicity in children (2-17 years). Assays for clinical testing, including ELISA assays as well as pseudotyped vesicular stomatitis virus (VSV) neutralisation assays, for both NiV-B and NiV-M, have already been developed and verified. Interim reference standard serum from NiV-B sG + NiV-M sG immunised rhesus macaques has also been generated and characterised, as have serum pools for normal controls (NC) and low- and high-titre quality controls (QC-L and QC-H, respectively).

Profectus will now pursue the animal rule regulatory pathway, with the HeV-sG-V IND. A request for fast-track was submitted to the FDA on December 13, 2019. The phase I study is likely to commence in February 2020.

ChAdOx1 Nipah vaccine

Professor Sarah Gilbert, Jenner Institute, University of Oxford

In spite of being replication deficient, Ad used in vaccines is still able to elicit strong immune responses: Not only does the virus present the antigen, but it also elicits danger signals in the host that are powerful immune activators. This leads to a potent immune response with good immunological memory in the form of memory B- and T cells. Replication deficiency is an important safety measure to avoid dissemination in immunocompromised individuals. Using simian adenoviruses, which do not naturally infect humans, has the advantage of avoiding neutralisation of the vaccine vector upon vaccination into a patient who has already experienced human Ad infection (this has been seen for the human Ad5 vector). The antigen is expressed by double-stranded DNA fragments contained within the vector, and is not a structural part of the virion. This means that vaccines using the same strain Ad are structurally identical, streamlining the GMP production of Ad vaccines against a variety of different antigens, and eliminating the need for optimisation of each individual vaccine vector. Furthermore, the expression of antigen can be controlled by a repressor (halting expression during manufacture) and/or a mammalian promoter (inducing antigen production once injected into a human/mammalian recipient).

ChAdOx1- and ChAdOx2-vectored vaccines have been developed for a wide range of EIDs, including MERS, Lassa, Nipah, and Ebola. For each of the pathogens, a vaccine construct has already been made. The subsequent development involves 1) testing immunogenicity and capacity for inducing neutralising antibodies; 2) efficacy studies in animals; 3) obtaining funding for clinical trials; 4) phase I/II clinical testing. The Jenner Institute already has a number of vaccines in clinical development, including vaccines against pandemic flu, MERS, Zika, and Chikungunya. More than 250 volunteers have so far received a dose of ChAdOx1-vectored vaccine.

One big advantage of the ChAdOx vaccines, is that they can be thermostabilised by mixing with sugar and storing on a dry membrane. This solves the issue of maintaining a cold chain in an outbreak situation, and vaccines may be stored for months at an elevated temperature without loosing efficacy (as demonstrated for the ChAdOx1 rift valley fever [RVF] vaccine). Storing at ambient temperature will also greatly reduce the cost of stockpiling.

The ChAdOx1 NiV vaccine, expressing NiV G protein, proved to result in complete protection against NiV-B and NiV-M challenge in a study involving hamsters. A booster dose yielded higher titres of neutralising antibodies, but even one dose was protective. The vaccine was well tolerated by the hamsters, and circulating virus levels remained below the limit of detection throughout the study. The vaccine also resulted in partial protection against HeV after a single dose. Next steps for this vaccine include 1) testing in AGM 2) preparing seed stock for GMP manufacturing; 3) phase I trial in UK; 4) further studies in Bangladesh, most likely.

NiV is a pathogen for which it is really easy to demonstrate vaccine efficacy. Thus, other points are more important to consider: 1) Rapid onset of immunity; 2) One (ideally) versus two doses; 3) Duration of immunity; 4) Thermostability (long-term for stockpile, short-term for transport to clinic); 5) Safety for the whole population, including the very young, elderly, and pregnant women; 6) Plans for vaccine licensure, where immunobridging could help mitigate the issue of not being able to conduct a full-blown phase III clinical trial. In parallel to the development of vaccines, it is also important to 1) ensure the development of standardised assays (preferably cross-species); 2) make sure that clinical trial protocols are ready and available for whenever the next major Nipah outbreak occurs; 3) develop plans for vaccine licensure.

Development of measles virus-vector vaccine for Nipah virus infection

Professor Chieko Kai, University of Tokyo

Vaccines vectored by morbilliviruses such as measles virus (MV) and canine distemper virus (CDV) have been used world-wide for more than 50 years, and demonstrated excellent safety and stability, as well as good efficacy yielding life-long immunity. The MV and CDV vectors both have the capacity to express several immunogenic genes simultaneously, and are therefore attractive vector candidates for multivalent vaccines.

Using reverse genetics, the Edmonston MV strain was genetically modified to incorporate the NiV G protein and create a recombinant NiV vaccine strain (rMV-Ed-NiVG). In a golden hamster model, this vaccine (given twice, on day 0 and day 21) protected against intraperitoneal (ip) challenge with homologous rNiV (day 28), which was comparable to the results seen with rMV-HL-NiVG, a NiV G protein vector vaccine based on the wild-type MV HL strain. Other vaccine candidates using NiV G protein, but based on other MV vector strains, did not perform as well. The rMV-Ed-NiVG vaccine also protected against NiV infection in AGM, using a similar protocol.

Some concern has been raised regarding the chance of pre-existing antibodies against MV in humans affecting vaccine efficacy, but results from studies in hamster show that pre-immunisation with plain MV-Ed did not impair the ability of rMV-Ed-NiVG to elicit an antibody response. With funding from CEPI, the development of an MV-based vector vaccine against NiV will continue.

Development of a vesicular stomatitis virus-based vaccine to prevent Nipah virus disease

Dr. Gray Heppner, Crozet BioPharma LCC

The objective of Crozet BioPharma is to develop a safe, single-dose vaccine with a rapid onset of protective immunity against all Nipah strains. This work is based on experiences with the VSV Ebola vaccine, which had a rapid onset of protection of about 10 days when used in the Ebola outbreaks of West Africa and the Democratic Republic of Congo (DRC), caused by the Zaire Ebola virus (ZEBOV). The rVSV-Nipah vaccine candidate (rVSVΔG/ZEBOVgp/NiVG) is a live, attenuated recombinant VSV (rVSV) expressing NiV-B G protein, as well as glycoprotein (gp) from Ebola virus (EBOV), and is similar to Roche's now licensed rVSV-ZEBOV (Ervebo™) vaccine. The EBOV gp moiety is retained to maintain receptor-mediated viral entry of the vaccine, and support immunogenicity. A single dose of the rVSV-Nipah vaccine protects hamsters as well as AGM against NiV challenge. Furthermore, passive immunisation (in hamsters) with serum from rVSV-Nipah-immunised hamsters was protective, suggesting a role for neutralising antibodies in protection against Nipah disease.

The TPP of rVSV-Nipah include the following criteria for a successful vaccine: 1) Capable of controlling a NiV outbreak and prevent disease in high-risk groups; 2) Can be used on individuals of all ages; 3) Has a safety profile on par with WHO recommended vaccines; 4) Has > 90 % efficacy, with rapid onset of < 14 days; 5) One dose is sufficient for protection; 6) Protective for at least 6 months when used in an outbreak setting; 7) Intramuscular or subcutaneous administration; 8) Covers all circulating NiV strains (NiV-B, NiV-M); 9) Is stable for 5 years at 2-8 °C (for stockpiling); 10) Presented in 1-dose vials (liquid frozen or lyophilised); 11) Suitable for emergency use authorisation (EUA)/EUL; 12) Appropriate for WHO prequalification.

The VSV vaccine platform has certain advantages: 1) Naturally attenuated due to host range restriction (self-limited disease in horses, pigs, and cattle, but generally asymptomatic in humans); 2) Low prevalence of immunity to the vector; 3) VSV RNA does not integrate; 4) Allows for expression of large, foreign transgenes (multigenic potential); 5) Readily pseudotyped with heterologous viral glycoproteins; 6) Complete VSV G protein deletion results in attenuated phenotype; 7) VSV G protein does not elicit neutralising antibody responses targeting the vector; 8) Recombination has not been reported; 9) Strong documentation already exists for the potency of the vaccine platform (in a phase Ib trial, rVSV-ZEBOV induced rapid and long-lasting seroconversion upon a single immunisation with a wide range of vaccine doses [$n = 512$]; in the phase III trial in Guinea, 100 % efficacy was demonstrated in humans [$n = 3{,}537$]).

With funding from CEPI, pre-clinical and clinical development of the rVSV-Nipah vaccine will continue. Key activities include 1) production of CTM; 2) animal toxicology and immunogenicity/efficacy testing; 3) assay development for serology testing and virus detection/quantification; 4) defining surrogates of protection in NHPs; 5) clinical testing in phase I (U.S.) and phase II (Bangladesh) clinical trials.

F vs G Nipah vaccines: Stabilising the pre-fusion conformation of F for a fair comparison

Dr. Keith Chappell, University of Queensland

Most of the Nipah vaccines currently in development target the NiV G protein, but the F protein may also be a viable target. Before viral fusion to target cells, the F protein exists in a highly unstable pre-fusion conformation. For a fair comparison of vaccines based on NiV G versus NiV F, it is vital that the F protein is stabilised in its pre-fusion conformation. The importance of fusion proteins was first seen with respiratory syncytial virus (RSV), where antibodies targeting the pre-fusion form of the fusion protein were shown to be the ones responsible for neutralisation. These results were published in 2012.

The University of Queensland is developing a "molecular clamp" platform technology, which enables trimerisation of viral surface proteins, thereby exposing the surface protein's epitope that is primarily responsible for inducing neutralising antibodies. Trimerisation is achieved through the incorporation of a highly stable trimerisation domain into class I and III viral fusion proteins (which are trimers in their natural form). Importantly, there are a number of class I and III envelope proteins of human and veterinary importance, including MERS coronavirus (MERS-CoV), Lassa virus (LASV), and ZEBOV. The molecular clamp is a trimerisation domain based on the six-helix bundle of human immunodeficiency virus (HIV) gp41, providing very high stability and a melting temperature of about 90 °C.

The manufacture of antigen is conducted in CHO cells, which are well known to the industry, scalable, and fairly straightforward from a regulatory perspective. Protein produced in the endoplasmic reticulum naturally trimerises, are stabilised by the molecular clamp, and secreted. Monoclonal antibodies for the molecular clamp are used for purification, resulting in a high yield of soluble, pure, and stable recombinant protein. Trimerisation is verified by size exclusion chromatography and electron microscopy, and the antigens are tested against available clones of mAbs binding the neutralising epitope. With the molecular clamp platform, The University of Queensland aims to supply CEPI with highly stable reference antigens, which can be subjected to multiple freeze-thaw cycles without loosing their binding properties.

The question now is, which antigen will produce the better vaccine; sG or molecular clamp-stabilised F (mcsF)? This is addressed in the following talk.

Developing a 'One Health' Nipah virus vaccine to protect animal and public health

Dr. Simon Graham, The Pirbright Institute

Pigs played a really important role in the outbreak in Malaysia and Singapore. The damage that was done to the Malaysian pig industry in eradicating the virus is still felt today. Nipah infection in pigs results in a less severe disease, yet poses a threat to human health. In a One Health perspective, a

Nipah vaccine for pigs could reduce the severe economic consequences of an outbreak, as well as the risk for human disease.

Eight vaccine candidates for NiV were selected and compared (see Figure 10), all of which had been tested for immunogenicity in pigs, and three of which had been tested for efficacy. Six of the candidates targeted the NiV G protein, whereas two targeted the F protein. The antigens used included mRNA, protein, and viral vectors.

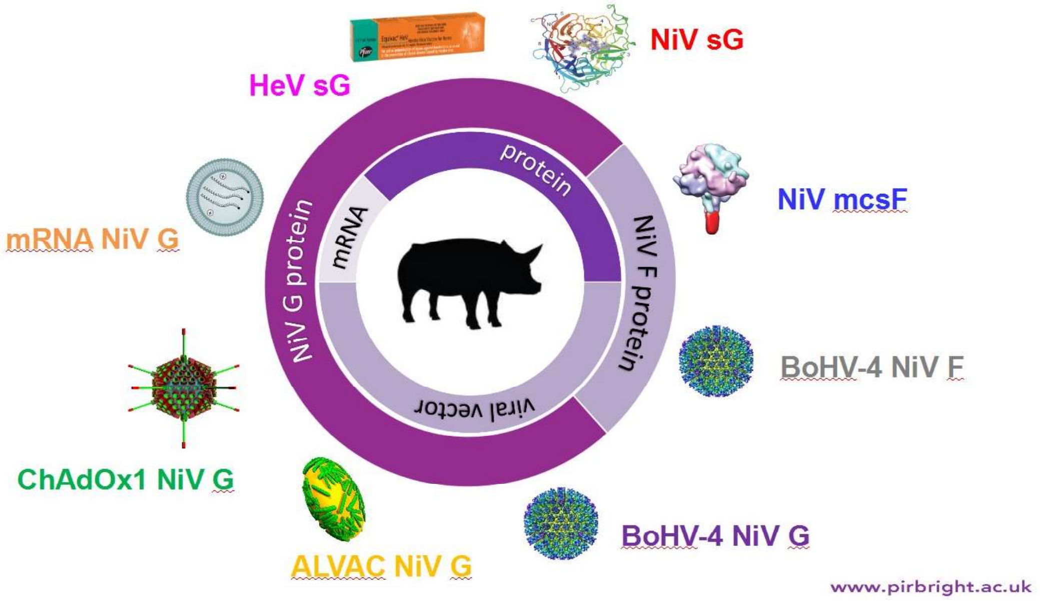


Figure 10: Nipah virus vaccine candidates (Pirbright Institute)

ALVAC-NiV G was the only one to have demonstrated protection against NiV in pigs in experimental studies. Herpes viruses (HVs) naturally stimulate very strong T-cell responses, and this property is being exploited to develop HV vector vaccines with the potential to elicit strong cell-mediated immunity. All vaccines were tested in the same regimen, with intramuscular immunisations at day 0 and day 21, and antibody titres were tested. All of the vaccines elicited NiV antigen-specific antibodies and neutralising antibodies (ALVAC-NiV G only after the second immunisation), where the NiV sG vaccine yielded the highest short-term titres. NiV sG, mcsF, and bovine HV NiV G (BoHV-NiV G) provided the highest titres of NiV cell-to-cell fusion inhibiting antibodies. The HV vector vaccines yielded the strongest T-cell responses, as measured by intracellular interferon gamma (IFN-γ) and tumour necrosis factor alpha (TNF-α) double-positive cluster of differentiation (CD) 4 and CD8 T cells on flow cytometry.

Efficacy was also tested, though only for three of the vaccine candidates (NiV sG, NiV mcsF, ChAdOx1 NiV G), with the same vaccination protocol. All three vaccines resulted in strongly reduced titres of circulating virus, as well as reduced levels of virus found in tissue biopsies, indicating a satisfactory level of protection. With immunogenicity and efficacy tests conducted, next steps include

1) testing single-shot efficacy; 2) selecting a prototype vaccine; 3) studying duration of immunogenicity and, finally, safety and immunogenicity in pigs under field conditions in Bangladesh and Malaysia.

The Pirbright Institute is also tracking NiV G-specific plasma B-cell responses, and using cell sorting to isolate NiV sG tetramer-labelled B cells. These, in turn, are cloned, and the resulting mAbs are tested for NiV G specificity. In an early attempt, one of the isolated mAbs was found to be cross-reactive to NiV sG and HeV sG, as well as neutralising in a pseudo-type assay.

Marketability of NiV vaccines for pigs may be challenging due to the sporadic nature of NiV outbreaks. An alternative strategy could be to include NiV antigen in a vaccine that is already widely used, creating a bivalent vaccine. Live attenuated porcine reproductive and respiratory syndrome virus (PRRSV) vaccines are extensively used in Southeast Asia, due to the impact of PRRSV on porcine reproduction. Reverse genetic engineering allows for expression of NiV G in PRRSV modified live virus (MLV), which could be an attractive vaccine for the veterinary market. The Pirbright Institute now hopes to test this bivalent vaccine in pigs.

Session 8 Q&A

Q: With a HeV antigen, as used in the HeV-sG-V Nipah vaccine, what are your thoughts for a HeV vaccine?

A: Regulatory work is in progress for use of the HeV-sG-V vaccine against HeV in Australia. The vaccine has been shown, pre-clinically, to be effective against both HeV and NiV.

Q: What is the intended vaccination schedule of the ChAdOx1 vaccine?

A: A single vaccination is sufficient in animals, and although both one and two doses will be tried in the phase I trial, the hope is that one dose will be sufficient to achieve protection.

Q: Can you explain the striking differences in vaccine efficacy seen with different MV strains?

A: This could potentially result from the different levels of attenuation of the different strains. For a lethal disease like Nipah, limiting side effects of vaccination through attenuation is not an objective, and one should focus on using the most efficacious strain. For less potent diseases, a broader range of the strains would perhaps provide sufficient protection, but for Nipah only a couple of the strains were potent enough.

Q: Is there a chance that VSV may persist or be shed from recipients?

A: In the clinical trials, saliva, urine, and blood will be tested for viremia. From the Ebola trials, we are aware of some shedding from adults and children. There is no precedent of VSV persisting.

Q: Can rVSV-Nipah cause neurovirulence?

A: Given the nature of NiV, neurovirulence studies will be conducted, and discussed further with the regulatory authorities.

Q: Has the molecular clamp approach been used for any other pathogen?

A: We aim to show that this approach works for a well characterised pathogen, with well-known correlates of protection, such as the flu virus.

Q: Is two-dose vaccination the standard approach when immunising pigs?

A: May be. We will see in a few months time if a one-dose regimen is effective.

Chair: There are a number of NiV vaccine candidates with very strong preclinical data, in a number of different animal models. This is encouraging in terms of succeeding in developing a Nipah vaccine, and it is encouraging to see that some of the vaccine candidates are about to commence clinical testing.

SESSION 9 – Progress and challenges in therapeutics development

Chair: Professor Benhur Lee, Mount Sinai

Putative Nipah therapeutics: pathophysiologic, target profile, and trial design considerations

Dr. Libby Higgs, NIAID/NIH

NIAID's involvement in the development of therapeutics for Nipah was originally inspired by the 2018 Kerala outbreak, with WHO requesting our support for the development of a concept and protocol for the use of Nipah therapeutics in the context of the outbreak, along with the WHO R&D Blueprint Therapeutics Trial Design working group, ICMR, and Kerala Officials. The protocol was prepared quickly, leveraging previous work, but was only approved as the outbreak ended. Monoclonal antibody shipped from Australia to be tested therapeutically in the outbreak was left unused. The work continued, however, and the ambition is to establish a feasible multinational, multi outbreak Nipah treatment protocol for establishing the safety and efficacy of candidate Nipah therapeutics (and, ideally post-exposure prophylaxis [PEP], but this work has not yet started), with the support of WHO, CDC, ICMR, and NIAID. Currently, an IRB-approved treatment protocol exists that is suitable for use internationally, and linked to more than 50 SOPs developed by ICMR. India and Bangladesh have accepted the protocol and are working to implement it, and other interested countries are encouraged to join. The short-lived nature of Nipah outbreaks requires the immediate implementation of the protocol from the start of an outbreak, and ongoing planning for such an event. Rapid implementation is facilitated by a stand-by multinational research capacity, as well as prepared sites in areas previously affected by an outbreak. In addition, mobile teams with specially adapted field equipment are preparing to respond to new outbreak areas.

Early identification of infected individuals is key to success with therapeutics. With delayed seroconversion (IgM at day 4), there is a need for rapid POC diagnostics (such as the mobile NAT developed by ICMR) and active surveillance of both pulmonary and CNS disease. We already have a fairly good understanding of the Nipah pathogenesis, supported by prospective natural history studies in NHP and humans, which will help inform the TPP for therapeutics. To facilitate access of therapeutics to future outbreaks, ICMR has taken the lead in ensuring free production and supply, as well as putting in place shipping agreements with manufacturers.

In designing a treatment protocol, a number of factors need to be considered: 1) What is the objective of the treatment (reducing morbidity/mortality, preventing infection); 2) What clinical phenotypes can be expected, based on viral tropisms; 3) How to account for NiV strain differences. There are currently a limited number of therapeutics with efficacy data in NHP and at least phase I study in humans, of which m102.4 and remdesivir are the most prominent candidates. A protocol for acute Nipah disease has now been established, but protocols for PEP in high-risk contacts and HCW are still missing. In the latter, the m102.4 is likely to be a good candidate.

Acute clinical Nipah disease phenotypes include vasculitis, encephalitis, pulmonary disease, and myocarditis, and represent a broader clinical spectrum than is accounted for in the current clinical case definitions. Thus, we may need to take on a broader set of case definitions in Nipah surveillance. The AGM model is not perfect, but it does emulate the clinical disease and is helpful for screening therapeutics. The late onset of viremia seen in animal models, due to the tropism of NiV for the smaller endothelial cells found in microvasculature, suggests that therapeutics should be able to penetrate organs and tissues. Also, it means that rapid diagnostics cannot depend on testing of peripheral blood.

The differences between NiV-B and NiV-M are challenging to account for in a multinational, multi outbreak protocol for clinical testing of therapeutics: Which strain should the studies be powered for, given the differences in mortality rates (75-100 % for NiV-B, 47 % for NiV-M)? With a DSNB with close oversight one can do both, stratified by outbreak and with different rules for the different pathogens: The DSNB can stop the study in the event of higher mortality rates, which allows for a smaller *n* with a successful therapeutic. Alternatively, one can do a pre-planned sample size readjustment. Both of these approaches have been tested in clinical trials against Ebola.

Delivering therapeutics to the brain for treatment of NiV encephalitis (and in general) has proven very difficult, due to the BBB. Tailored transporters are being developed, but are not available at this time. Ideal characteristics for a Nipah therapeutic are: 1) Quick onset of antiviral activity; 2) Effectiveness against both NiV-B and NiV-M; 3) Penetrates affected tissues and cells; 4) Long half-life for easier and safer clinical management; 5) Acceptable safety profile in humans. Monoclonal antibodies do not cross the BBB, and use in combination with a therapeutic that does, such as remdesivir, may be necessary. One could also consider using a cocktail of mAbs.

The idea is for the study protocol to run continuously, across outbreaks/strains and in different countries, to continuously optimise Nipah therapy as new treatments become available. The participants will be randomised to standard of care (SOC) plus placebo or SOC plus treatment at a 1:1 ratio. Once an endpoint has been reached, the study will be notified by the DSMB, and the study can continue with testing the new standard of care (if changed as a result of the study, for example by including m102.4 in the standard of care) with the next therapeutics candidate. For the study to be able to compare different study sites and settings, it is important that clinicians come together to establish a common standard of care. The issue with strain diversity is resolved through stratification on outbreak. In addition, one will stratify for neurologic involvement, based on a simple yes/no assessment. Due to the possibility of relapse of NiV infection (as has been the case for Ebola), a new treatment paradigm is considered where acute treatment is followed by maintenance therapy to prevent relapse from residual virus.

Monoclonal antibody countermeasures for pathogenic henipaviruses

Professor Christopher Broder, Uniformed Services University, Bethesda

NiV tropism is conferred by the Ephrin-B2 and Ephrin-B3 receptors expressed on the surface of endothelial cells, which bind NiV G. The sG was developed to study these receptors, and also with the intent of testing its use in vaccines. As it turned out, immunisation with sG elicits strong immune responses resulting in good titres of cross-reacting, neutralising antibodies in animal models. The m102.4 monoclonal antibody was identified through recombinant phage-display human antibody isolation, using HeV sG to fish out monoclonal Fab fragments from human antibody libraries. Among the identified Fab fragments, the m102.4 Fab was selected for its ability to detect both HeV and NiV with high affinity. Subsequently, it was light-chain shuffled, affinity maturated, put into an IgG1 format, and m102.4 IgG1 was produced in CHO cells for use in passive immunisation experiments.

Passive immunisation with NiV antibodies was first piloted in hamsters, using hamster serum and mouse mAbs. Prof. Broder and his team started testing with human antibodies in parallel, in the newly developed ferret model (the first study was published in 2009). They showed that intravenous transfer of m102.4, 10 hours after infection, provided complete protection against NiV in ferrets. Later, it was shown that m102.4 blocked the binding of HeV and NiV to the Ephrin B2/B3 receptors (and, thus, viral cell entry) through binding to the Ephrin B2/B3 binding sites of HeV and NiV G. Passive transfer of m102.4 also protected against NiV-M challenge in AGM, even when administered after the onset of disease symptoms (the animals survived). Thus, it is believed that the administration of a NiV neutralising antibody provides a critical window of relief in the about 10 days it takes the host's own adaptive immune system to mount an effective response against the virus. The recovered animals, even when receiving the antibody after the onset of disease symptoms, showed no signs of viral antigen in autopsied tissues. In contrast, when challenged with NiV-B, protection was only afforded when the antibody was administered prior to the onset of disease symptoms.

The demonstrated efficacy of m102.4 in animals has spurred compassionate use on a few occasions where people have been known to be exposed to HeV or NiV, with the first case being a mother and daughter having had close contact with a horse dying from HeV infection. None of the recipients got infected, and none of them had any adverse effects. The m102.4 CHO-K1 cell line has since been donated to Queensland Health for GMP manufacture of m102.4 and controlled clinical testing. Results from a dose escalation study in humans is now accepted for publication, and the antibody seems to have been well tolerated.

A cross-reactive neutralising mAb for NiV F has also been identified, the humanised version being known as h5B3.1. This, too, neutralises NiV-B and NiV-M, as well as HeV. Human 5B3.1 has been found to bind the pre-fusion conformation of F, blocking transition to the extended intermediate conformation, and thereby preventing viral entry. The antibody has been found to bind a highly conserved epitope of F, which explains its cross-reactivity. In the extended form of F, the epitope is broken.

Animal data and results from clinical testing suggest a role for mAbs as therapeutics agents against henipavirus infection. The ability to protect from disease even when administered post infection is key to the use of these antibodies as therapeutics or PEP. It is conceivable that new, optimised antibodies and the use of mAb cocktails can further enhance the therapeutic efficacy of such treatment.

Therapeutic remdesivir treatment protects African green monkeys from lethal Nipah virus, Bangladesh challenge

Dr. Emmie de Wit, Laboratory of Virology, NIAID, NIH

Notes from this presentation are not available.

Inhibition of Nipah virus infection by targeting viral cell attachment and entry

Dr. Branka Horvat – INSERM

The Ephrin B2/B3 receptors are highly conserved among different mammalian species, which is why the henipaviruses have such broad species tropisms. Using recombinant NiV expressing enhanced green fluorescent protein (EGFP), it was shown that among the leukocytes, NiV only infects dendritic cells (DCs), at low levels. It remains possible, however, that leukocytes could capture NiV particles on their surface and trans-infect other susceptible cells. The question is if this could be used to limit NiV infection therapeutically.

With an *in vitro* transinfection assay – which involved 1) co-culture of NiV and lymphocytes; 2) washing and treating the lymphocytes with different enzymes; and 3) co-culture of the lymphocytes with Vero cells, which are susceptible to NiV – it was determined that the NiV attachment receptor (assuming a receptor was involved) was susceptible to pronase and heparinase treatment. Proteoglycans (also known as glycosaminoglycans [GAG]), of which heparan sulphate (HS; similar to heparin, except membrane-bound instead of secreted) is one example, were deemed the most likely receptor candidate. It was found that CHO cells, which do not express the Ephrin B2/B3 receptors, were fully capable of transinfection, though that this ability was cancelled with treatment of heparinase. Furthermore, cells deficient of HS had a much smaller ability to trans-infect with NiV. Heparin was also demonstrated to bind NiV, and treatment of cells with heparin pre- or post infection resulted reduced cellular transinfection. Thus, transinfection was dependent on HS and could be inhibited by heparin in a competitive manner. *In vivo*, treatment with heparin devoid of anticoagulant activity (achieved by periodate oxidation treatment of the heparin) improved survival of hamsters infected with NiV. Thus, heparin is suggested as a potential low-cost co-treatment against henipavirus infection.

The function of the henipavirus F (fusion) protein involves a conformational change resulting in the insertion of a so-called "fusion peptide" domain of the protein into the cell membrane of the target cell. The domain next to the fusion peptide, the N-terminal Heptad repeat (HRN) domain, then interacts with the C-terminal Heptad repeat (HRC) domain to initiate the fusing of viral and target cell membranes. However, lipid-anchored peptides have been designed that prevent the viral fusion, consisting of a 35 amino-acid peptide, a polyethyleneglycol (PEG) sequence, and a lipid moiety (cholesterol or tocopherol). A β-galactosidase complementation reporter assay was conducted to measure fusion of viral particles to HEK-293 cells, and the best peptide candidates were tested in animal studies. Here, it was shown that intranasally administered lipid-tagged peptides resulted in 50 % survival of NiV-infected hamsters (compared to 0 % in controls). Similarly, in AGM, the lipid-tagged peptides resulted in 33 % survival of monkeys subjected to an excessively lethal NiV inoculum. Administration of the peptide by aerosolisation instead of parenteral injection reduced the observed development of neutralising Abs against the peptide. Now, the ambition is to develop a fusion-blocking peptide in the form of a nasal spray that can be used prophylactically against henipavirus infection.

Characterization of novel inhibitors of Nipah virus

Dr. Michael Lo, Viral Special Pathogens Branch, US CDC

Notes from this presentation are not available.

Session 9 Q&A

Q: Developing standard clinical treatment guidelines is important. Will there be any stage in the multinational, multi outbreak study where treatment is only given to some patients, based on randomisation?

A: Any patient would be given treatment. It is likely that late-stage patients do not respond to treatment, but they will still be included, so that clinicians will not question whether or not to include them.

C: With the experiences made in other viruses, such as HIV, it seems prudent to also use henipavirus mAbs in combination, rather than alone.

A: Actually, the fact that evidence of antigen is never seen after recovery of treated individuals suggests the opposite.

Q: Do the ferrets ever manifest neurologic disease, and have you been able to treat them at that stage?

A: The ferrets do exhibit neurologic disease. An experiment where ferrets with such symptoms have been subjected to therapy has not yet been conducted. The closest we have come, so far, is successfully treating NHP with fever.

Q: Have you measured mAb levels in the brain?

A: No, we have never looked for the presence of mAb in the brain. Based on the damage observed in the microvasculature, however, it is likely that the mAb has leaked into the CNS. We have given up on the work of tailoring mAbs for increased passage across the BBB.

SESSION 10 – Panel discussion: Collaboration & Synergy

Chair: Professor Linfa Wang & Dr. Raúl Gómez Román

1 Exchange of materials and SOPs, biobanking

Professor Benhur Lee, Mount Sinai

Throughout Nipah@20, we have heard people mention the difficulties they have experienced getting access to samples and standards. For example, Professor Steve Luby (WHO NiV R&D Roadmap) mentioned the limited availability of clinical samples as a major hurdle in the development of new diagnostics, and the WHO R&D Blueprint suggesting to create a virtual repository of clinical reference samples for use in R&D. Dr. Jillian Sacks (FIND) and Dr. Laura Mazzola (WHO) both pointed to the need for international reference standards and accessible sample repositories. Dr. John Klena (CDC) addressed the increased difficulty of sharing positive controls internationally. Thus, a centralisation of this function to an "approved" facility may be advantageous, for instance abiding to the Clinical Laboratory Improvement Amendments (CLIA) standards for laboratories.

Dr. Kim Halpin (AAHL), representing the only OIE henipavirus reference lab, advocated for an "informal" network of reference labs for henipaviruses. How about one that is *formal*, modelled after the WHO network of influenza laboratories? Dr. Yoshihiro Kaku (NIID) told of his generation of IgM positive controls from immunised macaques, but could this also be achieved through the sequencing and synthesis of mAbs? Their development of a pseudotyped VSV neutralisation assay allows for both screening and confirmatory test, in the absence of BSL-4. It is important that such techniques are shared internationally, like they offer to do, for more efficient development of diagnostics and therapeutics. Dr. Emily Gurley (Johns Hopkins) points to a weak point of current research on NiV; the inaccurate reporting of the strains used. Notably, in particular the NiV-B strain really constitutes a number of different strains, each with small genetic differences that may impact the pathogenicity and tropisms of the virus.

The best way forward in henipavirus R&D involves more proactive collaboration across fields and nations, and avoiding a practice of working in scientific silos. Biobanking and exchange of materials through a centralised entity will be beneficial, both in terms of access and the ease with which reagents may be shared. With a centralised function, legal and IP issues may be negotiated ahead of time, allowing for straight-forward sharing with vetted institutions across the world. The function could be assigned to an existing entity, such as BEI Resources or the National Collection of Pathogenic Viruses (NCPV), or to a new one. Finally, it is important to secure funding for all of the prioritised activities mentioned, such as standardised reagent generation, sequence curation, and so on.

2 Inter-nation collaboration

Sino-French NiV taskforce

Dr. Zhengli Shi, Wuhan Institute of Virology

A Sino-French agreement to collaborate on emerging infectious diseases was established in 2004, following the SARS outbreak. The collaboration involves three Chinese and ten French institutions, and has resulted in the building of a BSL-4 laboratory in Wuhan – the first of its kind in China. Pathogens studied at this facility include Lassa, Nipah, Hendra, Ebola, and other EIDs, with work conducted on cells and in small animals. The Wuhan facility offers repositories of biological resources, conducts R&D and biosafety training, and aims to be accredited as a WHO reference laboratory for one or more BSL-4 pathogens.

Nipah represents a priority pathogen for the Wuhan facility, due to 1) its ability to infect animals and humans; 2) its high mortality in humans; and 3) the prevalence of henipaviruses and henipa-like viruses in countries of Southeast Asia, including China. Work on Nipah is divided into six work packages: 1) NiV pathogenesis; 2) Epidemiology; 3) Development of a DC-based prophylactic mucosal vaccine; 4) Therapeutics development; 5) Diagnostics development; 6) Biostatistics analyses.

The Wuhan BSL-4 facility has an annual call around April for external organisations wanting access to the facility to test their own samples or use samples from the in-house repositories. In addition, they offer an international BSL-4 biosafety training course in an annual call around September. The 9th International Symposium on Emerging Viral Diseases will be held in Wuhan, China, on October 18-20, 2020.

Update from SEARO meeting and the International Research Collaboration Platform in India/Bangladesh (requirements for therapeutics trials)

Dr. Nivedita Gupta, Scientist F, Division of Epidemiology & Communicable Diseases, ICMR

Conducting a multi-country, multi-outbreak, multi-intervention clinical trial on NiV therapeutics requires regional collaboration. Thus, on three occasions so far in 2018 and 2019, scientists from across Southeast Asia have convened to discuss issues related to Nipah R&D. Preparations for a clinical Nipah trial, with support from NIH, NIAID, and the WHO Southeast Asia Regional Office (SEARO), were on the agenda. The ICMR has committed to conducting a trial, through 1) dedicated funding; 2) establishment of a multi-disciplinary trial team; 3) adaptation of trial protocol to the Indian setting; 4) developing necessary SOPs; 5) developing and validating indigenous POC PCR diagnostics; 6) signing an MOU with the Henry Jackson Foundation (U.S.) and the Serum Institute of India for production of m102.4; 7) adapting the trial protocol to the Bangladesh setting (where chances of recruiting a sufficient number of participants are the best).

The Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on NiV, but also other EIDs. The platform has decided on dengue fever as the first priority disease, with more to come. Of the 11 member states in the WHO Southeast Asia Region (SEAR), 10 participated in the second meeting of the RESEARCH Platform, on December 3-4, 2019. Here, concept proposals on six tracks concerning dengue were developed: 1) Clinical management of dengue; 2) Entomology and vector control; 3) Epidemiology and vaccines; 4) Community engagement; 5) PoC diagnostics; 6) Governance.

Comments from representatives from WHO Regional Offices

SEARO & WIPRO

WHO were not available for comment at this time.

3 Challenges in vaccine safety monitoring

Need to maximise safety monitoring across programmes

Dr. Robert Chen, Brighton Collaboration

The Brighton Collaboration was formed in 2000 with the goal to build trust in the safety of vaccines via rigorous science. Unlike efficacy, safety generally cannot be measured directly, but is inferred from the relative absence of adverse events following immunisation (AEFI). Rare AEFI are easily missed in the absence of a standard case definition. Thus, the mission of the Brighton Collaboration is to develop internationally accepted and harmonised standards for monitoring vaccine safety throughout the vaccine life cycle. They do this with the help of > 750 volunteers. In its 20 years of operation, the Brighton Collaboration has delivered > 60 AEFI case definitions, tiered by 3 levels of evidence, and including guidance for the collection and reporting of vaccine safety data. These case definitions have been endorsed by key regulatory stakeholders such as FDA, EMA, and WHO.

The Brighton Collaboration's Safety Platform for Emergency vACcines (SPEAC), which is being tailored to CEPI's needs, has the following goals: 1) To provide coordinated safety data review capacity, with a fully functional pool of potential DSMB members; a liaison observer for each CEPI vaccine trial; and a meta-DSMB to integrate safety knowledge across different products, pathogens and platforms; 2) To harmonise vaccine safety monitoring during CEPI preclinical and clinical trials, with landscape analyses for potential vaccine issues; an online vaccine safety resource of standards, templates, and tools; identifying relevant vaccine safety issues for CEPI vaccine candidates; developing new adverse event case definitions for CEPI clinical trials; and completing a standard template for communicating risk/benefit data; 3) To provide a continuous improvement framework.

4 General discussion

There was no time for a general discussion.

Confidential *Draft 19.03.2020*

Authors: Members of the International Organising Committee for Nipah@20
Target audience: scientific (mSphere)
Expected length: ideally no more than 5 pages

Draft summary/outline for mSphere

The Nipah Virus International Conference of 2019 (Nipah@20) was co-hosted by the Coalition for Epidemic Preparedness Innovations (CEPI), the World Health Organization (WHO), the U.S. National Institute of Allergy and Infectious Diseases (NIH/NIAID) and the Duke-NUS Medical School (Duke-NUS).

The Conference marked the 20th anniversary of the discovery of Nipah virus. Since its first identification in Malaysia and Singapore in 1999, the understanding of Nipah disease and its pandemic potential has advanced substantially. The Conference provided a forum to review the history and key scientific findings over the last 20 years, and to understand the current challenges in developing Nipah diagnostics, therapeutics and vaccines.

To foster international collaboration in the context of epidemic preparedness, Nipah@20 brought together 218 scientists and public health professionals working in 21 different countries around the globe. Importantly, all henipavirus-affected countries (Australia, Bangladesh, India, Malaysia, the Philippines and Singapore) were represented in the Conference, with their delegations accounting for 46% of all attendees.

In terms of outcomes, the two-day Conference created a scientific evidence-based framework to: (a) inform discussions between global health stakeholders participating in CEPI's Joint Coordination Group (JCG) on December 11, 2019, (b) discuss the creation of a Nipah-focused regulatory working group to facilitate data sharing and joint review of Nipah vaccine candidates, and (c) identify further multidisciplinary actions needed to respond to the pandemic threat posed by Nipah virus.

Highlights from the Conference are summarized in **Table 1.** The page numbers refer to the Proceedings from the Conference, which are publicly available at (**CEPI Communications** working on the branded document and website for citation).

Table 1. Highlights from Nipah Virus International Conference

	Session	Highlighted Topics in Proceedings	Page number in Proceedings
1	Historic Review of Nipah Outbreaks		
2	WHO Nipah R&D Roadmap	Policy and implementation issues: 1) Without effective therapy available at a medical facility, there is no clinical justification/incentive for testing/surveillance. 2) Development of a sound business case for product development is needed to move medical countermeasures forward.	21-22
3	Progress and challenges in surveillance of Nipah virus	1) ICMR has found several new viruses among bats and is exploring EID potential. Pathogen X implications and possible candidates for test runs of rapid response. 2) A Ghanian henipavirus sequence has been isolated in S. Africa.	27, 29

	Session	**Highlighted Topics in Proceedings**	**Page number in Proceedings**
		3) A lot of work on bat surveillance, but unclear how to translate into impact.	
4	Progress and challenges in diagnostics	1) International reference standards needed for calibration, comparison, quality controls. 2) A mobile diagnostic system (MolBio) is being used in India & Bangladesh and could have applications in epi, clinical trials, and outbreak response. ~11USD per test. 3) FLI ELISAs use sG expressed in *Leishmania tarentolae.* Could be alternative for sourcing protein for assays.	34, 35, 38
5	Pathogenesis and animal models	1) NIH working on **aerosol** challenge model in AGMs. Importantly, no apparent role for antibodies in protection against challenge! 500 pfu used. 2) UTMB using an ***intranasal*** atomization device. 2,000 – 20,000 pfu uniformly lethal in AGMs. 500,000 ***intratracheal*** in cynos, not uniformly lethal. 3) CSIRO working on ***intranasal*** challenge in ferrets. Shedding not sufficient to cause transmission, arguing against aerosol route. No animal model is yet exploring myocarditis – a key clinical attribute of the disease observed in India & Bangladesh.	41-47
6	Transmission/Case management	1) Several key clinical observations that are currently not being contemplated in animal model development, for example, myocarditis and hypoxia in ABG analysis. Would be easy to implement in animal models. 2) Relapse and late-onset henipavirus infections observed in Malaysian patients several years after the acute infection – unclear if there is viremia during relapse. No animal model for relapsing disease.	48-49, 51
7	Epidemiological needs for clinical trials	1) In the absence of randomised controlled trials (RCTs), observational studies such as case-control studies can provide valuable evidence, according to WHO. 2) A case-control study with vaccination in Faridpur and Rajbari (Bangladesh) and recruitment of	54-55, 56, 57

	Session	**Highlighted Topics in Proceedings**	**Page number in Proceedings**
		10 matched controls whenever a case is identified would require only 7 years to be completed (provided 70 % vaccine coverage), according to S. Luby. 3) DGDA, the regulatory authority in Bangladesh, has several requirements outlined on top of pg. 56. 4) 3 of 279 close contacts from the 2018 Kerala outbreak had subclinical infection. Similarly, 8 % of Nipah-infected Malaysian patients had subclinical infection with positive serology. Could be important to analyse immune responses in subclinical infections, to try to emulate this type of immunity with a vaccine.	
8	Progress and challenges in vaccine development	Someone asked if the PHV/Crozet VSV-based vaccine caused neurovirulence. G. Hepner replied neurovirulence studies are planned and will be discussed with authorities.	67-68
9	Progress and challenges in therapeutics development	1) Monoclonal antibody shipped from Australia to be tested therapeutically in the outbreak was left unused. 2) To facilitate access of therapeutics to future outbreaks, ICMR has taken the lead in ensuring free production and supply, as well as putting in place shipping agreements with manufacturers. Interesting equitable access example. 3) Other CMCs: antibodies to sG and F, though abs don't cross the brain-blood barrier; heparin as low-cost method; lipid-anchored peptides to prevent viral fusion. Working on a nasal spray with these compounds to be used prophylactically vs NiV. Keep an eye on non-vaccine MCM portfolio.	69, 73
10	Collaboration and Synergy	1) A Sino-French agreement to collaborate on emerging infectious diseases was established in 2004, following the SARS outbreak. *BSL4 labs were established in Wuhan as a result of SARS.* 2) (Before the COVID-19 days), the Wuhan BSL-4 facility has an annual call around April for external organisations wanting	75-76

	Session	**Highlighted Topics in Proceedings**	**Page number in Proceedings**
		access to the facility to test their own samples or use samples from the in-house repositories. 3) The Regional Enabler for the Southeast Asia Research Collaboration for Health (RESEARCH) Platform was established on August 28, 2019, with ICMR as secretariat. The goal of the platform is to facilitate clinical research across the region, leveraging the unique capabilities of each country and sharing expertise. With the platform in place, it will be easier to mount rapid responses to new outbreaks, and to conduct clinical trials – not only on NiV, but also other EIDs.

Hi there

I'm not sure if others have contributed to the *mSphere* article as requested by Raul (email below), but please find my contribution.
Others are welcome to build on this, if they have time. It would be great to see a few more comments to round out the summary of this amazing (and somewhat prophetic!) conference.
I think Benhur wanted this by 30th March – so I'm cutting this a bit fine – sorry.

Thanks everyone
Kind regards
Kim

Subject: [WARNING : MESSAGE ENCRYPTED]Proceedings from Nipah Virus International Conference

Dear International Organizing Committee (IOC) members for the Nipah Virus International Conference,

Please find a ***draft*** (pdf) with the Proceedings from the Nipah Virus International Conference, which took place in Singapore last December. The password for this document is [redacted]. Please consider this document under 'embargo' until cleared by the the respective Communications departments from CEPI and its Conference organizing partners (WHO, NIAID, Duke-NUS).

We hope this email finds you well. We apologise for not sharing the Proceedings with you sooner, but we hope you will understand all of us have been swamped with the present COVID-19 situation. Although we do appreciate the Nipah Conference may be perceived as less of a global priority now comparted to COVID-19, we believe the Proceedings contain relevant insights that should be shared with the global community in a pandemic situation.

Our plan is to upload a refined and cleared version of the Proceedings into a suitable online platform for distribution with our partners, ideally within 4 months of the Conference having taken place (i.e. before April 11th).

In addition, and thanks to Benhur Lee, the Editor-in-Chief for *mSphere* has also agreed to publish a *summary* version of this and we have started working on that. Please also find the *word* document with a *draft* summary of Conference. We would like to invite you to co-author this summary and edit/add comments to this **by Monday, March 30**. If you do not wish to co-author the summary, please let us know.

Again, we do recognise that this may be perceived as less of a priority now, but we hope the insights from the Conference can shed light in some of the scientific issues being discussed now. We would like to thank you again for your valuable contributions to this Conference, and we look forward to your participation in this process.

Best wishes,
Raúl

Manuscript Region of Origin: AUSTRALIA

Abstract: Background
The monoclonal antibody (mAb) m102·4 is a potent fully human antibody that neutralizes Hendra and Nipah viruses in vitro and in vivo. We investigated its safety, tolerability, pharmacokinetics, and immunogenicity in healthy adults.
Methods
In this double-blind, placebo-controlled, single-centre, dose escalation phase 1 trial of m102·4, we randomised healthy adults aged 18-50 years with a body-mass index of 18·0—35·0 kg/m2 to one of five cohorts. A sentinel pair for each cohort was randomised to either m102·4 or placebo. The remaining participants in each cohort were randomised 5:1 to receive m102·4 or placebo. Cohorts 1 to 4 received a single intravenous infusion of m102·4 at doses of 1, 3, 10, and 20 mg/kg respectively, and were monitored for 113 days. Cohort 5 received two infusions of 20 mg/kg, 72 hours apart, with monitoring for 123 days. The primary objective was safety and tolerability; secondary objectives were pharmacokinetics and immunogenicity. Analyses were completed according to protocol. The study was registered on the Australian New Zealand Clinical Trials Registry, registration number ACTRN12615000395538.
Findings
Between March 27, 2015 and June 16, 2016, 40 of 77 healthy screened adults were enrolled in the study; eight were assigned to each cohort (six received m102·4, and two received placebo). Eighty-six treatment-emergent adverse events were reported, with similar rates between placebo and treatment groups. The most common treatment-related event was headache (12 of 30 [40%] in the combined m102·4 group, and 3 of 10 [30%] in the pooled placebo group). There were no deaths or severe adverse

events leading to study discontinuation. Pharmacokinetics based on those receiving m102·4 (n=30) were linear, with a mean half-life of 16·5—27·6 days across Cohorts 1-4. The elimination kinetics of those receiving repeated dosing (Cohort 5) were comparable to single-dose recipients. Anti-m102·4 antibodies were not detected at any time-point during the study.

Interpretation

m102·4 single and repeated dosing were well tolerated, displayed linear pharmacokinetics, and showed no evidence of an immunogenic response. This study will inform future dosing regimens for m102·4 to achieve prolonged exposure for systemic efficacy to prevent and treat henipavirus infections.

Funding

Queensland Department of Health, the National Health and Medical Research Council and the National Hendra Virus Research Program.

October 16th 2019

Manuscript reference number: THELANCETID-D-19-01274

Dear Dr. De Ambrogi

We are most grateful to the Reviewers for their positive and constructive comments of our manuscript. We have addressed these comments and edited our manuscript accordingly. As requested we have submitted two versions of the manuscript, one that indicates the changes made in track changes, and the revised manuscript with all changes incorporated.

Overall the conclusions of the paper remain unchanged and we hope we have now met all requirements.

A separate document detailing our point-by-point response to each reviewer has been uploaded separately with the revised manuscript.

Thank you for your further consideration of our manuscript, and we look forward to your response.

Sincerely

A/Prof. Elliott Geoffrey Playford MB,BS; MMed; PhD; FRACP; FRCPA

Editor's comments

1- Why three years have passed between the conclusion of the trial and the submission of the paper? I have sent you an email with this question but I did not receive any reply. It is very important for us to have an answer because this is something that can influence the final decision.

- *Author response:* The trial reported in this paper was organised and funded under an atypical arrangement, i.e. this was not funded and sponsored under the auspices of a pharmaceutical company, rather by a state health department in Australia. This was the first clinical trial our Department had sponsored, and as such it meant we had to contract some of the expertise required, as well as develop clinical trials processes and approvals where none existed. Study reports and reporting had to pass through a more complex approval process than would normally be the case, and unfortunately were sometimes held up in this chain awaiting approval from busy people with competing priorities. Given the novelty of our findings, and their relevance to current henipavirus epidemiology, we believe the paper is still current and appropriate for publication in Lancet Infectious Diseases.

2- Is there any plan to move forward with the development of m102•4 in other clinical studies? I realize the difficulty to test the antibody in clinical cases given the relative rarity of the infections but it would be useful to have at least a line in the paper mentioning what is planned next.

- *Author response:* The primary objective of the reported clinical study of m102.4 was to assess its safety and, hence, to support its use as post-exposure prophylaxis in persons in Australia who have been exposed to Hendra virus (usually through contact with infected horses). Having achieved this objective, we will continue to undertake ongoing observational surveillance of the effectiveness of risk assessment (i.e. as to the decision to offer m102.4 post-exposure prophylaxis) and of post-exposure prophylaxis in such contacts.

  Although we anticipate that clinical cases of human Hendra virus infection to be rare (given the rapid and extensive nature of public health contact tracing following any equine cases in Australia), we would plan to utilise m102.4 in a therapeutic context should a human clinical infection eventuate. Observational clinical and pharmacokinetic evaluation would then be undertaken.

3- Even if the study is a dose escalating trial, I cannot find any mention of the dose that would be chosen for future studies/clinical practice. Could you clarify this point in the text, please?

- *Author response:* All humans offered post-exposure m102.4 in Australia have been dosed at ~20mg/kg as a single dose (as outlined in Supplementary Table 2). Given the safety data from the reported phase 1 trial, together with previously reported animal challenge studies, this dosing regimen remains that recommended in Australia for post-exposure prophylaxis. Regarding dose recommendations for established infection, we feel that, based upon the two African green monkey studies (refs 23 and 24), a regimen that involves two doses of 20mg/kg separated by 48 hours would be appropriate.
- *Manuscript amendments:*
  - We have therefore amended the final sentence in the third last paragraph in the Discussion to now read "The safety profile of both single and repeat dosing of m102·4, and the standard elimination pharmacokinetic profile presented in this study, underpins the current standard of care to offer *a single dose of 20mg/kg of m102·4* to humans with high levels of exposure to HeV and NiV.

    - Further, a new final sentence to this paragraph has been added that reads “It also supports its potential use for patients with established clinical manifestations of henipavirus infection; based upon African green monkey challenge studies (refs 23 and 24), two doses separated by 48 hours would seem appropriate.”

4- Two reviewers asked for more clarity about the use of the antibody and I tend to agree. Would it be used for post-exposure prophylaxis or also for therapy if the infection is confirmed? Please clarify this point in the text.

- *Author response:* As outlined above (Editor’s comments point 2), the major anticipated need for m102.4 is for post-exposure prophylaxis, although clearly, should a human clinical infection eventuate, it would also be offered.
- *Manuscript amendments:*
    - We have amended the final sentence in the Summary/Interpretation to read “This study will inform future dosing regimens for m102.4 to achieve prolonged exposure for systemic efficacy to prevent and treat henipavirus infections.”
    - We have also added the sentence described above (point #3) regarding its potential use in a therapeutic setting for established infections to the third last paragraph in the discussion.

5- It is essential that you ensure that your paper (abstract and main text) conforms as much as possible to the necessary reporting guidelines (CONSORT for randomised trials); you can find a list of these guidelines with relevant flow-charts and checklists here: http://www.equator-network.org/

- *Author response:* We have conformed as much as possible to CONSORT reporting guidelines for randomised trials.

6- Please use these formatting guidelines for RCTs as a reference when you revise the article: http://www.thelancet.com/laninf/information-for-authors/formatting-guidelines Please be aware that the Methods should go after the Introduction.

- *Author response:* We believe that we have conformed to the formatting guidelines for RCTs as outlined in the above link. Currently as submitted, the Methods section follows the Introduction on page 8

7- The word limit for the Summary is 350 words so please be aware of this limit when you revise the paper.

- *Author response and manuscript amendment:* We have revised the Summary to 350 words.

8- Please give absolute numbers (numerator and denominator) not just percentages for the main results in the abstract and in the main paper (in the text, tables, or figures).

- *Author response and manuscript amendment:* We have made the requested adjustments providing both numerator and denominator with percentages in brackets in the Summary and main paper.

9- Please indicate the date of start of the trial in the Summary.

- *Author response and manuscript amendment:* The first participant was screened on 27th March 2015. We have revised the statement in the Summary regarding enrolment to

"Between March 27, 2015 and June 16, 2016, 40 of 77 healthy screened adults were enrolled in the study."

10- Please be aware that the maximum number of references is 30 (please keep the most relevant and recent).

- *Author response:* We have adhered to the maximum 30 cited references

11- Please be aware that the word count for a trial should not be over 4500 words.

- *Author response:* The revised manuscript is within the word count limit of 4500 words

12- Please ensure that you provide your figures in an editable format and as separate files they should not be part of the text). For trial profiles a word file made of editable text boxes is the preferred format. For any statistical images (histograms, survival or time-to-even curves, line graphs, scatter graphs, forest plots, etc) you should provide editable vector files (ie, the original artwork generated by the statistical package used to make the image). Our preferred formats for these files are .ai, .eps, or .pdf. We cannot guarantee accurate reproduction of images without these files.

- *Author response:* The figure(s) have been provided as requested.

13- Be aware that the maximum number of non-text items (figures and tables) in the main article is six. You have five non-text items at the moment so if you add more than one table/figure, something will need to be moved to the Appendix (that should be a single PDF file with page numbers). The flow chart and the table with the baseline characteristics need to be in the main article. In the text, any reference to the Appendix (including tables and figures) must be something like "Appendix, page X".

- *Author response:* We have not added any further non-text items. We have added the relevant page numbers where the Appendix has been referenced.

14- Please check that all authors' names and affiliations are correct.

- *Author response:* All authors' names and affiliations are correct

15- All authors should complete and sign the author statement form and upload the signed copy (just check if you have sent already all forms). The form can be downloaded from the page (http://www.thelancet.com/for-authors/forms#author-sigs) from the fourth line of "Authors and contributions". The corresponding author must countersign manually the forms at the bottom of the page and send us the scanned version. Electronic signatures are accepted.

- *Author response:* Signed author contribution forms were uploaded with the original submission.

16- All authors are required to provide a Conflict of Interest Statement and should complete a standard form, which is available at http://www.thelancet.com/for-authors/forms#icmje-coi. This form can be uploaded with the manuscript at submission. (Just check if you have already sent all forms)

- *Author response:* Completed Conflict of Interest Statements from all authors were uploaded at submission.

17- Please also include written consent of any cited individual(s) noted in acknowledgments or cited as personal communications.

- *Author response:* Individuals cited in Acknowledgments have provided written consent which have been uploaded with the resubmission. No personal communications were cited in the manuscript.

Reviewers' comments:

Reviewer #1: The present double-blind, placebo-controlled, single-centre, phase 1 RCT was performed to examine the safety and tolerability of single and double intravenous doses of the human monoclonal antibody m102.4. The trial participants were recruited at one centre, in Queensland, Australia, between April 2015 and June 2016. The authors concluded that the treatment and repeated dosing is safe and well tolerated by healthy adult volunteers. The manuscript is very clearly written including the study design and statistical analysis. There was no formal sample size calculation, which is not surprising considering this was a phase 1 trial. I only have a couple of minor comments that the authors may wish to consider:

How were participants allocated to the cohorts and how were the sentinel pair selected? Were cohorts completed by after the other in that the first 8 volunteers allocated to cohort 1 and then cohort 2 and so on? Were the first two volunteers in each cohort allocated as the sentinel pair?

- *Author Response:* The two sentinel individuals were randomized to m102.4 or placebo a minimum of 14 days before the remaining six participants for all cohorts. This allowed review of safety and tolerability data by the Principal Investigator and Medical Monitor. The decision to progress to the next higher dose was made after safety and tolerability data was reviewed for each dose group. Repeat dosing (Cohort 5) did not commence until all pharmacokinetic data was reviewed for Cohorts 1-4 (see Appendix pgs 3 & 19).
- *Manuscript amendments:* We have added the following statement just before the last sentence of the second to last paragraph of Randomisation and Masking sub-section: "*The decision to progress to the next higher dose was made after safety and tolerability data was reviewed for each dose group. Repeat dosing (Cohort 5) did not commence until all pharmacokinetic data was reviewed for Cohorts 1-4 (see Appendix pgs 3 & 19).*"
-

Reviewer #2: This study analyzes the use of a human monoclonal antibody in a rand. The antibody was overall well tolerated up to 20 mg per kg with one to two inoculation. The antibody showed a reasonable halflife time and preserved its neutralizing ability. There are no concerns with the presented data or the design of the study.

However, this study is a toxicity study which does not provide a lot more info as previously was available. I feel this is a critical study but would be better suited for a more specialized journal because of the interest of a very restricted panel of readers.

- *Author response:* We thank Reviewer #2 for these comments. We would, however, disagree that this manuscript is more suited to a more specialized journal. Henipaviruses are an important and serious emerging zoonotic infectious threat. The paradigm of using a human monoclonal antibody with demonstrated animal model efficacy for the post-challenge prevention or treatment of infection, together with human clinical safety data (as reported in this manuscript) is applicable to other serious emerging viral infections. This approach is particularly justifiable for infections where there are no other efficacious treatments and where human efficacy data cannot be ethically obtained from later phase clinical trials.

Reviewer #3: The present manuscript by Playford et al describes the results of a phase 1 clinical trial evaluating the safety, tolerability, pharmacokinetics, and immunogenicity of m102.4, a humanized monoclonal antibody targeting the henipavirus glycoprotein. The henipaviruses Nipah and Hendra are emerging human pathogenic paramyxoviruses that can cause severe and fatal disease in patients. Hendra and Nipah virus have the potential to cause larger outbreaks in Southeast Asia and Nipah virus is listed as a priority pathogen on the WHO blueprint list. Currently, no approved vaccines or therapeutics are available for human use. m102.4 has previously been shown to be effective in preventing henipavirus induced lethal disease in the ferret and non-human primate models. Furthermore, it has already been used on compassionate grounds following exposure to Hendra virus (13 cases) and Nipah virus (1 case).

This manuscript describes results form a first in human clinical phase 1 dose-escalation study. The study outline is fairly standard for a phase 1 clinical trial. Four different doses were administered once via the intravenous route. A fifth group received the highest concentration of 20 mg/kg twice, three days apart. Overall, the administration was well received and only minor side effects, such as headache and slightly elevated ALT values were recorded. The mean half-life of m102.4 ranged from 16 to 27 days. Importantly, serum samples were able to neutralize both, Hendra and Nipah viruses in a neutralization assay for at least 8 days after administration. These data indicate that repeated dosing of m102.4 three days apart was safe and well tolerated.

Overall, the presented data are straight forward and of importance for the further development of this monoclonal antibody for future use in humans. There are few minor comments that should be addressed:

Line 57: Therapeutic application could be mentioned in addition to prophylactic treatment.

- *Author response and manuscript amendment:* see response to Editor’s comments (point #4)

Lines 150 to 159: The two strains for NiV should already be mentioned in the Introduction.

- *Author response:* We have updated the third paragraph of the Introduction which deals with NiV to include the two strains of NiV
- *Manuscript amendments:* The following statements have been added just before the second last sentence of the third paragraph of the Introduction: *“At least two strains of NiV have been identified in genetic analysis; NiV_M associated with the 1998 Malaysian outbreak, and NiV_B that has caused repeated outbreaks in Bangladesh and northeastern India.”*

Line 155: Should read "consumption of raw date palm sap".

- *Author response and manuscript amendment:* We have added the word “raw” to this sentence

Lines 299 to 300: Specify the HeV isolate and which NiV strain have been used for the neutralization assays.

- *Author response:* The HeV isolate was Hendra virus/Australia/Horse/2008/Redlands, and the NiV strain was NiV/Bangladesh/human/2004/Rajbari, R1

- *Manuscript Amendment:* This sentence has now been amended to read “Samples of HeV (HeV/Australia/Horse/2008/Redlands) and NiV (NiV/Bangladesh/human/2004/Rajbari, R1) were diluted to contain 100 $TCID_{50}$ of virus and added to the required wells.”

Lines 415 to 417: Please list reference for this statement.

- *Author response:* Broder et al (Ref # 4), listed at the end of the subsequent sentence, comprehensively reviews immunisation strategies and was intended to cover both statements. To avoid exceeding current limit of 30 references, we have not added any new references, but have now added Ref # 4 at the end of the statement at Lines 415 to 417.

Line 427: Could specify the various time points for m102.4 administration.

- *Author response:* We have added the time points to this statement.

- *Manuscript amendment:* We have deleted “at various time points post-infection” and added “beginning at 1, 3, or 5 days post-infection, and again 2 days later.”

Lines 432 to 436: It might be worth adding a brief statement regarding long-term neurological complications. These are typically not addressed in animal studies, because studies are terminated after 3 to 4 weeks. A recent study evaluating the efficacy of remdesivir in the non-human primate model for Nipah virus showed that one out of 4 surviving animals had viral RNA in brain tissue after termination of the study at day 92 post infection.

- *Author response:* We thank the Reviewer for making this point. We have already briefly mentioned the occurrence of long-term and delayed neurological complications from both Hendra and Nipah viruses (see last sentence of first paragraph in Introduction). We would be willing to make this point again in the Discussion if strongly desired, although to adhere to the required word count, we have currently left the manuscript unamended.

Line 439: Supplementary Table 2 does not contain information for the one case in the US that received m102.4.

- *Author response:* We have added the US NiV case to Supplementary Table 2. In addition, in reviewing the data in Supplementary Table, we corrected the Exposure data for Patient # 2 which should read “HeV infected horse”, NOT “HeV-infected needle-stick injury”.

Page 15 of the clinical protocol indicates that the first patient who received m102.4 already displayed progressed clinical disease and did not survive. However, in the main text of the manuscript references to patients who received m102.4 were described to have all survived. This might require some clarification.

- *Author response:* We apologise for the confusion. The patient (the first human to have ever received m102.4) was, as stated, in the terminal phase of established Hendra virus encephalitis. A small (100mg; ~1.5mg/kg) dose of the product was available and was administered on compassionate grounds. It was not expected that this would be efficacious, however, given the absence of other therapeutic options, it was given. Hence, we felt that including this patient’s details in the current manuscript together with those that received a more likely efficacious dose in a post-exposure setting (i.e. not in a setting with pre-terminal established infection) would introduce confusion.

Table 2 lists that overall 45% of the participants had infections and infestations. This is not discussed in the Results.

- *Manuscript amendment:* The following has been added to the 2nd paragraph of the Results: "*The most frequently reported events were infections and infestations, classed as mild to moderate; 13 were reported in 11 of 24 single-dose participants (45.8%), two of six (33%) repeat dose participants, and five of 10 (50%) in the pooled placebo group.*"

Reviewer #4: This clinical trial is an important step towards control of a global pandemic potential of henipavirus infection. This monoclonal antibody should be available to the affected population soon.

Minor comments are as follow:

1. NiV infected all age group people. Almost half of the cases identified in Bangladesh till date is beyond age group 18-50 years. Need discussion on this point.

- *Author response:* We thank Reviewer #4 for this comment and note that age appears to be associated with prognosis of NiV (Goh et al NEJM 2000 & Banerjee et al 2019 review article). However, in the interest of adhering to CONSORT reporting requirement, we did not feel that discussion on this point was within the scope of this report, but we agree that this warrants further investigation in an appropriately designed study.

2. In the introduction section, Page 6, line 153, the way it is written seems like, India also experience NiV outbreak almost every year, which is not true. Only Bangladesh is experiencing Nipah outbreak almost yearly. Please rephrase.

- *Author response and manuscript amendment:* We have removed the word "India" and restricted the statement to Bangladesh.

3. Page 6, line 156, "consumption of date palm sap that had been contaminated by fruit bats" is not correct. Because, though few infrared camera studies in Bangladesh have identified bat visits in shaved part of date palm tree, there is no direct evidence that the date palm sap that the cases drank was bat contaminated. Therefore, the authors might rephrase as "consumption of date palm sap that might had been contaminated by fruit bats".

- *Author response and manuscript amendment:* We have rephrased the statement to "consumption of raw date palm sap that may have been contaminated by fruit bats"

4. Page 6, line 158, I strongly feel that, to describe the gravity of the problem, authors should state corpse of human transmission of NiV has been reported from Bangladesh in 2010 (Ref: Sazzad HM, Hossain MJ, Gurley ES, Ameen KM, Parveen S, Islam MS, et al. Nipah virus infection outbreak with nosocomial and corpse-to-human transmission, Bangladesh. Emerg Infect Dis. 2013;19(2):210-7). This phenomenon was evident in other highly fatal pathogens like Ebola.

- *Author response and manuscript amendment:* We thank Reviewer #4 for the recommended reference and have included the following statement on page 6 with the recommended reference: "Corpse-to-human transmission of NiV has also been documented in a case series report of sporadic cases in Bangladesh in 2010."

5. Though the use of monoclonal antibody is targeted as a postexposure prophylaxis, the NiV cases in the community will be both primary and secondary cases. Primary cases usually take around one

week following onset of illness to tertiary surveillance hospitals. Secondary cases might be a potential candidate for monoclonal antibody as a post exposure prophylaxis. The authors may discuss about the timeline/ natural history of henipaviurs infection and scope of administering the monoclonal antibody in the field.

- *Author response and manuscript amendment:* We understand the point that Reviewer #4 is making. We believe that the amendments that we have made (see Editor’s comments points #3 and #4) addresses – in general – this point (i.e. that m102.4 may have a role in treating established henipavirus infections in addition to its role as post-exposure prophylaxis). In the interests of space, we did not feel that discussing this aspect in greater detail was justified.

Title

Safety, tolerability, pharmacokinetics, and immunogenicity of a human monoclonal antibody targeting the G glycoprotein of Henipaviruses in healthy adults: a randomised, first-in-human phase 1 study.

Summary

Background

The monoclonal antibody (mAb) m102·4 is a potent fully human antibody that neutralizes Hendra and Nipah viruses *in vitro* and *in vivo*. We investigated its safety, tolerability, pharmacokinetics, and immunogenicity in healthy adults.

Methods

In this double-blind, placebo-controlled, single-centre, dose escalation phase 1 trial of m102·4, we randomised healthy adults aged 18–50 years with a body-mass index of 18·0–35·0 kg/m^2 to one of five cohorts. A sentinel pair for each cohort was randomised to either m102·4 or placebo. The remaining participants in each cohort were randomised 5:1 to receive m102·4 or placebo. Cohorts 1 to 4 received a single intravenous infusion of m102·4 at doses of 1, 3, 10, and 20 mg/kg respectively, and were monitored for 113 days. Cohort 5 received two infusions of 20 mg/kg, 72 hours apart, with monitoring for 123 days. The primary objective was safety and tolerability; secondary objectives were pharmacokinetics and immunogenicity. Analyses were completed according to protocol. The study was registered on the Australian New Zealand Clinical Trials Registry, registration number ACTRN12615000395538.

Findings

Between March 27, 2015 and June 16, 2016, 40 of 77 healthy screened adults were enrolled in the study; eight were assigned to each cohort (six received m102·4, and two received placebo). Eighty-six treatment-emergent adverse events were reported, with similar rates between placebo and treatment groups. The most common treatment-related event was headache (12 of 30 [40%] in the combined m102·4 group, and 3 of 10 [30%] in the pooled placebo group). There were no deaths or severe adverse events leading to study discontinuation. Pharmacokinetics based on those receiving m102·4 (n=30) were linear, with a mean half-life of 16·5–27·6 days across Cohorts 1–4. The elimination kinetics of those receiving repeated dosing (Cohort 5) were comparable to single-dose recipients. Anti-m102·4 antibodies were not detected at any time-point during the study.

Interpretation

m102·4 single and repeated dosing were well tolerated, displayed linear pharmacokinetics, and showed no evidence of an immunogenic response. This study will inform future dosing regimens for m102·4 to achieve prolonged exposure for systemic efficacy to prevent and treat henipavirus infections.

Funding

Queensland Department of Health, the National Health and Medical Research Council and the National Hendra Virus Research Program.

Research in Context

Evidence before this study

We searched PubMed on May 31, 2019 for studies using the following terms: (“Hendra” OR “Nipah”) AND (“monoclonal antibody” OR “monoclonal antibodies”) without language restrictions. We restricted article type to clinical trials and species to human. There were no articles describing clinical trials of monoclonal antibodies designed for human prophylaxis. The human monoclonal antibody m102·4 binds to the same/similar region of the G glycoprotein of Hendra and Nipah viruses as the ephrin receptors. The m102·4 monoclonal antibody demonstrated protection from infection, and was effective when administered following experimental challenge with Hendra and/or Nipah viruses in ferret and non-human primate models.

The m102·4 has been available since 2010 for compassionate therapy following high-risk Hendra virus exposures. It has been used on 14 occasions (13 in Queensland, Australia and one in the United States). The safety and tolerability of the m102·4 has not been systematically assessed.

Added value of this study

This is the first study to assess the safety, tolerability, pharmacokinetics, and immunogenicity of the m102·4 in healthy adults using a variety of single dosing regimens (1 mg/kg, 3 mg/kg, 10 mg/kg, and 20 mg/kg) and a repeat dosing regimen of 20 mg/kg separated by 72 hours. The four single and one repeat dosing regimens of the m102·4 were generally safe and well tolerated, and had a half-life of 16·5–27·6 days with no observed immunogenicity associated with the m102·4.

Implications of all the available evidence

The findings of this study support the use of the m102·4 in humans following high-risk henipavirus exposure. Two doses of 20 mg/kg separated by 72 hours were as well tolerated as a single dose of 20 mg/kg.

Introduction

Nipah virus (NiV) and Hendra virus (HeV) are enveloped, single-stranded negative sense RNA viruses and the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae.*[1] Bats of the genus *Pteropus* appear to be the major natural reservoir hosts for henipaviruses, from which all bat isolates of HeV and NiV have been derived.[2,3] HeV and NiV are two emerged zoonotic, transboundary agents with uniquely broad host tropism capable of infecting at least 18 animal species across six orders of mammals, including their natural bat hosts.[4,5] HeV and NiV are highly pathogenic, and cause wide-spread infection with severe disease in multiple organ systems in at least 11 mammalian species. Fatality rates range from 40–100%.[6] In humans, HeV and NiV infection results in a systemic and often fatal respiratory and/or neurological disease.[7,8] Both HeV and NiV can also cause a relapsing of encephalitis following recovery from an acute infection; this appears to result from a recrudescence of virus replication in the central nervous system.[9]

HeV was first recognized in 1994 during an outbreak of fatal cases of a severe respiratory disease in horses and humans which occurred in the Brisbane suburb of Hendra, Australia.[10] In all, 14 horses and their trainer succumbed to infection together with the non-fatal infection of seven additional horses and a stablehand. To date, HeV has appeared in eastern Australia on 61 occasions, causing fatalities in four of seven human cases, death or euthanasia of more than 100 horses, and euthanasia of two HeV antibody positive dogs.[4,11]

A large outbreak of encephalitis in 1998 among pig farmers in Peninsular Malaysia led to the identification of NiV, a Hendra-like virus isolated from the cerebrospinal fluid of two patients.[12] Outbreaks of human cases of NiV infection have been recorded almost annually since 2001 in Bangladesh. Between 1998 and 2018, a total of 637 cases of human NiV infection with 373 fatalities were reported in South and Southeast Asia. The mode of NiV transmission was direct human contact with infected pigs, consumption of raw date palm sap that may have been contaminated by fruit bats, or human-to-human transmission.[13] Corpse-to-human transmission of NiV has also been documented in a case series report of sporadic cases in Bangladesh in 2010. [14] At least two strains of NiV have been identified in genetic analysis; NiV_M associated with the 1998 Malaysian outbreak, and NiV_B that has caused repeated outbreaks in Bangladesh and northeastern India.[15] There is considerable genetic heterogeneity in human isolates of NiV, particularly from the Bangladesh outbreaks.

This feature of NiV, in combination with transmission modes that include human-to-human, raises concerns of a pandemic potential.[16]

There are no approved vaccines or therapeutics to prevent or treat disease in humans. NiV and HeV are currently listed among WHO priority diseases for which a research and development blueprint of action to prevent epidemics has been developed.[17] Both are also emerging viruses selected for the human vaccine development initiative funded by the Coalition for Epidemic Preparedness Innovations.[18]

HeV and NiV particles possess surface projections composed of the viral transmembrane anchored fusion (F) and attachment (G) glycoproteins, which are the mediators of virus attachment and host cell infection. They are also the major antigenic targets of virus-neutralising antibodies. Both the HeV and NiV G glycoproteins bind to the host cell membrane proteins ephrin-B2 and ephrin-B3, which are highly conserved across known susceptible hosts, as reviewed by Broder and colleagues.[4] HeV- and NiV-neutralising human antibody fragments reactive to the G glycoproteins of both HeV and NiV have previously been isolated using recombinant antibody technology.[19] One monoclonal antibody (mAb), m102, possessed strong cross-reactive and neutralising activity against HeV and NiV, and was subsequently affinity matured to m102·4 , formatted as an IgG1 mAb, and produced in a CHO-K1 cell line.[20] The m102·4 epitope localises to the ephrin receptor binding site on the G glycoprotein and binds in a similar fashion as the ephrin molecule.[21] In a post-exposure NiV challenge experiment in the ferret model, a single dose of m102·4 administered by intravenous (IV) infusion ten hours after a lethal virus challenge was shown to provide complete protection.[22] The m102·4 was also shown to be effective against both NiV and HeV infection in nonhuman primates in studies designed to reflect a potential real-world infection exposure scenario,[15,23,24] highlighting clear potential for future approved human use.

In 2010, the m102·4 cell line was provided to the Queensland Government, (Queensland Health, Australia), to produce the m102·4 for compassionate emergency use in the event of high-risk human HeV exposure. Following an unprecedented number of equine HeV notifications (22 horses on 18 properties) in Queensland and New South Wales in 2011,[11] planning commenced in 2012 for the first phase 1 clinical trial of the m102·4 in human participants.[25] This trial aimed to evaluate the safety, tolerability, immunogenicity, and pharmacokinetics of single and multiple IV administrations of m102·4 in healthy participants, and was completed in 2016. Here we report the results of this safety trial.

Methods

Study design and Participants

We performed a single-centre, randomised, double blind, placebo-controlled, dose escalation phase 1 study to assess the safety, tolerability, pharmacokinetics, and immunogenicity of m102·4 in healthy adults at Q-Pharm Pty Ltd (Queensland, Australia). Ethics approval was obtained from the study site's Human Research Ethics Committee at the QIMR Berghofer Medical Research Institute before participant enrolment commenced. The study was conducted under the Therapeutic Goods Administration (TGA) Clinical Trial Notification Scheme (CTN) and in accordance with the Declaration of Helsinki, Good Clinical Practice guidelines, and the National Health and Medical Research (NHMRC) statement on ethical conduct in human research.

Healthy males and females between 18 and 50 years of age, with a body mass index of 18·0 to ≤35·0 kg/m^2 and weight ≥50 kg to ≤100 kg, normal values for blood haematology, coagulation profiles, clinical chemistry, and urinalysis results, were eligible for inclusion. Exclusion criteria included close, unprotected exposure to sick horses with an unexplained illness within 4 weeks; known exposure to potential HeV infected horses; positive tests for HIV or hepatitis B or C viruses; treatment with an investigational drug or biologic agent within 60 days; sexually active males with a partner capable of becoming pregnant; and females capable of becoming pregnant in the absence of an effective method of birth control. Use of prescription drugs within 14 days or five half-lives prior to mAb administration, and pregnancy or breastfeeding were also exclusion criteria. Additional details of inclusion and exclusion criteria are outlined in the trial protocol (appendix pg 42).

All participants understood the study requirements and treatment procedures, and were willing to comply with all study restrictions. Participants provided written informed consent before any study-specific tests or procedures were performed.

Randomisation and masking

Participants were given a sequential screening number at their screening visit. Eligible participants were assigned to one of five cohorts, each with eight participants. In each cohort, six participants were randomised to receive m102·4 , and two were randomised to receive placebo in accordance with the randomisation plan prepared and maintained by Clinical Network Services, (Queensland, Australia), the contract research organisation.

In each cohort, two individuals in a sentinel pair were randomised in a double blinded manner to receive active and placebo in a 1:1 ratio. Sentinel pairs were dosed seven days prior to the other participants in that cohort in order to detect any serious adverse advents (SAEs) in accordance with the European Medical Agency first-in-man guidelines.[26] The remaining participants in each cohort received either m102·4 or placebo (0·9% saline) in a 5:1 ratio following review of safety data by the Investigator and the Medical Monitor. The decision to progress to the next higher dose was made after safety and tolerability data was reviewed for each dose group. Repeat dosing (Cohort 5) did not commence until all pharmacokinetic data was reviewed for Cohorts 1-4 (see Appendix pg 3 & 19). As this was a single site trial with eight participants allocated to five cohorts, no block randomisation was performed.

To maintain the blinding of the study, the randomisation plan was available only to the un-blinded pharmacist. Treatment allocation was double blinded, and m102·4 and placebo were identical in appearance and volume for each participant in each cohort.

Procedures

The m102·4 drug substance for the phase 1 study was manufactured at the National Biologics Facility (NBF) located at the University of Queensland (Queensland, Australia) using a recombinant Chinese Hamster Ovary (CHO) cell line. A parent cell line was obtained from the National Institutes of Health, (Bethesda, MD, USA) and then subcloned and adapted to a serum- and protein-free commercially available medium. Cells were expanded from a qualified master cell bank using a conventional seed-train, followed by a fed-batch bioreactor process. The clarified harvest containing secreted m102·4 was subjected to a two-step purification process including MabSelect SuRe™ LX protein A and mixed mode Capto™adhere chromatography. The process included two viral inactivation/removal steps, a low pH hold, and nanofiltration (Viresolve® Pro Modus) respectively. The m102·4 was formulated at a concentration of 10 mg/mL in phosphate buffered saline pH 7·3 and aseptically dispensed into 10 mL vials at Sypharma Pty Ltd (Victoria, Australia). The final product complied with specifications commonly accepted by regulatory agencies for identity, purity, potency, and safety.

Prior to clinical studies, Good Laboratory Practice (GLP) compliant, repeat dose toxicology studies were conducted in the Sprague-Dawley rat at vivoPharm Pty Ltd (Victoria, Australia). The m102·4 was administered once per week for four weeks at doses of 0, 10, 30, and 100 mg/kg. The antibody was well tolerated and the no-observed-adverse-effect-level (NOAEL) was determined to be 100 mg/kg, the highest dose tested.

An enzyme-linked immunosorbent assay (ELISA) was developed by the NBF, then validated and used to measure the concentration of m102·4 in human serum samples at vivoPharm Pty Ltd. Briefly, serum m102·4 bound to Hendra virus soluble G protein coated on a plate, was detected with a custom rabbit anti-m102·4 horseradish peroxidase conjugate followed by the addition of 3,3',5,5'-Tetramethylbenzidine substrate. The validated assay met criteria in the relevant US guideline[27], and had a working range of 1·7–163·2 ng/mL, which corresponded to the lower and upper limits of quantitation, respectively. All samples were diluted within this working range, quantitated via standard curve interpolation, and pharmacokinetic parameters were calculated using noncompartmental techniques.

An anti-drug antibody ELISA was developed and validated to determine the presence of anti-m102·4 antibodies in human serum samples. A bridging assay design was employed where m102·4, previously coupled either with biotin or horseradish peroxidase, was mixed with serum or positive control (a custom anti-m102·4 rabbit polyclonal antibody) to form a complex which was captured onto a streptavidin coated plate. The assay procedure included an acidification step to dissociate drug-antibody complexes. The validated assay met criteria consistent with the US guidelines,[27] and had a sensitivity of 100 ng/mL. Human serum samples were considered positive if both the screening cut-point (determined statistically based on a 95% upper confidence limit from negative normal donor sera) and specificity confirmation cut-point (where excess m102·4 was added) were exceeded.

Based on animal models of Henipavirus challenge,[1,22-24,28] a target dose of 20 mg/kg was selected as the maximum dose to be tested. Treatment recipients in the five cohorts were dosed with four concentrations of m102·4. Cohorts 1 and 2 received single IV doses of 1 mg/kg and 3 mg/kg, respectively, or placebo, infused in a total volume of 100 mL of 0·9% saline. Cohorts 3 and 4 received single IV infusions of 10 mg/kg and 20 mg/kg, respectively, or placebo, in a total volume of 500 mL of 0·9% saline, while Cohort 5 received two IV infusions of 20 mg/kg, or placebo, in 500 mL of 0·9% saline 72 hours apart. All infusions were given over a 1-hour period using a peristaltic infusion pump.

Participants in Cohorts 1–4 were domiciled for a total period of 3·5 days for initial safety and tolerability monitoring, and to facilitate blood sampling for pharmacokinetics, virus neutralisation, and immunogenicity analysis. Participants received the m102·4 mAb or placebo on day 1, and follow-up assessments were scheduled on days 4, 6, 8, 15, 29, 43, 57, 85, and 113. Participants in Cohort 5 were domiciled for a total period of 6·5 days receiving a single dose of m102·4 or placebo on days 1 and 4. Follow up visits to the clinical site were scheduled on days 7, 9, 11, 18, 25, 32, 39, 53, 67, 95, and 123. For all cohorts, the final safety assessment was scheduled to occur within a maximum period of 16 weeks after the last infusion.

Dose escalation from one cohort to the next followed review and approval of safety data for at least six participants per group. In addition, blinded pharmacokinetic data for Cohort 1 was reviewed to confirm estimation of m102·4 elimination half-life. Initiation of dosing in Cohort 5 followed review of available unblinded pharmacokinetic data for Cohorts 1–4.

A virus neutralisation assay was designed and performed by the Australian Animal Health Laboratory (AAHL) located at the Commonwealth Scientific and Industrial Research Organisation (CSIRO, Victoria, Australia). Briefly, sera from five Cohort 4 participants (20 mg/kg, a clinically relevant dose) were tested against HeV and NiV to assess the ability of circulating m102·4 to neutralise each virus in samples at four different time points post-infusion (12hr, 24hr, Day 4, and Day 8). Samples were diluted to achieve an end-point for neutralisation. Control plates were set up using m102·4-spiked media + 10% normal human serum to achieve final concentrations ranging from 50 to 0·4 µg/mL. Samples of HeV (HeV/Australia/Horse/2008/Redlands) and NiV (NiV/Bangladesh/human/2004/Rajbari, R1) were diluted to contain 100 $TCID_{50}$ of virus and added to the required wells. Serum, cell and virus controls were included. Vero cell suspension was added to every well at a concentration of $4x10^5$ cells/mL. Plates were incubated at 37°C in a humid atmosphere containing 5% CO_2 for 45–60 min. Cells were examined after 3 days under an inverted microscope for cytopathic effect.

Outcomes

The primary objective of the phase 1 trial was to assess the safety and tolerability of single and multiple IV doses of m102·4 in healthy human participants; the second objective was to determine the pharmacokinetic and immunogenicity of single and multiple doses; and the third objective was to explore the pharmacodynamics of m102·4 against HeV and NiV.

The safety and tolerability of m102·4 across all cohorts was evaluated according to the following specific assessments: physical examination, clinical laboratory tests, vital signs, electrocardiogram, signs and symptoms of tolerability, infusion site reactions, and adverse events (AEs). All AEs and treatment-emergent AEs (TEAEs) were reported for participants from dosing until the end of the study. Definitions of AEs and TEAEs can be found in the trial protocol (appendix pg 50–52).

Calculated pharmacokinetic values included maximum observed drug concentration (C_{max}), time to maximum observed drug concentration (T_{max}), area under the drug concentration-time curve ($AUC_{0\text{-last}}$ and $AUC_{0\text{-inf}}$), elimination half-life ($t_{½}$), clearance (CL), and volume of distribution (V_z). We also took blood samples pre-dose and at nominal post-dose time-points for measurement of m102·4 HeV and NiV virus neutralisation, and for assessment of anti- m102·4 antibodies.

Statistical analysis

Statistical analysis comprised summary descriptive statistics of the five dose groups and placebo group. Given the exploratory nature of the study, the sample size was not based on power calculations, but was consistent with the typical sample size used for similar studies. Descriptive statistics were performed with SAS version 9·4. Pharmacokinetic data were analysed with Phoenix WinNonlinSoftware version 6·3, with pharmacokinetic listings, tables, and figures generated using SAS Software version 9·4. The study is registered on the Australian New Zealand Clinical Trials Registry, registration number ACTRN12615000395538.

Role of the funding source

The funders of the study had no role in data collection, data analysis, data interpretation, or writing of the report. The corresponding author had full access to all the data in the study and had final responsibility for the decision to submit for publication.

Results

Between 15 April 2015 and 18 February 2016, 40 participants were allocated into five cohorts as described (figure 1). All enrolled participants received their full assigned treatments and completed the study according to schedule apart from two participants in cohort 4 who failed to attend their day 43 and day 85 visits, respectively. Demographic characteristics did not vary between treatment groups (table 1).

Overall the dosage of m102·4 appeared safe and well tolerated. No deaths, life threatening events, serious adverse events, or adverse events leading to study discontinuation occurred. Across all cohorts, a total of 37 of 40 (93%) participants had at least one TEAE, with a total of 86 TEAEs reported (table 2). The occurrence of TEAEs was similar across all active treatment and placebo groups. The most frequently reported events were infections and infestations, classed as mild to moderate; 13 were reported in 11 of 24 single-dose participants (45.8%), two of six (33%) repeat dose participants, and five of 10 (50%) in the pooled placebo group. A possible association between dose and headache was noted, occurring in eight of 12 (67%) participants dosed in Cohorts 4 and 5 compared with four of 18 (22%) participants dosed in Cohorts 1–3, and three of 10 (30%) participants in the pooled placebo group. All TEAEs were resolved upon follow-up without specific intervention.

Of all TEAEs, 31 in 20 participants were considered treatment-related, occurring in three of six (50%) participants dosed in Cohort 1, two of six (33%) participants dosed in Cohorts 2, 3, and 5, five of six (83%) participants dosed in Cohort 4, and five of 10 (50%) participants in the pooled placebo group. The most common treatment-related TEAEs were headaches (10 participants: one each in Cohorts 1–3, four dosed in Cohort 4, two dosed in Cohort 5, and one in the pooled placebo group), intravenous catheter site bruising (three participants: two dosed in Cohort 3 and one in the pooled placebo group), and elevated alanine aminotransferase (ALT) levels (three participants: two in Cohort 5 and one in placebo). Of the 20 treatment-related TEAEs, 15 were rated as mild and five as moderate. Moderate TEAEs included two headaches; one each in Cohorts 4 and 5, one intravenous catheter site bruising in Cohort 3, lethargy in a placebo participant, and reduced appetite in Cohort 3. There were no severe TEAEs (Table 2).

No clinically significant changes in haematological or coagulation parameters were observed in any participant. Three participants had elevated ALT levels, two dosed in Cohort 5 and one in the pooled placebo group; Cohort 5 participants had elevated ALT levels at day 4 and 11, respectively; both findings following m102·4 administration were considered to be mild and treatment-related. ALT levels returned to normal after day 11 without intervention, and were not considered to be clinically significant (Supplementary Table 1). No other clinically significant abnormalities in biochemical parameters, urinalysis, vital signs, or ECG findings were observed. One clinically significant abnormal physical examination finding was reported in one participant dosed in Cohort 3; pityriasis rosea was noted on the arms, legs, and abdomen on day 113 but was not assessed as treatment-related. No pregnancies were reported during the study period.

All participants had negative anti-drug antibody results at days 1, 29 (Cohorts 1–4) or day 39 (Cohort 5) and day 113 (Cohorts 1–4) or day 123 (Cohort 5). Following a single dose of m102·4, the median T_{max} for Cohort 1, 2, 3 and 4 was 8, 4, 2·5, and 4·1 hours respectively. C_{max} and $AUC_{0\text{-last}}$ increased linearly with dose, with mean C_{max} and $AUC_{0\text{-last}}$ values for Cohort 4 being 692 µg/mL and 131,648 h·µg/mL, respectively (table 3 and figure 2). Concentration over time profiles demonstrated an initial rapid peak followed by a bi-exponential decline consistent with multi-compartmental distribution kinetics. The median $t_{1/2}$ was similar for Cohorts 2–4 (between 397 and 467 hours) but higher for Cohort 1 (663 hours). Relatively low inter-individual variability of pharmacokinetic parameters was observed. Among the repeat dose cohort (Cohort 5), the T_{max} and C_{max} for the first and second dose were 6 hours and 2·5 hours, respectively and 834 µg/mL and 1077 µg/mL, respectively.

Virus-neutralisation activity for both HeV and NiV was exhibited for all samples and time points tested. The viral neutralising titres ranged from 1/8 to ≥ 1/64 across all samples, corresponding to m102·4 concentrations of 2–10 µg/mL as measured by the pharmacokinetic ELISA. In 4 out of 5 participant samples, the Day 8 neutralising titre was within 1 or 2 doubling dilutions of the 12-hour sample from the same participant. For the 5th participant sample, the Day 8 neutralising titre was within 3 doubling dilutions of the 12-hour sample for HeV, and 1 doubling dilution for NiV. These results were considered to be within experimental variation, and therefore it was concluded that the m102·4 remained active for at least 8 days following mAb administration.

Discussion

In this phase 1 study we assessed the safety and tolerability of single and multiple IV doses of m102·4 in healthy human adults. All 40 participants completed the trial, with safety data indicating that m102·4 was safe and well tolerated. The maximum dose of 20 mg/kg was in-line with the human equivalent dose conversion (based on body surface area) at the NOAEL of 100 mg/kg, assigned from the 4 x weekly dosing rat toxicology study. Therefore the maximum clinical dosing of 2 x 20 mg/kg m102·4 was supported by the nonclinical data, and is a dose hypothesised to be pharmacologically relevant based on animal challenge data (see below).

TEAE reports were similar between placebo and active treatment groups. There was an increase in treatment-related headaches recorded among participants receiving single dose m102·4 compared to those administered placebo (66·7% vs 10%); there was no increase in treatment-related headaches among those with repeat dosing. Dose-related changes in ALT of three participants were noted; however these were mild abnormalities and were not considered clinically significant. There were no deaths or severe adverse events leading to withdrawals or premature discontinuations during the study. Pharmacokinetics based on those receiving active treatment (n=30) were linear, with the mean half-life ranging from 16·5 to 27·6 days across Cohorts 1–4. There was a small to moderate accumulation of mAb in those receiving repeat dose (Cohort 5), with elimination kinetics that were comparable to those receiving single dose regimens.

A variety of active immunisation strategies have been previously explored for HeV and NiV infection involving various recombinant viral vector-based vaccines in animal challenge models.[4] These studies demonstrated the possibility of inducing strong neutralising antibody response that could afford protection in livestock or an emergency-use scenario.[4] Among the most notable studies was the identification of the m102·4, the first fully-human monoclonal antibody that cross-neutralised *in vivo* all HeV and NiV isolates, including those from the Australian 1994 HeV outbreak and the Malaysian and Bangladesh NiV outbreaks. A single dose of m102·4 administered to ferrets 10 hours after lethal virus challenge was shown to be fully protective with no evidence of toxicity.[20,22]

In subsequent studies designed to closely reflect real-world human exposure, non-human primates were challenged with lethal doses of HeV and NiV by an intratracheal route, then infused twice with m102·4 mAb (15 mg/kg), beginning at 1, 3, or 5 days post-infection, and again 2 days later. Untreated control animals succumbed to disease eight days post-infection, while those in the treatment groups recovered by day 16.[23,24] Also tissue samples collected from treated animals had no evidence of infectious HeV or NiV at the termination of the study, demonstrating the potential of m102·4 to treat HeV and NiV infections in human and animal populations. A potential challenge to developing antiviral therapies for RNA viruses is their heterogeneity and mutational instability. However, the m102·4 recognises epitopes that are highly conserved among virus variants, making it unlikely that the virus will escape neutralisation due to mutation activity, and in the context of therapeutic dosing, in an immunocompetent individual.

Prior to this trial, a total of 14 individuals received prophylactic high-dose m102·4 on compassionate grounds following high level exposure to HeV (13 in Australia) or NiV (one in the United States; Supplementary Table 2). Individuals ranged from 8–59 years of age. No individual demonstrated clinical or laboratory evidence of infection prior to, or following m102·4 administration. The m102·4 administration was generally well tolerated; two individuals developed infusion-related febrile reactions to early production lots of antibody.

Because of the available data and findings on m102·4, including those presented here, the recent outbreak of NiV in Kerala, India, encouraged a number of organisations, including the Indian Council of Medical Research (ICMR), the Henry M. Jackson Foundation (HJF), the WHO, and the US National Institute of Allergy and Infectious Diseases (NIAID) and US National Institutes of Health (NIH) to work towards the development of an NiV therapeutics protocol for the use of m102·4 in the event of another outbreak of NiV in India or Bangladesh. To date, treatment for NiV has been limited to supportive care and management of acute encephalitis syndrome, as well as standard infection control practices to limit person-to-person transmission.[29] One pharmacologic option that was used for post-exposure prophylaxis during the Malaysian NiV outbreak of 1999 was the anti-viral Ribavirin. While this was associated with a significant reduction in mortality due to acute encephalitis, treatment allocation was not randomised, and the lack of clinical trial safety data beyond short-term emergency administration limits its use in outbreak circumstances.[30] The safety profile of both single and repeat dosing of m102·4, and the standard elimination pharmacokinetic profile presented in this study, underpins the current standard of care to offer a single dose of 20 mg/kg of m102·4 to humans with high levels of exposure to HeV and NiV. It also supports its potential use for patients with established clinical manifestations of henipavirus infection; based upon African green monkey challenge studies,[23,24] two doses separated by 48 hours would seem appropriate.

The main limitation of our study is the small number of participants, which is not uncommon in phase 1 studies. Also pharmacokinetic parameters were based on active treatment cohorts only consisting of 30 individuals. Future studies will be needed to ascertain the efficacy of m102·4 for treatment and prophylaxis against different viral strains of NiV and HeV virus, particularly among populations living in settings where there is the potential for an outbreak. Also, while there is no evidence of escape mutants to m102·4, the potential for this cannot be ruled out with RNA viruses. It may be necessary to consider a cocktail of mAbs with additional targets to combat the likelihood of diminished efficacy of m102·4.

In summary, m102·4 single and repeated dosing of up to two doses, three days apart appears to be safe and well tolerated when administered to healthy volunteers. Given that a 57% mortality rate has been observed from the seven known cases of human infection with HeV, and that m102·4 has demonstrated protective efficacy in non-human challenge studies, m102·4 is the most promising therapeutic opportunity to date for addressing this unmet medical need. This study will inform future dosing regimens for m102·4 to achieve systemic efficacy against HeV and NiV as post-exposure prophylaxis.

Contributors

EGP was the lead investigator involved in study design, data collection and analysis, and interpretation; TM was responsible for pre-clinical and clinical monoclonal antibody production; PPG and SMM were responsible for study design; MG was responsible for antibody quality review and data analysis; MLJ, KLH, BH, EH and KH were responsible for antibody manufacture and project management; CdB was involved in analytical and stability testing of m102·4 for clinical trial, and animal toxicology studies; RK implemented virus neutralization studies; L-FW and ILS designed and analysed virus neutralization studies;

PG and SE were involved in clinical trial study design, conduct, supervision and data interpretation; MEG was the clinical trial coordinator for patient screening procedures; SBL, HC, DES and KDL were involved in the planning and implementation phase of the clinical trial. SBL also reviewed and interpreted safety data from the trial; CCB supplied preclinical materials including the master cell bank and data on monoclonal antibody, and contributed to study design and data analysis; MGS negotiated the transfer of preclinical materials and data on mAb from the USA to Australia; DSD contributed to trial design and supplied the cell line for production of antibody for trial. All authors reviewed and approved the final manuscript.

Declaration of interests

CCB is a US federal employee; and CCB and DSD are co-inventors on US patent Nos. 7,988,971 and 8,313,746 “Human monoclonal antibodies against Hendra and Nipah viruses”; assignees are The United States of America as represented by the Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (Bethesda, MD). All other authors declare no competing interests.

Data Sharing

Data generated in this study will be shared as deidentified data. Study protocol, statistical analysis plan, and informed consent forms are available with this publication. Any additional data may be made available upon request to the corresponding author following review by the protocol team.

Acknowledgements

We thank the participants who generously gave their time to participate in this study, and without whom the study would not have been possible. We acknowledge Roz Glazebrook and Wendy Morotti (Queensland Health) for initial coordination and preparation of trial related activity, and support with maintaining the study; Terry Hurst (Q-Pharm Pty Limited) for initial preparation and planning of initial grant funding of this phase 1 clinical trial; Gary Crameri (CSIRO Australian Animal Health Laboratory) for technical assistance with virus neutralization studies. We thank Clinic Manager Sharon Rankine and the Q-Pharm clinic team. We thank Drs Sonya Bennett (Executive Director) and Jeannette Young (Chief Health Officer) of Queensland Health, for ongoing support for this project, and securing a significant portion of the funding for this trial. The manufacture of m102·4 drug substance was performed at the National Biologics Facility (NBF), at the University of Queensland. The NBF is supported by Therapeutic Innovation Australia (TIA), which is supported by the Australian Government through the National Collaborative Research Infrastructure Strategy (NCRIS) program. The authors thank Dr Sharon Johnatty of SugarApple Communications for providing medical writing support, which was funded by Queensland Health, Brisbane, Australia, in accordance with Good Publication Practice (GPP3) guidelines (https://www.ismpp.org/gpp3).

Summary

Background

~~The henipaviruses, Hendra virus and Nipah virus, are emerging zoonotic pathogens of bat origins that have been associated with poor clinical outcomes in humans.~~ The monoclonal antibody (mAb) m102·4 is a potent fully human antibody that neutralizes Hendra and Nipah viruses *in vitro* and *in vivo*. ~~Clinical trials in humans represent the next stage in the utilization of this antibody in the prophylactic treatment and prevention of deaths from henipavirus infections~~We investigated its safety, tolerability, pharmacokinetics, and immunogenicity in healthy adults.~~.~~

Methods

In this ~~We performed a randomised,~~ double-blind, placebo-controlled, single-centre, dose escalation phase 1 trial of~~study using the human monoclonal antibody~~ m102·4, we randomised h~~. H~~ealthy adults aged 18–50 years with a body-mass index of 18·0–~~– to ≤~~35·0 kg/m^2 ~~were assigned~~ to one of five cohorts. A sentinel pair for each cohort was randomised to~~in a 1:1 ratio to receive~~ either m102·4 ~~active treatment~~ or placebo. The remaining participants in each cohort were randomised 5:1 to receive m102·4 or placebo. Cohorts 1 to 4 received a single intravenous infusion of m102·4 at doses of 1, 3, 10, and 20 mg/kg respectively, and were monitored for 113 days. Cohort 5 received two infusions of 20 mg/kg, 72 hours apart, with monitoring for 123 days. The primary objective was~~ to assess the~~ safety and tolerability; secondary objectives were~~ of single and multiple intravenous doses of m102·4 mAb. We also assessed~~ pharmacokinetics and~~,~~ immunogenicity~~, and virus neutralisation~~. Analyses were completed according to protocol. The study was registered on the Australian New Zealand Clinical Trials Registry, registration number ACTRN12615000395538.

Findings

Between March 27~~April 15~~, 2015 and June 16, 2016, 40 of 77 healthy screened adults were enrolled in~~ were screened and 40 participants were enrolled in~~ the study; eight were assigned to each cohort (six ~~randomised to~~ receive~~-~~d m102·4, and~~ two randomised to~~ two received placebo~~ per cohort~~). Eighty-six~~A total of 86~~ treatment-emergent adverse events were reported,~~ by the 40 participants~~ with similar rates between placebo and ~~active treatment~~ treatment groups. The most common treatment-related event was headache (12 of 30 [40%] in the combined m102·4 group, and 3 of 10 [30%] in the pooled placebo group). ~~Thirty one events reported in 20 participants (50%) receiving m102·4 were considered treatment related, and six events were reported in five participants (50%) receiving placebo. A possible trend of treatment related headaches with m102·4 was noted; this was reported in 66.7% of participants administered single dose m102·4 compared with 10% of those administered placebo. There was no increase in treatment related headaches among those with repeat dosing.~~ There were no deaths or severe adverse events leading to study~~withdrawals or premature~~ discontinuation~~s during the study~~. Pharmacokinetics based on those receiving m102·4 ~~active treatment~~ (n=30) were linear, with a~~the~~ mean half-life of ~~ranging from~~ 16·5–~~ to~~ 27·6 days across Cohorts 1–4. ~~There was small to moderate accumulation of monoclonal antibody in those receiving a repeat dose (Cohort 5), with~~ The elimination kinetics of those receiving repeated dosing (Cohort 5) ~~that~~ were comparable to ~~those receiving a~~ single-~~-~~dose recipients. Anti-m102·4 antibodies were not detected at any time-point during the study.~~ All serum samples at all time points exhibited virus-neutralisation activity when tested *in vitro* for both HeV and NiV.~~

Interpretation

m102·4 single and repeated dosing ~~of up to two doses separated by 3 days~~ were ~~safe and~~ well tolerated, displayed ~~when administered to healthy adult volunteers. A~~ linear~~standard~~ pharmacokinetics~~ profile was observed with linear elimination kinetics~~, and showed ~~. There was~~ no evidence of an immunogenic response~~ to m102·4. Exploratory virus neutralisation studies confirmed that m102·4 remained active for at least 8 days following administration of a clinically relevant dose.~~ . This study will inform future dosing regimens for m102·4 to achieve prolonged exposure for systemic efficacy to prevent and treat~~ against~~ henipavirus infections~~es~~.

Research in Context

Evidence before this study

We searched PubMed on May 31, 2019 for studies using the following terms: (“Hendra” OR “Nipah”) AND (“monoclonal antibody” OR “monoclonal antibodies”) without language restrictions. We restricted article type to clinical trials and species to human. There were no articles describing clinical trials of monoclonal antibodies designed for human prophylaxis. The human monoclonal antibody m102·4 binds to the same/similar region of the G glycoprotein of Hendra and Nipah viruses as the ephrin receptors. The m102·4 monoclonal antibody demonstrated protection from infection, and was effective when administered following experimental challenge with Hendra and/or Nipah viruses in ferret and non-human primate models.

The m102·4 has been available since 2010 for compassionate therapy following high-risk Hendra virus exposures. It has been used on 14 occasions (13 in Queensland, Australia and one in the United States). The safety and tolerability of the m102·4 has not been systematically assessed.

Added value of this study

This is the first study to assess the safety, tolerability, pharmacokinetics, and immunogenicity of the m102·4 in healthy adults using a variety of single dosing regimens (1 mg/kg, 3 mg/kg, 10 mg/kg, and 20 mg/kg) and a repeat dosing regimen of 20 mg/kg separated by 72 hours. The four single and one repeat dosing regimens of the m102·4 were generally safe and well tolerated, and had a half-life of 16·5–27·6 days with no observed immunogenicity associated with the m102·4.

Implications of all the available evidence

The findings of this study support the use of the m102·4 in humans following high-risk henipavirus exposure. Two doses of 20 mg/kg separated by 72 hours were as well tolerated as a single dose of 20 mg/kg.

Introduction

Nipah virus (NiV) and Hendra virus (HeV) are enveloped, single-stranded negative sense RNA viruses and the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae.*[1] Bats of the genus *Pteropus* appear to be the major natural reservoir hosts for henipaviruses, from which all bat isolates of HeV and NiV have been derived.[2,3] HeV and NiV are two emerged zoonotic, transboundary agents with uniquely broad host tropism capable of infecting at least 18 animal species across six orders of mammals, including their natural bat hosts.[4,5] HeV and NiV are highly pathogenic, and cause wide-spread infection with severe disease in multiple organ systems in at least 11 mammalian species. Fatality rates range from 40–100%.[6] In humans, HeV and NiV infection results in a systemic and often fatal respiratory and/or neurological disease.[7,8] Both HeV and NiV can also cause a relapsing of encephalitis following recovery from an acute infection; this appears to result from a recrudescence of virus replication in the central nervous system.[9]

HeV was first recognized in 1994 during an outbreak of fatal cases of a severe respiratory disease in horses and humans which occurred in the Brisbane suburb of Hendra, Australia.[10] In all, 14 horses and their trainer succumbed to infection together with the non-fatal infection of seven additional horses and a stablehand. To date, HeV has appeared in eastern Australia on 61 occasions, causing fatalities in four of seven human cases, death or euthanasia of more than 100 horses, and euthanasia of two HeV antibody positive dogs.[4,11]

A large outbreak of encephalitis in 1998 among pig farmers in Peninsular Malaysia led to the identification of NiV, a Hendra-like virus isolated from the cerebrospinal fluid of two patients.[12] Outbreaks of human cases of NiV infection have been recorded almost annually since 2001 in Bangladesh~~ and India~~. Between 1998 and 2018, a total of 637 cases of human NiV infection with 373 fatalities were reported in South and Southeast Asia. The mode of NiV transmission was direct human contact with infected pigs, consumption of raw date palm sap that may have ~~had~~ been contaminated by fruit bats, or human-to-human transmission.[13] Corpse-to-human transmission of NiV has also been documented in a case series report of sporadic cases in Bangladesh in 2010.[14] At least two strains of NiV have been identified in genetic analysis; NiV_M associated with the 1998 Malaysian outbreak, and NiV_B that has caused repeated outbreaks in Bangladesh and northeastern India.[15] There is considerable genetic heterogeneity in human isolates of NiV, particularly from the

Bangladesh outbreaks. This feature of NiV, in combination with transmission modes that include human-to-human, raises concerns of a pandemic potential.[16]

There are no approved vaccines or therapeutics to prevent or treat disease in humans. NiV and HeV are currently listed among WHO priority diseases for which a research and development blueprint of action to prevent epidemics has been developed.[17] Both are also emerging viruses selected for the human vaccine development initiative funded by the Coalition for Epidemic Preparedness Innovations~~ (CEPI)~~.[18]~~[18,19]~~

HeV and NiV particles possess surface projections composed of the viral transmembrane anchored fusion (F) and attachment (G) glycoproteins, which are the mediators of virus attachment and host cell infection. They are also the major antigenic targets of virus-neutralising antibodies. Both the HeV and NiV G glycoproteins bind to the host cell membrane proteins ephrin-B2 and ephrin-B3, which are highly conserved across known susceptible hosts, as reviewed by Broder and colleagues.[4] HeV- and NiV-neutralising human antibody fragments reactive to the G glycoproteins of both HeV and NiV have previously been isolated using recombinant antibody technology.[19] One monoclonal antibody (mAb), m102, possessed strong cross-reactive and neutralising activity against HeV and NiV, and was subsequently affinity matured to m102·4 , formatted as an IgG1 mAb, and produced in a CHO-K1 cell line.[20] The m102·4 epitope localises to the ephrin receptor binding site on the G glycoprotein and binds in a similar fashion as the ephrin molecule.[21] In a post-exposure NiV challenge experiment in the ferret model, a single dose of m102·4 administered by intravenous (IV) infusion ten hours after a lethal virus challenge was shown to provide complete protection.[22] The m102·4 was also shown to be effective against both NiV and HeV infection in nonhuman primates in studies designed to reflect a potential real-world infection exposure scenario,[15,23,24] highlighting clear potential for future approved human use.

In 2010, the m102·4 cell line was provided to the Queensland Government, (Queensland Health, Australia), to produce the m102·4 for compassionate emergency use in the event of high-risk human HeV exposure. Following an unprecedented number of equine HeV notifications (22 horses on 18 properties) in Queensland and New South Wales in 2011,[11] planning commenced in 2012 for the first phase 1 clinical trial of the m102·4 in human participants.[25] This trial aimed to evaluate the safety, tolerability, immunogenicity, and pharmacokinetics of single and multiple IV administrations of m102·4 in healthy participants, and was completed in 2016. Here we report the results of this safety trial.

Methods

Study design and Participants

We performed a single-centre, randomised, double blind, placebo-controlled, dose escalation phase 1 study to assess the safety, tolerability, pharmacokinetics, and immunogenicity of m102·4 in healthy adults at Q-Pharm Pty Ltd (Queensland, Australia). Ethics approval was obtained from the study site's Human Research Ethics Committee at the QIMR Berghofer Medical Research Institute before participant enrolment commenced. The study was conducted under the Therapeutic Goods Administration (TGA) Clinical Trial Notification Scheme (CTN) and in accordance with the Declaration of Helsinki, Good Clinical Practice guidelines, and the National Health and Medical Research (NHMRC) statement on ethical conduct in human research.

Healthy males and females between 18 and 50 years of age, with a body mass index of 18·0 to ≤35·0 kg/m^2 and weight ≥50 kg to ≤100 kg, normal values for blood haematology, coagulation profiles, clinical chemistry, and urinalysis results, were eligible for inclusion. Exclusion criteria included close, unprotected exposure to sick horses with an unexplained illness within 4 weeks; known exposure to potential HeV infected horses; positive tests for HIV or hepatitis B or C viruses; treatment with an investigational drug or biologic agent within 60 days; sexually active males with a partner capable of becoming pregnant; and females capable of becoming pregnant in the absence of an effective method of birth control. Use of prescription drugs within 14 days or five half-lives prior to mAb administration, and pregnancy or breastfeeding were also exclusion criteria. Additional details of inclusion and exclusion criteria are outlined in the trial protocol (appendix pg 42). All participants understood the study requirements and treatment procedures, and were willing to comply with all study restrictions. Participants provided written informed consent before any study-specific tests or procedures were performed.

Randomisation and masking

Participants were given a sequential screening number at their screening visit. Eligible participants were assigned to one of five cohorts, each with eight participants. In each cohort, six participants were randomised to receive m102·4 , and two were randomised to receive placebo in accordance with the randomisation plan prepared and maintained by Clinical Network Services, (Queensland, Australia), the contract research organisation.

In each cohort, two individuals in a sentinel pair were randomised in a double blinded manner to receive active and placebo in a 1:1 ratio. Sentinel pairs were dosed seven days prior to the other participants in that cohort in order to detect any serious adverse advents (SAEs) in accordance with the European Medical Agency first-in-man guidelines.[26] The remaining participants in each cohort received either m102·4 or placebo (0·9% saline) in a 5:1 ratio following review of safety data by the Investigator and the Medical Monitor. The decision to progress to the next higher dose was made after safety and tolerability data was reviewed for each dose group. Repeat dosing (Cohort 5) did not commence until all pharmacokinetic data was reviewed for Cohorts 1-4 (see Appendix pg 3 & 19). As this was a single site trial with eight participants allocated to five cohorts, no block randomisation was performed.

To maintain the blinding of the study, the randomisation plan was available only to the un-blinded pharmacist. Treatment allocation was double blinded, and m102·4 and placebo were identical in appearance and volume for each participant in each cohort.

Procedures

The m102·4 drug substance for the phase 1 study was manufactured at the National Biologics Facility (NBF) located at the University of Queensland (Queensland, Australia) using a recombinant Chinese Hamster Ovary (CHO) cell line. A parent cell line was obtained from the National Institutes of Health, (Bethesda, MD, USA) and then subcloned and adapted to a serum- and protein-free commercially available medium. Cells were expanded from a qualified master cell bank using a conventional seed-train, followed by a fed-batch bioreactor process. The clarified harvest containing secreted m102·4 was subjected to a two-step purification process including MabSelect SuRe^{TM} LX protein A and mixed mode Capto^{TM}adhere chromatography. The process included two viral inactivation/removal steps, a low pH hold, and nanofiltration (Viresolve® Pro Modus) respectively. The m102·4 was formulated at a concentration of 10 mg/mL in phosphate buffered saline pH 7·3 and aseptically dispensed into 10 mL vials at Sypharma Pty Ltd (Victoria, Australia). The final product complied with specifications commonly accepted by regulatory agencies for identity, purity, potency, and safety.

Prior to clinical studies, Good Laboratory Practice (GLP) compliant, repeat dose toxicology studies were conducted in the Sprague-Dawley rat at vivoPharm Pty Ltd (Victoria, Australia). The m102·4 was administered once per week for four weeks at doses of 0, 10, 30, and 100 mg/kg. The antibody was well tolerated and the no-observed-adverse-effect-level (NOAEL) was determined to be 100 mg/kg, the highest dose tested.

An enzyme-linked immunosorbent assay (ELISA) was developed by the NBF, then validated and used to measure the concentration of m102·4 in human serum samples at vivoPharm Pty Ltd. Briefly, serum m102·4 bound to Hendra virus soluble G protein coated on a plate, was detected with a custom rabbit anti-m102·4 horseradish peroxidase conjugate followed by the addition of 3,3',5,5'-Tetramethylbenzidine substrate. The validated assay met criteria in the relevant US guideline[27], and had a working range of 1·7–163·2 ng/mL, which corresponded to the lower and upper limits of quantitation, respectively. All samples were diluted within this working range, quantitated via standard curve interpolation, and pharmacokinetic parameters were calculated using noncompartmental techniques.

An anti-drug antibody ELISA was developed and validated to determine the presence of anti-m102·4 antibodies in human serum samples. A bridging assay design was employed where m102·4, previously coupled either with biotin or horseradish peroxidase, was mixed with serum or positive control (a custom anti-m102·4 rabbit polyclonal antibody) to form a complex which was captured onto a streptavidin coated plate. The assay procedure included an acidification step to dissociate drug-antibody complexes. The validated assay met criteria consistent with the US guidelines,[27] and had a sensitivity of 100 ng/mL. Human serum samples were considered positive if both the screening cut-point (determined statistically based on a 95% upper confidence limit from negative normal donor sera) and specificity confirmation cut-point (where excess m102·4 was added) were exceeded.

Based on animal models of Henipavirus challenge,[1,22-24,28] a target dose of 20 mg/kg was selected as the maximum dose to be tested. Treatment recipients in the five cohorts were dosed with four concentrations of m102·4. Cohorts 1 and 2 received single IV doses of 1 mg/kg and 3 mg/kg, respectively, or placebo, infused in a total volume of 100 mL of 0·9% saline. Cohorts 3 and 4 received single IV infusions of 10 mg/kg and 20 mg/kg, respectively, or placebo, in a total volume of 500 mL of 0·9% saline, while Cohort 5 received two IV infusions of 20 mg/kg, or placebo, in 500 mL of 0·9% saline 72 hours apart. All infusions were given over a 1-hour period using a peristaltic infusion pump.

Participants in Cohorts 1–4 were domiciled for a total period of 3·5 days for initial safety and tolerability monitoring, and to facilitate blood sampling for pharmacokinetics, virus neutralisation, and immunogenicity analysis. Participants received the m102·4 mAb or placebo on day 1, and follow-up assessments were scheduled on days 4, 6, 8, 15, 29, 43, 57, 85, and 113. Participants in Cohort 5 were domiciled for a total period of 6·5 days receiving a single dose of m102·4 or placebo on days 1 and 4. Follow up visits to the clinical site were scheduled on days 7, 9, 11, 18, 25, 32, 39, 53, 67, 95, and 123. For all cohorts, the final safety assessment was scheduled to occur within a maximum period of 16 weeks after the last infusion.

Dose escalation from one cohort to the next followed review and approval of safety data for at least six participants per group. In addition, blinded pharmacokinetic data for Cohort 1 was reviewed to confirm estimation of m102·4 elimination half-life. Initiation of dosing in Cohort 5 followed review of available unblinded pharmacokinetic data for Cohorts 1–4.

A virus neutralisation assay was designed and performed by the Australian Animal Health Laboratory (AAHL) located at the Commonwealth Scientific and Industrial Research Organisation (CSIRO, Victoria, Australia). Briefly, sera from five Cohort 4 participants (20 mg/kg, a clinically relevant dose) were tested against HeV and NiV to assess the ability of circulating m102·4 to neutralise each virus in samples at four different time points post-infusion (12hr, 24hr, Day 4, and Day 8). Samples were diluted to achieve an end-point for neutralisation. Control plates were set up using m102·4-spiked media + 10% normal human serum to achieve final concentrations ranging from 50 to 0·4 µg/mL. Samples of HeV (HeV/Australia/Horse/2008/Redlands) and NiV (NiV/Bangladesh/human/2004/Rajbari, R1) were diluted to contain 100 $TCID_{50}$ of virus and added to the required wells. Serum, cell and virus controls were included. Vero cell suspension was added to every well at a concentration of $4x10^5$ cells/mL. Plates were incubated at 37°C in a humid atmosphere containing 5% CO_2 for 45–60 min. Cells were examined after 3 days under an inverted microscope for cytopathic effect.

Outcomes

The primary objective of the phase 1 trial was to assess the safety and tolerability of single and multiple IV doses of m102·4 in healthy human participants; the second objective was to determine the pharmacokinetic and immunogenicity of single and multiple doses; and the third objective was to explore the pharmacodynamics of m102·4 against HeV and NiV.

The safety and tolerability of m102·4 across all cohorts was evaluated according to the following specific assessments: physical examination, clinical laboratory tests, vital signs, electrocardiogram, signs and symptoms of tolerability, infusion site reactions, and adverse events (AEs). All AEs and treatment-emergent AEs (TEAEs) were reported for participants from dosing until the end of the study. Definitions of AEs and TEAEs can be found in the trial protocol (appendix pg 50–52).

Calculated pharmacokinetic values included maximum observed drug concentration (C_{max}), time to maximum observed drug concentration (T_{max}), area under the drug concentration-time curve ($AUC_{0\text{-last}}$ and $AUC_{0\text{-inf}}$), elimination half-life ($t_{½}$), clearance (CL), and volume of distribution (V_z). We also took blood samples pre-dose and at nominal post-dose time-points for measurement of m102·4 HeV and NiV virus neutralisation, and for assessment of anti- m102·4 antibodies.

Statistical analysis

Statistical analysis comprised summary descriptive statistics of the five dose groups and placebo group. Given the exploratory nature of the study, the sample size was not based on power calculations, but was consistent with the typical sample size used for similar studies. Descriptive statistics were performed with SAS version 9·4. Pharmacokinetic data were analysed with Phoenix WinNonlinSoftware version 6·3, with pharmacokinetic listings, tables, and figures generated using SAS Software version 9·4. The study is registered on the Australian New Zealand Clinical Trials Registry, registration number ACTRN12615000395538.

Role of the funding source

The funders of the study had no role in data collection, data analysis, data interpretation, or writing of the report. The corresponding author had full access to all the data in the study and had final responsibility for the decision to submit for publication.

Results

Between 15 April 2015 and 18 February 2016, 40 participants were allocated into five cohorts as described (figure 1). All enrolled participants received their full assigned treatments and completed the study according to schedule apart from two participants in cohort 4 who failed to attend their day 43 and day 85 visits, respectively. Demographic characteristics did not vary between treatment groups (table 1).

Overall the dosage of m102·4 appeared safe and well tolerated. No deaths, life threatening events, serious adverse events, or adverse events leading to study discontinuation occurred. Across all cohorts, a total of 37 of 40 (93%) participants had at least one TEAE, with a total of 86 TEAEs reported (table 2). The occurrence of TEAEs was similar across all active treatment and placebo groups.~~ ~~ The most frequently reported events were infections and infestations, classed as mild to moderate; 13 were reported in 11 of 24 single-dose participants (45.8%), two of six (33%) repeat dose participants, and five of 10 (50%) in the pooled placebo group. A possible association between dose and headache was noted, occurring in eight of 12 (67%)~~ of~~ participants dosed in Cohorts 4 and 5 compared with four of 18 (22~~5~~%)~~ of~~ participants dosed in Cohorts 1–3, and three of 10 (30%) participants in the~~ and~~ pooled placebo group. All TEAEs were resolved upon follow-up without specific intervention.

Of all TEAEs, 31 in 20 participants were considered treatment-related, occurring in three of six (50%) ~~of ~~participants dosed in Cohort 1, two of six (33%) participants dosed in Cohorts 2, 3, and 5, five of six (83%) participants dosed in Cohort 4, and five of 10 (50%) participants in ~~of ~~the pooled placebo group. The most common treatment-related TEAEs were headaches (10 participants: one each in Cohorts 1–3, four dosed in Cohort 4, two dosed in Cohort 5, and one in the pooled placebo group), intravenous catheter site bruising (three participants: two dosed in Cohort 3 and one in the pooled placebo group), and elevated alanine aminotransferase (ALT) levels (three participants: two in Cohort 5 and one in placebo). Of the 20 treatment-related TEAEs, 15 were rated as mild and five as moderate. Moderate TEAEs included two headaches; one each in Cohorts 4 and 5, one intravenous catheter site bruising in Cohort 3, lethargy in a placebo participant, and reduced appetite in Cohort 3. There were no severe TEAEs (Table 2).

No clinically significant changes in haematological or coagulation parameters were observed in any participant. Three participants had elevated ALT levels, two dosed in Cohort 5 and one in the pooled placebo group; Cohort 5 participants had elevated ALT levels at day 4 and 11, respectively; both findings following m102·4 administration were considered to be mild and treatment-related. ALT levels returned to normal after day 11 without intervention, and were not considered to be clinically significant (Supplementary Table 1~~2~~). No other clinically significant abnormalities in biochemical parameters, urinalysis, vital signs, or ECG findings were observed. One clinically significant abnormal physical examination finding was reported in one participant dosed in Cohort 3; pityriasis rosea was noted on the arms, legs, and abdomen on day 113 but was not assessed as treatment-related. No pregnancies were reported during the study period.

All participants had negative anti-drug antibody results at days 1, 29 (Cohorts 1–4) or day 39 (Cohort 5) and day 113 (Cohorts 1–4) or day 123 (Cohort 5). Following a single dose of m102·4, the median T_{max} for Cohort 1, 2, 3 and 4 was 8, 4, 2·5, and 4·1 hours respectively. C_{max} and $AUC_{0\text{-}last}$ increased linearly with dose, with mean C_{max} and $AUC_{0\text{-}last}$ values for Cohort 4 being 692 µg/mL and 131,648 h·µg/mL, respectively (table 3 and figure 2). Concentration over time profiles demonstrated an initial rapid peak followed by a bi-exponential decline consistent with multi-compartmental distribution kinetics. The median $t_{1/2}$ was similar for Cohorts 2–4 (between 397 and 467 hours) but higher for Cohort 1 (663 hours). Relatively low inter-individual variability of pharmacokinetic parameters was observed. Among the repeat dose cohort (Cohort 5), the T_{max} and C_{max} for the first and second dose were 6 hours and 2·5 hours, respectively and 834 µg/mL and 1077 µg/mL, respectively.

Virus-neutralisation activity for both HeV and NiV was exhibited for all samples and time points tested. The viral neutralising titres ranged from 1/8 to ≥ 1/64 across all samples, corresponding to m102·4 concentrations of 2–10 µg/mL as measured by the pharmacokinetic ELISA. In 4 out of 5 participant samples, the Day 8 neutralising titre was within 1 or 2 doubling dilutions of the 12-hour sample from the same participant. For the 5th participant sample, the Day 8 neutralising titre was within 3 doubling dilutions of the 12-hour sample for HeV, and 1 doubling dilution for NiV. These results were considered to be within experimental variation, and therefore it was concluded that the m102·4 remained active for at least 8 days following mAb administration.

Discussion

In this phase 1 study we assessed the safety and tolerability of single and multiple IV doses of m102·4 in healthy human adults. All 40 participants completed the trial, with safety data indicating that m102·4 was safe and well tolerated. The maximum dose of 20 mg/kg was in-line with the human equivalent dose conversion (based on body surface area) at the NOAEL of 100 mg/kg, assigned from the 4 x weekly dosing rat toxicology study. Therefore the maximum clinical dosing of 2 x 20 mg/kg m102·4 was supported by the nonclinical data, and is a dose hypothesised to be pharmacologically relevant based on animal challenge data (see below).

TEAE reports were similar between placebo and active treatment groups. There was an increase in treatment-related headaches recorded among participants receiving single dose m102·4 compared to those administered placebo (66·7% vs 10%); there was no increase in treatment-related headaches among those with repeat dosing. Dose-related changes in ALT of three participants were noted; however these were mild abnormalities and were not considered clinically significant. There were no deaths or severe adverse events leading to withdrawals or premature discontinuations during the study. Pharmacokinetics based on those receiving active treatment (n=30) were linear, with the mean half-life ranging from 16·5 to 27·6 days across Cohorts 1–4. There was a small to moderate accumulation of mAb in those receiving repeat dose (Cohort 5), with elimination kinetics that were comparable to those receiving single dose regimens.

A variety of active immunisation strategies have been previously explored for HeV and NiV infection involving various recombinant viral vector-based vaccines in animal challenge models.[4] These studies demonstrated the possibility of inducing strong neutralising antibody response that could afford protection in livestock or an emergency-use scenario.[4] Among the most notable studies was the identification of the m102·4, the first fully-human monoclonal antibody that cross-neutralised *in vivo* all HeV and NiV isolates, including those from the Australian 1994 HeV outbreak and the Malaysian and Bangladesh NiV outbreaks. A single dose of m102·4 administered to ferrets 10 hours after lethal virus challenge was shown to be fully protective with no evidence of toxicity.[20,22]

In subsequent studies designed to closely reflect real-world human exposure, non-human primates were challenged with lethal doses of HeV and NiV by an intratracheal route, then infused twice with m102·4 mAb (15 mg/kg), beginning at 1, 3, or 5 days ~~at various time points~~ post-infection, and again 2 days later. Untreated control animals succumbed to disease eight days post-infection, while those in the treatment groups recovered by day 16.[23,24] Also tissue samples collected from treated animals had no evidence of infectious HeV or NiV at the termination of the study, demonstrating the potential of m102·4 to treat HeV and NiV infections in human and animal populations. A potential challenge to developing antiviral therapies for RNA viruses is their heterogeneity and mutational instability. However, the m102·4 recognises epitopes that are highly conserved among virus variants, making it unlikely that the virus will escape neutralisation due to mutation activity, and in the context of therapeutic dosing, in an immunocompetent individual.

Prior to this trial, a total of 14 individuals received prophylactic high-dose m102·4 on compassionate grounds following high level exposure to HeV (13 in Australia) or NiV (one in the United States; Supplementary Table 2). Individuals ranged from 8–59 years of age. No individual demonstrated clinical or laboratory evidence of infection prior to, or following m102·4 administration. The m102·4 administration was generally well tolerated; two individuals developed infusion-related febrile reactions to early production lots of antibody.

Because of the available data and findings on m102·4, including those presented here, the recent outbreak of NiV in Kerala, India, encouraged a number of organisations, including the Indian Council of Medical Research (ICMR), the Henry M. Jackson Foundation (HJF), the WHO, and the US National Institute of Allergy and Infectious Diseases (NIAID) and US National Institutes of Health (NIH) to work towards the development of an NiV therapeutics protocol for the use of m102·4 in the event of another outbreak of NiV in India or Bangladesh. To date, treatment for NiV has been limited to supportive care and management of acute encephalitis syndrome, as well as standard infection control practices to limit person-to-person transmission.[29] One pharmacologic option that was used for post-exposure prophylaxis during the Malaysian NiV outbreak of 1999 was the anti-viral Ribavirin. While this was associated with a significant reduction in mortality due to acute encephalitis, treatment allocation was not randomised, and the lack of clinical trial safety data beyond short-term emergency administration limits its use in outbreak circumstances.[30] The safety profile of both single and repeat dosing of m102·4, and the standard elimination pharmacokinetic profile presented in this study, underpins the current standard of care to offer a single dose of 20 mg/kg of m102·4 to humans with high levels of exposure to HeV and NiV. It also supports its potential use for patients with established clinical manifestations of henipavirus infection; based upon African green monkey challenge studies,[23,24] two doses separated by 48 hours would seem appropriate.

The main limitation of our study is the small number of participants, which is not uncommon in phase 1 studies. Also pharmacokinetic parameters were based on active treatment cohorts only consisting of 30 individuals. Future studies will be needed to ascertain the efficacy of m102·4 for treatment and prophylaxis against different viral strains of NiV and HeV virus, particularly among populations living in settings where there is the potential for an outbreak. Also, while there is no evidence of escape mutants to m102·4, the potential for this cannot be ruled out with RNA viruses. It may be necessary to consider a cocktail of mAbs with additional targets to combat the likelihood of diminished efficacy of m102·4.

In summary, m102·4 single and repeated dosing of up to two doses, three days apart appears to be safe and well tolerated when administered to healthy volunteers. Given that a 57% mortality rate has been observed from the seven known cases of human infection with HeV, and that m102·4 has demonstrated protective efficacy in non-human challenge studies, m102·4 is the most promising therapeutic opportunity to date for addressing this unmet medical need. This study will inform future dosing regimens for m102·4 to achieve systemic efficacy against HeV and NiV as post-exposure prophylaxis.

Contributors

EGP was the lead investigator involved in study design, data collection and analysis, and interpretation; TM was responsible for pre-clinical and clinical monoclonal antibody production; PPG and SMM were responsible for study design; MG was responsible for antibody quality review and data analysis; MLJ, KLH, BH, EH and KH were responsible for antibody manufacture and project management; CdB was involved in analytical and stability testing of m102·4 for clinical trial, and animal toxicology studies; RK implemented virus neutralization studies; L-FW and ILS designed and analysed virus neutralization studies;

PG and SE were involved in clinical trial study design, conduct, supervision and data interpretation; MEG was the clinical trial coordinator for patient screening procedures; SBL, HC, DES and KDL were involved in the planning and implementation phase of the clinical trial. SBL also reviewed and interpreted safety data from the trial; CCB supplied preclinical materials including the master cell bank and data on monoclonal antibody, and contributed to study design and data analysis; MGS negotiated the transfer of preclinical materials and data on mAb from the USA to Australia; DSD contributed to trial design and supplied the cell line for production of antibody for trial. All authors reviewed and approved the final manuscript.

Declaration of interests

CCB is a US federal employee; and CCB and DSD are co-inventors on US patent Nos. 7,988,971 and 8,313,746 "Human monoclonal antibodies against Hendra and Nipah viruses"; assignees are The United States of America as represented by the Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (Bethesda, MD). All other authors declare no competing interests.

Data Sharing

Data generated in this study will be shared as deidentified data. Study protocol, statistical analysis plan, and informed consent forms are available with this publication. Any additional data may be made available upon request to the corresponding author following review by the protocol team.

Acknowledgements

We thank the participants who generously gave their time to participate in this study, and without whom the study would not have been possible. We acknowledge Roz Glazebrook and Wendy Morotti (Queensland Health) for initial coordination and preparation of trial related activity, and support with maintaining the study; Terry Hurst (Q-Pharm Pty Limited) for initial preparation and planning of initial grant funding of this phase 1 clinical trial; Gary Crameri (CSIRO Australian Animal Health Laboratory) for technical assistance with virus neutralization studies. We thank Clinic Manager Sharon Rankine and the Q-Pharm clinic team. We thank Drs Sonya Bennett (Executive Director) and Jeannette Young (Chief Health Officer) of Queensland Health, for ongoing support for this project, and securing a significant portion of the funding for this trial. The manufacture of m102·4 drug substance was performed at the National Biologics Facility (NBF), at the University of Queensland. The NBF is supported by Therapeutic Innovation Australia (TIA), which is supported by the Australian Government through the National Collaborative Research Infrastructure Strategy (NCRIS) program. The authors thank Dr Sharon Johnatty of SugarApple Communications for providing medical writing support, which was funded by Queensland Health, Brisbane, Australia, in accordance with Good Publication Practice (GPP3) guidelines (https://www.ismpp.org/gpp3).

Supplementary Tables

Supplementary Table 1: Reported changes in alanine aminotransferase levels of three participants.

	Placebo	Cohort 5 (2x20 mg/kg) Participant #1	Cohort 5 (2x20 mg/kg) Participant #2
Screening	44	18	32
Day -1	24	18	38
Day 2	22	17	41
Day 4	45	21	69
Day 5	62	31	78
Day 6			71
Day 7	101		
Day 9			67
Day 11	56	61	57
Day 18	49	36	35
Day 25	38	23	33
Day 39	68	21	32
Day 67	62	18	37
Day 95	54	21	39
Day 123	28	15	38

Day number refers to the number of days relative to the day of dose administration of m102·4 where Day 1 is the first dosing day. Participants in Cohort 5 received two doses of 20 mg/kg 72 hours apart. Alanine aminotransferase is reported as U/L; normal range is considered 5–40 U/L; blank cells indicate measurements not taken on those days.

Supplementary Table 2: Treatment data and outcomes for 13 compassionate use cases in Australia who received m102·4 as post-exposure prophylaxis.

Patient	Year	Exposure	Dose (mg/kg)	Adverse events	Follow up
1	2010	HeV-infected horse	17·9	Infusion-related febrile reaction	No seroconversion
2	2010	HeV-infected horse	18·3	Infusion-related febrile reaction *Pseudomonas aeruginosa* intravenous line-related bloodstream infection	No seroconversion
3	2012	HeV-infected horse	20·0	Nil	No seroconversion
4	2012	HeV-infected horse	20·0	Nil	No seroconversion
5	2013	NiV-Bangladesh infected NHP	2 x 20·0 at 0 and 48 hours	Nl	No seroconversion
6	2014	HeV-infected horse	19·8	Nil	No seroconversion
7	2014	HeV-infected horse	20·0	Nil	No seroconversion
8	2014	HeV-infected horse	20·0	Nil	No seroconversion
9	2014	HeV-infected horse	20·0	Nil	No seroconversion
10	2014	HeV-infected horse	20·0	Nil	No seroconversion
11	2015	HeV-infected horse	20·1	Nil	No seroconversion
12	2017	HeV-infected horse	20·0	Nil	No seroconversion
13	2017	HeV-infected horse	20·1	Nil	No seroconversion
14	2017	HeV-infected horse	20·1	Nil	No seroconversion

NHP: nonhuman primate (African green monkey)

PROTOCOL SYNOPSIS

Protocol Title:	A Phase I, Randomized, Double-blind, Placebo-controlled Study of the Safety, Tolerability, Pharmacokinetics and Immunogenicity of Various Dosing Regimens of Intravenous anti-Hendra Virus Antibody (mAb m102.4) in Healthy Subjects
Protocol Number:	QH-M102.4-001
Sponsor:	Queensland Department of Health, QLD, Australia
Compound no:	Human monoclonal antibody (mAb m102.4)
Phase of Development:	Phase I
Methodology:	A Phase I, randomized, double-blind, placebo-controlled, dose escalation study.
Study Duration:	Study duration is approximately 5 months per subject (including screening). For subjects in Cohorts 1-4, study duration will include a Screening period of up to 28 days prior to first dose of investigational product (IP), one dose of IP and a maximum 16-week follow-up period. For subjects in Cohort 5, there will be two dosing days, 3 days (72 hours) apart, in addition to the Screening period and maximum 16-week post second dose follow-up period.
Study Center:	Q-Pharm Pty Ltd, Herston, QLD, Australia
Objectives:	1. To determine the safety and tolerability of single and multiple intravenous (IV) administration of mAb m102.4 in healthy subjects 2. To determine the pharmacokinetics (PK), and immunogenicity of single and multiple IV administration of mAb m102.4 in healthy subjects 3. To explore the pharmacodynamics (PD) of single and multiple IV administration of mAb m102.4 in healthy subjects against Hendra (and possibly Nipah) virus.
Sample Size:	40 healthy subjects in 5 cohorts with 8 subjects in each cohort (6 randomized to receive mAb m102.4 and 2 randomized to receive placebo)
Investigational Medicinal	mAb m102.4 at doses of 1 mg/kg and 3 mg/kg in a 100 mL bag of

Product (IMP):	normal saline and 10 mg/kg and 20 mg/kg in a 500 mL bag normal saline administered IV for approximately 1 hour. In Cohort 5, 20 mg/kg will be administered twice, with 3 days (72 hours) between dosing. Doses may be adjusted following cohort reviews by the Safety Review Committee (SRC).
Reference Therapy:	Placebo (normal saline, prepared to maintain the blind)
Study Design:	All subjects will undergo Screening procedures within 28 days of the first dose of IP. Subjects in Cohorts 1-4 will be admitted to the clinical research unit (CRU) on the afternoon of Day -1 and receive a single dose of IP on Day 1 following overnight fast. Cohort 1-4 subjects will be allowed to leave the CRU on the morning of Day 3. The subjects for Cohort 5 will be admitted to the CRU on the afternoon of Day -1 to be dosed with IP on the mornings of Day 1 and Day 4 following overnight fast in each case. Cohort 5 subjects will be allowed to leave the CRU on the morning of Day 6. Safety assessments for **Cohort 1-4** will be conducted upon admission to the CRU, at baseline (Day 1) and during the clinical stay. Subjects will return to the CRU on Days 4, 6, 8, 15, 22, 29, 43, 57, 85 and 113 for PK and immunogenicity sampling and/or safety assessments. Safety assessments for **Cohort 5** will be conducted upon admission to the CRU, at baseline (Day 1) and during the clinical stay. Subjects will return to the CRU on Days 7, 9, 11, 18, 25, 32, 39, 53, 67, 95 and 123 for PK and immunogenicity sampling and/or safety assessments. The final safety assessment is scheduled for a maximum of 16 weeks after the last dose of IP. This is based on a mAb m102.4 t½ of 21-23 days. Where applicable, serious adverse events (SAEs) will be followed for a further 30 days after the final safety assessment, or until resolved, whichever is the earlier. For all cohorts two sentinel subjects will be randomized in a blinded fashion in which one subject receives mAb m102.4 and one subject receives placebo. The remaining six subjects in each cohort will receive IP (5 x mAb m102.4: 1 x placebo) a minimum of 14 days after the sentinel pair, following review of safety and tolerability data by the Principal Investigator (PI) and Medical Monitor. The decision to progress to the next higher dose will be made after

	data are reviewed for each dose group for at least six subjects per group through to a minimum of Day 29, and after the SRC determines that it is safe to proceed to the next dose level. PK data for Cohort 1 through to Day 43 will be analyzed and data reviewed by the SRC whilst Cohort 2 is ongoing. Subsequent cohort assessments, sampling times and the overall period of monitoring may be adjusted depending on the outcome of the data review. All PK data for Cohorts 1-4 will be reviewed prior to the commencement of Cohort 5 to confirm that dose and planned dosing interval for Cohort 5 is optimal.
Safety:	The following assessments will be performed during the study: physical examination, clinical laboratory tests (haematology [including coagulation], clinical chemistry, urinalysis, virus neutralization and anti-m104.2 antibodies), vital signs (blood pressure, pulse rate, temperature and respiratory rate), electrocardiogram (ECG), signs and symptoms of tolerability, infusion site reactions and adverse events (AEs). Assessments according to the schedule of events will be conducted at the following time points (vital signs will be performed at all time points): **Cohorts 1-4:** Screening, on admission (Day -1), pre-dose, Days 1, 2, 3, 4, 6, 8, 15, 22, 29, 43, 57, 85 and 113 post-dose (after the start of the infusion) **Cohort 5:** Screening, on admission (Day -1), pre-dose, Days 1, 2, 3, 4, 5, 6, 7, 9, 11, 18, 25, 32, 39, 53, 67, 95 and 123 post-dose (after the start of the first infusion). AEs will be collected from the commencement of the first dose of IP until the end of the study, and in the case of SAEs until resolution or up to 30 days after study completion whichever is the earlier. A full physical examination will be performed at Screening and at the final visit (Day 113 for Cohorts 1-4 and Day 123 for Cohort 5). A brief physical examination will be performed pre-dose on Days 1, 3, 29 and 57 for Cohorts 1-4 and pre-dose, Days 4, 6, 39 and 67 for Cohort 5. ECGs will be performed at Screening, pre-dose on Day 1, Days 2,

	8, 29, 57, 85 and 113 post-dose for Cohorts 1-4. For Cohort 5 ECGs will be performed at Screening, pre first dose on Day 1, Days 2, 4, 5, 6, 11, 39, 67, 95 and 123 post-dose.
Pharmacokinetics (PK):	PK samples will be taken at the following time points for **Cohorts 1-4:** pre-dose on Day 1 and at 1, 4, 8, 12, and 24, hours post commencement of infusion and at the following visit to the CRU on Days 4, 6, 8, 15, 29, 43, 85 and 113 post dose. PK samples will be taken at the following time points for **Cohort 5:** pre first dose on Day 1 and at 1, 4, 8, 12, 24 and 48 hours post commencement of the first infusion; pre second dose on Day 4 and at 1, 4, 8, 12, and 24 hours post commencement of the second infusion and at the following visits to the CRU on Days 7, 11, 18, 32, 53, 95 and 123 post first dose. The PK sampling for Cohort 5 may be adjusted depending on the PK data obtained from Cohorts 1-4.
Immunogenicity and Virus Neutralization:	The presence of anti mAb m102.4 antibodies will be assessed pre-dose and on Days 29 and 113 for Cohorts 1-4 and pre-dose and on Days 39 and 123 for Cohort 5. Blood samples for mAb m102.4 Hendra (and possibly Nipah) virus neutralization studies will be taken and potentially assessed at pre-dose, 12 hours, Days 2 (24 hours), 4, 8, 29, and 113 for Cohorts 1-4 and pre-dose, 12 hours, Days 2 (24 hours), 4, 6, 9, 39, and 123 for Cohort 5.

Inclusion Criteria:	Subjects who meet all of the following criteria are eligible for the study: 1. Written informed consent from the subject; 2. Healthy males and females as determined by medical history and physical examination between 18 and 50 years of age (inclusive); 3. Body mass index (BMI) of 18.0 to 35.0 kg/m^2 (inclusive) at screening (Weight $\geq$50 kg or $\leq$100 Kg); 4. Haematology, coagulation, clinical chemistry, and urinalysis test results not deviating from the normal range to a clinically relevant extent at screening; 5. Able to comply with requirements for concomitant medications and consumption of caffeine, alcohol, tobacco and nicotine; 6. Willing to attend all the study visits.
Exclusion Criteria:	Subjects are not eligible for this study if they meet any of the following criteria: 1. Close, unprotected exposure to sick horses with an unexplained illness within 4 weeks of Day 1; or known exposure to potential Hendra infected horses; 2. Clinically significant abnormalities in laboratory test results at Screening or Baseline (Day-1) (biochemistry, haematology and urinalysis parameters) (Liver function tests > 1.5 x upper limit of normal [ULN]); 3. Immunoglobulin G (IgG) and complement level outside normal limits (at Screening); 4. Positive urine screen for potential drugs of abuse at Screening and prior to randomization; 5. Presence or history (in last 2 years) of alcohol abuse confirmed by medical history, or daily alcohol intake of more than 2 standard drinks (16 g) for females or more than 3 standard drinks for males, or a positive breath alcohol test at screening or prior to randomization, and the inability to stop alcohol intake for 2 weeks post-infusion; One standard drink is (8 g) is equivalent to 280 mL of beer, one measure (25 mL) of spirits or 1 small glass (125 mL) of wine; 6. Excessive use of caffeine-containing beverages including coffee, tea, cola, energy drinks or chocolates, exceeding 500 mg caffeine/day (approximately 5 cups of coffee or 10 cups of tea) and the inability to refrain from the use of caffeine-containing beverages during confinement in the CRU;

	7. Smoke >5 cigarettes per day; 8. Positive tests for human immunodeficiency virus (HIV) or viral hepatitis (hepatitis B surface antigen [HepBsAg], or anti-hepatitis C [HCV]); 9. Treatment with an investigational drug or biologic within 60 days preceding treatment or plans to take another investigational drug or biologic in the 3 months following IP administration; 10. Blood donation or significant blood loss 60 days prior to Day 1; 11. Plasma donation within 60 days prior to Day 1 or planned donation in the 6 months following IP administration; 12. Males who are sexually active and have a partner who is capable of becoming pregnant, neither of which have had surgery to become sterilized, who are not using an effective method of birth control (e.g., surgically implanted hormonal therapy, intrauterine devices, or oral birth control with barrier method). In addition, male subjects must agree not to donate sperm during the study and in the 6 months following IP administration; 13. Females who are capable of becoming pregnant and who have not had surgery to become sterilized and who are not using an effective method of birth control (e.g., surgically implanted hormonal therapy, intrauterine devices, or oral birth control with barrier method [female condom or male partners to use condom]). For exclusively homosexually active females, not planning a pregnancy during or in the 6 month period following completion of the study, the restrictions for adequate contraception will not apply (if lifestyle choices change, contraceptive requirements will be applicable); 14. Poor peripheral venous access; 15. Subjects with clinically significant findings from medical history that, in the opinion of the investigator, could interfere with the objectives of the study or put the subject at risk; 16. Subject is unwilling or unable to abide by the requirements of the protocol or inability to be available for follow-up assessments or protocol related procedures; 17. Subject is on staff at the investigator site; or a relative of personnel of the investigator site or of the Sponsor (or Sponsor's affiliates); 18. Use of prescription or non-prescription drugs within 14 days or 5 half-lives (whichever is longer) prior to IP administration and for the duration of the study.

	Contraceptives for females are allowed – must have been using the same contraceptive for a minimum period of 3 months and must not change the contraceptive during the study; 19. Presence or history of drug hypersensitivity, or allergic disease diagnosed and treated by a physician or history of a severe allergic reaction, anaphylaxis or convulsions following any vaccination or infusion; 20. BP systolic >160 mmHg or diastolic >90 mmHg. Allow one repeat measure; 21. Personal or family history of congenital QT syndrome or sudden unexplained death; 22. ECG clinically significant abnormalities including (QTc>450 msec for males and >460 msec for females), AF or atrial flutter, notably bradycardia (<40 bpm) or tachycardia (>100 bpm), complete left or right bundle branch block, Wolf-Parkinson White Syndrome or presence of cardiac pacemaker; 23. Any vaccination in the last month. 24. Pregnant or breastfeeding females.
Statistical Methods:	The sample size for this study was not based on statistical power calculation, but is consistent with the typical sample size used for similar studies to assess preliminary safety, PK and immunogenicity data.

1 INTRODUCTION

1.1 Background

Hendra virus (HeV) infection in humans is a rare serious zoonotic disease with a high mortality rate. In Australia the natural hosts of HeV are bats (flying foxes), which can then pass the virus onto horses. There are seven known cases of human HeV infection where humans have become unwell with an influenza-like illness or encephalitis following close contact with an infected horse. One case had an initial mild clinical illness, which re-emerged 13 months later and resulted in encephalitis and death. Human HeV infection has resulted in fatal severe encephalitis and multi-system involvement in 4 of the 7 (57%) infected individuals. The sole survivor of acute encephalitis has residual high-level cognitive impairment.

There is no known effective treatment for HeV infection and clinical management is based on treating symptoms as they arise.

A neutralizing human monoclonal antibody (mAb), m102.4, was developed by researchers in the United States. These antibodies have been successful in protecting ferrets and African green monkeys challenged with HeV. The mAb m102.4 are currently the only pharmaceutical agent available to prevent infection in people exposed to the HeV.

In 2010, the Queensland Department of Health, Chief Health Officer obtained a license from the US Department of Defence, Uniformed Services University of the Health Sciences to produce the experimental mAb m102.4 for the purpose of compassionate use in human cases of HeV exposure.

The mAb m102.4 has not been assessed in any safety or efficacy trials in humans. A predecessor of the product has previously been administered to eleven humans. The first person was late in disease progression with encephalitis in the Intensive Care Unit (ICU) and subsequently died. The second and third had moderately high-risk exposures, but no evidence of infection and did not develop illness or seroconversion. They experienced transfusion-like reactions to administration of mAb m102.4 which was attributed to endotoxins in the predecessor product. The fourth person received mAb m102.4 in 2012 after high-level exposure to HeV and did not experience any adverse reactions to the antibodies. The mAb m102.4 were given to a male (the 5th person) in the United States who was accidently bitten by a Nipah virus infected monkey. The male was administered treatment in 2013 under the same regime used by Dr Geoffrey Playford (the Principal Investigator [PI] for this trial) for the Queensland patients. This included a test dose and two IV administrations of m102.4 three days apart. No untoward affects associated with the administration of the antibodies were noted. The sixth and seventh individuals received the mAb on 20 March 2014 and remained well. Four more people received mAb 102.4 in June 2014, including one from Queensland and three from New South Wales.

These four people were assessed as having had high exposure to Hendra virus infected horses. With the exception of the male in the United States who received two doses, all other individuals received a single dose of mAb m102.4.

Currently mAb m102.4 are offered to people with high exposure to infected horse blood/secretions following ethics approval for each individual and appropriate consenting. Monoclonal antibodies are not offered to people with lower exposures because of the potential for unknown adverse effects of mAb m102.4 administration and a low risk of infection.

The mAbs prepared for use in this study were refined and purified at the Brisbane Based Australian Institute for Bioengineering and Nanotechnology (AIBN), which is part of the University of Queensland.

Phase 1 trials are normally conducted in healthy subjects. These trials are designed to test an experimental drug or treatment in a small group of people (20-80) for the first time to evaluate its safety, determine a safe dosage range, and identify side effects.

All medicines in use today must be proven safe and effective in clinical trials before they can be made available for use within the community. Early phase clinical trials are a vital step in this development process.

HeV is not used at any stage for the production of the mAbs and this safety trial is the final stage before the experimental drug is considered to be safe for use in humans.

Monoclonal antibodies have shown great promise in treating human diseases including arthritis and tumors associated with breast and colon cancer. They are also being trialed as treatments for viral infections such as human immunodeficiency virus (HIV) and hepatitis.

It is important to understand that mAb therapy is not a vaccine for the general population, but a treatment, which maximizes a person's chance of survival once they have been exposed to the disease.

This trial is necessary in humans to ensure there are no significant adverse side effects. Success of this safety trial will provide clinicians with the confidence to offer treatment to patients who have been exposed to medium to high levels of HeV without the fears of potentially serious side effects.

1.1 Justification for Dose Chosen

The maximum therapeutic human dose given for compassionate reasons was based on doses administered in animal studies, and was around 15-20 mg/kg. It is know from the animal studies that they were challenged with lethal doses of Hendra and Nipah virus and mAb m102.4 doses were effective. Typically humans are not exposed to such high levels of the virus through natural infection. Animals are challenged via the intra-tracheal route, whereas humans are exposed via the mucosal route and with much lower levels of virus. A dose that is effective in ferrets and monkeys for such large challenge doses of virus should be more than adequate to cope with much lower levels of the HeV that humans are experiencing.

Fourteen monkeys were challenged intra-tracheally with HeV and 12 animals were infused twice with a 100 mg dose (20 mg/kg) of m102.4 beginning at either 10, 24 or 72 hours after introduction to the virus and received a second infusion of m102.4 48 hours later. All 12 animals that received m102.4 survived the infection; whereas the untreated control monkeys succumbed to severe systemic disease by Day 8[1]. There was no evidence of HeV mediated pathology in any of the m102.4-treated animals and no infectious HeV could be recovered from any tissues from any m102.4-treated animals.

The starting dose for this study has been set at 1 mg/kg. This is based on a repeat dose toxicology study where four groups of male and female rats, 30 per group, were administered a once weekly dose of m102.4 or vehicle control via IV injection for four weeks. Necropsies were performed at the end of the dosing period (20 rats per group) and after a 2-week recovery (10 rats per group). The m102.4 treatment was well tolerated and there were no unscheduled deaths prior to completion of the main study or recovery period. Test article treatment was not associated with morbidity or clinical signs of toxicity. There was no adverse treatment related effect on body weight, or food and water consumption. There was a trend towards elevated WBC count in male and female rats at the end of the main study (significant in male rats treated with high-dose m102.4, and in female rats treated with mid- and high-dose m102.4). There were significant findings in differential white cell counts mostly in the high-dose group. While the trend in elevated total WBC count persisted at all doses at the end of the recovery phase, the findings were not significant. Significant findings in differential white cell count at the end of the recovery phase were observed at all doses in male rats, and at the low and high dose groups in female rats. There were no adverse treatment dependent differences in serum biochemical profile or urinalysis findings. A treatment-related increase in incidence of lung granuloma was seen at the end of the treatment phase, particularly in female rats all receiving doses of m102.4. Both male and female animals treated with m102.4 showed evidence of decreased incidence of lung granuloma following the recovery phase. There was no treatment-related induction of anti-drug antibodies following once weekly dosing with m102.4, for 28 days at all doses administered.

The no observed adverse effect level (NOAEL) for m102.4 was 100 mg/kg. This amount is well in excess of the dose range (1 mg/kg – 20 mg/kg) planned for this trial.

2 STUDY OBJECTIVES AND PURPOSE

2.1 Purpose of the Study

The purpose of the study is to assess the safety, tolerability, Pharmacokinetics (PK), immunogenicity and exploratory Pharmacodynamics (PD) of mAb m102.4 administered via Intravenous (IV) infusion to healthy subjects in four single escalating doses and one multiple dose at the highest concentration.

2.2 Objectives

The objectives of this study are:

1 To determine the safety and tolerability of single and multiple IV administration of mAb m102.4 in healthy subjects
2 To determine the PK and immunogenicity of single and multiple IV administration of mAb m102.4 in healthy subjects
3 To explore the PD of single and multiple IV administration of mAb m102.4 in healthy subjects against Hendra (and possibly Nipah) virus

3 STUDY DESIGN

3.1 Overall Study Design

This is a Phase I, randomized, double-blind, placebo-controlled, dose escalation study. Subjects will be dosed with four concentrations of mAb m102.4 across five cohorts. The first four cohorts (Cohorts 1 to 4) will receive a single, IV infusion of mAb m102.4 at a concentration of 1 mg/kg, 3 mg/kg, 10 mg/kg or 20 mg/kg over a period of 1 hour. The fifth cohort (Cohort 5) will receive two IV infusions of mAb m102.4 at a concentration of 20 mg/kg given over the period of 1 hour, with 72 hours between each infusion.

All subjects will undergo Screening procedures within 28 days of the first dose of investigational product (IP). Subjects in cohorts 1-4 will be admitted to the clinical research unit (CRU) on the afternoon of Day -1 and receive a single dose of IP on Day 1 following overnight fast. Each subject dosed will be confined for a total period of 3 days (Day -1 to Day 3) and allowed to leave the CRU on the morning of Day 3. The subjects in Cohort 5 will be admitted to the CRU on the afternoon of Day -1 to be dosed with IP on the mornings of Day 1 and Day 4 following overnight fast in each case. Each Cohort 5 subject dosed will be confined for a total period of 6 days (Day -1 to Day 6) and allowed to leave the CRU on the morning of Day 6.

Safety assessments for **Cohort 1-4** will be conducted upon admission to the CRU, at baseline (Day 1) and during the clinical stay. Subjects will return to the CRU on Days 4, 6, 8, 15, 22, 29, 43, 57, 85 and 113 for PK and immunogenicity sampling and safety assessments.

Safety assessments for **Cohort 5** will be conducted upon admission to the CRU, at baseline (Day 1) and during the clinical stay. Subjects will return to the CRU on Days 7, 9, 11, 18, 25, 32, 39, 53, 67, 95 and 123 for PK and immunogenicity sampling and safety assessments.

The final safety assessment is scheduled for a maximum of 16 weeks after the last dose of IP. This is based on a mAb m102.4 t½ of 21-23 days.

Where applicable, Serious Adverse Events (SAEs) will be followed for a further 30 days after the final safety assessment, or until resolved, whichever is the earlier.

For all cohorts, two sentinel subjects will be randomized in a blinded fashion in which 1 subject receives mAb m102.4 and 1 subject receives placebo. The remaining 6 subjects in each cohort will receive IP (5 x mAb m102.4: 1 x placebo) a minimum of 14 days after the sentinel pair, following review of by the PI and the Medical Monitor.

The decision to progress to each successive higher dose will be made after completion of safety data review through Day 29 for at least six subjects per group, and after the Safety Review Committee (SRC) determines that it is safe to proceed to the next dose level.

The assessments, sampling times and follow-up period for subsequent cohorts may be adjusted following SRC review of PK data through to Day 43 for Cohort 1. PK analysis and review will occur whilst Cohort 2 is ongoing.

All PK data for Cohorts 1-4 will be reviewed by the SRC prior to the commencement of Cohort 5 to ensure that the dose and planned dosing interval are optimal. Adjustments to the dose and dosing interval for Cohort 5 may be made depending on the outcome of the review.

3.1.1 Study Centre

This study will be conducted at QPharm Pty Ltd, who have extensive experience in phase I studies involving mAbs and vaccines as well as an excellent record of recruitment for studies of this nature and compliance with study protocols and regulations.

3.1.2 Study Duration

The duration of this study will be approximately 5 months per subject, based on a Screening period of up to 28 days prior to dosing, one (Cohorts 1-4) or two doses (72 hours apart, Cohort 5) of IP and a maximum 16-week follow-up period.

The schedules of assessment for Cohorts 1-4 and Cohort 5 are presented in Table 1 to Table 5.

SRC Review											DE				

1 Weight only
2 Brief physical examination
3 Blood pressure, pulse rate, respiratory rate, temperature
4 Haematology (Red blood count, haemoglobin, haematocrit, mean cell volume, platelets, white blood cell count with differential including neutrophils, lymphocytes, eosinophils, basophils) and biochemistry (albumin, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, bicarbonate, total and direct bilirubin, blood urea nitrogen, calcium, chloride, creatinine, glucose, potassium, uric acid, total protein)
5 Coagulation (PT, INR, aPTT) only at Screening, Day -1, Days 2, 8 and 113 (EOS)
6 IgG and complement at Screening only
7 Test for Hepatitis B and C, HIV, Retain sample for Hendra and Nipah virus
8 Pregnancy test: Serum pregnancy test at Screening and urine pregnancy test at other time points. Positive or equivocal urine pregnancy results will be confirmed by serum test. IP should be held during the interval between positive urine test and receipt of serum test results.
9 AEs will be collected from commencement of the infusion
10 Samples to be stored
DE: Minimum data required per Cohort for dose escalation review
EOS: End of Study
SRC: Safety Review Committee

3.2 Summary of Study Procedures

All subjects must give their informed consent before any study-specific procedures are performed.

The following deviations of the timing of assessments will be allowed:

All Cohorts during confinement period:

Pre-dose samples up to 45 minutes prior to dosing
Samples between 0-4 hours inclusive post infusion +2 minutes
Samples between 4-14 hours inclusive post infusion +5 minutes
Sampling between 14-16 hours inclusive post infusion +15 minutes
Sampling at more than 16 hours post infusion ± 30 minutes

Cohorts 1-4:

± 4 hours for Day 5-11, ±1 day for Days 12-15, ±2 days for Days 16-22, ±3 days for Day 23-32, ±4 days for Day 33-43, ±5 days for Day 44-57, ±6 days for Day 58-85 and ± 7 days for Day 86-113.

Cohort 5:

± 4 hours for Day 8-11, ±1 day for Days 12-15, ±2 days for Days 16-22, ±3 days for Day 23-32, ±4 days for Day 33-43, ±5 days for Day 44-57, ±6 days for Day 58-85 and ± 7 days for Day 86-123.

The following procedures will be performed at each study visit.

3.2.1 Screening Visit

- Demographic data (Date of birth, gender, race, ethnicity)
- Obtain medical history
- Collect prior and concomitant medication (for the last 90 days for contraception and last 60 days for other medications)
- Inclusion and exclusion criteria check
- Physical examination
- Weight and height (with calculation of BMI)
- Perform alcohol breathalyzer
- Collect urine for urinalysis and urine drug screen
- Obtain vital signs (systolic and diastolic blood pressure, pulse rate, respiration rate and body temperature)

- Perform 12-lead ECG
- Collect blood for pregnancy test (females of child-bearing potential only)
- Blood samples for haematology, biochemistry, coagulation, serology (test for HIV, HepBsAg and anti-HCV, retain samples for Hendra and Nipah virus), IgG and complement

3.2.2 Day -1

Subjects will be admitted to the CRU in the late afternoon for dosing the next morning. The following procedures will be performed following admission to the CRU:

- Update prior and concomitant medication
- Weight
- Perform alcohol breathalyzer
- Collect urine for urinalysis, urine drug screen and urine pregnancy test
- Vital signs
- Inclusion and exclusion criteria check
- Blood samples for haematology, biochemistry and coagulation

3.2.3 Day 1 (pre-dose)

- Update prior and concomitant medications
- Brief physical examination
- Vital signs
- Perform 12-lead ECG
- Inclusion and exclusion criteria check
- Randomization
- Baseline blood samples for mAb m102.4 antibodies
- Baseline blood samples for virus neutralization
- PK sampling

3.2.4 Day 1/Dosing

All of the time points provided for Day 1 to End of Study are provided relative to the commencement of the first infusion of IP for all subjects.

- Time 0: commencement of IV IP administration for 1 hour
- Blood samples for virus neutralization (12 hours)
- PK sampling (1, 4, 8 and 12 hours)
- Vital signs (1, 2, 4, 8 and 12 hours)

- Perform 12-lead ECG (2, 4 and 8 hours)
- Record all concomitant medication use
- Record all AEs

3.2.5 Day 2/24 hours

- Blood samples for haematology, biochemistry and coagulation
- Vital signs
- Perform 12-lead ECG
- Blood samples for virus neutralization
- PK sampling
- Record all concomitant medication use
- Record all AEs

3.2.6 Day 3/48 hours

Cohorts 1-4

- Brief physical examination, vital signs
- Record all concomitant medication use
- Record all AEs
- Leave the CRU

Cohort 5

- Record all concomitant medication use
- Weight
- Vital signs
- PK sampling
- Record all AEs

3.2.7 Day 4

Cohorts 1-4

- Vital signs
- Blood samples for virus neutralization
- PK sampling
- Record all concomitant medication use
- Record all AEs

Cohort 5

Pre-second dose:

- Record all AEs
- Record all concomitant medication use
- Brief physical examination
- Urine sample for urinalysis
- Vital signs
- Perform 12-lead ECG
- Blood samples for haematology and biochemistry
- Blood samples for virus neutralization
- PK sampling
- Inclusion and exclusion criteria check
- Time 0: commencement of IV IP administration for 1 hour (2nd dose)

Post-dose: (Dosing is at 72 hours post first dose; Time = 0 h post second dose)

- Vital signs (73, 74, 76, 80 and 84 hours post 1st dose)
  (1, 2, 4, 8 and 12 hours post 2nd dose)
- PK sampling (73, 76, 80 and 84 hours post 1st dose)
  (1, 4, 8 and 12 hours post 2nd dose)
- 12-lead ECG (74, 76 and 80 hours post 1st dose)
  (2, 4 and 8 hours post 2nd dose)
- Record all concomitant medication use
- Record all AEs

3.2.8 Day 5 (96 hours, Cohort 5 only)

(24 hours post 2nd dose)

- Vital signs
- Blood samples for haematology, biochemistry and coagulation
- PK sampling
- 12-lead ECG
- Record all concomitant medication use
- Record all AEs

3.2.9 Day 6

Cohorts 1-4

- Vital signs
- PK sampling
- Record all concomitant medication use
- Record all AEs

Cohort 5 (120 hours)

(48 hours post 2nd dose; before leaving the CRU)

- Brief physical examination
- Vital signs
- 12-lead ECG
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.10 Day 7 (Cohort 5 only)

- Vital signs
- PK sampling
- Record all concomitant medication use
- Record all AEs

3.2.11 Day 8 (Cohorts 1-4 only)

- Vital signs
- Blood samples for virus neutralization
- PK sampling
- Blood samples for haematology, biochemistry and coagulation
- 12-lead ECG
- Record all concomitant medication use
- Record all AEs

3.2.12 Day 9 (Cohort 5 only)

- Vital signs
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.13 Day 11 (Cohort 5 only)

- Vital signs
- PK sampling
- Blood samples for haematology, biochemistry and coagulation
- 12-lead ECG
- Record all concomitant medication use
- Record all AEs

3.2.14 Day 15 (Cohorts 1-4 only)

- Vital signs
- PK sampling
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.15 Day 18 (Cohort 5 only)

- Vital signs
- PK sampling
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.16 Day 22 (Cohorts 1-4 only)

- Vital signs
- Record all concomitant medication use
- Record all AEs

3.2.17 Day 25 (Cohort 5 only)

- Vital signs
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.18 Day 29 (Cohorts 1-4 only)

- Brief physical examination
- Vital signs
- PK sampling

- 12-lead ECG
- Blood samples for haematology and biochemistry
- Blood samples for mAb m102.4 antibodies
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.19 Day 32 (Cohort 5 only)

- Vital signs
- PK sampling
- Record all concomitant medication use
- Record all AEs

3.2.20 Day 39 (Cohort 5 only)

- Brief physical examination
- Vital signs
- 12-lead ECG
- Blood samples for haematology and biochemistry
- Blood samples for mAb m102.4 antibodies
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.21 Day 43 (Cohorts 1-4 only)

- Vital signs
- PK sampling
- Record all concomitant medication use
- Record all AEs

3.2.22 Day 53 (Cohort 5 only)

- Vital signs
- PK sampling
- Record all concomitant medication use
- Record all AEs

3.2.23 Day 57 (Cohorts 1-4 only)

- Brief physical examination
- Vital signs

- 12-lead ECG
- Blood samples for haematology and biochemistry
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.24 Day 67 (Cohort 5 only)

- Brief physical examination
- Vital signs
- 12-lead ECG
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.25 Day 85 (Cohorts 1-4 only)

- Vital signs
- 12-lead ECG
- PK sampling
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.26 Day 95 (Cohort 5 only)

- Vital signs
- 12-lead ECG
- PK sampling
- Blood samples for haematology and biochemistry
- Record all concomitant medication use
- Record all AEs

3.2.27 Days 113 (Cohorts 1-4) and Day 123 (Cohort 5)

End of study visit for all subjects.

- Physical examination
- Vital signs
- Urine sample for urinalysis and pregnancy test (females of child-bearing potential only)
- PK sampling
- 12-lead ECG

- Blood samples for haematology, biochemistry and coagulation
- Blood samples for mAb m102.4 antibodies
- Blood samples for virus neutralization
- Record all concomitant medication use
- Record all AEs

3.2.28 Early Termination/Discontinuation Visit

Subjects that withdraw from the study, or who are discontinued by the Investigator will be asked to attend an early termination visit at the CRU. Assessments to be conducted at the early termination visit are as described for the end of study visit above.

3.2.29 Unscheduled Visits

Subjects will be asked to attend the CRU for unscheduled visits as the need arises. Instances where this may be required are for follow-up on any AEs/SAEs or for repeat blood tests or safety assessments.

3.3 Allocation to Treatment/Blinding

Subjects will be assigned a sequential screening number at their Screening visit. Eligible subjects be randomized on the morning of Day 1 and will be allocated a randomization number. Each subject will have a corresponding IP or placebo allocated on the randomization list. The two sentinel subjects in each cohort will be dosed first. In accordance with the randomization list one subject from the sentinel pair will receive IP and the other will receive placebo. The remaining six subjects per cohort will be randomized to receive either IP or placebo in a 5:1 ratio. In order to maintain the study blind the randomization list will only be available to the un-blinded pharmacist and will be held in a secure location with restricted access.

3.4 Breaking the Blind

Only in the case of an emergency, when knowledge of the IP is essential for the welfare of the subject, the Investigator may un-blind a subject's treatment assignment. If the blind is broken for any reason, the Investigator must notify the Medical Monitor immediately of the un-blinding incident. Emergency un-blinding may be performed using the code-break envelopes supplied to the PI at the site. The code-break envelope must be signed and dated when the code is broken and the reason for un-blinding provided on the envelope and documented in the source notes. All code-break envelopes, whether sealed or opened, must be returned to the Sponsor at the end of the study.

If an unexpected and related SAE is reported, the treatment assignment for that individual subject may be un-blinded for regulatory reporting.

If a severe AE or SAE in a patient leads to a pause or discontinuation of enrolment per protocol, treatment assignment for that individual subject may be un-blinded. During subsequent investigation, if the Medical Monitor and Safety Committee discover other subjects with relevant AEs, they may additionally request un-blinding of these subjects, if necessary for their determination of whether or not to resume enrollment.

3.5 Dose Escalation and Stopping rules

Based on emerging safety and PK data, the SRC may recommend repeating a dose cohort at a dose shown to be well-tolerated, or initiating an intermediate or lower dose cohort. Initiation of an intermediate dose cohort will only proceed when the previous lower dose(s) have been found to be well tolerated following a blinded review of available safety data through study Day 29 of the current cohort and all available safety data of the previous cohort(s), a positive recommendation by the SRC. The SRC will consist of the PI, medical monitor and Sponsor representative.

There will be a pause in dose escalation to the next planned dose and dose adjustments may be made if any of the following "pausing criteria" are met:

- An SAE reported in more than ≥ 1 subject.
- ≥ 2 subjects experience a common terminology criteria for adverse events (CTCAE) Grade 3 (or higher) event in the same organ or body system.
- ≥ 50% of the subjects in one dose cohort show clinically relevant AEs of moderate to severe intensity

Termination of the study may be considered if these events are considered related to IP to the agreement of the SRC.

3.5.1 Dose Escalation Review

The will review the blinded safety (abnormal pathology, vital signs, ECG) and tolerability (AEs and concomitant medications) of the subjects at various time points. The data for the sentinel subjects from each cohort will be reviewed by the PI and the Medical Monitor only, after a minimum of 14 days to determine whether additional dosing of the remaining six subjects in the cohort can proceed.

Data for at least six of the eight subjects in each cohort will be reviewed through to Day 29 to determine whether dose escalation to the next cohort (i.e., subsequent, higher dose) can proceed.

For both additional dosing and dose escalation the SRC members will formally document their decision to proceed or otherwise.

The SRC members will also review PK data generated for Cohort 1 through to Day 43. Review of the data will be to confirm the mAb m102.4 half-life. Assessment and sampling times and the overall monitoring period for subsequent cohorts may be adjusted depending on the outcome of the review.

In addition, PK data for Cohorts 1-4 will be reviewed prior to the commencement of Cohort 5. Cohort 5 timelines for planned dose and dosing intervals may be adjusted depending on the outcome of the review.

3.6 Concomitant Treatment(s)

3.6.1 Permitted Treatment(s)

Paracetamol is a permitted concomitant medication where clinically indicated. In addition, oral contraceptives will be allowed for females, provided that the subject has been using the oral contraceptive for at least 3 months prior to the Screening visit and no change to this contraception is planned or anticipated for the duration of the study.

The use of non-prescription medications will be discouraged during the course of the study. Prescription medications should be limited and avoided if possible, but will be allowed where clinically indicated. The use of all concomitant medication (including non-prescription medications) will be recorded for each subject for the duration of the study.

3.6.2 Lifestyle Restrictions

Subjects in Cohorts 1-4 will be admitted to the CRU on Day -1 and will be allowed to leave the unit on the morning of Day 3. Subjects in Cohort 5 will be admitted on Day -1 and will be allowed to leave the unit on the morning of Day 6.

Water is permitted without restriction during the conduct of the study, but subjects must fast from at least 8 hours prior to study dosing through 2 hours post-dosing. Meals will be provided following the restriction period and during confinement.

Alcohol will be restricted from 24 hours prior to Day -1 check-in and will not be allowed for 2 weeks following the last infusion of IP. Thereafter, no more than 2 standard drinks per female and 3 standard drinks per male per day will be allowed. One standard drink is (8 g) is equivalent to 280 mL of beer, one measure (25 mL) of spirits or 1 small glass (125 mL) of wine. Alcohol Breath test must be negative for eligibility.

No caffeine-containing beverages will be allowed during confinement in the unit. Caffeine-free beverages will be provided after 4 hours post-dose. Post confinement, no excessive use of caffeine-containing beverages including coffee, tea, cola, energy drinks or chocolates, exceeding 500 mg caffeine/day (approximately 5 cups of coffee or 10 cups of tea) will be allowed.

Subjects are not allowed to smoke > 5 cigarettes per day with only occasional/non-habitual use of nicotine considered acceptable. Subjects should refrain from smoking 48 hours prior to Day -1 check-in. Subjects will not be permitted to smoke whilst inside the study site. Cotinine test must be negative for eligibility at screening and Day -1.

Subjects should refrain from any strenuous physical activity 24 hours prior to Day-1 check-in or follow up blood tests.

3.7 Treatment Compliance

The IP will be given per IV infusion over an hour in the CRU by trained personnel and will be documented in the case report form (CRF). Any deviations will be noted.

3.8 Measures to Minimize Bias

Subjects will be allocated their treatment according to a computer generated randomization schedule.

All site personnel will be blinded, with the exception for the un-blinded pharmacist who prepares the IP for dispensing to clinical staff. The randomization list will be kept in a secure locked facility. The blind will be maintained for the subjects, Investigators and clinic staff, Sponsor personnel, the Project manager and main monitor for the study. An un-blinded pharmacy monitor will be employed to monitor pharmacy compliance and drug accountability.

IP and placebo will be identical in appearance and volume for each subject in each cohort.

4 SELECTION AND WITHDRAWAL OF SUBJECTS

4.1 Number of Subjects

A total of up to 40 subjects will be enrolled to dose in this study (eight subjects in five cohorts).

4.2 Inclusion Criteria

A subject must meet the following inclusion criteria to participate in this study:

1. Written informed consent from the subject;
2. Healthy males and females as determined by medical history and physical examination between 18 and 50 years of age (inclusive);
3. Body mass index (BMI) of 18.0 to 35.0 kg/m^2 (inclusive) at screening (Weight ≥ 50 kg or ≤ 100 kg);
4. Haematology, coagulation, clinical chemistry, and urinalysis test results not deviating from the normal range to a clinically relevant extent at screening
5. Able to comply with requirements for concomitant medications and consumption of caffeine, alcohol, tobacco and nicotine;
6. Willing to attend all the study visits.

4.3 Exclusion Criteria

A subject will be excluded from participating in this study if any of they meet any of the following criteria:

1. Close, unprotected exposure to sick horses with an unexplained illness within 4 weeks of Day 1; or known exposure to potential Hendra infected horses;
2. Clinically significant abnormalities in laboratory test results at Screening or Baseline (Day -1) (biochemistry, haematology and urinalysis parameters) (Liver function tests >1.5 x upper limit of normal [ULN]);
3. Immunoglobulin G (IgG) and complement level outside normal limits (at Screening);
4. Positive urine screen for potential drugs of abuse at Screening and prior to randomization;
5. Presence or history (in last 2 years) of alcohol abuse confirmed by medical history, or daily alcohol intake of more than 2 standard drinks (16 g) for females or more than 3 standard drinks for males, or a positive breath alcohol test at screening or prior to randomization, and the inability to stop alcohol intake for 2 weeks post-infusion
   One standard drink is (8 g) is equivalent to 280 mL of beer, one measure (25 mL) of spirits or 1 small glass (125 mL) of wine;
6. Excessive use of caffeine-containing beverages including coffee, tea, cola, energy drinks or chocolates, exceeding 500 mg caffeine/day (approximately 5 cups of coffee or 10 cups of tea) and the inability to refrain from the use of caffeine-containing beverages during confinement in the CRU;
7. Smoke >5 cigarettes per day;

8. Positive tests for HIV or viral hepatitis (hepatitis B surface antigen [HepBsAg], or anti-hepatitis C [HCV]);
9. Treatment with an investigational drug or biologic within 60 days preceding treatment or plans to take another investigational drug or biologic in the 3 months following IP administration;
10. Blood donation or significant blood loss 60 days prior to Day 1;
11. Plasma donation within 60 days prior to Day 1 or planned donation in the 6 months following IP administration;
12. Males who are sexually active and have a partner who is capable of becoming pregnant, neither of which have had surgery to become sterilized, who are not using an effective method of birth control (e.g., surgically implanted hormonal therapy, intrauterine devices, or oral birth control with barrier method). In addition, male subjects must agree not to donate sperm during the study and in the 6 months following IP administration;
13. Females who are capable of becoming pregnant and who have not had surgery to become sterilized and who are not using an effective method of birth control (e.g., surgically implanted hormonal therapy, intrauterine devices, or oral birth control with barrier method [female condom or male partners to use condom]). For exclusively homosexually active females the restrictions for adequate contraception does not apply (if lifestyle choice change, contraceptive requirements will be applicable);
14. Poor peripheral venous access;
15. Subjects with clinically significant findings from medical history that, in the opinion of the investigator, could interfere with the objectives of the study or put the subject at risk;
16. Subject is unwilling or unable to abide by the requirements of the protocol or inability to be available for follow-up assessments or protocol related procedures;
17. Subject is on staff at the investigator site; or a relative of personnel of the investigator site or of the Sponsor (or Sponsor's affiliates);
18. Use of prescription or non-prescription drugs within 14 days or 5 half-lives (whichever is longer) prior to IP administration and for the duration of the study. Contraceptives for females are allowed – must have been using the same contraceptive for a minimum period of 3 months and must not change the contraceptive during the study;
19. History of allergies, allergic reactions or hypersensitivity to medications;
20. BP systolic >160 mmHg or diastolic >90 mmHg. Allow one repeat measure;
21. Personal or family history of congenital QT syndrome or sudden unexplained death;
22. ECG clinically significant abnormalities including (QTc>450 msec for males and >460 msec for females), AF or atrial flutter, notably bradycardia (<40 bpm) or tachycardia (>100 bpm), complete left or right bundle branch block, Wolf-Parkinson White Syndrome or presence of cardiac pacemaker;
23. Any vaccination in the last month;
24. Pregnant or breastfeeding females.

4.4 Withdrawal Criteria

Subjects should be encouraged to complete all study assessments. However, subjects may withdraw consent to participate in this study at any time and for any reason without penalty or loss of benefits to which they were otherwise entitled. The Sponsor or the Investigator may withdraw subjects at any time for safety or administrative reasons.

A subject may be withdrawn, if any of the following occur during the study:

1. Subject requests withdrawal from the study;
2. Subject withdraws consent;
3. AE makes the continuation of the subject impossible or inadvisable;
4. Pregnancy;
5. Subject is lost to follow-up;
6. Subject discovered after enrollment not to have met the protocol inclusion criteria;
7. Subject refuses to comply with required study procedures;
8. Use of any additional experimental drug or device or participation in another clinical study;
9. The study sponsor terminates the Investigator Site or the study.

If a subject withdraws, the Investigator is to make a reasonable effort to determine the reason for the subject's withdrawal from the study. The reason(s) for subject withdrawal will be recorded on the CRF for all subjects.

Subjects who withdraw from the study will not be replaced. All subjects that withdraw or are discontinued from the study by the Investigator will be asked to complete and early termination visit at the CRU.

5 INVESTIGATIONAL PRODUCT (IP)

5.1 Treatment Groups

There will be five cohorts dosed with mAb m102.4 in this study. The first four cohorts will receive a single dose of 1 mg/kg, 3 mg/kg, 10 mg/kg or 20 mg/kg. Cohort 5 will receive 20 mg/kg in two separate doses, 72 hours apart. There will be eight subjects in each cohort with six randomized to receive mAb m102.4 and two randomized to receive placebo.

5.2 Description of Investigational Product

The IP in this study is the human mAb m102.4, and placebo (normal saline control). The mAb m102.4 is a fully human, IgG_1 κ directed against the HeV G protein.

5.3 Investigational Product Packaging and Labeling

Active mAb m102.4 IP will be packaged with an open-label in single use, 10 mL glass vials containing 10 mL of 10 mg/mL mAb m102.4 formulated with 1x DPBS pH 7.4. Vials are closed with a rubber stopper and flip-off aluminum seal.

5.4 Investigational Product Storage and Disposal

All active IP will be shipped to the CRU frozen and should be stored at -15°C or lower until ready to use. The IP must be thawed before compounding, see the Pharmacy manual for instructions.

IP will be stored in a secure location with limited access under appropriate environmental conditions. Only appropriate personnel will have access to the IP.

Any unused IP will be returned to AIBN/UQ for storage or to organize storage at an appropriate facility.

5.5 Administration of Investigational Product

The IP will be delivered intravenously in normal saline in a volume of 100 mL (Cohorts 1 and 2) and 500 mL (Cohorts 3-5) over a 1-hour period using a peristaltic infusion pump. An experienced and qualified staff member will perform placement of the IV access. Before and after each IV infusion, the IV access will be flushed with normal saline.

The preparation of the IP is described in detail in the Pharmacy manual.

Administration of each individual subject will not occur until 30 minutes from the previous subject infusion. Medical therapy and supportive care should be deployed as necessary for any symptoms of drug hypersensitivity. Physicians and nurses involved with the administration of IP are trained in intermediate life support techniques and appropriate medical therapies will be immediately available.

5.6 Investigational Product Accountability

The Investigator and study pharmacist are responsible for maintaining a current record of the IP. IP received from the Sponsor, dispensed to the subjects and returned to the Sponsor will be recorded with corresponding dates.

For more information regarding IP handling and preparation please see the Pharmacy manual, provided as a separate document.

An un-blinded pharmacy monitor will be employed to review product accountability and verify appropriate pharmacy procedures for the study are adhered to.

6 ASSESMENT OF PHARMACODYNAMICS (PD) AND PHARMACOKINETICS (PK)

6.1 Immunogenicity and Virus Neutralization

Immunogenicity and Hendra (possibly also Nipah) virus neutralization will be collected per the study schedule and potentially assessed at the end of the study.

6.2 Pharmacokinetics

Blood samples for the measurement of mAb m102.4 levels will be collected by a qualified staff member during the visits as indicated in the schedule of assessments. Blood samples will be collected via direct venipuncture or cannula.

Detailed instructions for the collection, labeling, handling, processing, storage, and shipment of the PK samples will be documented in the site laboratory manual. All study personnel will be trained in the appropriate study procedures prior to the initiation of subject enrollment.

PK samples for Cohort 1 will have an interim analysis after collection of the Day 43 sample. Data will be reviewed by the SRC and adjustments to assessments, sample timings and follow-up period for subsequent cohorts may be implemented. Analysis and review of the Cohort 1 PK samples and data will be conducted whilst Cohort 2 is ongoing.

PK samples for the remainder of Cohort 1 and Cohorts 2-4 will be analyzed after completion of Cohort 4. All PK samples for Cohorts 1-4 will be reviewed by the SRC prior to the commencement of Cohort 5 to ensure that the dose and planned dosing interval is optimal. Adjustments may be made to the dose and dosing interval for Cohort 5 as deemed appropriate following review.

7 ASESSMENT OF SAFETY

7.1 Safety Endpoint(s)

Safety will be assessed during the study through physical examination, urinalysis, vital signs, ECG and laboratory tests as outlined in the Schedules of assessment (Table 1 to Table 5).

7.2 Physical Examination

A complete physical examination will include assessments of general appearance; skin and lymphatics; eyes; ears; nose; throat; cardiovascular system; respiratory system; abdomen/gastrointestinal system; musculoskeletal and neurological systems. Other body systems may also be examined.

A brief physical examination will include assessments of general appearance; cardiovascular system; respiratory system and abdomen/gastrointestinal system. Other body systems may also be examined if indicated through subject complaints.

Clinically significant changes from baseline (Day 1) will be recorded as AEs.

7.3 Height, Weight and BMI

Height will be recorded in centimeters (cm) and only at Screening. Weight will be recorded in kilograms (kg) and will be taken at Screening, Day -1 (all subjects) and Day 3 (Cohort 5 only). Weight is measured with subjects wearing light clothing without shoes. BMI will be calculated using the formula kg/m^2.

7.4 Vital signs

Vital signs include systolic and diastolic blood pressure, pulse rate, respiration rate and body temperature. Blood pressure and heart rate will be measured in a sitting position after resting for 5 minutes. Systolic blood pressure (SBP) and diastolic blood pressure (DBP) should be measured in millimeters of mercury (mmHg), heart rate in beats per minute, respiration rate in breaths per minute and temperature (oral) in degrees Celsius (°C). Vital signs will be measured at every visit.

7.5 12-lead ECGs

ECGs will be taken as indicated in the schedules of assessments.

The subject must be resting in a semi-supine or supine position for at least 5 minutes prior to performing the ECG. The same ECG machine should be used for all recordings from an individual subject, when possible. ECGs will be read by the Investigator or designated physician at the unit. Machine-read automated ECG intervals (PR, QRS, QT and HR), and calculated RR intervals will be captured on the CRF and if applicable any other abnormalities noted. QTcF values will be derived from the data available.

Single ECG recordings will be taken at each time point. One repeat is allowed for screening purposes if abnormal findings are observed.

For safety monitoring purposes, the investigator or designee must review, sign and date all ECG tracings. Paper copies will be kept at the study center with the subject's clinical file as part of the permanent record. The ECG intervals and interpretation will be recorded on the CRF. Paper ECG recordings should be photocopied and maintained as a permanent source document. The Sponsor reserves the right to request copies of paper ECG recordings for independent cardiology review.

7.6 Clinical Laboratory Tests

Laboratory data obtained on Day -1 (pre-dose) will be used as baseline in the safety analyses. Safety Laboratory Data include:

- Complete blood count (CBC): haemoglobin, haematocrit, RBC count, MCV, WBC with differential (neutrophils, bands, lymphocytes, monocytes, eosinophils, basophils), and platelets.
- Coagulation: Prothrombin time (PT), international normalized ration (INR), activated partial PT (aPTT).
- Chemistry panel: Albumin, alkaline phosphatase (ALP), alanine aminotransferase (ALT, SGPT), aspartate aminotransferase (AST, SGOT), bicarbonate, total and direct bilirubin, blood urea nitrogen (BUN), calcium, chloride, creatinine, glucose, potassium, uric acid and total protein). Estimated glomerular filtration rate (eGFR) will be calculated with each serum creatinine measurement using the Cockroft Gault equation.
- Urinalysis: specific gravity, pH, protein, glucose, ketones, bilirubin, blood, nitrite, and leukocyte esterase.
    - Specimens with abnormal Protein, WBC or RBC will be submitted for microscopy testing and reporting on WBCs, RBCs, epithelial cells, casts, crystals, yeast, and bacteria. Specimens with elevated WBC may be submitted for microbiological testing for infection.

Screening blood tests include:

- Serology: hepatitis (HepB surface antigen, anti-HCV), HIV
- Immunology: IgG and complement (Screening only)

Drug Screening includes:

- Urine Drug Screen:
  - Cocaine, narcotics, cannabis, barbiturates, benzodiazepines, amphetamines
  - Cotinine
- Breath Alcohol test

Immunogenicity and Virus Neutralization

- Formation of anti-mAb m102.4 antibodies will be tested. These samples will be stored as frozen samples for future testing upon completion of the study.
- mAb m102.4 virus neutralization for Hendra (and possibly Nipah) will possibly be assessed (samples to be stored)

7.7 Pregnancy Tests

All females of child-bearing potential will have pregnancy tests performed at the designated time points. A serum pregnancy test will be performed at Screening and urine pregnancy tests at the other time points. In the event of a positive or equivocal urine pregnancy test, a confirmatory serum pregnancy test will be performed.

7.8 Adverse Events (AEs)

7.8.1 Definitions

AEs are any untoward medical occurrence in a patient or clinical investigational subject administered a pharmaceutical product and which does not necessarily have to have a causal relationship with this treatment.

Treatment-emergent AEs (TEAEs) are events that are not present at baseline, or if present at baseline, have worsened in severity.

A pre-existing condition is one that is present at the start of the study and is reported as part of the subject's medical history. A pre-existing condition should be reported as an AE only if its frequency, intensity or character worsens during study treatment.

Study subjects should be instructed to report all AEs to the Investigator and all AEs that occur from the time of commencement of IP through the follow-Up Visit or premature termination visit will be recorded. All AEs must be appropriately documented in the subject's original source documents and on the CRFs. Investigators should report syndromes rather than list symptoms.

7.8.2 Grading of Adverse Events

The severity of each AE will be categorized using the following criteria:

Grade 1 (Mild): usually transient; requires no special treatment and does not interfere with the subject's daily activities. No limitation in daily activity.

Grade 2 (Moderate): produces a low level of inconvenience to the subject and may interfere with daily activities. These events are usually ameliorated by simple therapeutic measures. Some limitation in daily activity.

Grade 3 (Severe): interrupts daily activity and requires systemic drug therapy or other medical treatment. Unable to perform daily activity.

7.8.3 Relationship to Investigational Product

The Investigator must make an assessment of the relationship of the event to the IP using the following scale:

Unrelated: The event is definitely not or unlikely to be associated with IP administration and is judged due to causes other than the IP (alternative cause to be specified on the CRF).

Related: The event is possibly or probably related with IP administration. If related, the event should be further classified as possibly or probably related:

- Events considered to be possibly related are those that follow a reasonable temporal sequence from administration of the IP, but that may be due to another cause and could also be reasonably explained by the subject's clinical state or other modes of therapy administered to the subject.
- Events considered to be probably related are those that follow a reasonable temporal sequence from administration of the IP, that is not easily explained by another cause such as known characteristics of the subject's clinical state or other treatment, and is confirmed by improvement on stopping or slowing administration of the study agent (de-challenge), if applicable.

7.8.4 Laboratory Test and other Test Abnormalities as Adverse Events

Only laboratory abnormalities or other tests (ECG, vital sign) that have been judged by the Investigator as clinically significant, have clinical manifestations, or requires therapeutic intervention should be reported by the Investigator as AEs. When possible, syndromes/diagnosis, not laboratory values, should be reported as AEs. For example, decreased haemoglobin and haematocrit requiring iron supplementation should be recorded as "anaemia."

7.9 Serious Adverse Events

The Investigator is required to determine if each AE is an SAE. According to the ICH guidelines for Good clinical practice (GCP) (E6), an SAE is any untoward medical occurrence during the course of the clinical investigation that is characterized by one or more of the following:

- Results in death, or
- Is life-threatening, or
- Requires inpatient hospitalization or prolongation of existing hospitalization, or
- Results in persistent or significant disability/incapacity, or
- Is a congenital anomaly/birth defect.

Important medical events that may not result in death, be life-threatening, or require hospitalization may be considered SAEs when, based upon appropriate medical judgment, they may jeopardize the subject and may require medical or surgical intervention to prevent one of the outcomes listed in this definition.

In the event of death, the cause of death should be recorded as the SAE (death is an outcome, not the AE itself).

Any planned procedures that require admission to hospital for compliance with this protocol as well as any planned elective procedures are not considered SAEs (unless the underlying condition has worsened or the procedure results in a worsening of the subject's condition). In addition pregnancy that occurs during the course of the study or absence of a treatment effect will also not be considered to be an SAE.

7.9.1 Reporting for Serious Adverse Events (24 Hours)

An SAE must be followed clinically until resolution or stabilization.

All SAEs after the time of consent must be reported to the Sponsor or the Sponsor's representative within 24 hours of the CRU's knowledge of the occurrence. The CRU will either telephone the report to the Sponsor's Medical Monitor or transmit by email or facsimile a SAE Report to the Sponsor's Medical Monitor of the Sponsor's representative. If the initial report is made via telephone, a completed SAE report (SAER) must be emailed or faxed within 24 hours of the CRU's knowledge of the event. Investigational sites will be provided with the necessary forms.

The SAE information phoned/emailed/faxed to the Sponsor or the Sponsor's representative will include the following (as available):

- Subject identification, Investigator name

- SAE information: event term, onset date, severity, and casual relationship
- Basic demographic information (e.g., age, gender, weight)
- The outcomes attributable to the event (death, a life-threatening adverse drug experience, inpatient hospitalization or prolongation of existing hospitalization, a persistent or significant disability/incapacity, other important medical event[s])
- The first and last dates of IP administration, if applicable
- A statement whether IP was discontinued or IP administration schedule modified
- A statement whether event recurred after reintroduction of IP if administration had been discontinued or withheld
- Supplemental information may include the following hospital records: laboratory results, progress notes, admission and emergency room notes, observation notes, discharge summaries, autopsy reports, and death certificates, etc.

The SAER should be emailed/faxed within 24 hours with as much of the above information as available at the time. Supplemental information may be transmitted using a follow-up report and should not delay the initial report.

For regulatory purposes, initial reports of SAEs should be transmitted within the prescribed time frame as long as the following minimum information is available: subject identification, suspect IP, reporting source, and an event or outcome that can be identified as being both serious and unexpected for which the Investigator can make a relationship assessment.

The SAE report will be sent Dr Stephen Lambert, Medical Epidemiologist, Queensland Department of Health.

8 STATISTICS

8.1 Statistical Methods

This is a randomized, parallel arm, double-blind, placebo-controlled study designed to determine the safety, tolerability, and PK of mAb m102.4 in healthy subjects. No formal hypothesis tests will be conducted in this study. The statistical analysis will comprise summary descriptive statistics of the 5 dose groups and placebo group over the time points of observation. For continuous variables, the summary statistics will include: the number of observations, number of missing observations, mean, median, standard deviation, interquartile range, minimum and maximum. The interquartile range, minimum and maximum values will be presented to the same number of decimal places as recorded in the CRF. Mean, median and standard deviation will be presented to 1 more decimal place than the raw data. For binary or categorical variables the summary statistics will include frequency counts and percentages. Percentages will be rounded to 1 decimal place, with the denominator being the number of subjects in the relevant population, unless otherwise stated. All confidence intervals reported will be two-sided 95% confidence levels.

Subjects who withdraw from the study, for any reason, prior to study completion will have all data applied to planned analyses, regardless of treatment duration, up to the point of discontinuation.

Planned change from baseline analyses will utilize the last available assessment prior to drug administration as the baseline value. If the subject has a missing baseline assessment then that subject will be excluded from any change from baseline analysis.

All planned analyses will be completed using SAS Software® (version 9.1 or greater), unless otherwise specified.

A comprehensive statistical analysis plan will be completed that will describe the full details of prospective analyses for the study.

8.2 Sample Size

The sample size for this study was not based on statistical power calculation, but is consistent with the typical sample size used for similar studies to assess preliminary safety, PK and immunogenicity data. If a safety signal occurred in 25% of randomly selected subjects, then with 6 subjects in each dose cohort, the probability of observing the safety signal in at least one patient equals 0.82, which is judged to be adequate power.

8.3 Analysis Populations and/or Subsets

Safety Population: The Safety population shall consist of all randomized subjects who receive at least one dose of IP whether a complete dose or not. The Safety Population will be analyzed as treated regardless of the randomized treatment.

Pharmacokinetic Population: The PK population will comprise all randomized and dosed subjects who have sufficient observed plasma concentrations to allow calculation of the PK parameters. PK parameters will be calculated for mAb m102.4 based on the actual treatment received. A review of the plasma samples obtained will be completed by a pharmacokineticist to determine if sufficient samples exist for each subject to allow for computation of PK parameters. A listing will be provided of excluded subjects, with the reason for exclusion for the PK population.

8.4 Safety Analyses

Safety analyses will be conducted on the safety population and summarized by the 5 dose cohorts and placebo cohort.

AEs will be grouped by the Medical Dictionary for Regulatory Activities (MedDRA) system organ class and preferred term. The summary tables will present the number and percentage of subjects and number of events, by system organ class and preferred term. AE summaries will be by 5 dose cohorts and placebo cohort. For each subject, the maximum severity of each AE that is mapped to the same preferred term will be considered in the summaries. In addition, separate summaries will be provided for AEs by severity and relationship to IP. SAEs and AEs that lead to premature discontinuation or death will be listed separately.

Safety laboratory data (hematology, biochemistry, coagulation and urinalysis), vital signs, weight and ECG data will be summarized by time points and the 5 dose cohorts and placebo cohort. Shifts from normal to abnormal will be summarized for ECG, hematology, biochemistry, coagulation, selected urinalysis parameters and selected vital signs parameters.

Physical examination, and pregnancy test data may be listed only. All safety parameters will be presented for individual subjects in data listings.

8.5 PK Analyses

PK parameters will be calculated for each subject using actual sampling times and standard non-compartmental methods. In all calculations, concentrations below the quantification limit will be set to zero.

Individual and mean plasma mAb m102.4 concentrations at each sampling time point will be summarized in a graphical and tabular manner by dose cohort, and time. Individual and mean concentrations versus time plots will be depicted on linear and semi-logarithmic scales. Summary statistics (including means, geometric mean, ranges, standard deviation, and coefficients of variation) of mAb m102.4 plasma concentration by time point and PK parameters will be presented.

8.6 Missing Data

There will be no imputation for missing data.

8.7 Interim Analyses

PK data through Day 43 for Cohort 1 will be analyzed in at least 6 of the 8 subjects. Additionally, PK data for Cohorts 1-4 will be analyzed at the end of Cohort 4, before Cohort 5 will be dosed.

9 STUDY ADMINISTRATION

9.1 Ethical Considerations

9.1.1 Ethical Principles

This study will be conducted under a protocol reviewed by an Human Research Ethics Committee (HREC), the study is to be conducted by scientifically and medically qualified persons, the benefits of the study are in proportion to the risks, the rights and welfare of the subjects will be respected, the physicians conducting the study will ensure that the hazards do not outweigh the potential benefits and the results to be reported will be accurate. The study will conform to ICH GCP guidelines, the ethical principles that have their origin in the Declaration of Helsinki, and all applicable regulatory requirements.

9.1.2 Informed Consent

All subjects for this study will be provided a consent form describing this study and providing sufficient information for subjects to make an informed decision about their participation in this study. The Investigator or his/her designee will fully explain in layman's terms the nature of the study, along with the aims, methods, anticipated benefits, potential risks, and any discomfort participation may entail.

This consent form will be submitted with the protocol for review and approval by the HREC. The Investigator is responsible for obtaining the formal consent of a subject (competent to do so and not under duress), using the approved Informed Consent Form (ICF). Consent will be obtained before the subject undergoes any study procedure(s). This ICF must be signed by the subject or legally acceptable representative, and the Investigator-designated study personnel obtaining the consent. A copy of the signed ICF will be given to the subject and the original retained by the Investigator with the site's copy of the CRFs.

9.1.3 Human Research Ethics Committee Approval

The PI at the site is responsible for obtaining written HREC approval for the final protocol, Sponsor-approved ICF, subject information sheet and any advertisements to recruit subjects or tools used by subjects during the study. Written approval for these documents must be obtained from the committee before any subject is enrolled. The PI is also responsible for:

- Obtaining HREC approval for any protocol amendments and ICF revisions before implementing the changes.
- Providing the HREC with any required information before or during the study.

- Submitting progress reports to the HREC, as required, during the duration of the study.
- Notifying the HREC of all serious and unexpected AEs reported by the Sponsor.

9.2 Data Handling and Record Keeping

9.2.1 Data Collection and Reporting

The Investigator must maintain required documents for all study subjects. Data for this study will be recorded in the subject's source documents and on the CRFs. The source documents are to be separate and distinct from the CRFs, except for cases in which the Sponsor has predetermined that direct data entry into specified pages of the subject's CRF is appropriate.

All data on these CRFs should be recorded completely and promptly. A copy of the completed CRFs for each subject will be retained by the CRU.

9.2.2 Monitoring

All aspects of the study will be monitored carefully by the Sponsor's designees with respect to current GCP and standard operating procedures (SOPs) for compliance with applicable government regulations, the study protocol and Investigator's obligations. It is the responsibility of the Investigator to provide all study records, including CRFs, source documents, among other records, for review and inspection by the monitor.

All CRFs will be 100% source verified against corresponding source documentation for each subject. Monitors will periodically evaluate the progress of the study, including the verification of the accuracy and completeness of the CRFs. The completed CRFs must be promptly reviewed, signed and dated by a qualified physician who is an investigator on the study.

9.2.3 Study Records Retention

A file for each subject is maintained, and it includes the signed ICF and the copies of all source documents for that subject. Investigators are required to maintain all documentation, including documents in electronic format, for a minimum of 15 years following the end of the study. The Investigator must inform the Sponsor immediately if any documents are to be destroyed, transferred to a different facility or transferred to a different owner. The Sponsor will notify the site if the trial records are no longer needed.

The study may be selected for an audit to inspect the facilities and review the study-related records in order to evaluate the trial conduct and compliance with the protocol, ICH, GCP and applicable regulatory requirements.

9.3 Financing and Insurance

The study is fully financed by Queensland Department of Health.

The Sponsor has provided a Medicines Australia Form of Indemnity for Clinical Trials in the standard form. The Sponsor has agreed to indemnify and hold harmless Q-Pharm Pty Ltd and its employees, agents in respect of and against all claims and proceedings made or brought by or on behalf of Participants for personal injury to Participants arising out of or relating to the administration and/or use of the products under investigation or any clinical intervention or procedure provided for or required by the Protocol to which the Participants would not have been exposed but for the participation of the Participants in the Study. The indemnity provided by the Sponsor does not extend to any claim or proceeding to the extent that:

a) such personal injury is caused by the negligent or wrongful acts or omissions or breach of statutory duty by those indemnified; and
b) such personal injury is caused by the failure of Q-Pharm Pty Ltd, its employees or agents to conduct the Study in accordance with the Protocol.

If injury is suffered by a Participant while participating in the Study, the Sponsor agrees to adhere to the 'Guidelines for Compensation for Injury Resulting From Participation in a Company-sponsored Clinical Trial' published by Medicines Australia ('Guidelines').

The Sponsor will ensure that it maintains sufficient insurance to enable it to provide the indemnity referred to above and comply with the Guidelines.

9.4 Use of Information

All information not previously published concerning the test product and Queensland Department of Health is considered confidential and is the sole property of Queensland Department of Health. Site personnel agree to use this information only in connection with this study and will not use it for other purposes without written permission from Queensland Department of Health.

9.5 Data Disclosure and Subject Confidentiality

In order to maintain subject confidentiality, all CRFs, study reports and communications that relate to the study, will identify subjects by their initials and assigned subject numbers. Subjects will not be identified by name. The laboratory samples, forms, report or any other records that leave the site will only be identified by a code in order to maintain subject confidentiality. Records are to be kept in a locked facility.

The Investigator will allow the Sponsor or their designee's access to all pertinent records in order to verify the data gather on the CRFs. This access is in accordance to local, national and federal regulations. Regulatory authorities might also request access to the study records, including the source documents. Clinical information will not be released without the written permission of the subject as outlined in the subject consent form.

9.6 Publication Policy

It is agreed that before publication of any study-related data, Queensland Department of Health will be given the opportunity to review and comment upon any manuscript that contains data derived from this study.

Dear authors

We've had positive feedback from the Lancet senior editor on our resubmitted HeV manuscript that was uploaded on Wednesday of this week - - see comments below. The resubmission which includes reviewers comments and our responses, is attached for your records. It is now with the editor-in-chief who hopefully will render a final decision soon.

Will keep you posted.

Kind regards

Sharon

Hi Sharon

Good news thus far.

Please forward to the entire authorship group.

Regards

Geoffrey

Dear Professor Playford,

I hope this email finds you well. I have received your revised version of the article THELANCETID-D-19-01274 “Safety, tolerability, pharmacokinetics, and immunogenicity of a human monoclonal antibody targeting the G glycoprotein of Henipaviruses in healthy adults: a randomised, first-in-human phase 1

study”. I just wanted to let you know that I am happy with the revision and I have passed now the paper to our Editor-in-Chief who needs to make his check.
I had asked you about the delay between trial and submission because we always need to ask when we notice this (there have been instances when major issues were disclosed after probing authors for this issue): I had no doubt that there was a good reason in your case and I want to reassure that the explanation is fine and I am very happy that you sent the paper to us.
Kind regards,

Marco

(Note: The word count will be below 2,000 once the references are in number format.)

Introduction

As part of implementing the World Health Organization’s (WHO’s)*R&D Blueprint for Action to Prevent Epidemics*(WHO 2016), in 2017 WHO embarked on a process to generate a research and development (R&D) roadmap for medical countermeasures (diagnostics, therapeutics, and vaccines) aimed at human infections caused by Nipah virus (NiV). WHO considers NiV a priority pathogen because of its disease severity, the potential for broad global spread of the virus, and the lack of available medical countermeasures. The entire roadmap can be found in the Supplemental Appendix and this report provides a summary of key highlights. NiV, a paramyxovirus of the Henipavirus genus,was first identified after an outbreak of respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000). No additional outbreaks have been reported in these countries; however, since 2001 outbreaks of NiV infection have occurred nearly annually in Bangladesh (Hsu 2004, WHO 2018). Outbreaks also have recently been recognized in India (Arunkumar 2019, Sharma 2018, Chattu 2018) and a possible NiV outbreak occurred in the Philippines in 2014 (Ching 2015).NiV infection is most commonly associated with severe, rapidly progressive encephalitis,which may be of late onset or relapsing (Goh 2000, Hossain 2008, Tan 2002). Some patients also have respiratory involvement or respiratory illness only, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The case-fatality rate is estimated at 40% to 75% (Hossain 2008, WHO 2019).

Commented [Shahana1]: To give more specific feature, may phrase ‘rate of high case fatality’

Fruit bats of the Pteropus genus, which have a wide geographic range, are considered the primary natural reservoir for NiV. Evidence of NiV infection has been found in Pteropus bat

species and other bat species in South Asia, Southeast Asia, the Western Pacific region, and Africa(Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010,Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2019, Yob 2001). The wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing. Person-to-person transmission is well-documented (Arunkumar 2019, Chadha 2006,Gurley 2007, Luby 2009, Nikolay 2019) and respiratorytransmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019**;** Spiropoulou 2019). Concern has been raised about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Cross-Cutting Issues

A major challenge for development of NiV medical countermeasures is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Further efforts are needed to ensure that policy makers in affected countries and global stakeholders understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control. To accomplish this, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate

Commented [Shahana2]: May include early/rapid detection

human populations in areas of predicted risk using a One Health approach (Chattu 2018, Kulkarni 2013).

Optimization of relevant animal modelsis needed, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval of therapeutics or vaccines(Rockx 2014). Issues include: (1) determining the most appropriate animal model(s) for screening assay development; (2) standardizing the challenge strain and dosing parameters (including identifying the most appropriate lethal challenge dose); (3) determining when after challenge medical countermeasures should be administered to best mimic realistic timing of use in humans; (4) bridging data from animal models to humans;and (5) identifying the best models for studying chronic (relapsing) infection(Dhondt 2013, Johnston 2015, Mathieu 2015, Mire 2019). Currently, the African green monkey is considered the most relevant animal model for evaluating candidate therapeutics and vaccines intended for human use (Bossart 2012, Geisbert 2010, Johnston 2015); however, costs, space requirements, and ethical concernsconstrain its use.

To inform NiV medical countermeasure development, additional researchalso is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. Important topics include evaluating pathophysiologic differences between different NiV strains, determining mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to infection.Standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains are also needed to advance research for medical countermeasures(Satterfield 2016).

Diagnostics

The most commonly used methods for diagnosing NiV infection includeenzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies and real time-polymerase chain reaction (RT-PCR) nucleic acid testing (Chadha 2006, Guillaume 2004,Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009, Mazzola 2019). Most laboratories use in-house NiV assays; also only a few commercial PCR kits are available and there is only one commercial source for reagents for ELISA testing (Mazzola 2019). More recently,neutralization assays using non-infectious pseudotyped virus particleshave been developed, which can be used under biosafety level 2 (BSL-2) conditions in laboratories with limited diagnostic capabilities(Bae 2019,Kaku 2009, Kaku 2012, Tamin 2009). Newer technologies are under investigation, such as antigen-capture ELISAs using monoclonal antibodies (Chiang 2010) and reverse transcription-loop-mediated isothermal amplification(RT-LAMP) (Ma 2019); however, more information is needed regarding their performance characteristics, particularly under field conditions.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012);thus, etiologic diagnosis is not always pursued. Rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure and are affordable are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samplesis needed to move NiV diagnostic testing forward. Development of a repository requires addressing complex issues such as determining the governance structure, establishing protocols for sample collection and maintenance, and prioritizing use and access to samples. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients. Comparison of outcomes using 54 historical controls found a lower mortality rate among treated patients (Chong 2001); however, findings may have been biased by use of historical controls.No additional clinical studies using ribavirin have been conducted and limited studies in animal models have not demonstrated efficacy following NiV or Hendra virus challenge(Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may have utility for post-exposure prophylaxis (PEP) (Banerjee 2019).

A promising therapeutic option is monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004).The human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009) and has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Other potential options for NiV treatment include favipiravir, fusion inhibitory peptides, and remdesivir (GS-5734). Initial animal model

studies involving these agents have reported favorable results (Dawes 2018, Mathieu 2018, Lo 2019); however, additional preclinical data are needed to further assess their utility.

Additional considerations for NiV therapeutics include: (1) expanding the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents; (2) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promisingtreatments;(3) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (4) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in endemic areas.

A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that occur each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane

proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus,Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Keshwara 2019, Satterfield 2016).

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials) are not feasible.

Commented [Shahana3]: Also rapid diagnosis of the suspected cases

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized.Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful increating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

---

Dear Kris,

Thank you for sharing the revised draft.

I have attached some minor comments for your consideration.

I concur with the content of the roadmap, reviewed the draft and agree to be listed as a co-author on the manuscript.

Regards,
Shahana

Dear all. Please read the email below. This is just a reminder to send me any comments on the June 2019 version of the Nipah roadmap paper and to confirm that you are willing to be a co-author on the manuscript as outlined below.

Thank you so much for your time!

Warm regards,

Kris

Subject: Revised Nipah R&D roadmap manuscript--please respond by June 25
Importance: High

Dear Colleagues: I hope this message finds each of you well. Per the email that you received in May, I have provided an updated version of the Nipah R&D roadmap manuscript. I have also provided the full roadmap—just in case you want to refer back to that.

Our current plan is to submit this to the NEJM as a Sounding Board article per advice from Marie-Pierre. They will also provide a Supplemental Appendix with the full roadmap. WHO will then publish the roadmap once it has been published in NEJM.

Sounding Board articles have a 2,000 word limit and are structured as commentaries rather than as reviews, so the article has been substantially shortened—please keep that in mind as you go through it.

The process for submission is as follows:

1. Please review this version of the manuscript and **send any comments or edits to me by June 25** (through replying to this email). Please send a response even if you have no comments.
2. In your email response, also please state that you are willing to be a co-author on the manuscript and that you agree you fulfill the criteria for authorship, which for NEJM are:
    - Substantial contributions to conception and design; or acquisition, analysis, or interpretation of data AND
    - Drafting of the article or critical revision for important intellectual content AND
    - Final approval of the version to be published AND
    - Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the article are appropriately investigated and resolved

3. If NEJM decides to request a revised version and move to the next step of accepting the manuscript, there will be three forms each co-author will need to complete—one on conflict of interest, one on copyright transfer, and one stating that you fulfill the authorship requirements. Those will be sent to you at a later time.
4. You will also need to sign off on the final version of the manuscript.

Again, thank you for your time in this important process.

Warm regards,

Kris

(Note: The word count will be below 2,000 once the references are in number format.)

Introduction

As part of implementing the World Health Organization's (WHO's) *R&D Blueprint for Action to Prevent Epidemics* (WHO 2016), in 2017 WHO embarked on a process to generate a research and development (R&D) roadmap for medical countermeasures (diagnostics, therapeutics, and vaccines) aimed at human infections caused by Nipah virus (NiV). WHO considers NiV a priority pathogen because of its disease severity, the potential for broad global spread of the virus, and the lack of available medical countermeasures. The entire roadmap can be found in the Supplemental Appendix and this report provides a summary of key highlights. NiV, a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000). No additional outbreaks have been reported in these countries; however, since 2001 outbreaks of NiV infection have occurred nearly annually in Bangladesh (Hsu 2004, WHO 2018). Outbreaks also have recently been recognized in India (Arunkumar 2019, Sharma 2018, Chattu 2018) and a possible NiV outbreak occurred in the Philippines in 2014 (Ching 2015). NiV infection is most commonly associated with severe, rapidly progressive encephalitis, which may be of late onset or relapsing (Goh 2000, Hossain 2008, Tan 2002). Some patients also have respiratory involvement or respiratory illness only, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The case-fatality rate is estimated at 40% to 75% (Hossain 2008, WHO 2019).

Commented [MR1]: Disease severity can be measured by hospitalization rate, ICU care rate and CFR. In my opinion WHO considered it due to high CFR therefore, I would propose to use high CRF instead of Disease severity to be more specific.

Commented [MR2]: Currently, it is average 72% and may give rise to 100%.

Fruit bats of the Pteropus genus, which have a wide geographic range, are considered the primary natural reservoir for NiV. Evidence of NiV infection has been found in Pteropus bat

species and other bat species in South Asia, Southeast Asia, the Western Pacific region, and Africa (Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2019, Yob 2001). The wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing. Person-to-person transmission is well-documented (Arunkumar 2019, Chadha 2006, Gurley 2007, Luby 2009, Nikolay 2019) and respiratory transmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019**;** Spiropoulou 2019). Concern has been raised about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Cross-Cutting Issues

A major challenge for development of NiV medical countermeasures is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Further efforts are needed to ensure that policy makers in affected countries and global stakeholders understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control. To accomplish this, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate

human populations in areas of predicted risk using a One Health approach (Chattu 2018, Kulkarni 2013).

Optimization of relevant animal models is needed, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval of therapeutics or vaccines (Rockx 2014). Issues include: (1) determining the most appropriate animal model(s) for screening assay development; (2) standardizing the challenge strain and dosing parameters (including identifying the most appropriate lethal challenge dose); (3) determining when after challenge medical countermeasures should be administered to best mimic realistic timing of use in humans; (4) bridging data from animal models to humans; and (5) identifying the best models for studying chronic (relapsing) infection (Dhondt 2013, Johnston 2015, Mathieu 2015, Mire 2019). Currently, the African green monkey is considered the most relevant animal model for evaluating candidate therapeutics and vaccines intended for human use (Bossart 2012, Geisbert 2010, Johnston 2015); however, costs, space requirements, and ethical concerns constrain its use.

To inform NiV medical countermeasure development, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. Important topics include evaluating pathophysiologic differences between different NiV strains, determining mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to infection. Standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains are also needed to advance research for medical countermeasures (Satterfield 2016).

Diagnostics

The most commonly used methods for diagnosing NiV infection include enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies and real time-polymerase chain reaction (RT-PCR) nucleic acid testing (Chadha 2006, Guillaume 2004, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009, Mazzola 2019). Most laboratories use in-house NiV assays; also only a few commercial PCR kits are available and there is only one commercial source for reagents for ELISA testing (Mazzola 2019). More recently, neutralization assays using non-infectious pseudotyped virus particles have been developed, which can be used under biosafety level 2 (BSL-2) conditions in laboratories with limited diagnostic capabilities (Bae 2019, Kaku 2009, Kaku 2012, Tamin 2009). Newer technologies are under investigation, such as antigen-capture ELISAs using monoclonal antibodies (Chiang 2010) and reverse transcription-loop-mediated isothermal amplification (RT-LAMP) (Ma 2019); however, more information is needed regarding their performance characteristics, particularly under field conditions.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. Rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure and are affordable are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of a repository requires addressing complex issues such as determining the governance structure, establishing protocols for sample collection and maintenance, and prioritizing use and access to samples. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients. Comparison of outcomes using 54 historical controls found a lower mortality rate among treated patients (Chong 2001); however, findings may have been biased by use of historical controls. No additional clinical studies using ribavirin have been conducted and limited studies in animal models have not demonstrated efficacy following NiV or Hendra virus challenge (Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may have utility for post-exposure prophylaxis (PEP) (Banerjee 2019).

A promising therapeutic option is monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). The human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009) and has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Other potential options for NiV treatment include favipiravir, fusion inhibitory peptides, and remdesivir (GS-5734). Initial animal model

studies involving these agents have reported favorable results (Dawes 2018, Mathieu 2018, Lo 2019); however, additional preclinical data are needed to further assess their utility.

Additional considerations for NiV therapeutics include: (1) expanding the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents; (2) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising treatments; (3) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (4) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in endemic areas.

A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that occur each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane

proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Keshwara 2019, Satterfield 2016).

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research should focus primarily on the humoral immune

response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Dear Kris,

Greetings from Bangladesh !!!

Please find attached herewith the manuscript with my comments for your consideration. However, I concur with the content agree to be a co-author.

Best regards,

Mahmud

> Our current plan is to submit this to the NEJM as a Sounding Board article per advice from Marie-Pierre. They will also provide a Supplemental Appendix with the full roadmap. WHO will then publish the roadmap once it has been published in NEJM.
>
> Sounding Board articles have a 2,000 word limit and are structured as commentaries rather than as reviews, so the article has been substantially shortened—please keep that in mind as you go through it.
>
> The process for submission is as follows:
>
> 1. Please review this version of the manuscript and **send any comments or edits to me by**

June 25 (through replying to this email). Please send a response even if you have no comments.

2. In your email response, also please state that you are willing to be a co-author on the manuscript and that you agree you fulfill the criteria for authorship, which for NEJM are:

- Substantial contributions to conception and design; or acquisition, analysis, or interpretation of data AND
- Drafting of the article or critical revision for important intellectual content AND
- Final approval of the version to be published AND
- Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the article are appropriately investigated and resolved

3. If NEJM decides to request a revised version and move to the next step of accepting the manuscript, there will be three forms each co-author will need to complete—one on conflict of interest, one on copyright transfer, and one stating that you fulfill the authorship requirements. Those will be sent to you at a later time.

4. You will also need to sign off on the final version of the manuscript.

Again, thank you for your time in this important process.

Warm regards,

Kris

NipahResearch and Development (R&D) Roadmap

Roadmap purpose: To provide a framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research to advanced development, licensure, manufacture, and deployment) for accelerating the collaborative development of medical countermeasures (MCMs) against Nipah virus infection.

*(**Note:**This draft roadmap is organized into the three main categories of MCMs—diagnostics, therapeutics, and vaccines—to allow reviewers an opportunity to examine the development of the roadmap components for each countermeasure. Some of the topics and issues apply to more than one MCM; these are highlighted as cross-cutting.This document is relatively detailed to ensure that it includes the most important topics and issues. As this draft is refined, the content may be reorganized and certain items may be "rolled up" into a smaller number of broader topics and issues, strategic goals, and priority areas and activities.)*

INTRODUCTION

Nipah virus (NiV)is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving severe respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported inthese countries since May 1999.NiV infection was subsequently recognized, however,in Bangladeshin 2001 and nearly annual outbreaks have occurred in that country since, with disease also ~~occurring~~ being recognized periodically in eastern India; associated case fatality rates in these countries have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (Pteropusbatspecies)and several other bat species in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected human-to-human NiV transmission. Additionally, several other animal species were found to be infected with NiV on the farms involved in the outbreak, including horses, cats, and dogs. In theoutbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary NiV sources being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen (Hendra virus [HeV]), which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely

related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat and in healthcare workers who cared for cases. Detailed genomic information for this virus is limited.

In humans, NiV infection results in neurologic and respiratory syndromes, with fever, headache, dizziness,cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated ~~that two distinct~~multiple strains of NiV. The strain responsible for the outbreak in Malaysia is different from the strains seen in ~~were responsible for the outbreaks in Southeast Asia (NiV$_M$) and in~~ Bangladesh/India (NiV$_B$).

Commented [SPL1]: We have isolated multiple different strains in Bangladesh.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of medical countermeasures to enable effective and timely emergency response to infectious disease epidemics. NiV is identified in the Blueprint's list of "priority pathogens" (defined as pathogens that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority pathogens to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in the roadmap ranges from basic research to late-stage development, licensure, and early use of MCMs to prevent and control NiV outbreaks and endemic disease.

Commented [SPL2]: I recommend spelling out this acronym, so that readers don't need to learn a new acronym to understand the article.

Other aspects of public health preparedness and response, in addition to R&D for MCMs, are critical to successful NiV infection prevention and control. Examples include enhanced surveillance systems, minimizing NiV transmission at the human-animal interface, improved personal protective equipment (PPE), effective community engagement, adequate infection prevention and control practices, and workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap, but need to be addressed as part of a broader public health control strategy.

VISION

Robust MCMs to detect, respond, prevent, and control outbreaks of NiV infection(and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid, accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING TOPICS AND ISSUES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Economic incentives to invest in Nipah research are not readily apparent, as the disease primarily occurs in under-resourced areas of South Asia and disease incidence is low; therefore, securing funding for Nipah research represents a substantial challenge. The development of a sustainable value propositionfor industry and international philanthropic public-private partnershipsare needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs.

- Regulatory approval pathways for MCMs can be prohibitively expensive for product developers. For example, obtaining regulatory approval for diagnostic tests through the premarket approval (PMA) process is costly, but may be necessary when an Emergency Use Authorization (EUA), which is associated with lower approval costs, is not applicable. Furthermore, licensure of vaccines and therapeutics using alternative regulatory pathways also can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (BSL-4) conditions.
- To date, NiV spillovers to human communities have occurred almost exclusively in rural communities in Bangladesh and East India; the healthcare facilities that serve these communities ~~have very rudimentary~~ are primary in nature in terms of laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the Pteropus genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing.
- Because NiV infection results in low mortality rates in livestock (e.g., approximately 1% to 5% in pigs), infection in animal herds may not be recognized until after human cases are identified. This delay in diagnosis may lead to an entire herd being infected before livestock are tested for NiV, which could cause large financial losses forlivestock owners and increases the likelihood of NiV infection in exposed animal husbandry workers.
- While ferrets, Syrian hamsters, and IFNAR-KO mice are well-established animal models for NiV research applicable to humans, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Conducting phase 1 clinical trials, and possibly phase 2 clinical trials,is likely feasible in endemic regions. However, because NiV infection occurs as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting phase 3 clinical trials for demonstrating efficacy. Therefore, alternative regulatory pathways and/or innovative study designs (e.g., including combining clinical trial data across outbreaks over time) may need to be

considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not applicable.

Key needs

- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- Standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. (Assays that can be used at lower biosafety levels are an important priority.)
- Clear criteria for down-selection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research.
- A determination regardingthe feasibility of conducting clinical trials of therapeutics and vaccines for NiV infection, which is needed before considering alternative regulatory pathways for licensure (such as the United States Food and Drug Administration's [FDA's] Animal Rule).
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities may vary between countries; therefore, early engagement is essential to identify country-specific considerations.
- Outreach and education to clinicians in endemic and at-risk areas to improve NiV awareness and training, and increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.
- Enhanced capabilities for data reporting in resource-limited settings to promote collaborative sharing of NiV sequence and strain data, which can be used to support MCM development.
- Collaboration with ~~local~~ government authorities in endemic ~~and at-risk areas~~countries to support NiV surveillance and facilitate effective communication with communities regarding disease prevention activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturingto endemic and at-risk areas.

Commented [Mahmudur3]: It will be necessary to involve the development partners who support the countries

Knowledge gaps

- Continued R&D, manufacture, deployment, and assessment of MCMs, as well as other preventive measures, are dependent on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses in the natural reservoir of Pteropus bats and potentially other fruit bats.
- Additional research is needed torefine, standardize, and validate relevant animal challenge models(e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) to define their role in

supporting basic research on the pathogenesis and immunology of NiV infection, which is essential for development and evaluation of MCMs. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) determine the most appropriate lethal NiV dose for MCM development; (3)determine when MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data between animal models and humans, such as identifying thresholds of vaccine protection; and (5) identify the best models for studying chronic (relapsing) infection, particularly if investigators use the US FDA's Animal Rule to obtain regulatory approval.

- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between ~~NiV$_B$ and NiV$_M$ infection~~different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes over time that may impact the epidemiologic and clinical features of disease, and thereby influence MCM development.
- Some evidence suggests that there are differences in ~~NiV$_B$ and NiV$_M$~~ pathogenesis among different strains of NiV that may have implications for the development of safe and effective NiV vaccines or therapies.More information on this issue is needed.
- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hostsand pathogenicity.
- Additional research is needed to develop and assess next generation sequencing (NGS) for whole gene analysis, which can be used to enhance understanding of the global distribution of henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage at-risk populations (including vulnerable populations such as pregnant women, children, and immunocompromised persons) for participation in clinical trials and to ensure acceptance of new NiVMCMs, especially if therapeutics and vaccines do not consistently prevent disease. Efforts are needed to: (1) assess potential barriers for conducting clinical trials; (2) assess MCM acceptability in at-risk populations; (3) determine culturally appropriate messaging to enhance MCM acceptance; and (4) identify public health strategies to promote vaccine use.

Strategic Goals

1. Identify sources of funding and develop appropriate private-sector incentives and competitions to promote R&D of NiV MCMs.
2. Stimulate and support basic science research for better understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animals.

3. Strategically strengthen laboratory, clinical, and public health infrastructure and capacity at the local and national levels in areas of known or potential NiV spillover.
4. Engage NRAs (particularly in endemic and at-risk areas) to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact MCM development, acceptance, and post-licensure surveillance.

~~4.~~5.

Commented [Mahmudur4]: Consider adding "Enhance disease detection capabilities through active and passive surveillance"

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform**phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** the key differences between NiV$_{B}$ and NiV$_{M}$ pathogenesisthat may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine, validate, and standardize** relevant animal models to support the development and evaluation of NiV MCMs.
- **Generate** research tools to promote R&D of MCMs for NiV infection (i.e., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research on the uses of NGS for understanding henipavirus distribution.
- **Determine** the feasibility of conducting phase 3 clinical trials or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Commented [SPL5]: As noted above, I do not consider this dichotomous framing appropriate. It has been used in the literature, but I see this as erroneous. There is not a single strain of NiV$_{B}$, but rather multiple.

Product development

- **Define** criteria for down-selection and prioritization of candidate MCMs that should be moved forward.
- **Promote**early communication between developers and appropriate NRAs forclarity and guidance on the regulatory aspects ofMCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** surveillance capacityto: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiVsurveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorizationfrom appropriate NRAs for NiVMCMs.This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Clarify**the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Commented [SPL6]: This is a key component. The general description of research needs and capacity development, seem to me to be fairly complete, but a thoughtful consideration of priority in sequence could help direct development.

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

DIAGNOSTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection arenonspecific and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in instituting effective and timely infection control measures. Additionally, latent disease can occur long after initial infection.

- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often lacking or inadequate, which can lead to delays in diagnosis.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.
- Owing to the biosafety precautions necessary when working with the NiV virus, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using PCR and ELISA methods poses challenges, given the rapid disease progression of NiV infection.
- Pteropus bat species (and perhaps other bat species)appear to carry other henipaviruses (in addition to NiV and HeV), some of which may prove to be pathogenic in humans and livestock. Capacity to identify additional pathogenic henipaviruses is an important challenge forensuring diagnostic preparednessto respond tofuture outbreaks.

Commented [SPL7]: A related problem is that in many of the contexts where these patients present, etiologic diagnosis is often not pursued. We need more than an inexpensive sensitive and specific Nipah diagnostic. For this to be used clinicians need to see value in conducting the tests. Having a specific therapeutic treatment could help motivate this. A multiplex diagnostic tool that provided insight on other pathogens (especially if they were treatable) would also encourage more frequent testing.

Key needs

- A target product profile (TPP) for NiV diagnostics, identifying optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A biobankof human and animal clinical samples to assess and validate diagnostic tests and a process for how best to judiciously use the samples. A clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid, etc.); (2) outline the purposes of sample collection; (3) identify who would have access to the samples; and (4) prioritize use of samples and sample distribution.
- Clarification regarding the use cases for different diagnostic assays and what viruses are targeted (i.e., NiV, NiV and HeV, or all henipaviruses), since the corresponding performance, validation, and regulatory approval requirements may differ depending on how and in which population (i.e., human or animal) the test will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific. In animals, it may be desirable to have a diagnostic test with high sensitivity to screen reservoir populations and a highly specific test for livestock. Diagnostic use cases need to be considered in tandem with the use of therapeutics and other interventions.
- Rapid point-of-care diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course,are robust for use under a variety of conditions (e.g., varying humidity, temperature, etc.), can be applied in both human and animal populations, and have a high degree of sensitivity and specificity for different NiV strains.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- International reference standards to calibrate diagnostic assays.

- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic preparedness to detect NiV, HeV, and other emergent henipaviruses in humans and animals as they arise.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, given the costs of regulatory approval.
- If feasible, multiplex syndrome-based assay panels for use in humans and animals that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern that may cause similar clinical syndromes in endemic or at-risk areas. Since validation and regulatory approval of multiplex assays can prove challenging, an alternate approach would be the development of multiple single assays that can be run in parallel.
- Long-term need: if NiV or HeV vaccines become widely used in livestock, serological testing to differentiate vaccinated animals from infected animals, such as the Differentiating Infected from Vaccinated Animals (DIVA) test.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease. Additionally, further research on the kinetics of NiV in the animal reservoirs is needed.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotyped neutralization assays and antigen-capture ELISAs) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
- A clear understanding is needed of the potential for cross-reactivity of diagnostic tests in animal populations to allow accurate interpretation of test results, since substantive economic consequences (such as trade restriction for livestock) could be triggered by positive results.

Strategic Goals

1. Obtain a better understanding of the kinetics of NiV detectionat various points during the clinical course of illness to allow improved diagnostic capability across the disease spectrum.
2. Develop and assess affordable, highly sensitive and specific, point-of-care NiVdiagnostic tests for use in humans and animalsthat are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training. Consideration also should be given to development of multiplex assays that can detect related henipaviruses, in addition to NiV, or that can detect other pathogens of concern in endemic and at-risk areas.
3. Generate guidance on deployment strategies and use of diagnostic tests for NiV detection in areas of known or potential henipavirus spillover risk.

4. Enhance diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Explore** new diagnostic approaches that may allow for earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiVinfectionat different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.
- **Create** a biobank of clinical human and animal samples for use in researching new diagnostic agents.
- **Continue to research** cross-reactivity of diagnostic tests in animal populations.

Product development

- **Generate** a TPP for NiV diagnostics.
- **Define** use cases for diagnostic assays.
- **Develop, evaluate, and validate** point-of-care rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific, available for use in humans and animals, and can capture antigenically diverse strains of the virus and be performed accurately and safely in remote areas under a variety of circumstances.
- **Develop** multiplex syndrome-based assay panels that can detect NiV infection while simultaneously screening for the presence of other henipaviruses or other pathogens of concern in the geographic region that cause similar clinical syndromes.
- **Develop** diagnostics applicable to mass testing in livestock to identify NiV infection early and to reduce the likelihood of transmission of NiV from livestock to humans.
- **Develop** serologic testing to differentiate vaccinated from infected animals (such as a DIVA test), if NiV or HeV vaccines become widely used (long-term consideration).

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses in humans and animals.

Policy and commercialization

- **Develop** guidance on optimal strategies for deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

THERAPEUTICS

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in providing early treatment and PEP to exposed persons.
- In the NiV-endemic region of Bangladesh, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis, but do not have NiV infection. In the absence of confirmatory testing, treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore accurate and rapid diagnosis is critical.
- Studies in animals often evaluate usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well an agent will work in the field.
- Nipah virus can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control systems in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- A TPP for NiV therapeutic agents, identifying optimal and desirable characteristics to guide the development of promising treatment approaches in the context of individual and community priorities.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat chronic (relapsing) NiV infection to decrease associated long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- Ribavirin may be an option for treatment of NiV infection, but animal studies in hamsters and AGMs have not supported efficacy for ribavirin. Further research into the potential effectiveness of ribavirin for NiV infection is needed.
- The human monoclonal antibody (mAb) m102.4 has demonstrated protectionagainst lethal NiV challenge in animal models and has been provided as a compassionate use for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia, but results are not yet available. Additional animal studies and clinical trials using both NiV$_M$ and NiV$_B$are needed to assess the safety, tolerability, and efficacyof m102.4 (and possibly other mAbs) for PEPand potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the mostpromising novel treatments (such as fusion inhibitory peptides, antifusion peptides, and GS-4734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for both NiV$_B$ and NiV$_M$, as highlighted by a recent study in AGMs that showed the therapeutic window for m102.4 against NiV$_B$ to be shorter than for NiV$_M$.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamics (PK/PD) relationship of promising therapeutic candidates.
- Additional studies of therapeutic candidates in the AGM model, followed by human clinical trials for safety, feasibility, and efficacy.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer.This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially-exposed persons annually that could be candidates for PEP.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies,diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials, to inform best-practice guidelines.

Commented [SPL8]: I suspect there is differences of opinion on this. On the one hand there is observational data from the Malaysian outbreak that NiV patients who received ribavirin had lower case fatality than NIV patients who did not. The unanswered question is whether this improved survival was a result of the ribavirin or whether it was primarily a result of ribavirin being used later in the outbreak once clinicians recognized the disease and possibly implemented better supportive care. The absence of impact on animal models suggests (but does not prove) that the improvement in human survival was due to confounding rather than biological effect. Given a fixed amount of resources and the opportunity cost of identifying patients who might benefit, I personally would not be particularly enthusiastic to conduct a phase III trial of ribavirin in Nipah patients in Bangladesh.

Strategic Goals

1. Develop, evaluate, and license therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection, and ensure that therapies are readily available, affordable, and accessible in areas of known or potential NiV spillover.
2. Develop guidance for the use of therapeutics for disease treatment and PEP as new therapies become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of investigational therapies (such as ribavirin and m102.4) for treating and preventing NiV infection, including conduct of animal studies andclinical trialsas appropriate and feasible.
- **Continue to identify** new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Generate** a TPP for NiV infection therapeutics.
- **Develop, evaluate, and license** safe and effective therapeutic agents for treatment of NiV infectionthat are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against both NiV_B and $NiV_M$and other NiV strains or pathogenic henipaviruses that may emerge.

Key capacities

- **Promote** enhancements to the healthcare delivery systems in impacted areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for outbreak control.

Policy and commercialization

- **Identify** a company to advance therapeutic use of m102.4 and **secure** financing for its manufacture and distribution.
- **Develop**guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

VACCINES

Current Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Sociocultural issues may hinder trust in the formal human, veterinary, and public health systems, which could impact acceptance of NiV vaccinesfor use in humans or animals.
- The absence of improved diagnostic assays for timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that can protect against both NiV_M and NiV_Bin humans and animals, and that provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on use of NiVvaccines (or broader henipavirus vaccines)to include vaccination strategies, potentially in both humans and animals, for different epidemiologic scenarios and different vaccine attributes.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategiesover time.

Knowledge gaps

- While neutralizing antibodies are likely a primary mediator of protection against NiV infection, cellular immunity appears to also play a role. Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines, such as the soluble G glycoprotein subunit (sG) and recombinant vesicular stomatitis (rVSV) vaccine.
- Further research is needed to determine the henipavirus cross-protection efficacy for NiV of the HeV-sG subunit vaccines, such as the recombinant subunit vaccine HeV-sG (Equivac® HeV, Zoetis).
- Additional research is needed to determine if vaccine candidates are cross-protective between NiV_M and NiV_B, including recent strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates of protection in humans and animals and standardized mechanisms for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms.
- Evaluation of vaccine safety in target populations is needed to better understand the risk of adverse incidents associated with vaccine use.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than

one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus [MV]) for use in NiV endemic areas.

- Mathematical modelling may be useful in estimating the potential impact of NiV vaccines, estimating the vaccine quantity for stockpiles, and in simulating various epidemiologic scenarios and possiblestrategies for vaccine use.
- Because livestock (e.g., pigs and horses) are intermediary hosts for NiV and HeV, vaccination of livestock populations has been suggested as a possible mitigation strategy for preventing secondary transmission to humans. While one HeV vaccine is available for horses, antibodies against HeV have not been found to be cross-reactive with NiV. Ongoing research into developing NiV/HeV vaccines for livestock(or other animals) and the potential for their use in endemic regions is needed to further assess the merit of this potential control strategy.
- Additional research is needed to determine if development of multivalent vaccines for animals(that protect against more than one disease) would increase the likelihood of vaccine uptake by food animal producers and the broader veterinary community.

Strategic Goals

1. Develop, evaluate, license, and deployNiV vaccines for use in humans and potentially animals (e.g., livestock, companion animals).
2. Continue to research cross-protection of candidate vaccines against NiV and HeV (and potentially other emergent henipaviruses as needed).
3. Develop and refine guidance on vaccine use in humans and animals that aligns with current NiV epidemiology and takes into consideration attributes of new vaccines as they become available.

Landmark Goals/Milestones

[TBD once the strategic goals have been determined.]

Priority Areas/Activities

Research

- **Determine** the innate, cell-mediated, and humoral immune responses that contribute to protective immunity against NiV infection for use in developing and evaluatingNiV vaccines.
- **Further study** cross protection of various vaccine candidates against NiV_B and NiV_M strains,and between NiV strains and HeV strains.
- **Identify and standardize** correlates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure through non-traditional regulatory pathways.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Determine** whether multivalent vaccines for animal populations would increase vaccine acceptability and uptake by food-animal producers and the broader veterinary community.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

Product development

- **Develop, clinically evaluate, and license** safe and effectivemonovalent NiV vaccines for humans and animals.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines for use in humans that protect against more than one disease (e.g., vaccines that protect against both NiV and MV or HeV), if broader population-based vaccination is warranted at some point in the future.
- **Develop, clinically evaluate, and license** safe and effective multivalent vaccines that protect against more than one disease for use in animal populations, if this is deemed to be a worthwhile approach.

Key capacities

- **Improve**surveillance capabilities,particularly in rural areas of resource-limited settings, to assess the impact of vaccination strategies, once vaccines become available.
- **Support** plans for adequate manufacturing and stockpiling of licensed NiV vaccines for use when outbreaks occur.

Policy and commercialization

- **Provide**guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Consider** development of a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent, or if an NiV strain emerges with increased capacity for person-to-person transmission, and thus more rapid spread.

Schedule of Resources, Coordination, and Implementation

[TBD; will obtain input later in the process.]

Critical Path Analysis

[TBD once the primary activities have been vetted by subject matter experts.]

Hi Kris,

This looks great. I attach a couple minor suggestions.

I am willing to be listed as a co-author on the manuscript. I have fulfilled the criteria for authorship.

Steve

Introduction

As part of implementing the World Health Organization's (WHO's) *R&D Blueprint for Action to Prevent Epidemics* (WHO 2016), in 2017 WHO embarked on a process to generate a research and development (R&D) roadmap for medical countermeasures (diagnostics, therapeutics, and vaccines) aimed at human infections caused by Nipah virus (NiV). WHO considers NiV a priority pathogen because of its disease severity, the potential for broad global spread of the virus, and the lack of available medical countermeasures. The entire roadmap can be found in the Supplemental Appendix and this report provides a summary of key highlights. NiV, a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000). No additional outbreaks have been reported in these countries; however, since 2001 outbreaks of NiV infection have occurred nearly annually in Bangladesh (Hsu 2004, WHO 2018). Outbreaks also have recently been recognized in India (Arunkumar 2019, Sharma 2018, Chattu 2018) and a possible NiV outbreak occurred in the Philippines in 2014 (Ching 2015). NiV infection is most commonly associated with severe, rapidly progressive encephalitis, which may be of late onset or relapsing (Goh 2000, Hossain 2008, Tan 2002). Some patients also have respiratory involvement or respiratory illness only, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The case-fatality rate is estimated at 40% to 75% (Hossain 2008, WHO 2019).

Fruit bats of the Pteropus genus, which have a wide geographic range, are considered the primary natural reservoir for NiV. Evidence of NiV infection has been found in Pteropus bat

species and other bat species in South Asia, Southeast Asia, the Western Pacific region, and Africa (Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2019, Yob 2001). The wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing. Person-to-person transmission is well-documented (Arunkumar 2019, Chadha 2006, Gurley 2007, Luby 2009, Nikolay 2019) and respiratory transmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019**;** Spiropoulou 2019). Concern has been raised about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Cross-Cutting Issues

A major challenge for development of NiV medical countermeasures is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Further efforts are needed to ensure that policy makers in affected countries and global stakeholders understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control. To accomplish this, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate

Commented [GES2]: The opening sentence of this section is about funding for research, which could be a component of each of these, but not these things themselves. Perhaps one way to square this is to make the opening sentence broader, and refer to research as well as public health programs.

human populations in areas of predicted risk using a One Health approach (Chattu 2018, Kulkarni 2013).

Optimization of relevant animal models is needed, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval of therapeutics or vaccines (Rockx 2014). Issues include: (1) determining the most appropriate animal model(s) for screening assay development; (2) standardizing the challenge strain and dosing parameters (including identifying the most appropriate lethal challenge dose); (3) determining when after challenge medical countermeasures should be administered to best mimic realistic timing of use in humans; (4) bridging data from animal models to humans; and (5) identifying the best models for studying chronic (relapsing) infection (Dhondt 2013, Johnston 2015, Mathieu 2015, Mire 2019). Currently, the African green monkey is considered the most relevant animal model for evaluating candidate therapeutics and vaccines intended for human use (Bossart 2012, Geisbert 2010, Johnston 2015); however, costs, space requirements, and ethical concerns constrain its use.

To inform NiV medical countermeasure development, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. Important topics include evaluating pathophysiologic differences between different NiV strains, determining mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to infection. Standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains are also needed to advance research for medical countermeasures (Satterfield 2016).

Diagnostics

The most commonly used methods for diagnosing NiV infection include enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies and real time-polymerase chain reaction (RT-PCR) nucleic acid testing (Chadha 2006, Guillaume 2004, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009, Mazzola 2019). Most laboratories use in-house NiV assays; also only a few commercial PCR kits are available and there is only one commercial source for reagents for ELISA testing (Mazzola 2019). More recently, neutralization assays using non-infectious pseudotyped virus particles have been developed, which can be used under biosafety level 2 (BSL-2) conditions in laboratories with limited diagnostic capabilities (Bae 2019, Kaku 2009, Kaku 2012, Tamin 2009). Newer technologies are under investigation, such as antigen-capture ELISAs using monoclonal antibodies (Chiang 2010) and reverse transcription-loop-mediated isothermal amplification (RT-LAMP) (Ma 2019); however, more information is needed regarding their performance characteristics, particularly under field conditions.

Commented [GES3]: I think this is true for almost all of the diagnostics used above. There is no accepted 'gold standard' by which to compare. Further development and validation of new diagnostics will require the establishment of a known confirmed positive/negative patient specimen set. I'm not sure that any of the available diagnostics have been validating using this kind of approach.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. Rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure and are affordable are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of a repository requires addressing complex issues such as determining the governance structure, establishing protocols for sample collection and maintenance, and prioritizing use and access to samples. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

Commented [GES4]: And perhaps validation of existing...

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients. Comparison of outcomes using 54 historical controls found a lower mortality rate among treated patients (Chong 2001); however, findings may have been biased by use of historical controls. No additional clinical studies using ribavirin have been conducted and limited studies in animal models have not demonstrated efficacy following NiV or Hendra virus challenge (Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may have utility for post-exposure prophylaxis (PEP) (Banerjee 2019).

A promising therapeutic option is monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). The human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009) and has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Other potential options for NiV treatment include favipiravir, fusion inhibitory peptides, and remdesivir (GS-5734). Initial animal model

Commented [GES5]: The previous para rightly distinguishes between therapeutic and PEP effects. The same should be done here. It's really two separate uses and delivery strategies.

studies involving these agents have reported favorable results (Dawes 2018, Mathieu 2018, Lo 2019); however, additional preclinical data are needed to further assess their utility.

Additional considerations for NiV therapeutics include: (1) expanding the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents; (2) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising treatments; (3) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (4) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in endemic areas.

A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that occur each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane

proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Keshwara 2019, Satterfield 2016).

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research should focus primarily on the humoral immune

response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Kris,

Thanks for the update and very happy to see this work move ahead in a manuscript forma.

I've attached a couple of minor comments, in case they are useful.

I agree to coauthor this work and attest that I have made significant contributions to the content of the roadmap, its interpretations, and have contributed to and reviewed this draft.

Best,
Emily

Dear all. Please read the email below. This is just a reminder to send me any comments on the June 2019 version of the Nipah roadmap paper and to confirm that you are willing to be a co-author on the manuscript as outlined below.

Thank you so much for your time!

Warm regards,

Kris

Subject: Revised Nipah R&D roadmap manuscript--please respond by June 25
Importance: High

Dear Colleagues: I hope this message finds each of you well. Per the email that you received in May, I have provided an updated version of the Nipah R&D roadmap manuscript. I have also provided the full roadmap—just in case you want to refer back to that.

Our current plan is to submit this to the NEJM as a Sounding Board article per advice from Marie-Pierre. They will also provide a Supplemental Appendix with the full roadmap. WHO will then publish the roadmap once it has been published in NEJM.

Sounding Board articles have a 2,000 word limit and are structured as commentaries rather than as reviews, so the article has been substantially shortened—please keep that in mind as you go through it.

The process for submission is as follows:

1. Please review this version of the manuscript and **send any comments or edits to me by June 25** (through replying to this email). Please send a response even if you have no comments.
2. In your email response, also please state that you are willing to be a co-author on the manuscript and that you agree you fulfill the criteria for authorship, which for NEJM are:
    - Substantial contributions to conception and design; or acquisition, analysis, or interpretation of data AND
    - Drafting of the article or critical revision for important intellectual content AND
    - Final approval of the version to be published AND
    - Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the article are appropriately investigated and resolved
3. If NEJM decides to request a revised version and move to the next step of accepting the manuscript, there will be three forms each co-author will need to complete—one on conflict of interest, one on copyright transfer, and one stating that you fulfill the authorship requirements. Those will be sent to you at a later time.
4. You will also need to sign off on the final version of the manuscript.

Again, thank you for your time in this important process.

Warm regards,

Kris

(Note: The word count will be below 2,000 once the references are in number format.)

Introduction

As part of implementing the World Health Organization's (WHO's) *R&D Blueprint for Action to Prevent Epidemics* (WHO 2016), in 2017 WHO embarked on a process to generate a research and development (R&D) roadmap for medical countermeasures (diagnostics, therapeutics, and vaccines) aimed at human infections caused by Nipah virus (NiV). WHO considers NiV a priority pathogen because of its disease severity, the potential for broad global spread of the virus, and the lack of available medical countermeasures. The entire roadmap can be found in the Supplemental Appendix and this report provides a summary of key highlights. NiV, a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000). No additional outbreaks have been reported in these countries; however, since 2001 outbreaks of NiV infection have occurred nearly annually in Bangladesh (Hsu 2004, WHO 2018). Outbreaks also have recently been recognized in India (Arunkumar 2019, Sharma 2018, Chattu 2018) and a possible NiV outbreak occurred in the Philippines in 2014 (Ching 2015). NiV infection is most commonly associated with severe, rapidly progressive encephalitis, which may be of late onset or relapsing (Goh 2000, Hossain 2008, Tan 2002). Some patients also have respiratory involvement or respiratory illness only, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The case-fatality rate is estimated at 40% to 75% (Hossain 2008, WHO 2019).

Fruit bats of the Pteropus genus, which have a wide geographic range, are considered the primary natural reservoir for NiV. Evidence of NiV infection has been found in Pteropus bat

species and other bat species in South Asia, Southeast Asia, the Western Pacific region, and Africa (Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2019, Yob 2001). The wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition and lack of available laboratory testing. Person-to-person transmission is well-documented (Arunkumar 2019, Chadha 2006, Gurley 2007, Luby 2009, Nikolay 2019) and respiratory transmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019**;** Spiropoulou 2019). Concern has been raised about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Cross-Cutting Issues

A major challenge for development of NiV medical countermeasures is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Further efforts are needed to ensure that policy makers in affected countries and global stakeholders understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control. To accomplish this, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate

human populations in areas of predicted risk using a One Health approach (Chattu 2018, Kulkarni 2013).

Optimization of relevant animal models is needed, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval of therapeutics or vaccines (Rockx 2014). Issues include: (1) determining the most appropriate animal model(s) for screening assay development; (2) standardizing the challenge strain and dosing parameters (including identifying the most appropriate lethal challenge dose); (3) determining when after challenge medical countermeasures should be administered to best mimic realistic timing of use in humans; (4) bridging data from animal models to humans; and (5) identifying the best models for studying chronic (relapsing) infection (Dhondt 2013, Johnston 2015, Mathieu 2015, Mire 2019). Currently, the African green monkey is considered the most relevant animal model for evaluating candidate therapeutics and vaccines intended for human use (Bossart 2012, Geisbert 2010, Johnston 2015); however, costs, space requirements, and ethical concerns constrain its use.

To inform NiV medical countermeasure development, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. Important topics include evaluating pathophysiologic differences between different NiV strains, determining mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to infection. Standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains are also needed to advance research for medical countermeasures (Satterfield 2016).

Diagnostics

The most commonly used methods for diagnosing NiV infection include enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies and real time-polymerase chain reaction (RT-PCR) nucleic acid testing (Chadha 2006, Guillaume 2004, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009, Mazzola 2019). Most laboratories use in-house NiV assays; also only a few commercial PCR kits are available and there is only one commercial source for reagents for ELISA testing (Mazzola 2019). More recently, neutralization assays using non-infectious pseudotyped virus particles have been developed, which can be used under biosafety level 2 (BSL-2) conditions in laboratories with limited diagnostic capabilities (Bae 2019, Kaku 2009, Kaku 2012, Tamin 2009). Newer technologies are under investigation, such as antigen-capture ELISAs using monoclonal antibodies (Chiang 2010) and reverse transcription-loop-mediated isothermal amplification (RT-LAMP) (Ma 2019); however, more information is needed regarding their performance characteristics, particularly under field conditions.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. Rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure and are affordable are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of a repository requires addressing complex issues such as determining the governance structure, establishing protocols for sample collection and maintenance, and prioritizing use and access to samples. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients. Comparison of outcomes using 54 historical controls found a lower mortality rate among treated patients (Chong 2001); however, findings may have been biased by use of historical controls. No additional clinical studies using ribavirin have been conducted and limited studies in animal models have not demonstrated efficacy following NiV or Hendra virus challenge (Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may have utility for post-exposure prophylaxis (PEP) (Banerjee 2019).

A promising therapeutic option is monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). The human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009) and has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Other potential options for NiV treatment include favipiravir, fusion inhibitory peptides, and remdesivir (GS-5734). Initial animal model

studies involving these agents have reported favorable results (Dawes 2018, Mathieu 2018, Lo 2019); however, additional preclinical data are needed to further assess their utility.

Additional considerations for NiV therapeutics include: (1) expanding the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents; (2) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising treatments; (3) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (4) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in endemic areas.

A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that occur each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane

proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Keshwara 2019, Satterfield 2016).

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research should focus primarily on the humoral immune

response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (*Pteropus* species and several other bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species (including horses, cats, and dogs) were found to be infected with NiV on the farms involved in the outbreak. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India. Some differences have been noted in the clinical features of infection, with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiV infection is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Ready availability and accessibility of r~~R~~**obust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses)** ~~that are readily available and accessible~~ **for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.**

CROSS-CUTTING ISSUES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research represents a substantial challenge, since economic incentives to invest in Nipah research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions, which can increase the cost of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- While ferrets, Syrian hamsters, and interferon-alpha/beta receptor knockout (IFNAR-KO) mice are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major

challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures.
- Obtaining additional prospective serosurveillance data of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk should be explored as a strategy to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure.
- Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains for R&D of MCMs for NiV infection. Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
- Clear criteria for downselection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or other regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.

- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species.
- Additional research is needed to optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) for promoting development and evaluation of MCMs, particularly if investigators are required to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurologic sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development.

- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole-genome sequencing of NiV are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains to facilitate R&D of NiV MCMs.

2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and that may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.
- **Generate** research tools to promote R&D of MCMs for NiV infection (e.g., standardized and validated assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for downselection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.

- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific, and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and investigation into the cause of infection is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.

- Owing to the biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the rapid disease progression of NiV infection.
- Currently, no approved tests for diagnosis of NiV infection are commercially available.
- *Pteropus* species (and perhaps other bat species) appear to carry other henipaviruses in addition to NiV and HeV, some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate using serologic assays which henipaviruses are in circulation. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests. As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature), and have a high sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

- Improved diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, particularly given the costs of regulatory approval.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotype neutralization assays and antigen-capture enzyme-linked immunosorbent assays [ELISAs]) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries: Bangladesh and India.

2. By 2021, identify funding and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.

Priority Areas/Activities

Research

- **Create** a virtual repository of clinical reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- **Develop and evaluate** point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons.
- In NiV-endemic areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis but do not have NiV infection. Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore, accurate and rapid diagnosis is critical.
- Studies in animals often evaluate the usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control– programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.
- A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that are detected annually.

Key needs

- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas, particularly during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).
- A transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials, given the limited number of cases that could potentially be enrolled in trials each year.

Knowledge gaps

- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to further assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection and strengthen the therapeutic pipeline.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
3. By 2019, identify an approach for downselecting promising therapeutic candidates for further study in clinical trials, given limited annual case numbers for enrollment.
4. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
5. By 2020, generate a reliable source of m102.4 (or other promising agent[s] or agent combinations) to be ~~used~~ assessed in clinical trials.

Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4 and favipiravir) for treating and preventing NiV infection, including conducting studies in animal models and clinical trials as appropriate and feasible.
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Generate** a reliable source of m102.4 to be used in clinical trials.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development, and few companies are willing to invest in the generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could diminish the acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA’s Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen, and therefore multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed involving target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- Additional sociological research is needed to explore perceptions and concerns of at-risk populations regarding NiV vaccine implementation.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the need for licensure and future use of NiV vaccines. This consultation should include representatives from in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.

- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Evaluate** the feasibility of generating multivalent vaccines (i.e., that protect against more than one disease) and determine whether or not such vaccines would be useful in future NiV control efforts.

Product development

- **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Dear all. Please read the email below. This is just a reminder to send me any comments on the June 2019 version of the Nipah roadmap paper and to confirm that you are willing to be a co-author on the manuscript as outlined below.

Thank you so much for your time!

Warm regards,

Kris

Subject: Revised Nipah R&D roadmap manuscript--please respond by June 25
Importance: High

Dear Colleagues: I hope this message finds each of you well. Per the email that you received in May, I have provided an updated version of the Nipah R&D roadmap manuscript. I have also provided the full roadmap—just in case you want to refer back to that.

Our current plan is to submit this to the NEJM as a Sounding Board article per advice from Marie-Pierre. They will also provide a Supplemental Appendix with the full roadmap. WHO will then publish the roadmap once it has been published in NEJM.

Sounding Board articles have a 2,000 word limit and are structured as commentaries rather than as reviews, so the article has been substantially shortened—please keep that in mind as you go through it.

The process for submission is as follows:

1. Please review this version of the manuscript and **send any comments or edits to me by June 25** (through replying to this email). Please send a response even if you have no comments.

2. In your email response, also please state that you are willing to be a co-author on the manuscript and that you agree you fulfill the criteria for authorship, which for NEJM are:

    - Substantial contributions to conception and design; or acquisition, analysis, or interpretation of data AND
    - Drafting of the article or critical revision for important intellectual content AND
    - Final approval of the version to be published AND
    - Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the article are appropriately investigated and resolved

3. If NEJM decides to request a revised version and move to the next step of accepting the manuscript, there will be three forms each co-author will need to complete—one on conflict of interest, one on copyright transfer, and one stating that you fulfill the authorship requirements. Those will be sent to you at a later time.
4. You will also need to sign off on the final version of the manuscript.

Again, thank you for your time in this important process.

Warm regards,

Kris

<H1>History

Hendra virus (HeV), the first known member of the genus *Henipavirus* in the family *Paramyxoviridae*, came to light in September 1994 as the causative agent of a sudden outbreak of acute respiratory disease in thoroughbred horses at a stable in Brisbane, Australia. A total of 21 horses and 2 humans (a horse trainer and a stable hand) became infected. The horse trainer and 14 horses died.(1,2) A virus was isolated, initially called *Equine Morbillivirus* but later re-named *Hendra virus* after the Brisbane suburb where the outbreak occurred. A second person died from HeV infection 13 months after the Brisbane outbreak, a farmer from Mackay, nearly 1000 km north of Brisbane. Unlike the first case, however, the man succumbed to encephalitis caused by HeV infection14 months after his initial mild meningitic illness.(3) (4). After initial serologic evidence suggested that fruit bats (flying foxes) of the genus *Pteropus* in the suborder Yinpterochiroptera were the reservoir hosts,(5) HeV was isolated from two species of flying fox.(6) In total, there have been 60 recognized occurrences of HeV in Australia between 1994–2018, with at least one occurrence per year since 2006 (Table 14.1A-online).(7) Every occurrence of HeV has involved horses as the initial infected host, causing lethal respiratory disease and/or encephalitis, along with a total of seven human cases arising from exposure to infected horses, among which four have been fatal and the most recent in 2009 (Table 14.1B-online).(8)

Nipah virus (NiV), the second known member of the genus *Henipavirus,* emerged as the cause of an outbreak of disease in pigs and humans in Peninsular Malaysia in 1998 through 1999. The epidemic started in Perak State as clusters of cases of encephalitis among pig farmers. It was initially believed to be caused by Japanese encephalitis virus; however, various features of the outbreak, including a high proportion of cases in direct contact with pigs and illness and deaths in pigs, differed from those expected with Japanese encephalitis.(9) Indeed, respiratory illness and encephalitis in pigs preceded human cases in the same district.(10) The epidemic spread south to the intensive pig-farming areas of Negeri Sembilan in December 1998 and subsequently peaked between February and April 1999. More than 1 million pigs were destroyed to halt the spread of the epidemic, and by late May, 265 human cases of acute encephalitis with 105 deaths were recorded.(9,11) A cluster of 11 cases with 1 death occurred among abattoir workers in Singapore.(12) In early March 1999, a virus was isolated from the cerebrospinal fluid (CSF) of a patient with encephalitis and identified as the etiologic agent.(9,11) Named *Nipah virus* after the village from which the patient had come, it was shown to be closely related to HeV. NiV was subsequently isolated from the urine of Malaysian flying foxes.(13) A highly related NiV emerged in Bangladesh in 2001,(14) and outbreaks of NiV-related encephalitis have occurred in people from that country almost every year since, along with three reports of NiV encephalitis in India(15,16), albeit in Bangladesh adjacent regions. However, the most recent outbreak of NiV occurred in 2018 in Kerala (India), more than 2,500 km south-west of NiV-endemic Bangladesh counties. This outbreak claimed 21 lives out of 23 infected human cases.(17) In 2014, a NiV outbreak occurred in the Province of Sultan Kudarat, the Phillipines, which resulted in the death of 9 humans from 11 which showed an acute encephalitis syndrome.(18) The human case fatality rate of these NiV outbreaks averages around 60% (Table 14.1C). So far human NiV oubreaks have been documented in a total of five countries: Malaysia, Singapore, Bangladesh, India and the Philippines. Sero-epidemiological evidence for henipavirus spillover events from bats into high-risk human populations have also been reported in Cameroon.(19)

<TAB14.1C>

<H1>Infectious Agent

<H2>Classification

When HeV was first isolated in 1994, partial sequencing of the matrix gene (M) revealed that it most closely resembled members of the genus *Morbillivirus* in the subfamily

Paramyxovirinae.(2) Subsequent characterization of the full-length genome, however, revealed that many of the genetic features of HeV were unique among paramyxoviruses and that the virus did not fit within any of the existing genera at that time.(20,21) After the isolation of NiV in 1999, it was shown that sera raised against HeV were able to neutralize NiV and vice versa, and that both viruses shared a high degree of similarity in genome organization and protein size and sequence.(11,22-24) In 2002, the genus *Henipavirus* was created to accommodate these novel paramyxoviruses, and HeV was designated the type species.(25) Since 1994, there have been 38 isolations of HeV or NiV from humans, bats, horses, and pigs over a wide geographic area and spanning a period of approximately 20 years (Table 14.2-online). The susceptibility of humans, the virulence of the viruses, and absence of therapeutics and vaccines led to classification of HeV and NiV as biosafety level 4 (BSL4) pathogens. In the latest report from the paramyxovirus study group under the order Mononegavirales, the genus *Henipavirus* has been expanded to include three new species,(26,27) they are *Cedar henipavirus* (Cedar virus, CedV) isolated from bats in Australia, (28) *Ghanaian bat henipavirus* (Ghana virus, GhV) detected in bats from Ghana, (29) and *Mojiang henipavirus* (Mòjiāng, MojV) detected in rats in China.(30) These three new species are highly divergent from NiV and HeV, and only CedV has been isolated. GhV and MojV are only known from sequence information. *Henipavirus* is now classified as one of the seven ICTV-approved genera in the family *Paramyxoviridae*.

<H2>Propagation in Cell Culture and Cytopathic Effect

The ultrastructural characteristics of henipavirus-infected cells resemble those found in cells infected by other members of the *Paramyxoviridae.* Shared features include generation of large syncytia and the presence of viral nucleocapsids in cytoplasmic inclusion bodies and underlying electron-dense areas of the plasma membrane.(31,32) In Vero cells, NiV-induced syncytia are significantly larger than those generated by HeV and nuclei and nucleocapsids are frequently located at the cell periphery, compared with HeV-induced syncytia, where they tend to be more centrally located or distributed randomly throughout the cytoplasm (Fig. 14.1). Henipavirus-infected cells also contain structures that are not seen with other paramyxoviruses—specifically a network of membrane-like reticular structures in the cytoplasm and long tubules that appear to be continuous with the plasma membrane in NiV-infected cells. Tubules can also be observed in NiV virions (Fig. 14.2A). *In situ* hybridization suggests that these reticular structures contain viral RNA and may play a role in viral transcription.(31)

<FIG14.1><FIG14.2>

<H2>Virus Morphology

Henipavirus particles are pleomorphic, varying from spherical to filamentous and ranging in size from 40 to 1,900 nm. (2,31,32) Nucleocapsids have a diameter of 18 to 19 nm with an average pitch of 5 nm. When examined by electron microscopy (EM), HeV has a unique double-fringed appearance, caused by the presence of surface projections 15 ± 1 nm and 8 ± 1 nm in length (see Fig. 14.2B). Approximately 95% of virions contain the double fringe, and the remaining 5% display a uniform fringe length of 15 ± 1 nm. Unlike HeV, NiV possesses a single layer of surface projections with an average length of 17 ± 1 nm, and NiV particles released into the culture medium are difficult to image because they are routinely penetrated by negative stains. This suggests that the viruses may differ in the physical nature of their envelope.(32)

<H2>Genome Length and Organization

In the family *Paramyxoviridae,* the genome length of all characterized viruses is divisible by six, an observation caused by the requirement of each N protein in the viral ribonucleoprotein to bind 6 nucleotide (nt) residues (see Chapter 13). This is also true for HeV and NiV despite their much larger genome sizes.(24) The genomes of the Malaysian (MY) and Bangladesh (BD) strains of NiV differ by 6 nt because of a 6-nt increase in the 3′ untranslated region of the *F* gene in NiV-BD.(33) A minigenome replicon study confirms that NiV complies with the rule of six.(34) When the complete genome sequence of HeV was determined, its length (18,234 nt) was more than 2,700 nt, or 15% longer than the genomes of all other paramyxoviruses known at that time.(21) The size of NiV genomes at 18,246 nt to 18,252 nt are slightly larger than that of HeV.(22,23,33) These large genome sizes of >18 kb is a conserved feature of henipaviruses as even the recently discovered and more divergent CedV, GhV, and MojV all have genomes between 18,162 nt (CedV) to ~18,430 nt (GhV). Given the caveat that there is wide variation amongst individual species of the other paramyxovirus genera, the extra length of the henipavirus genome is primarily due to the longer 3' untranslated regions (3'UTRs) at the end of several of its six genes, and a larger *P* gene relative to the other paramyxovirus genera. A comparison of genome length and gene organisation of representative members of the *Paramyxoviridae* is shown in Fig. 14.3A. The nomenclature of each of the six major genes common to all paramyxoviruses have been updated to reflect the latest ICTV convention.(35) An analysis of the 3' UTR lengths between extant henipaviruses and representative species from each paramyxovirus genera that infects mammals is presented in Fig. 14.3B. The most significant differences are in the 3'UTRs of *N*, *P*, and *RBP* genes even given the wide variance seen within each genus. The significance of long 3' UTRs, especially in HeV and NiV, is generally unknown. However, the N gene 3'UTR of NiV appears to play a role in the downregulation of N mRNAs via specific interactions with hnRNP D.(36)

<FIG14.3A><FIG14.3B>

The genome organization of henipaviruses resembles that in the genera *Respirovirus* and *Morbillivirus.* The first 12 nt of the 3′ and 5′ genomic terminal sequences of paramyxoviruses are highly conserved and complementary, containing promoter elements for replication and transcription (see Chapter 13). The first 3 nt of the henipavirus genome termini are 5′-ACC-3′—a sequence that is absolutely conserved in members of the family *Paramyxoviridae* and different from that found in the family *Pneumoviridae.*

<H2>Virus Proteins and Their Properties

Analysis of purified viruses by polyacrylamide gel electrophoresis reveals RdRP (L), P, RBP (G), F_0, N, F_1, M, and F_2 proteins$^{(20,24)}$ where F_0 is the uncleaved and F_1 and F_2 the cleaved products of the *F* gene (Fig. 14.4A). Interestingly, F_0 is more readily detected in HeV compared with other paramyxoviruses, including NiV,$^{(24,37)}$ which may suggest that HeV-F is less efficiently cleaved. Overall, the proteins of henipaviruses are typical of those of *Paramyxoviridae*, with the exception of the P protein, which is significantly larger than cognate proteins in this virus family.$^{(26)}$ The P protein is translated from messenger RNA (mRNA) that is co-linear with genomic RNA. For most henipaviruses, the *P* gene also encodes V and W proteins, produced from mRNA in which one and two nontemplated G residues, respectively, are inserted at the RNA editing site during transcription. The P, V, and W proteins, therefore, are identical for the first 405 amino acid residues. A C protein is encoded by the 5′ end of the gene in an overlapping reading frame and is produced by an internal translational initiation mechanism, which is common to other members of *Paramyxoviridae*, except for rubulaviruses (see Chapter 13). The *P*-derived V, W, and C proteins are present in HeV-infected and/or NiV-infected cells.$^{(24,38)}$ It is worth noting that Cedar virus lacks both the RNA editing and expression of the V protein.$^{(28)}$ Similar to other paramyxoviruses, P itself and its derived proteins (V, W and C in the case of most henipaviruses), all antagonize innate immune responses via a diverse set of mechanisms.$^{(39,40)}$ The C protein also interacts with the host cell ESCRT machinery and the virus matrix (M) protein itself to facilitate virus budding (see Pathogenesis section for details on the function of these *P*-derived proteins).$^{(41)}$

<FIG14.4A><FIG14.4B>

Paramyxovirus N, P, and RdRP proteins are necessary and sufficient for replication of viral RNA both *in vitro* and *in vivo* as discussed in chapter 13. This has been confirmed for henipaviruses by reverse genetics using a minigenome replicon containing leader and trailer sequences of the NiV genome with its entire coding region replaced with a reporter gene.(34),(42) NiV N, P, and RdRP proteins were also able to rescue a HeV minigenome, demonstrating the close genetic relationship between the viruses. Full-length recombinant NiV bearing the matrix (M), fusion (F) and receptor binding protein (RBP) genes from HeV, singly or in combination, can also be functionally rescued. These chimeric but isogenic rNiVs replicate well in primary human endothelial and neuronal cells, further underscoring the genetic relatedness of NiV and HeV that allows for heterotypic complementation between their major structural proteins.(43) These henipavirus structural proteins contribute to unique aspects of the henipavirus life cycle (Fig. 14.4B), and play different roles in the spread and virulence of henipaviruses. Indeed, multiple groups have developed recombinant virus systems for NiV, HeV and CedV bearing various reporters and/or relevant mutations.(43-53) These additional tools have facilitated work towards understanding the virological and pathogenic similarities and differences amongst the henipaviruses. (see Pathogenesis section for details).

The RdRP protein of nonsegmented, negative-stranded RNA (NNR) viruses in the order *Mononegavirales* contains a highly conserved GDNQ motif, believed to be important for polymerase activity.(54) Henipaviruses were the first NNR viruses in which GDNQ was replaced by GDNE. It was speculated that this motif might be unique to paramyxoviruses with relatively large genomes(21,24); however, the GDNE motif has since been found in the RdRP protein of Mossman virus that has a genome length of 16,650 nt.(55) Conversely, other henipaviruses of both Asiatic (CedV) and African lineages (GhV) also have the GDNQ motif that is common to most other NNR viruses. High-resolution cryo-EM structures of VSV-RdRP (another NNR virus, family *Rhabdoviridae*) suggest that GDN is the truly conserved catalytic motif essential for the polymerase function of RdRP.(56)

The receptor binding proteins (RBPs) of the *Paramyxoviridae* display hemagglutination (H) and neuraminidase (N) activities in a predominantly genus-specific manner. Viruses in the genera *Respirovirus, Avulavirus*, and *Rubulavirus* possess both activities, hence their RBPs were formerly termed HN proteins(57) whereas viruses in the genus *Morbillivirus* do not behave uniformly and only some possess hemagglutination activity, but nonetheless their RBPs were formerly termed H.(58) This is an unfortunate misnomer. Paramyxoviruses with RBPs bearing HN activity genuinely use sialic acid based receptors for entry whereas "H" activity of some morbilliviruses arise from the ability of their RBPs to bind CD46 expressed on some non-human primate (NHP) red blood cells.(59) In contrast, henipavirus RBPs have neither of these activities(24,60); rather, they utilize at least ephrin-B2, and in many cases, also ephrin-B3 expressed on host cell surfaces as attachment and entry receptors (61-64),(28,65). The exception is MojV, which does not appear to use any known paramyxovirus receptors.(66) Recent solution structures of various henipavirus RBPs alone and in complex with the ephrin-B2 and/or ephrin-B3 receptors have revealed the details of the virus–host cell binding process, distinguishing it from other paramyxoviruses's receptor binding strategies.(67-69), (59,65,66) (Fig. 14.5)

<FIG14.5>

Proteolytic processing of paramyxovirus F proteins is essential for the generation of a fusogenic form of the protein. For most paramyxoviruses that generate systemic infections, furin-like proteases in the secretory pathway cleave their F proteins at a multibasic cleavage site.(70) Surprisingly, henipavirus F proteins are cleaved without the involvement of furin and, although cleavage occurs at a single basic residue—lysine for HeV and arginine for NiV.(37)

—activation of the NiV F protein does not require a basic amino acid at the cleavage site.(71) Instead, endosomal/lysosomal cysteine proteases such as cathepsins L and B are responsible for the cleavage of henipavirus F proteins.(72-75) To access cathepsins L/B, henipavirus F proteins are endocytosed upon initially reaching the cell surface in an uncleaved form, and subsequently have to traffic back to the cell surface once they are cleaved into a fusion-competent form (Fig. 14.4B). [55,57] Classical endocytic YXXØ motifs(76,77) in the cytoplasmic tails of henipavirus F proteins and specific residues in the transmembrane domain of at least HeV-F regulate this trafficking behaviour through the early/sorting (S490) and recycling endosomal (Y498) compartments.(78) Henipavirus F proteins also have the ability to bud by themselves forming F-only particles in the absence of M.(79,80)

The matrix protein (M) plays a major role in the efficient assembly and budding of infectious paramyxoviruses.(81,82) M interacts specifically with N, the cytoplasmic tail of F, as well as cognate lipid ligands along the vesicular trafficking pathway. These orchestrated interactions help to co-ordinate the envelopment of encapsidated viral genomes (RNPs) and the budding of infectious virions bearing a relatively high density of viral envelope glycoprotein spikes. General details on the role that matrix plays in paramyxovirus assembly and budding are given in the previous chapter 13.

Henipavirus M exhibits some relatively unique behaviours and functions. For example, NiV and HeV M have classical nuclear localization and export sequences (NLS, NES) that when mutated give the relevant nuclear exclusion and nuclear retention phenotypes, respectively.(83) Time-course monitoring of M trafficking during live NiV and HeV infection indicates that M first appears in the nucleus, localizes to subnuclear compartments, including the nucleolus, before exiting into the cytoplasm and trafficking to the plasma membrane to coordinate virus assembly and budding (Fig. 14.4B).(83,84) This nuclear transit is regulated by ubiquitination and is critical for M to acquire its budding functionality.(83,85) Henipavirus M is multi-mono and poly-ubiquitinated; a lysine to arginine mutation of a key residue in its bipartite NLS is sufficient to dysregulate ubiquitination of M and abrogate its budding function.(83,85) The latter is true not only in HeV and NiV, but also in divergent henipaviruses (GhV, CedV, MojV), albeit to varying degrees.(86) Matrix interactome studies have identified many nuclear interacting factors, including importins and exportins, consistent with the nuclear-cytoplasmic trafficking phenotype of M.(85,87)

<H2>Host Range

For most paramyxoviruses, host range is limited and interspecies transmission is rare. In contrast, henipaviruses display a broad species tropism. In addition to a large number of bat hosts at various geographic locations (see more detail in Epidemiology section), NiV has naturally infected pigs, humans, dogs, horses, and cats,(10,11,88-90) whereas HeV infects all four Australian flying fox species and has naturally infected humans, horses and dogs.(2,91-93) Confirmation of the wide host range of these henipaviruses and the identical cell tropism of HeV and NiV were obtained early using an *in vitro* cell fusion system that relies on vaccinia virus–mediated cell surface expression of G and F glycoproteins.(94-96) Bats, guinea pigs, hamsters, ferrets, squirrel monkeys, and African green monkeys are also susceptible to experimental NiV infection.(97-101) Laboratory studies have added cats, guinea pigs, hamsters, ferrets, dogs and African green monkeys to the list of HeV-susceptible species.(93,102-106) CedV, isolated from flying foxes (*Pteropus sp.*) in Cedar Grove, Australia, can establish transient but non-pathogenic infections in laboratory challenged guinea pigs and ferrets. GhV and MojV, known only from sequence information, were identified from bats(29) and rats,(30) respectively.

<H1>Pathogenesis and Pathology

<H2>Entry into the host

Epidemiological and experimental studies generally support an oronasal (8,107,108) or oropharygeal(109-111) route of entry. This occurs directly or indirectly via saliva, urine, or oronasal sceretions that are contaminated with relatively high levels of HeV or NiV.(93,105,107,112-123) Fig. 14.6 summarizes what is known about how NiV is transmitted to humans either directly from their pteropid reservoir hosts—fruit bats or flying foxes—or indirectly via a secondary amplifying host such as pigs, horses and humans. Direct bat-to-human transmission has been associated with consuming contaminated fruit or liquid (e.g. date palm sap)(109-111). Human-to-human transmission of NiV has been well-documented, especially in Bangladesh(117,124-126) and the most recent outbreak in Kerala (India).(17) However, all 7 known cases of HeV infections in humans have resulted from contact with sick horses already exhibiting symptoms of respiratory distress,(127) likely after being exposed to food or water contaminated with saliva and urine/droppings from HeV-infected flying foxes.(128) While patients that succumb to henipavirus infections eventually die from encephalitic complications that often involve brainstem neuronal dysfunction,(108,129) there is diversity of clinical presentations.(130) For example, NiV-MY infected patients in Malaysia present less often with respiratory involvement (~40%) than the vast majority of NiV-BD infected patients in Bangladesh and India. The handful of HeV infected humans have also presented with encephalitic illness with or without a respiratory component (see Clinical Features section). To better understand the pathogenesis and pathology associated with henipavirus disease in humans, many relevant animal models have been developed that either represent natural amplifying hosts (pigs and horses) or that reproduce well the respiratory and encephalitic disease seen in humans (hamsters, ferrets and African green monkeys (AGMs)).(131,132) Despite the broad host range mentioned in the prior section, other animal challenge models (guinea pigs, cats, dogs) either do not represent the full spectrum of disease seen in humans, or are relatively asymptomatic when challenged with NiV and/or HeV.(93,131)

<FIG14.6>

<H2>Site of primary replication, virus spread, and cell and tissue tropism

The clinical and pathological data from humans (see Clinical Features section), relevant animal models, and cell tropism studies (Table 14.3) indicate that the initial site of replication is within the respiratory system, likely involving cells lining the oro-/naso-pharyngeal epithelium as well as bronchiolar epithelial cells, type I pneumocytes, alveolar macrophages or pulmonary airway dendritic cells (DCs).(40,132-135) The distribution and time of appearance of lesions throughout the vasculature and in the brain and lung in NiV encephalitis suggest that secondary infection probably arises via hematogenous spread of the virus, with secondary replication occurring in vascular endothelium.(136) Inflammation of blood vessels (vasculitis) occurs in most organs but is particularly prominent in the brain, lung, heart, kidney and spleen.(9,136,137) Vasculitis is limited to small arteries, arterioles, and capillaries where NiV antigen is found in both endothelial cells and the smooth muscle of the tunica media. The pattern and time of appearance of vasculitis and viral antigen distribution are consistent with endothelial cell infection occurring before infection of the smooth muscle. The 5-day interval between maximal vasculitis in the brain and parenchymal infection in acute NiV encephalitis suggests that virus replication occurs first in endothelial cells, with infection of neurons occurring as a result of vascular damage and breakdown of the blood-brain barrier (BBB). In humans as well as in pigs and hamsters, viral antigen positive brain microvascular endothelial cells can be observed in areas of compromised BBB integrity.(136,138,139) The presence of inclusion bodies and viral antigen in neurons, along with widespread histologic and radiologic lesions, suggests that neurologic impairment in NiV (and HeV) encephalitis may be caused by both the effects of ischemia and infarction and viral infection of neurons.(12,107,136)

<TAB14.3>

In addition to the systemic vasculitis, NiV antigen is clearly present in the parenchyma of multiple organs mentioned above. The same pathology has been reported for a fatal case of acute HeV encephalitis.(140) Similar widespread infection and multiorgan vasculopathy has been demonstrated in relevant animal models with the highest viral antigen load consistently seen in the lung and brain (Fig. 14.7). *(131,132)* Interestingly, intranasal inoculation in pigs, hamsters, and ferrets suggests that NiV can also directly invade the central nervous system (CNS) through the olfactory epithelium (OE). NiV antigen positive neurons or olfactory nerves can be found extending through the cribiform plate or in the nasal turbinate into the olfactory bulb.(133,139,141) While primary human OE cells are susceptible to henipavirus infection(142), the olfactory route is unlikely to be the major mode of CNS invasion in humans (and the AGM model). Primates have a relatively smaller area of OE compared to hamsters, pigs, or ferrets where the majority of evidence regarding the olfactory route of entry has been gathered.(97,139,141) In addition, NiV antigen was not detected in the olfactory bulbs of at least nine infected patients from the autopsy series reported from the Malaysian outbreak.(136)

<FIG14.7>

The widespread cell and tissue tropism of NiV and HeV seen in humans and the various animal models is determined by the expression pattern of the henipavirus receptors, ephrin-B2 and ephrin-B3.(61-64) The ephrinB ligands and their cognate EphB receptors are both receptor tyrosine kinases that mediate bidirectional cell–cell signaling events upon engaging each other. They are critical modulators of cell remodeling events, especially within the nervous and vascular systems.(143,144) They are also highly conserved among vertebrates, which explains, at least in part, the unusually broad species tropism of henipaviruses. Ephrin-B2 is found in arteries, arterioles, and capillaries in multiple organs, and is more broadly distributed across multiple tissues and cell types (Fig. 14.8), including neurons, arterial smooth muscle and human bronchiolar epithelial cells,(143,145-147) but is absent from venous components of the vasculature.(148,149) In contrast, ephrin-B3 is essentially restricted to the brain(144) where it is expressed higher than ephrin-B2 (Fig. 14.8). Its relative absence from organs such as lung, kidney, and spleen, as well as from arterial endothelium suggest that the systemic vasculitis, respiratory distress, and other end-organ pathologies seen in henipavirus infections is largely a consequence of ephrin-B2-mediated entry. Conversely, ephrin-B3 mediated entry may play a larger role in the spread of HeV and NiV within the CNS.

<FIG14.8>

Human lymphocytes (mainly T- and B- cells), and monocytes, despite being non-permissive for NiV infection(150) or HeV-F/RBP induced fusion(94), can bind and transfer NiV to permissive microvascular endothelial cells *in vitro*.(150) This trans-infection phenotype, thought to be mediated by heparan sulfates,(151) may be an efficient form of hematogenous spread in addition to the free form viruses that make up the plasma viremia seen in acute NiV and HeV infections in humans. This acute but transient viremia appears about 4-7 days post-onset of illness (POI) and in survivors, is usually undetectable within 2-4 weeks POI depending on severity of the disease course.(17,152-154) A similar course of plasma viremia can also be detected in AGMs challenged intratracheally and orally with NiV.(98) The next section on the Immune Response will discuss possible mechanisms by which viremia is cleared in survivors.

<H2>Immune Response

Viral antagonism of innate immune responses

HeV and NiV have a broad host range that is uncommon in paramyxoviruses. This ability to replicate, spread, and cause acutely lethal disease amongst multiple species suggest that these viruses have evolved effective means to antagonize or evade innate antiviral responses that might otherwise keep them in check until adaptive immune responses develop.

In henipaviruses, as in other paramyxoviruses, (40) the major anti-interferon (IFN) activities are encoded by the *P* gene and *in vitro* studies indicate that *P* gene products inhibit both IFN induction and signalling (Fig. 14.9). (39) In IFN induction, various forms of viral double-stranded RNA (dsRNA) are detected by cytoplasmic RNA helicases(155-157) such as RIG-I and MDA-5, and by toll-like receptor-3 (TLR-3). (157,158) Both of these dsRNA signaling pathways, via a cascade of signaling events depicted in Fig. 14.9 (left) lead to activation and nuclear translocation of interferon regulatory factor (IRF)-3, or if present, IRF-7, and nuclear factor kappa B (NF-kB); transcription factors that induce the expression of IFN-α/β proteins. HeV and NiV inhibit dsRNA signaling via its V protein, which binds to MDA-5 and prevents downstream signaling(155,159,160) but does not abrogate dsRNA signaling through TLR-3.(161) Recent evidence suggest that NiV-V also binds RIG-I and its regulator (TRIM25), disrupting downstream signalling. (162) In an additional strategy unique to henipaviruses, the W protein, by virtue of a NLS located in the unique carboxy terminal, inhibits induction of IFN-α/β expression in the nucleus by targeting a process that is part of both helicase-dependent and TLR-3–dependent signaling pathways.(163) Unexpectedly, the NiV M protein, can also inhibit IFN-α/β induction by indirectly antagonizing the activity of IKKε, the kinase responsible for IRF-3 activation.(51)

<FIG14.9>

In the IFN signaling pathway (Fig. 14.9, right), IFN binds to the IFN-α/β receptor (IFNAR) on cells and initiates a signaling sequence that leads to activation of members of a family of proteins called *signal transducers and activators of transcription* (STAT).(164,165) Henipaviruses inhibit IFN signaling by sequestering STAT proteins in high molecular weight complexes and preventing their phospho-activation .(166,167) The anti-IFN signaling activity is a property of the V protein, as has been observed for other paramyxoviruses, but also of the W and P proteins.(161,166,167) (45)The P, V, and W proteins of henipaviruses have an N-terminal extension of 100 to 200 amino acids compared with cognate proteins in the subfamily,(20,23) and the STAT binding domain of NiV V maps to this region.(161,168,169) The V and P proteins bind STAT in the cytoplasm, whereas the W protein, which is imported into the nucleus via specific interactions of its NLS with importin α-3, (170) likely sequesters unactivated STAT1 in the nucleus.(161,163) Recently, NiV and HeV N proteins were also found to antagonize IFN-signaling by interfering with formation of activated phospho-(p)STAT1 complexes. This NiV-N mediated antagonism of pSTAT1 nuclear accumulation does not rely on direct binding to or inhibiting phosphorylation of STAT1 itself. (171) NiV C has also been demonstrated to interfere with IFN-signaling.(47,172) However, its mechanism and true function remains unclear. Antagonizing IFN-signaling is unlikely to be the main function of the C protein since recombinant C-deficient NiVs have an attenuated replication phenotype even in Vero cells, (41,45,46) which are genetically deficient in IFN production.

There is little doubt that inhibition of IFN-α/β production is one major contributor to the acute virulence of HeV and NiV *in vivo*. Daily administration of poly(I)-poly(C(12)U), a potent IFN-inducer, results in >80% survival in a lethal challenge hamster model for NiV infections.(173) Most of the studies described previously were carried out *in vitro* using single-gene transfection expression systems. Understanding the true function(s) of these proteins requires assessing their impact in the context of a live virus infection or the phenotype of viruses deficient in the cognate protein(s). For example, IFN signaling apparently remains functional during live HeV and NiV infection of human cell lines, whereas IFN production was inhibited.(174) However, henipaviruses also clearly antagonize both IFN production and signaling in bat cells derived from *Pteropus sp*. that serve as their natural hosts.(175)

The diverse phenotypes observed in the various animal models when challenged with recombinant viruses deficient in the various P-derived accessory proteins makes interpretation difficult. The clearest phenotype comes from rNiVs engineered to be V-deficient. rNiV-ΔV are extremely attenuated in both hamster and ferret challenge models.(46,50) Each model re-capitulates the respiratory and neurological disease seen in human infections when infected with wt NiV, albeit in different ways and in a dose-dependent fashion.(103,131,176) However, challenge with V-deficient rNiV under conditions where their wt counterparts effectuate 100% mortality always results in 100% survival, and almost never results in any overt respiratory or neurological signs.(46,50) On the other hand, C-deficient rNiVs give a variety of phenotypes that range from strong attenuation in the hamster model,(177) to 100% mortality in the ferret model, albeit with less severe histological lesions in the lung.(52) Similarly, W-deficient rNiVs did not show significant attenuation compared to their wild-type counterparts in both the hamster(46) and ferret models, although the disease symptomology appeared to be more neurologic in the latter.(50,52) Interestingly, a rNiV lacking both C and W still resulted in 60% mortality with reduced respiratory disease but markedly increased neurological disease.(52)

Adaptive immune responses.

In patients with encephalitis, anti-NiV antibodies were observed more frequently in the serum than the CSF. Immunoglobulin M (IgM) antibodies occurred more frequently than immunoglobulin G (IgG) antibodies in both locations.(9,12,136) The appearance of specific IgM antibodies in serum preceded their appearance in the CSF, a sequence consistent with viremia preceding central nervous system (CNS) infection. Anti-NiV antibodies were present in most patients with clinical NiV encephalitis; however, no difference was observed in clinical features, laboratory results, or mortality between seropositive and seronegative patients.(108,178) Seroconversion of IgG against HeV was seen in two human cases of HeV infection in 2008, with one progressing to fatal encephalitis.(8) From these cases, seroconversion in acute henipavirus disease may have diagnostic but no apparent prognostic value. Conversely, in the most recent NiV outbreak in Kerala involving 23 cases, careful monitoring of humoral and cellular immune responses in the 2 survivors revealed that there was a dramatic increase in activated (Ki67+) CD8+ T-cells with an acute effector phenotype (CD38+/HLA-DR+/Granzyme B+ /PD1+), suggesting that virus-specific naïve T-cells were actively proliferating in response to the virus. Interestingly, clearance of viremia coincided with the peak of proliferating Ki67+ CD8+ T-cells, and occurred before peak IgG titers. (152) Increases in activated CD8+ T-cells in lethal (NHP)(179) and non-lethal (Swine) animal models of NiV infection have also been observed; (180) in the latter, prevention of virus shedding appears correlated with such T-cell responses. However, most animal studies do not monitor adaptive immune responses with the requisite precision and sophistication in order to make definitive statements regarding the relative importance of T- or B- cell responses in protective immunity against acute henipavirus infections.(181)

The high CFR associated with the acute nature of henipavirus infections already suggests that the virus interferes with the timely generation of effective T- or B- cell responses during the *natural* history of the disease in the majority of infected individuals. Indeed, although NiV replicates poorly in DCs (Table 14.3),(150,182) *in vitro* NiV-infected DCs induces an inflammatory pro-apoptotic milieu (TNF-a, IL-1β, IL-8) that leads not only to defective T-cell priming, but apoptosis of cognate T-cells and DCs.(182) This in vitro phenomenon, if recapitulated *in vivo* by NiV-infected DCs that traffic to lymph nodes, may account for the lymphoid depletion and lymphoid necrotic lesions seen in humans*(136)* and various relevant animal models.*(50,183,184)*

<H2>Release from host and transmission

Transmission is generally accepted to occur via the oronasal route(8,107,108) or liquid/food (palm sap/fruit),(109-111) with transmissibility of HeV (horse-human or human-to-human)(185,186) being much less efficient than that of NiV transmission (pig-to-human or human-to-human).(9,15,17,108,115,117,126,187,188) Infectious NiV can be recovered from urine and the tracheal and nasopharyngeal secretions of infected patients in the early phase of their illness in the original Malaysian outbreak.(3,107,108) Nonetheless, human-to-human transmission in the Malaysian outbreak was extremely rare(189), although it has been reported in the more recent outbreak in the Philippines. In contrast, person-to-person transmission in Bangladesh has been well documented and typically occurs during the final stages of disease in the index patient when not only symptoms of respiratory involvement are most prominent, but also more frequent and closer contact with familial caretakers occurs. (125,187,188)

Replication in the respiratory epithelium and shedding in oronasal secretions is most likely responsible for virus release and transmission. Ferrets have been used to model the respiratory transmission of henipaviruses(112,184) as their respiratory symptoms (cough, serous nasal discharge, dyspnea) mimic the human disease.(97) Despite shedding relatively large amounts of virus in their oronasal secretions (4-5 log10 $TCID_{50}$ equivalents/ml at peak titers), passively cohoused naïve ferrets never got infected, regardless of whether the index ferrets were infected with HeV, NiV-MY, or NiV-BD.(112,184) However, following assisted or direct exposure to infectious oronasal fluids from the index ferrets, all the naïve ferrets developed acute infections, regardless of virus strain used.(112) Thus, the efficiency of NiV transmission appears low, and likely requires direct and repeated oro- or naso-mucosal exposure to infectious oronasal secretions. This is consistent with epidemiological investigations into the many recurrent outbreaks in Bangladesh where despite chains of person-to-person transmission, the estimated basic reproductive number R_0 of NiV-BD strains that have spilled over in Bangladesh have averaged 0.48.(187)

<H2>Virulence

Infection with HeV appears more severe than infection with NiV-MY and NiV-BD in the hamster(138,190) and AGM model.(191) The dose-dependent disease symptomology in the hamster model(138,192) makes it difficult to make generalize statements about any intrinsic pathogenic difference between these three genetically distinct henipaviruses. However, the intratracheal and intranasal AGM challenge model appears to recapitulate the clinical pathologies seen in human patients more robustly.(98,103) Interestingly, it is also in this model that NiV-BD is shown to be more pathogenic than NiV-MY,(191) which reflects the observed differences in pathogenicity between NiV-MY and NiV-BD. Previous studies comparing NiV-MY and NiV-BD in hamsters(190) and in ferrets(112) gave conflicting and confusing results. But more careful comparisons of fully-sequenced NiV-MY and NiV-BD strains in the AGM model provides support that NiV-BD is more pathogenic than NiV-MY,(191) consistent with the higher mortality rates associated with NiV-BD (see Table 14.1C). Under identical experimental conditions, NiV-BD is not only shown to be more pathogenic in terms of viral load in lungs, spleen, and blood, but also that the therapeutic window for post-exposure prophylaxis using human monoclonal antibody (m102.4) is significantly shorter in NiV-BD infected AGMs.(191) m102.4 is a potent neutralizing mAb previously shown to rescue NiV-MY and HeV infected AGMs even when administered up to 7 days post-infection.(193,194)

CedV lacks the editing site in the *P* gene and does not make the V protein,(28) a potent type I IFN antagonist required for henipavirus virulence *in vivo*.(39) Not surprisingly, CedV, which is naturally V-deficient, also does not induce any overt disease in ferrets and guinea pigs.(28) Reactive hyperplasia of oropharyngeal lymphoid tissues and detection of viral RNA in select bronchial associated lymphoid tissue (BALT) accompanied by increasing neutralizing Ab titers suggests that CedV likely replicates transiently in the upper and lower respiratory tracts of the challenged animals.(28) While recent evidence suggests that the CedV P protein itself is also a less efficient antagonizer of IFN-α signaling compared to HeV-P,(195) whether CedV is truly non-pathogenic in humans or horses remains to be seen. Given the fact that CedV does not appear to use ephrin-B3 as receptor, one might also predict CedV to be less encephalopathic even in more susceptible animals.

<H2>Persistence

A small percentage of NiV-infected patients (3-7%) experience late-onset or relapse encephalitis months to years after the initial NiV infection; the former describes patients with initially mild or asymptomatic NiV infections while the latter are survivors of acute NiV encephalitis.(108,129,196,197) One case of fatal late-onset HeV encephalitis has also been reported.(3,140) These cases suggest that NiV and HeV can persist in sanctuary sites like the brain especially since virus has never been isolated from oronasal secretions of relapsed encephalitis cases.(9,107,136,196-198) (see Clinical Features section for details). There is one report of NiV RNA being detected in the semen of a NiV survivor 4 weeks post-onset of illness, but this was gone 2 weeks later. Longitudinal studies on 2 HeV survivors shows no evidence of viral shedding by RT-qPCR, up to 6 years post-symptom onset.(154) It is unlikely that NiV and HeV in humans can persist in infectious forms. Thus, relapse henipavirus encephalitis might resemble measles virus associated subacute sclerosing panencephalitis, which can occur years after recovery from measles virus infection.(199,200)

<H1>Epidemiology

<H2>Age

The age of patients with encephalitis in the Malaysian outbreak ranged from 9 to 76 years, with almost 50% of cases occurring in those 40 to 44 years.(108,136,153,178,201) The male-to-female ratio was approximately 3:1, and more than 80% of the patients were Chinese, with statistics reflecting the increased risk to those working with infected pigs.(108,201) In Bangladesh, the age of patients ranged from 4 to 60 years, and males constituted 47% and 67% of the cases in the 2001 and 2003 outbreaks, respectively.(14,202) The outbreak in early 2011 in Bangladesh claimed at least 35 lives, including many children and infants, with ages ranging from 2 to 56 years.(127,203) Among the 18 suspected patients in the 2014 oubreak in the Phillipines, the age distribution is between 21-60 years old.(18) In the most recent NiV outbreak in Kerala, India, the age distribution ranged from a 17 year old male to a 75 year old female among a total of 23 human cases.(17)

<H2>Morbidity and Mortality

In Malaysia, between September 1998 and June 1999, 256 patients who developed acute NiV encephalitis were admitted to Malaysian hospitals and 105 died, a mortality rate of approximately 40%.(9,201) The rate of subclinical infection in households and farms where cases of NiV encephalitis occurred was calculated to be 8% and 11%, respectively.(196,201) In Singapore, where 11 patients were confirmed to have acute NiV encephalitis, a further 2 asymptomatic abattoir workers were serologically positive, representing a rate of subclinical infection of 15%.(204) Subsequently, 89 individuals were identified on the basis of positive serology as having experienced either an asymptomatic or mildly symptomatic NiV infection.(129) This increases the number of people infected with NiV to 345 and decreases the mortality rate to approximately 30%.(137) In Bangladesh, 98 of 135 patients died in eight outbreaks from 2001 to 2008, giving a combined case fatality rate of 73%.(117,188,202) In the Philippines outbreak, the case mortality is 53% out of all the suspected cases or 81% for those with encephalitic clinical signs.(18) The case mortality is 94% for the 2018 Kerala outbreak in India.(17) There have only been seven known human cases of HeV infection in Australia in the past 16 years, four of which have been fatal (three acute and one case of relapsed encephalitis).(2,3,8)

<H2>Origin and Spread of Epidemics

Fruit bats (flying foxes) in the genus *Pteropus*, family *Pteropodidae*, suborder *Megachiroptera* are main reservoir hosts of HeV and NiV.(5,6,13,89,205) In Australia, HeV has been shown to occur in all four flying fox species, with the crude seroprevalence of 47%, indicating an endemic pattern of infection throughout Australia.(91) Serologic tests show that NiV or NiV-related virus is widely dispersed in bats from Indonesia to the west border of

Africa (Fig. 14.10). NiV was first isolated from the urine of Island flying foxes and from the saliva on partially eaten fruit(13) and has since been isolated from Lyle's flying foxes (*Pteropus lylei*) in Cambodia(89) and *Pteropus medius* in Bangladesh.(206) The Indian flying fox (*Pteropus giganteus*) is the main pteropid species throughout Bangladesh and the Indian subcontinent with a high seroprevalence of henipavirus-specific antibody.(14,110,187,207) Additional serologic and limited nucleic acid evidence has suggested that related henipaviruses are circulating in other regions, including Thailand, Indonesia, Vietnam, China, Madagascar, and several countries and regions in Africa (Fig. 14.10 and Table 14.4-online). <FIG14.10>

Neither HeV nor NiV appear to cause clinical disease in naturally infected bats.(91,202,205,208) Experimental infection with doses of HeV that are lethal in horses generates sporadic vasculitis in the lung, spleen, meninges, kidney, and gastrointestinal tract, and even then, only in a proportion of infected bats.(105) Viral antigen is detected in the tunica media rather than endothelial cells, a fact that may spare these bats from the clinical effects associated with vasculitis.(209) In infected pregnant fruit bats, antigen was observed in similar locations and in the placenta.(210) The mode of transmission between fruit bats is unknown. Transplacental transmission has also been observed experimentally without apparent harm to the fetus.(210) Experimental infection of fruit bats with NiV produced a subclinical infection with a transient presence of virus within selected viscera along with periodic viral excretion in bat urine and seroconversion with neutralizing antibody present.(100)

The spillover and epidemic hosts of HeV and NiV were horses in Australia and Philippines, and pigs in Malaysia. All human infections with HeV in Australia and NiV in Malaysia have only occurred through transmission from these domestic animal hosts.(9,201) No evidence exists of direct transmission from pteropid bats to humans in Australia or Malaysia, despite many opportunities in Australia for transmission to bat carers.(196,211) In contrast, fruit bats apparently play a direct role in the transmission of NiV to humans in the many recent outbreaks of disease in Bangladesh, where epidemiologic evidence in support of a role for an intermediate host was lacking.(14,202) Three pathways of NiV transmission from bats to people have been identified based on epidemiologic investigations in Bangladesh.(117) Consumption of fresh date palm sap appears to be the predominant risk factor, and infrared camera studies have confirmed that *P. giganteus* bats frequently visit date palm sap trees and consume sap during collection.(212) In the 2005 NiV outbreak in Tangail District, Bangladesh, drinking raw date palm sap was the only activity significantly associated with illness (64% among cases vs. 18% among controls).(110) Another route of transmission for NiV from bats to people in Bangladesh could be via domestic animals. Contact with a sick cow in Meherpur, Bangladesh, in 2001 was strongly associated with NiV infection,(14) and contact with pigs and diseased goats have also been implicated in other occurrences of NiV in Bangladesh.(117) Although NiV has never been isolated in domestic livestock animals, serological evidence was reported for antibodies to NiV or NiV-related viruses in cattle, goats and pigs in Bangladesh.(213) Transmission via direct contact with NiV-infected bat secretions also appears possible from evidence in the Goalando outbreak in 2004, where individuals who climbed trees were more likely to develop NiV infection than controls.(214)

The mode of transmission from bats to spillover hosts in Australia and Malaysia remains to be determined. Three principal hypotheses exist. One is that masticated pellets of virus-contaminated, residual fruit pulp spat out by flying foxes are ingested by horses or pigs.(205) The second is that urine from infected animals contaminates pastures or pigsties. The third is that infected fetal tissues or fluids contaminate pastures or sties and are ingested. The latter is based largely on the fact that the HeV outbreaks have occurred during the birthing period of some species of flying fox and is supported by the isolation of virus from a pregnant flying fox and its fetus.(6)

HeV has been transmitted from horse to man on seven occasions from 1994 to 2009, twice during the initial outbreak in Brisbane,(1,2) twice during necropsy of horses that died in the field,(1,4) twice during either daily nasal cavity lavage and participating in a necropsy,(8) and once from performing an endoscopy on an infected horse.(8,215) HeV is rarely found in the bronchi or bronchioles of infected horses, which suggests that aerosol transmission to either man or horses is less likely(216) and horse-to-horse transmission of HeV has not been demonstrated.(105) The presence of HeV in equine saliva, however, suggests that close contact with infected horses, such as might occur during manual feeding of the animals, may facilitate horse-to-human transmission.(1) The presence of virus in a wide range of tissues and in the nasal discharge commonly found at the terminal stage of infection offers a range of sources for virus transmission during necropsy.(2,217) As shown in Fig. 14.7, high level of viral antigen can be detected in the nasal cavity of HeV-infected horses.

In the Malaysian NiV outbreak, contact with pigs or fresh pig products was required for transmission of the virus to humans, with greater likelihood of transfer to those in direct contact with sick or dying pigs on farms or in abattoirs.(9,201) The presence of NiV in the respiratory epithelium of naturally and experimentally infected pigs (Fig. 14.7) indicated that virus probably spread to humans and within the pig population by aerosol or by direct contact with oropharyngeal or nasal secretions.(10,121,139) The presence of the virus in a wide range of organs indicates that humans may also have been infected during processes such as slaughtering or farrowing. In Bangladesh, pigs were excluded as potential sources of NiV on epidemiological grounds, and human-to-human transmission was observed.(126,188) The virus may have been transmitted to human index cases directly through contact with fruit bat secretions in contaminated fruit or date palm sap before circulation in the human population (Fig. 14.6).(13,14,117,202) Nosocomial transmission has been detected in some of the Bangladesh and India outbreaks.(15,117,218) In the Philippines NiV outbreak, of the 17 case-patients, a total of 7 (41%) had participated in horse slaughtering and horse meat consumption; 3 (18%) had only consumed horse meat and but had no history of slaughtering or meat preparation; 5 (29%) case-patients had been exposed to other human casepatients but not to any horses. So it is possible that both horse-to-human and human-to-human transmission might have occurred (Fig. 14.6).(18) For the Kerala NiV outbreak, while it remains undefined how the index case was exposed to NiV, it was evident that human-to-human transmission was the main driver for the spread of the virus in both family/community and hospital settings (Fig. 14.6).(17)

<H2>Genetic Diversity

Genome sequencing revealed that HeV isolated from equine and human sources during the outbreak in Brisbane appears identical and differs little from HeV isolated from flying foxes 2 years later.(2,6) Sequencing of five additional horse isolates from five different locations from the 2006 to 2008 HeV occurrences has also demonstrated a very high genetic similarity.(219) Similar observations were made in Malaysia, where it was demonstrated that NiV isolated from pigs at the height of the outbreak and at its geographic focus were essentially identical to human isolates made at that time and isolates obtained from flying foxes several years later.(13,22,23,220)

In Bangladesh, four human isolates obtained in 2004 demonstrate significant genetic heterogeneity, which might suggest multiple spillovers of NiV from flying foxes into the human population.(33) The NiV sequences detected from human patients in India from 2001 to 2018 were more related to NiV from Bangladesh than NiV from Malaysia.(15,17,218) A recently whole genome sequencing study of ten NiV isolates obtained from bats in 2013 in Bangladesh at two different geographic locations revealed that the isolated viruses were very similar in sequences. This suggests that multiple strains were not co-circulating in the bat population at the time.(206) Furthermore, none of the bat NiV isolate sequences was identical with any previously detected human NiV isolate sequences, suggesting that NiV spillover into humans is a rare event and more intensive surveillance is required to appreciate the full genetic diversity of NiV in bats in an area with frequent spillover events into human populations.(206) NiV isolated from the flying fox *Pteropus lylei* in Cambodia(89) represents an evolutionary lineage that is separated from the Malaysia or Bangladesh/India cluster . Partial *N* gene sequences detected in *Pteropus lylei* in Thailand indicate the circulation of at least two lineages of NiV—one related to the Bangladesh NiV and the other more related to the Malaysian NiV.(119) On the other hand, NiV sequences detected in *Pteropus hypomelanus* in southern Thailand are clearly more related to the Malaysian NiV.(221) As the RNA-dependent RNA polymerase (RdRP), formerly known as the L protein, is the most highly conserved protein for paramyxoviruses, it has been used as a more reliable indicator of evolutionary relationship among different paramyxoviruses. Fig. 14.11 shows a RdRP-based phylogenetic tree of henipavirus species and strains, selected to represent major species origin, geographic location and time of isolation. Prototype species from other genera in the family *Paramyxoviridae* are also shown for context and comparison.

<FIG14.11>

The presence of henipavirus-reactive (but not neutralizing) antibodies and viral RNA in bats from other regions of the world (Fig. 14.10 and Table 14.4-online) indicate that a much greater genetic diversity of henipaviruses exists in different bat populations.(29,222,223) These divergent but yet to be characterized henipaviruses likely have different transmissibility, pathogenicity, and receptor usage patterns, as has already been shown for CedV,(28,53,195) GhV,(65,224,225) and MojV.(66) The latter is an outlier in many ways,(41,66,86) and is currently the only henipavirus identified in rodents rather than bats.(30)

<H1>Clinical Features

<H2>Incubation Period

Based on the time interval between the last exposure to pigs and onset of disease, the incubation period for NiV ranged from 2 to 45 days; however, for 90% of patients, it was 2 weeks or less.(108,153,178) An estimate of 2 to 3 weeks was made based on the time interval between importation of pigs from NiV-affected areas of Malaysia and development of human disease at a Singaporean abattoir.(204) A mean incubation period of 9.4 days was calculated for four patients who had a fixed period of exposure.(178) The NiV outbreak in Kerala, India, 2018, revealed a median incubation period was 9.5 days among 23 cases, 22 of which were nosocomial.(17) In the occurrence of HeV in Australia in 2008, a detailed examination of exposure histories from two infected patients (one fatal) suggested a likely incubation period of 9 to 16 days, with exposure occurring some 3 days before the onset of symptoms of HeV infection in the horse.(8)

<H2>Acute Clinical Features

The first two patients infected with HeV presented with fever, myalgia, headaches, lethargy, and vertigo. One patient recovered; however, the other developed pneumonitis, respiratory failure, renal failure, and arterial thrombosis, and died of cardiac arrest 7 days after admission to the hospital. Findings at autopsy were consistent with a viral infection; both lungs were congested, hemorrhagic, and filled with serous fluid, and the histology revealed focal necrotizing alveolitis with many giant cells, some syncytial formation, and viral inclusions.(1) Although the predominant clinical features of NiV encephalitis derived from CNS involvement in the initial Malaysia outbreak, a proportion (40%) of patients displayed pulmonary involvement, which presented as an atypical pneumonia with fever, cough, and headache.(12,108,136,178) In the Kerala, India NiV outbreak, 19 cases (83%) presented with acute respiratory distress syndrome (ARDS) and shortness of breath, and 20 cases (87%) had respiratory symptoms.(17) The clinical presentation of NiV infections in Bangladesh also shows severe respiratory disease involvement.(226) A chest X-ray of an acute NiV-infected human case showing diffuse bilateral opacities of the lung fields consistent with ARDS (Fig. 14.12A) and a similar presentation was reported in the first fatal human HeV case.(1) Chest X-ray images of NiV and HeV-infected AGMs have also demonstrated severe respiratory disease (Fig. 14.12B). Case definitions for suspected NiV infection in Bangladesh(226) and India(15,17) generally included individuals residing in an outbreak area who presented with fever, headache, vomiting or altered mental status or with history of cough or shortness of breath and fever.

<FIG14.12>

With NiV in Malaysia, most patients presented with acute encephalitis characterized by fever, headache, drowsiness, dizziness, myalgia, and vomiting, and more than 50% had a reduced level of consciousness.(9,12,108,178) The major clinical signs included drowsiness, areflexia, segmental myoclonus, tachycardia, hypertension, pinpoint pupils, and an abnormal doll's eye reflex. Such clinical features as these suggested involvement of the brain stem and upper cervical spinal cord, and were observed more frequently in patients with a reduced level of consciousness.(108,227) In Kerala, India, 2018, NiV-infected patients presented with altered sensorium (74%), along with myalgia, headache, vomiting, and seizures.(17) Patients in the NiV-Malaysia outbreak who retained normal levels of consciousness throughout their illness recovered fully; however, only 15% with reduced levels of consciousness survived. Fig.14.13 shows magnetic resonance imaging (MRI) images of human cases of acute NiV encephalitis. Such neurologic manifestations are consistent with vasculitis-induced thrombosis in the brain and the direct infection of neurons.(9,11,12,136) The multiple discrete lesions 1 to 5 mm in diameter in the cerebral white matter detected by MRI may be the site of such microinfarctions and are distinct from lesions caused by other viruses.(9,12,140,196,228) A third case of HeV infection presented first with meningitis and a 12-day history of sore throat, headache, drowsiness, vomiting, and neck stiffness. After an apparent full recovery, this patient developed fatal encephalitis 13 months later and was admitted to the hospital with a generalized tonic-clonic seizure after 2 weeks of irritable mood and low back pain. Recurrent focal motor seizures occurred over the next 7 days, as did secondarily generalized seizures and low-grade fever, followed by dense right hemiplegia, signs of brain stem involvement, and depressed consciousness requiring intubation. The patient remained comatose and died 25 days after admission.(3) Two patients in 2008(8) presented with initial influenza-like illness, although soon after apparent clinical improvement and an absence of fever, encephalitis developed in both. MRI revealed widespread cortical, subcortical, and deep white matter involvement, similar to the previous late-onset case of HeV encephalitis(3) and to NiV encephalitis cases (Fig. 14.13B).(108,196,229)

<FIG14.13>

<H2>Outcome of Infection

Most patients who survived acute NiV encephalitis in Malaysia made a full recovery; however, approximately 20% had residual neurologic deficits.(108,178,230) Neurologic sequelae included cognitive difficulties, tetraparesis, cerebellar signs, nerve palsies, and clinical depression. A few patients remained in a vegetative state. In patients with encephalitis who recovered, most brain lesions revealed by MRI disappeared or became smaller over a period of 12 to 18 months, although some remained unchanged.(230) Approximately 7.5% of patients who recovered from acute encephalitis and 3.4% of those who experienced nonencephalitic or asymptomatic infection developed late neurologic disease (Fig. 14.13).(108,129,196,197) Relapse encephalitis and late-onset encephalitis presented several months to 4 years after the initial infection, with the longest reported case 11 years after an initial acute infection.(231) Relapsed cases had elevated IgG, but not IgM, and no vasculitis, and unlike the situation in acute encephalitis, virus was not isolated from throat and nasal secretions.(9,107,136,196-198)

The clinical features associated with relapse and late-onset encephalitis resembled those found with acute NiV encephalitis, although decreased incidence was seen of fever, coma, segmental myoclonus, and meningism and an increased occurrence of seizures and focal cortical signs compared with the acute manifestation of the disease.(129) The clinical, radiologic, and pathologic features of relapse NiV encephalitis resembled those of the patient who became infected with HeV, suffered mild, transient aseptic meningitis, and recovered but died of a fatal meningoencephalitis 13 months later.(3,140) Most patients with relapse and late-onset encephalitis had only one neurologic episode, although some patients experienced two episodes separated by a mean of 7.6 months (6 weeks to 1 year).(129) The mortality rate associated with relapse and late-onset encephalitis at 18% was lower than that associated with acute encephalitis, at 30% to 40%. However, 61% of patients with relapse and late onset had further neurologic sequelae compared with 22% after acute encephalitis. Among NiV survivors in Bangladesh, some 30% have moderate to severe persistent neurologic dysfunction for years following acute infection.(196)

The demographics, clinical features, serology, and MRI of patients with relapsed and late-onset encephalitis were similar, suggesting that the two diseases have identical pathogenesis(129) and that the initial infection in late-onset encephalitis patients may not have been sufficiently severe to cause neurologic symptoms. MRI abnormalities similar to those observed in patients with acute encephalitis were also seen in 16% of asymptomatic patients, although the lesions were fewer in number. (227) The involvement of the cortex in relapse and late-onset encephalitis suggests a different pathologic mechanism compared with acute encephalitis. Relapse and late-onset encephalitis are considered to be caused by the recrudescence and rapid replication of virus that had persisted following acute or asymptomatic NiV infection.(129) NiV, however, was not isolated from CSF and brain tissue of patients with relapse and late-onset encephalitis.(129)

<FIG14.14>

The generalized understanding of the infection process along with the clinical features of human NiV and HeV infection is diagrammed in Fig. 14.14. Transmission is likely via the oronasal route as described above (Pathogenesis section). The initial site of replication in humans is likely within the respiratory system and disease onset is characterized by fever, myalgia, shortness of breath, cough, which may progress to ARDS. Possible invasion into the CNS via the olfactory bulb has been demonstrated in non-primate animal models. [133,139,141] Virus replication and hematogenous systemic spread occurs (cell-free or cell-associated viremia) and established infection is characterized by a widespread vasculitis with endothelial and smooth muscle cell tropism resulting in multinucleated syncytial cells.(136) CNS infection and encephalitis results in altered sensorium, headache, vomiting, and seizures along with fever and other systemic symptoms. Infection of other organs in addition to lung and brain in human cases occurs and has been reported in kidney, heart, spleen and lymphoid tissues,(136) and similar widespread infection has been demonstrated in multiple animal models.(131)

<H1>Diagnosis

Virus isolation, EM, immuno-EM, immunohistochemistry (IHC), serology, and polymerase chain reaction (PCR) played key roles in the initial discovery of HeV(2) and NiV.(11) They remain essential elements in the repertoire of procedures for the rapid and specific diagnosis of henipavirus infections in humans and animals.

During investigation of a suspected disease outbreak, attempts to grow henipaviruses may be initiated in a BSL3 laboratory. However, if a cytopathic effect (CPE) is observed and the growth of henipavirus is confirmed by PCR or immune staining, infected cultures needs to be handled under BSL4 conditions and subsequent work with live virus restricted to BSL4. Both HeV and NiV replicate in various cell lines—a feature that contributed to the efficiency with which they were isolated during the initial disease outbreak investigations.(2,11) Vero cells are commonly used, generating titers of virus as high as 10^8 infectious virions per milliliter.(153,232) In fatal cases, attempts should be made to isolate virus from brain, lung, kidney, and spleen.(232) For tissue specimens containing a high virus load, direct examination by immuno-EM and IHC can be very useful in providing early diagnosis. Various antibody reagents have been developed for this purpose, including polyclonal antisera, monospecific antibodies raised against recombinant antigens,(20) and monoclonal antibodies (mAb) raised against whole virions or vaccinia virus–expressed viral proteins.(233-236) Using HeV- or NiV-specific mAb, it is possible to differentiate between the two viruses.(235,236) Quantitative real-time PCR (TaqMan assay) has been the method of choice to detect viral materials in infected tissues because of its speed, specificity, and sensitivity. The first-generation henipavirus TaqMan assays are either HeV specific(237) or NiV specific.(238) Since then, several consensus henipavirus real-time PCR assays have been developed that target different conserved regions of the viral genome.(239) It should be cautioned that the current PCR tests may not work with new henipaviruses yet to be discovered, especially those from African bats, owing to expected greater genetic divergence than those detected in Australia and Asia.

For henipaviruses, serologic tests are important both during outbreak investigation and for disease surveillance. The virus neutralization test (VNT) is accepted as the reference standard.(232) Few laboratories, however, can conduct neutralization tests because of the requirement to handle live virus at BSL4. For surveillance and diagnostic purposes, three types of tests that do not require BSL4 containment have been developed:

1. *Enzyme-linked immunosorbent assay (ELISA):* Several ELISA-based tests have been reported for the detection of henipavirus antibodies.(232,240,241) For diagnosis of human infections, two different ELISA tests have been applied: an IgM capture ELISA for early diagnosis of infection and an indirect ELISA for detection of IgG antibodies.(232)

2. *Liquid protein array multiplex test:* A Luminex-based test based on recombinant soluble G proteins of HeV and NiV was developed that is capable of mimicking VNT with great sensitivity and differentiating between antibody responses of HeV versus NiV infection.(242)
3. *Pseudotype virus:* Different pseudotype systems carrying the henipavirus F and G proteins have been developed as a surrogate VNT for detecting henipavirus-specific antibodies.(18,243-245) Incorporation of reporter genes in these systems resulted in greater sensitivity and reproducibility.

<H1>Prevention, and Control

<H2>Drugs and Small molecules

Ribavirin, which inhibits replication of HeV *in vitro*,(246) was used during the NiV outbreak in Malaysia in an open-label study in which 140 patients with encephalitis were given the drug, and 54 patients who presented before ribavirin became available or who refused treatment acted as controls.(247) Mortality in the treated group was 32% compared with 54% in the control group, representing a 35% reduction ($P = 0.011$). Duration of ventilation and total hospital stay were both significantly shorter in the ribavirin group ($P = 0.0002$ and <0.0001, respectively). In the absence of other therapies, ribavirin may be an option for treatment of henipavirus infections. However, two HeV-infected patients in 2008(8) were given a high-dose intravenous regimen of ribavirin, although basal concentrations appeared inadequate given the results of *in vitro* susceptibility testing of HeV, and the efficacy of ribavirin as therapy or prophylaxis in people remains at best uncertain. Chloroquine, an antimalarial drug, was first demonstrated to block the critical proteolytic processing needed for HeV F maturation and function.(248) Not surprisingly, the drug was later shown to inhibit NiV and HeV infection in cell culture experiments.(249) Chloroquine was administered along with ribavirin to one HeV-infected individual in 2009(250) with no apparent clinical benefit. Remdesivir (GS-5734) is a nucleotide analog prodrug that showed therapeutic efficacy in a nonhuman primate model of Ebola virus infection.(251) GS-5734 has been administered under compassionate use to Ebola virus infected patients and is currently in Phase 2 clinical development for treatment of Ebola virus disease. The antiviral activities of GS-5734 has been demonstrated to be broad showing *in vitro* activity against viruses in the *Coronaviridae*, *Filoviridae* and the *Paramyxoviridae* including NiV and HeV.(252)

In vivo, ribavirin only delayed but did not prevent deaths caused by NiV and had no effect on HeV infection in a hamster model.(173,253) Ribavirin treatment also only delayed disease onset by 1 to 2 days in African green monkeys challenged with HeV with no significant benefit for disease progression or outcome.(103) Chloroquine administration, either alone or in combination with ribavirin, had no therapeutic benefit in ferrets challenged with NiV or hamsters challenged with either NiV or HeV.(253,254) Poly(I)-poly(C12U), which induces IFN-α and -β production and can completely block NiV replication *in vitro*, displayed ~80% protective efficacy in the hamster model of lethal NiV infection.(173)

<H2>Peptide Fusion Inhibitors

The first potential henipavirus-specific therapeutic was shown to be a heptad peptide-based fusion inhibitor,(95) analogous to HIV-1-specific peptide, enfuvirtide (Fuzeon) approved by the Food and Drug Administration (FDA) in March 2003. The henipavirus F_1 glycoprotein resembles other fusion glycoproteins in having α-helical heptad repeat (HR) domains proximal to both the fusion peptide at the amino (N) terminus and the transmembrane domain near the carboxy (C) terminus of the protein. The HR domains are involved in the formation of a trimer-of-hairpins structure during the membrane fusion and virus infection process. Addition of exogenous peptide from either HR domain blocks formation of the trimer-of-hairpins and abrogates membrane fusion and virus infection.(94,95,255) These observations were followed up with testing cholesterol tagged HR-derived peptides in the hamster model of NiV infection providing the first evidence of *in vivo* effectiveness of a fusion inhibiting peptide against NiV.(256)

<H2>Vaccines

A wide variety of immunization strategies have been developed for NiV and HeV prevention and include live-recombinant virus platforms, protein subunit, virus-like particles and DNA vaccines, however many of these approaches have only been examined for HeV- or NiV-specific neutralizing antibody induction.(257) A more limited number of vaccine candidates have been examined for both immune response and efficacy using a variety of animal challenge models (Table 14.5). Attenuated vaccinia virus strain NYVAC recombinants encoding either the NiV F or G glycoproteins used to immunize hamsters provided complete protection from NiV-mediated disease following challenge and demonstrated that an immune response to the viral envelope glycoproteins were an important immunogen in protection.(258) A second poxvirus-based approach was developed as a potential livestock vaccine using recombinant canarypox virus with the NiV F and G genes inserted into ALVAC vectors (Table 14.5). ALVAC vectors expressing either NiV F or NiV G were tested individually and in combination by vaccination of piglets, and animals were challenged intranasally with NiV. Piglets were protected from NiV-mediated illness by either ALVAC vector alone or in combination and immunized animals shed only low levels of nucleic acid detectable virus and no recoverable virus was evident.(259) Three other viral vector-based NiV vaccines have been examined in animal challenge studies (Table 14.5). An adeno-associated virus (AAV) platform using the NiV G glycoprotein was tested in the hamster model using NiV challenge, showing complete protection against NiV, but only low level cross-protection (3 of 6 animals) against a HeV challenge.(260) A recombinant measles virus vector encoding the NiV G glycoprotein was examined using two different vectors; the HL (rMV-HL-G) and Edmonston (rMV-Ed-G) measles virus strains(261) (Table 14.5). Here, complete protection from NiV disease was achievable in the hamster challenge model following vaccination with either rMV-HL-G or rMV-Ed-G, and the rMV-Ed-G was tested in the nonhuman primate model demonstrating 2 of 2 AGMs were protected against NiV challenge. Several groups have tested the vesicular stomatitis virus (VSV) based platform using the NiV F or G glycoproteins (Table 14.5). In the ferret model, a single immunization with VSV encoding either NiV F or NiV G could afford complete protection from NiV challenge.(262) Similarly, NiV G or F glycoproteins in VSV vectors were successful in protection from NiV challenge in the hamster model,(263,264) and a single immunization of NiV G encoding VSV was protective in the AGM model.(265,266)

<TAB14.5>

The most extensively tested vaccine against NiV and HeV has been a recombinant protein subunit strategy because of the inherent safety of such an approach. Soluble, secreted, oligomeric forms of the G glycoprotein (sG) from both NiV and HeV were developed and tested as possible vaccine candidates and the HeV-sG was show capable of eliciting a more potent cross-reactive polyclonal antibody response and also a better cross-protective response(267,268) (Table 14.5). HeV-sG is a soluble and secreted version of the molecule with a genetically deleted transmembrane and cytoplasmic tail that is produced in mammalian cell culture systems and is properly N-linked glycosylated(269) (Fig. 14.15). HeV-sG has been shown to retain many native characteristics including oligomerization and ability to bind ephrin receptors,(62,267) and is capable of eliciting potent cross-reactive (HeV and NiV) neutralizing antibody responses in a variety of animals including mice, rabbits, cats, ferrets, monkeys and horses.(257) The HeV-sG vaccine in the cat model provided complete protection against a lethal NiV challenge(268) and suggested a single subunit vaccine (HeV-sG) could be effective against both HeV and NiV. Further studies in the cat model revealed that antibody titers as low as 1:32 could protect against NiV-Malaysia challenge(270) (Table 14.5). Studies in the ferret model with low vaccine doses of HeV-sG formulated in CpG and Allhydrogel^{TM} could completely protect against high dose HeV challenge.(106) Immunization and challenge studies in ferrets with the NiV-Bangladesh strain also demonstrated complete protection.(271) In addition, good durable immunity was shown in other ferrets challenged 434 days post-vaccination.(271) However, preliminary studies with HeV-sG as a vaccine in the pig model was less effective against HeV and un-protective against NiV, and both humoral and cellular immune responses were required for protection of swine against henipaviruses in that challenge model.(180)

<FIG14.15>

The HeV-sG vaccine has also been extensively evaluated in nonhuman primates (AGMs). Monkeys immunized with HeV-sG formulated in Allhydrogel^{TM} and CpG were completely protected against intratracheal challenge with NiV-Malaysia, some with pre-challenge neutralizing titers as low as 1:28, and no evidence of clinical disease, virus replication, or pathology was observed in any vaccinated monkeys.(272) Similarly, HeV-sG vaccination and protection from a HeV challenge in AGMs has also been shown, including HeV-sG formulated in Allhydrogel^{TM} alone.(273) The inherent safety and effectiveness of the HeV-sG vaccine led to its development as an equine vaccine to prevent not only HeV infection of horses but also as the means to reduce the risk of HeV transmission to people (Figure 14.16A). HeV-sG was licensed by Zoetis™ Inc., (formerly Pfizer Animal Health) and developed as an equine vaccine for use in Australia. Horse HeV-sG vaccination and HeV challenge studies were conducted at the BSL-4 facilities of the Animal Health Laboratories (AAHL) in Geelong(274) (Table 14.5). HeV-sG was formulated in an approved equine adjuvant (Zoetis, Inc.) and two initial efficacy studies in horses tested 50 μg and 100 μg doses of the same HeV-sG used in published animal studies was used to immunize horses. Additional studies used a 100 μg dose of HeV-sG produced in CHO cells (Zoetis, Inc.).

Immunizations were two doses given intramuscularly 3-weeks apart. All horses in these efficacy studies were challenged oronasally with 2×10^6 $TCID_{50}$ of HeV. Seven horses were challenged at 28 days, and 3 horses were challenged 194 days, after the second immunization. All vaccinated horses remained clinically healthy following challenge, demonstrating protection with pre-challenge HeV neutralizing titers as low as 1:16.(274) There was no gross or histologic evidence of HeV infection in any of the vaccinated horses at study completion, and all tissues examined were negative for HeV antigen by immunohistochemistry, with no viral genome detected in any tissue. In 9 of 10 vaccinated horses, HeV nucleic acid was not detected in daily nasal, oral, or rectal swab specimens or from blood, urine, or feces samples collected before euthanasia, and no recoverable virus was present.(274)

<FIG14.16>

Equivac® HeV was launched in November 2012 on a Minor Use Permit by the regulatory authority, the Australian Pesticides and Veterinary Medicines Authority (APVMA), and is the first commercially developed and deployed vaccine against a BSL-4 agent and is currently the only licensed antiviral approach for henipavirus infection. All vaccinated horses receive a microchip and database is maintained, and in August, 2015 Equivac® HeV received full registration by the APVMA. To date, >640,000 doses of Equivac® HeV vaccine has been administered to >153,000 unique horses (Fig. 14.16B). Since vaccine release, laboratory confirmed HeV infections in horses (n=21) have only occurred in unvaccinated horses. The HeV-sG recombinant subunit vaccine for NiV and HeV is now in clinical development with support from the Coalition for Epidemic Preparedness Innovations (CEPI)(275) and Phase I clinical trials set to commence in 2019. Recent vaccination and challenge studies in nonhuman primates have shown that a single immunizing dose of HeV-sG in Allhydrogel™ can protect against HeV and NiV-Bangladesh challenge (Geisbert and Broder, unpublished) and together with the results of recombinant

VSV-based NiV vaccines, these findings highlight their potential usefulness in an emergency-use or outbreak scenario.

<H2>Passive immunization

Initial passive immunization studies using either NiV G and F-specific polyclonal antiserums, or mouse monoclonal antibodies (mAbs) specific for the NiV or HeV G or F glycoproteins were shown to be protective in the hamster model.(102,258,276) HeV- and NiV-neutralizing human mAbs reactive to the G glycoproteins of both HeV and NiV have been developed using recombinant antibody technology.(277) One mAb, m102.4, possessed strong cross-reactive neutralizing activity against HeV and NiV and was later produced in an IgG1 format in a CHO-K1 cell line.(278) The m102.4 mAb epitope maps to the receptor binding site of G and engages G in a similar fashion as the ephrin receptors(279) (Figure 14.5). The m102.4 mAb can neutralize all HeV and NiV isolates tested, including HeV-1994, HeV-Redlands, NiV-Malaysia and NiV-Bangladesh.(97,280) NiV challenge experiments in the ferret demonstrated complete protection was possible by a single dose of m102.4 mAb administered by intravenous infusion 10 hrs following a lethal virus challenge.(97) The therapeutic efficacy of mAb m102.4 has also been examined in nonhuman primates against both NiV and HeV challenge as a post-exposure therapeutic reflective of a potential real life virus exposure scenario(193,194) (Table 14.5). In one study, AGMs were challenged intratracheally with HeV and following virus administration they were infused twice with m102.4 (~15 mg/kg) beginning at 10 hrs, 24 hrs or 72 hrs post-infection followed by a the second infusion ~48 hrs after the first. In this study, all subjects became infected following challenge, and all animals that received m102.4 survived whereas all controls succumbed to severe systemic disease 8 days following virus challenge. Animals in a 72 hrs treatment group did exhibit neurological signs but all recovered by day 16, but there was no evidence of HeV-specific pathology in any of the m102.4-treated animals, and no infectious HeV could be recovered from any tissues from any m102.4-treated subjects. A later study evaluated the efficacy of m102.4 against NiV-Malaysia challenge in AGMs, at several time points after virus exposure by intratracheal challenge including as late as the onset of clinical illness.(194) Here, animals were infused twice with m102.4 (15 mg/kg) beginning at either 1, 3, or 5 days following NiV-Malaysia challenge and again 48 hrs after the first dose. All animals became infected following virus exposure, and again all subjects that received m102.4 therapy survived the infection, whereas the untreated control subjects succumbed to disease between days 8 and 10 following virus challenge. The m102.4 mAb was also shown to be effective the nonhuman primate model against NiV-Bangladesh infection, although its therapeutic window was much shorter as compared to NiV-Malaysia infected subjects.(191) Taken together, these studies have shown that m102.4 mAb therapy can prevent HeV or NiV lethal disease in exposed subjects is the only effective post-exposure therapeutic tested *in vivo* in nonhuman primates. The mAb m102.4 has since been used by emergency protocol in 13 people in Australia and one in the U.S. because of significant risk of HeV or NiV infection.(257) The m102.4 antibody has completed a Phase I clinical trial in Australia, and has recently been supplied to Government of India and included in an international Nipah treatment protocol sponsored by the Indian Council of Medical Research (ICMR) with support from the NIAID, NIH, USA.

<H1>Perspective

Nipah and henipaviral diseases remain on the latest WHO list of Blueprint priority diseases (Feb 2018).(281) This acknowledges that NiV (or related virulent henipaviruses) is a major threat to global public health, and calls for increased research and development into henipaviruses and their countermeasures, including surveillance and diagnostics. In addition, both NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to economically important livestock throughout South Asia and

Australia.(282) NiV is also one of the top three viral agents prioritized for vaccine development by the Coalition of Epidemic Preparedness Innovations (CEPI). (275,283) The high virulence of the henipaviruses and the requirement for BSL-4 facilities have hampered investigations into the biology and pathogenesis of these novel paramyxoviruses. Nonetheless, the advent of reverse genetics for henipaviruses, coupled with the development of animal models that recapitulate the clinical features and pathology seen in virus-infected humans, have provided insights into the functions of many henipavirus proteins and the role they play in the pathogenesis of henipavirus disease. While the virulence of henipaviruses necessitates the initial functional characterization of henipavirus proteins from cloned genes, it is imperative that these functional characteristics be examined in the context of a live virus infection. Even then, it appears increasingly important to investigate why henipaviruses appear so much more virulent in many of their terrestrial hosts versus their chiropteran counterparts.(284)

Despite our expanded understanding of the henipaviruses, many questions relating to the ecology and biology of henipaviruses remain unanswered. Pteropus species of fruit bats are clearly the major reservoir host of these viruses,(202,207,208) but new studies have suggested that an even wider group of chiropteran species host not only the known henipaviruses but also multiple divergent clades of new henipavirus species.(29,222,285) Molecular or serological evidence of henipaviruses can now be found in frugivorous and insectivorous bats that range from Australia and Austronesia, to China, South-East Asia, countries of the Indian subcontinent, through to Madagascar, sub-Saharan Africa and even into the New World (Costa Rica and Brazil).(19,29,207,286-297) The emergence of these and related viruses is probably associated with the destruction of the flying fox native habitats, driving the animals to seek food from orchards and ornamental trees in urban and periurban areas. Continued deforestation and amplification of factors that drive zoonotic spillover from reservoir hosts, will undoubtedly lead to further outbreaks of HeV, NiV, and novel related members of the genus.(298-301) Continued surveillance coupled with identification and characterization of these putative new species of henipavirus is required provide a proper assessment as to the countermeasures, such as the CEPI initiatives, that would be necessary to control or prevent future outbreaks and spillovers.

<Figure legends>

Figure 14.1. Syncytia induced in vero cells 24 hours after infection by Hendra virus (HeV) (A) and Nipah virus (NiV) (B). Methanol-fixed infected cells were labeled with rabbit monospecific antiserum to the HeV P protein and fluorescein-conjugated goat antirabbit immunoglobulin G. P protein is detected in extensive perinuclear ribonucleoprotein complexes (*small arrow*) and in discrete regularly shaped arrays (*large arrow*) distributed throughout the cytoplasm and believed to be sites of virus egress from the cell. Nuclei are indicated by *chevrons.*

Figure 14.2. A: Electron micrograph of Nipah virus (NiV)-infected Vero cells showing tubule-like structures, both in the cytoplasm and in a maturing virus particle (*arrows*). **B:** Electron micrograph of negatively stained Hendra virus (HeV) displaying the double fringe at the virus envelope (*small arrow*) and the herringbone nucleocapsids (*large arrow*). (Courtesy of Dr. Alex Hyatt, CSIRO Australian Animal Health Laboratory.)

Figure 14.3. Genome size and organization of Hendra virus in comparison with the type species in each of the other six genera in the family *Paramyxoviridae*. A: Genome length (in nucleotides) are given in brackets after each virus. Color coding: blue, proteins for the inner most nucleocapsid responsible for replication and transcription; green, envelope proteins. **B:** 3’UTR of certain genes in henipaviruses (N, P and G) are longer than their

counterparts from representative members of paramyxovirus genera that infect mammals. The 3'UTR length (number of nucleotides) of each gene from representative members of the indicated genera is compared separately in box-and-whisker plots (N, P, M, F, RBP, and RdRP). P values are calculated based on one-tailed t-test (*Henipavirus* vs all other genera); five virus species from *Henipavirus* (HeV, NC_001906; NiV, NC_002728; CedV, NC_025351.1; GhV, NC_025256.1; MojV, NC_025352.1), and three each from *Morbillivirus,* (MeV, NC_001498.1; CDV, NC_001921.1; FeMV, NC_039196.1), *Rubulavirus* (MuV, NC_002200.1; HPIV-2, NC_003443.1; PIV-5, NC_006430.1) and *Respirovirus* (SeV, NC_001552; HPIV-1, NC_003461; HPIV-3, NC_001796.2). Courtesy of Satoshi Ikegame and Christian Stevens, Icahn School of Medicine at Mount Sinai, New York.

Figure 14.4. The major proteins of Hendra virus and Nipah virus and their roles in the henipavirus life cycle. A: Viruses were purified and analyzed as described in Wang LF et al.(20) Major virus proteins and the molecular weights of standard marker proteins are shown on the right and left, respectively. Reproduced with permission from Wang LF et al, Molecular biology of Hendra and Nipah viruses. *Microbes Infect* 2001; 3:279-87**. B:** Henipavirus replication cycle is depicted. The virus receptor binding protein (RBP, deep blue lollipops) attaches the virus to the cell via its cognate receptor, typically ephrinB2/B3 **(1)**, and triggers virus-cell membrane fusion mediated by the viral fusion protein (F, filled orange trapezoids) **(2)**. Fusion delivers the nucleoprotein (N) encapsidated negative-sense virus RNA genome [vRNA(−), cyan] to the cytosol **(3).** The vRNA(-) serves as template for viral transcripts made by the transcriptase complex comprised of the phosphoprotein (P) and the large RNA-dependent RNA-polymerase (RdRP) (P-RdRP, transparent hexagons) **(4).** Viral transcripts are made following a 3′ to 5′ attenuation gradient. The vRNA(-) is also the template for making full-length antigenomic cRNA(+) **(5),** which in turn is a template for vRNA(−) synthesis during virus genome replication **(6).** Henipavirus genome replication

mediated by the N-P-RdRP replicase complex is similar to the details described for the *Paramyxoviridae* in chapter 13. However, some aspects of henipavirus assembly are relatively unique. The matrix protein (M, green octagons) needs to transit through the nucleus **(7)** in a ubiquitin-regulated manner **(8),** in order to traffic properly to the plasma membrane. This nuclear sojourn involves shuttling through subnuclear compartments such as nucleoli **(9).** Proper trafficking is required for M to orchestrate the assembly of the viral RNPs with the viral envelope glycoproteins into budding infectious virions bearing the vRNA(-) **(10).** Matrix also has non-structural functions such as antagonizing type-I IFN responses **(11);** see Fig. 14.8 and text for details. Additionally, in order for the henipavirus F protein to be cleaved and become fusion-competent, it needs to access cathepsins L/B in the endosomal compartment. To do this, F first reaches the plasma membrane via the secreory pathway in an uncleaved form (open orange trapezoids) **(12).** Subsequent endocytosis and recycling back to the plasma membrane **(12a)** is required to form infectious virions where cleaved fusion-competent F (filled orange trapezoids) **(12b)** is complexed with the RBP in its proper oligomeric state. Where this occurs along the vesicular trafficking pathway and/or the plasma membrane is unresolved **(13).** F protein cleavage is seldom complete and uncleaved F can be detected in budded virions **(14)** (Adapted from Aguilar HC and Lee B. Emerging paramyxoviruses: molecular mechanisms and antiviral strategies. *Expert Rev Mol Med* 2011;13:e6)

Figure 14.5. A structure-based phylogeny of paramyxoviral receptor binding proteins. Structure-based phylogenetic analysis on extant structures of all henipavirus RBPs and representative RBPs from at least one virus in other paramyxovirus genera for which structural data is available. RBPs are shown besides the tree and are rendered as surface representation (grey). All receptor-binding proteins, with the exception of the MojV-G, are shown in complex with their respective receptor molecules (yellow), with the receptor-

binding interface colored red. Analysis was performed and produced as described in Rissanen et al.(66) Paramyxoviral RBPs generally cluster according to their respective genera and cellular receptor usage with the exception MojV-RBP, which is almost equidistant to all structurally studied genera. Courtesy of Dr. Thomas Bowden, University of Oxford, U.K.

Figure 14.6. Nipah virus transmission. Major pathways of human Nipah virus infection are summarized for Malaysia (blue arrows), Bangladesh (red arrows), the Philippines (green arrows), and the latest outbreak in Kerala, India (orange arrows). (Adapted from Clayton BA. Nipah virus: transmission of a zoonotic paramyxovirus. *Curr Opin Virol* 2017; 22:97-104)

Figure 14.7. Immunohistochemistry detection of Nipah virus (NiV) and Hendra virus (HeV) antigen in henipavirus-infected tissues. A-D: Hendra virus infected tissues. **A:** Staining of HeV antigen (N protein-specific rabbit antibody) within the wall of superficial arteriole in the sub-mucosa of the nasal cavity in a HeV-infected horse. **B:** Immmunolabeling (N protein-specific rabbit antibody) of the endothelium of medium caliber vessels and alveolar septae in lung of a HeV-infected African green monkey (AGM) (10x). **C:** Immunolabeling of HeV antigen (N protein-specific rabbit antibody) within neurons in the brainstem of a HeV-infected AGM (40x). **D:** Immunolabeling of HeV antigens (mouse anti-HeV polyclonal antibody) in neurons of acute HeV-infected human case (40x). **E:** Positive immunolabelling (using anti-Nipah virus rabbit serum) within the lung of a NiV-infected pig. Involvement of bronchial epithelium and airway debris is noted. **F:** Immunolabeling (N protein-specific antibody) of the endothelium of medium caliber vessels and alveolar septae in lung of a NiV-infected AGM (20x). **G:** Immunolabeling of NiV antigen (N protein-specific antibody) within neurons in the brainstem of a NiV-infected AGM (40x). **H:** Immunolabeling of NiV antigens (hyperimmune anti-NiV mouse ascitic fluid) in the cytoplasm and nuclei of neurons, and neuronal processes in the brain of acute NiV-infected human case (158x). A and E, courtesy of Dr. Deborah Middleton, CSIRO Australian Animal

Health Laboratory. B, C, F and G, courtesy of Dr. Karla Fenton, University of Texas Medical Branch at Galveston, Texas. D, courtesy of Dr. Kum Thong Wong, University of Malaya; H, from Wong et al.(136)

Figure 14.8. Ephrin-B2 and ephrin-B3 RNA-seq expression data across representative human non-disease tissues. Shown here are ephrin-B2 (upper) and ephrin-B3 (lower) expression data obtained from the Genotype-Tissue Expression (GTEx) Portal. The GTEx project is a public resource where up to 53 non-disease tissue sites obtained from nearly 1,000 individuals are subjected to RNA-seq by next-generation sequencing amongst other assays. Details on datasets can be found on https://gtexportal.org. Data from all available brain regions are shown. The non-brain tissues are chosen for illustrative purposes based on their relevance to henipavirus pathogenesis. Expression data in transcripts per million are plotted as box plots with the medians and 25th and 27th percentiles shown; points are displayed as outliers if they are above or below 1.5 times the interquartile range. 1a Artery – Aorta; 1b Artery – Coronary; 2a Brain – Amygdala; 2b Brain - Anterior cingulate cortex (BA24); 2c Brain - Caudate (basal ganglia); 2d Brain - Cerebellar Hemisphere; 2e Brain – Cerebellum; 2f Brain – Cortex; 2g Brain - Frontal Cortex (BA9); 2h Brain – Hippocampus; 2i Brain – Hypothalamus; 2j Brain - Nucleus accumbens (basal ganglia); 2k Brain - Putamen (basal ganglia); 2l Brain - Spinal cord (cervical c-1); 2m Brain - Substantia nigra; 3 Breast - Mammary Tissue; 4 Colon – Transverse; 5 Esophagus - Gastroesophageal Junction; Esophagus – Mucosa; 6 Heart - Left Ventricle; 7 Kidney – Cortex; 8 Liver; 9 Lung; 10 Minor Salivary Gland; 11 Spleen; 12 Whole Blood.

Figure 14.9. Innate immune evasion mechanisms of the Nipah virus N, P, V, W and M proteins. Left: The V and W proteins (green diamonds) block IFN-α/β expression by different mechanisms. Depicted are simplified versions of the RIG-I-like receptor (RLR) signaling (blue arrows) and TLR3 signaling (black arrows) pathways. Both lead to activation

of interferon regulatory factors 3 and 7 (IRF-3 and IRF-7) (dashed arrow). RIG-I, MDA5 and TLR3 can sense RNAs produced during viral infection. Activation of RIG-I or MDA5 leads to their interaction with the mitochondria-associated adapter protein MAVS (1). This leads to activation of the kinases IKKε and/or TBK-1 (2), which phosphorylate and activate IRF-3 and, when present, IRF-7 (3). For clarity, MAVS activation of NF-κB is not shown. Activated IRF-3 and IRF-7 translocate into and accumulate in the nucleus; both contribute to IFN-α/β gene transcription (4). TLR3 signals through adaptor protein TRIF to activate IKKε/TBK-1 (5). The cytoplasmic NiV and HeV V proteins interact with and inhibit MDA5, thereby inhibiting the induction of IFN-α/β expression early on in the pathway (a); however NiV V does not appear to inhibit TLR3 signaling. The nucleo-cytoplasmic shuttling NiV M protein (green hexagon), while it is in the cytoplasm, antagonizes induction of type-I IFNs by blocking IKKε activation (b). This prevents downstream phosphorylation and nuclear translocation of IRF3, which also leads to a failure of IFN-α/β induction. The nuclear W protein (green trapezoid) effectively blocks RLR and TLR3 activation of the IFN-β promoter by preventing the accumulation of phosphorylated IRF-3 (c). This function requires the nuclear localization of W. **Right:** The Nipah virus N, P, V and W proteins each block IFN signaling pathways at distinct steps (red arrows), ultimately leading to reduced expression of interferon- stimulated (antiviral) genes (ISGs). The P, V and W proteins can each inhibit the phosphorylation and activation of STAT1 and STAT2 in response to IFN-α/β (6) and block the phosphorylation and activation of STAT1 in response to IFN-γ. The inhibition of the IFN-α/β signaling pathway is depicted. The cytoplasmic P and V proteins interact with and inhibit STAT1 (d). The V protein also interacts with STAT2, in a STAT1-dependent manner. P and V prevent nuclear accumulation of pSTAT1 /pSTAT2 following IFN-α/β addition to cells and cause the STAT proteins to accumulate in a high molecular weight complex. The NiV and HeV N proteins (green oval) were recently reported to disrupt phospho-STAT1 complex formation (7), though not phosphorylation of STAT1 itself (e). Nonetheless, this N-mediated disruption of STAT complexes reduces nuclear accumulation of the activated STAT complexes required to stimulate ISG expression (8). The nuclear W protein relocalizes non-phosphorylated STAT1 from its typically cytoplasmic localization to the nucleus (f). STAT1 relocalized to the nucleus by W remains unphosphorylated and does not activate transcription of ISGs in response to IFN-α/β addition. (Adapted from Basler CF. Nipah and Hendra virus interactions with the innnate immune system. *Curr Top Microbiol Immunol* 2012; 359: 123-52)

Figure 14.10. Distribution of frugivorous bats belonging to various genera in the *Pteropodidae* family where evidence of henipavirus presence have been detected. The presence of henipavirus is graded into four levels with known outbreak (red), virus isolation (pink), molecular detection (blue), and antibody detection (green).

Figure 14.11: Phylogenetic tree based on RdRP proteins of selected henipaviruses and prototype species of the other genera in the family *Paramyxoviridae.* Tree was constructed by using Neighbor-Joining approach with 1,000 bootstrap replicates. Numbers at the nodes represent bootstrap values. Scale bar indicates amino acid substitutions per site. Sequences are labelled with the following ordination when all relative information is available for any given genome sequence: Virus/Country/Host/Year/Strain (GenBank accession number). For example, NiV/BD/Human/2010/Faridpur(JN808864) represents a Nipah virus isolated in Bangladesh from humans in 2010 with Faridpur as its isolate name and JN808864 as its Genbank accession number.

Figure 14.12. Chest radiographs of a Nipah virus (NiV) infected patient and Nipah virus (NiV) and Hendra virus (HeV) infected African green monkeys. A: Chest X-ray of patient infected with Nipah virus (Nipah-Bangladesh clade) from Kerala, India, 2018, at 6 days following onset of symptoms showing diffuse bilateral opacities covering the majority of the

lung fields, consistent with acute respiratory distress syndrome (ARDS). **B:** Top, comparison of pre-challenge to Nipah virus (Nipah-Malaysia clade) infected African green monkey at 11 days post-challenge showing congestion and pneumonia with infiltrates on the lung fields. Bottom, comparison of pre-challenge to Hendra virus infected African green monkey at 8 days post-challenge showing diffuse interstitial infiltrates and pulmonary consolidation and severe respiratory distress. Panel A, courtesy of Prof. Govindakarnavar Arunkumar, Manipal Centre for Virus Research, Manipal Academy of Higher Education (deemed to be University), Karnataka State, India and Dr. Suresh Kumar. E.K, Malabar Institute of Medical Sciences, Kerala State, India. Panel B, top, from Geisbert et al.(98), bottom, from Rockx et al.(103) (reproduced with permission).

Figure 14.13. Magnetic resonance imaging scans of patients with Nipah virus (NiV) or Hendra virus (HeV) encephalitis. A: Left, patient with NiV encephalitis (Nipah-Bangladesh clade) from Kerala, India, 2018, at 6 days following onset of symptoms showing cortical and subcortical hyperintense foci (arrow heads). Middle, patient with acute NiV encephalitis (Nipah-Malaysia clade) from Malaysia, 1999, showing multiple discrete hyperintense lesions in the grey and white matter. Right, patient with relapsed NiV encephalitis from Malaysia, 1999, showing confluent lesions involving primarily the cortical grey matter. **B:** Left, acute HeV encephalitis in a patient on day 18 of illness, showing cortical and subcortical hyperintense foci. Right, relapsed HeV encephalitis in a patient on day 14 following symptoms onset showing widespread multifocal neocortical involvement. Panel A, left (India), courtesy of Prof. Govindakarnavar Arunkumar, Manipal Centre for Virus Research, Manipal Academy of Higher Education (deemed to be University), Karnataka State, India and Dr. Suresh Kumar. E.K, Malabar Institute of Medical Sciences, Kerala State, India. A, middle and right (Malaysia) from Goh, et al.(108) B, left, from Playford et al.(8); right, from O'Sullivan et al.(3) (reproduced with permission)

Figure 14.14. Generalized understanding of infection and clinical features of human Nipah virus (NiV) and Hendra virus (HeV) infection. **A:** Transmission is generally accepted to occur via the oronasal route presumably by virus contaminated respiratory secretions or droplets from infected animals or people, or liquid/food (palm sap/fruit); **B:** The initial site of replication in humans is ill-defined but is thought to occur within the respiratory system and disease onset is characterized by fever, myalgia, shortness of breath, cough, which may progress to an acute respiratory distress syndrome (ARDS); **C:** Possible invasion into the central nervous system (CNS) via the olfactory bulb has also been suggested and has been demonstrated in animal models; **D:** Virus replication and hematogenous systemic spread occurs (cell-free or cell-associated viremia) and established infection is characterized by a widespread vasculitis with endothelial and smooth muscle cell tropism resulting in multinucleated syncytial cells; **E:** CNS infection and encephalitis results in altered sensorium, headache, vomiting, and seizures along with fever and other systemic symptoms; **F:** Infection of other organs in addition to lung and brain in human cases occurs and has been reported in kidney, heart, spleen and lymphoid tissues, and similar widespread infection has been demonstrated in multiple animal models.

Figure 14.15. Model of the Hendra virus soluble G glycoprotein subunit vaccine (HeV-sG) and its complex with the Hendra and Nipah virus neutralizing human monoclonal antibody m102.4. **A:** The HeV-sG glycoprotein subunit vaccine is composed of the entire ectodomain (amino acids 76-604) of the HeV G glycoprotein. HeV-sG is shown as dimer with one monomer colored green and the other cyan. The secondary structure elements of the two globular head domains are derived from the crystal structure of the HeV G head domain, the stalk regions of each G monomer (residues 77-136) are modeled, and N-linked glycosylation sites shown as gray spheres. The ephrin-binding face of the cyan globular head is facing forward with an overlay of the interacting ephrin-B2 G-H loop residues in yellow.

B: The HeV-sG dimer is modeled in complex with two m102.4 Fab antibody fragments. The two HeV-sG monomers are colored green and cyan as in panel A and rotated slightly to the right, and the two Fab molecules are shown with their heavy chains colored in magenta and light chain – in yellow, each binding one globular head domains of G. Modified from Broder et al.(302)

Figure 14.16. One Health Vaccine strategy. A: The known modes of henipavirus transmission in different countries. In Australia, all seven human cases were infected via contacting infected horses. A One Health vaccine strategy was developed for immunization of horses with the dual purposes of saving horses from lethal Hendra virus infection and prevention of transmission from bats to humans via horses. **B:** Location densities of Equivac® HeV vaccine administered to horses around Australia. As of 2018, more than 640,000 doses of Equivac® HeV have been administered to horses around Australia, equating to more than 153,000 unique horses vaccinated. Courtesy of Dr. Richard L'Estrange, Zoetis Inc.

[a] Expression inferred from (1) transcriptional data (microarray, next-generation sequencing, RT-PCR, etc.) provided in the cited references, or (2) indepedently verified through the Gene Expression Omnibus (GEO) Database (https://www.ncbi.nlm.nih.gov/geo/), or (3) competition with soluble ephrinB ligands or interference with cognate henipavirus receptor binding proteins. [b] For clarity and uniformity, only infection-permissive (not fusion-permissive) data are indicated; infection includes use of live virus and/or pseudotyped virus. [c] References cited support expression, infection data, or cell-type origin where relevant, and are representative, not comprehensive. [d] Indicates >10-100-

fold below positive control when quantitative data is avialable. ND, not determined; (?), not specifically mentioned.

TABLE 14.4. Detection of Nipah or Nipah-related Virus Infection in Bats (Geographic surveillance studies)

Bat Species	Method and country of detection			Reference
	Serology	PCR	Isolation

Pteropus hypomelanus	Malaysia, Thailand	Thailand	Malaysia	(205); (221); (330)
Pteropus lylei	Cambodia, Thailand	Thailand	Cambodia	(89,290,331)
Pteropus medius		Bangladesh, India	Bangladesh	(332); (306); (333)
Pteropus rufus	Madgascar			(327)
Pteropus vampyrus	Malaysia, Thailand			(205); (286)
Suborder: Yangochiroptera				
Carolia perspicillta		Costa Rica		(329)
Miniopterus spp.	China			(287)
Myotis daubentoni	China			(287)
Myotis ricketti	China			(287)
Pteronotus parnellii		Costa Rica		(329)
Scotophilus kuhlii	Malaysia			(205)

TABLE 14.5. Summary of Advanced Henipavirus Vaccination Development Initiatives Evaluated in Animal Challenge Models

Platform	Viral antigen target or immunogen	Animal challenge model
Active vaccination Recombinant vaccinia virus Recombinant canarypox virus Recombinant VSV Recombinant AAV Recombinant measles	Nipah F and/or G glycoprotein Nipah F and/or G glycoprotein Nipah F and/or G glycoprotein Nipah G glycoprotein Nipah G glycoprotein Hendra soluble G glycoprotein	Hamster[a] (NiV) Pig[b] (NiV) Ferret[c] (NiV), Hamster[d] (NiV), nonhuman primate[e] (NiV) Hamster[f] (NiV, HeV) Hamster[g], Nonhuman primate (NiV, HeV) Cat[h] (NiV), Ferret[i] (HeV, NiV), nonhuman primate[j] (HeV, NiV) Horse[k]

virus Recombinant subunit		(HeV)
Passive immunization Human monoclonal antibody m102.4	Hendra / Nipah G glycoprotein	Ferret[l] (NiV) Nonhuman primate[m] (HeV, NiV)

[a]Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vaccinia viruses were protected against disease following intraperitoneal challenge with 10^3 PFU of NiV.(258)

[b]Pigs immunized with NiV F and/or G glycoprotein encoding recombinant canarypox viruses were protected against intranasal challenge with $2.5x10^5$ PFU of NiV.(259).

[c]Ferrets immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intranasal challenge with $5x10^3$ PFU of NiV.(262)

[d]Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intraperitoneal challenge with 10^5 $TCID_{50}$ of NiV;(264) or $6.8x10^4$ $TCID_{50}$ of NiV.(263)

[e]African green monkeys immunized with a NiV G encoding recombinant VSV vector were protected against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV.(265,266)

[f]Hamsters immunized with a NiV G encoding recombinant adeno-associated virus (AAV) vector were protected against lethal intraperitoneal with 10^4 PFU of NiV.(260)

[g]Hamsters and African green monkeys immunized with a NiV G encoding recombinant measles virus vector were protected against lethal intraperitoneal challenge with 10^3 $TCID_{50}$ of NiV (hamsters) or 10^5 $TCID_{50}$ of NiV (AGMs).(261)

[h]Hendra virus soluble G glycoprotein (HeV-sG) used to immunize cats protects against lethal subcutaneous (500 $TCID_{50}$)(268) or oronasal ($5x10^4$ $TCID_{50}$) NiV challenge.(270)

[i]HeV-sG used to immunize ferrets protects against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of HeV(106) or $5x10^3$ $TCID_{50}$ of NiV challenge.(271)

[j]HeV-sG used to immunize African green monkeys protects against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV(272) or $5x10^5$ PFU of HeV.(273)

[k]HeV-sG used to immunize horses protects against lethal oronasal challenge with $2x10^6$ $TCID_{50}$ of HeV(274).

[l]A NiV and HeV cross-reactive G glycoprotein specific neutralizing human mAb (m102.4) protects ferrets against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of NiV(97) or $5x10^3$ $TCID_{50}$ of HeV (J. Pallister and C. Broder, unpublished) by post-exposure infusion.

[m]Human mAb m102.4 protects African green monkeys by post-exposure infusion following lethal intratracheal challenge with $4x10^5$ $TCID_{50}$ of HeV(193) or lethal intratracheal challenge with $5x10^5$ PFU of NiV.(191,194)

Terms and Conditions	

INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.
3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:
"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."
4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.
5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions, deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com). No modifications can be made to any Lancet figures/tables and they must be reproduced in full.
6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.
7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never

granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.
9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.
10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.
11. No Transfer of License: This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person without publisher's written permission.
12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).
13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.
14. Revocation: Elsevier or Copyright Clearance Center may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or Copyright Clearance Center be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or Copyright Clearance Center for denied permissions.

LIMITED LICENSE

The following terms and conditions apply only to specific license types:
15. **Translation**: This permission is granted for non-exclusive world **English** rights only unless your license was granted for translation rights. If you licensed translation rights you may only translate this content into the languages you requested. A professional translator must perform all translations and reproduce the content word for word preserving the integrity of the article.
16. **Posting licensed content on any Website**: The following terms and conditions apply as follows: Licensing material from an Elsevier journal: All content posted to the web site must maintain the copyright information line on the bottom of each image; A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx or the Elsevier homepage for books at http://www.elsevier.com; Central Storage: This license does not include permission for a scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.
Licensing material from an Elsevier book: A hyper-text link must be included to the Elsevier homepage at http://www.elsevier.com . All content posted to the web site must maintain the copyright information line on the bottom of each image.

Posting licensed content on Electronic reserve: In addition to the above the following clauses are applicable: The web site must be password-protected and made available only to bona fide students registered on a relevant course. This permission is granted for 1 year only. You may obtain a new license for future website posting.

17. **For journal authors:** the following clauses are applicable in addition to the above:

Preprints:

A preprint is an author's own write-up of research results and analysis, it has not been peer-reviewed, nor has it had any other value added to it by a publisher (such as formatting, copyright, technical enhancement etc.).

Authors can share their preprints anywhere at any time. Preprints should not be added to or enhanced in any way in order to appear more like, or to substitute for, the final versions of articles however authors can update their preprints on arXiv or RePEc with their Accepted Author Manuscript (see below).

If accepted for publication, we encourage authors to link from the preprint to their formal publication via its DOI. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help users to find, access, cite and use the best available version. Please note that Cell Press, The Lancet and some society-owned have different preprint policies. Information on these policies is available on the journal homepage.

Accepted Author Manuscripts: An accepted author manuscript is the manuscript of an article that has been accepted for publication and which typically includes author-incorporated changes suggested during submission, peer review and editor-author communications.

Authors can share their accepted author manuscript:

- immediately
    - via their non-commercial person homepage or blog
    - by updating a preprint in arXiv or RePEc with the accepted manuscript
    - via their research institute or institutional repository for internal institutional uses or as part of an invitation-only research collaboration work-group
    - directly by providing copies to their students or to research collaborators for their personal use
    - for private scholarly sharing as part of an invitation-only work group on commercial sites with which Elsevier has an agreement
- After the embargo period
    - via non-commercial hosting platforms such as their institutional repository
    - via commercial sites with which Elsevier has an agreement

In all cases accepted manuscripts should:

- link to the formal publication via its DOI
- bear a CC-BY-NC-ND license - this is easy to do
- if aggregated with other manuscripts, for example in a repository or other site, be shared in alignment with our hosting policy not be added to or enhanced in any way to appear more like, or to substitute for, the published journal article.

Published journal article (JPA): A published journal article (PJA) is the definitive final record of published research that appears or will appear in the journal and embodies all value-adding publishing activities including peer review co-ordination, copy-editing, formatting, (if relevant) pagination and online enrichment.

Policies for sharing publishing journal articles differ for subscription and gold open access articles:

Subscription Articles: If you are an author, please share a link to your article rather than the full-text. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help your users to find, access, cite, and use the best available version. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

If you are affiliated with a library that subscribes to ScienceDirect you have additional private sharing rights for others' research accessed under that agreement. This includes use for classroom teaching and internal training at the institution (including use in course packs and courseware programs), and inclusion of the article for grant funding purposes.

Gold Open Access Articles: May be shared according to the author-selected end-user license and should contain a CrossMark logo, the end user license, and a DOI link to the formal publication on ScienceDirect.

Please refer to Elsevier's posting policy for further information.

18. **For book authors** the following clauses are applicable in addition to the above: Authors are permitted to place a brief summary of their work online only. You are not allowed to download and post the published electronic version of your chapter, nor may you scan the printed edition to create an electronic version. **Posting to a repository:** Authors are permitted to post a summary of their chapter only in their institution's repository.

19. **Thesis/Dissertation**: If your license is for use in a thesis/dissertation your thesis may be submitted to your institution in either print or electronic form. Should your thesis be published commercially, please reapply for permission. These requirements include permission for the Library and Archives of Canada to supply single copies, on demand, of the complete thesis and include permission for Proquest/UMI to supply single copies, on demand, of the complete thesis. Should your thesis be published commercially, please reapply for permission. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

Elsevier Open Access Terms and Conditions

You can publish open access with Elsevier in hundreds of open access journals or in nearly 2000 established subscription journals that support open access publishing. Permitted third party re-use of these open access articles is defined by the author's choice of Creative Commons user license. See our open access license policy for more information.

Terms & Conditions applicable to all Open Access articles published with Elsevier:

Any reuse of the article must not represent the author as endorsing the adaptation of the article nor should the article be modified in such a way as to damage the author's honour or reputation. If any changes have been made, such changes must be clearly indicated.

The author(s) must be appropriately credited and we ask that you include the end user license and a DOI link to the formal publication on ScienceDirect.

If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source it is the responsibility of the user to ensure their reuse complies with the terms and conditions determined by the rights holder.

Additional Terms & Conditions applicable to each Creative Commons user license:

CC BY: The CC-BY license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article and to make commercial use of the Article (including reuse and/or resale of the Article by commercial entities), provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. The full details of the license are

available at http://creativecommons.org/licenses/by/4.0.
CC BY NC SA: The CC BY-NC-SA license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article, provided this is not done for commercial purposes, and that the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. Further, any new works must be made available on the same conditions. The full details of the license are available at http://creativecommons.org/licenses/by-nc-sa/4.0.
CC BY NC ND: The CC BY-NC-ND license allows users to copy and distribute the Article, provided this is not done for commercial purposes and further does not permit distribution of the Article if it is changed or edited in any way, and provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, and that the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by-nc-nd/4.0.
Any commercial reuse of Open Access articles published with a CC BY NC SA or CC BY NC ND license requires permission from Elsevier and will be subject to a fee.
Commercial reuse includes:

- Associating advertising with the full text of the Article
- Charging fees for document delivery or access
- Article aggregation
- Systematic distribution via e-mail lists or share buttons

Posting or linking by commercial companies for use by customers of those companies.

20. **Other Conditions**:

Terms and Conditions	

INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.
3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:
"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."
4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.
5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions, deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com). No modifications can be made to any Lancet figures/tables and they must be reproduced in full.
6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.
7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed

use, no license is finally effective unless and until full payment is received from you (either by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.

9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.

10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.

11. No Transfer of License: This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person without publisher's written permission.

12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).

13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.

14. Revocation: Elsevier or Copyright Clearance Center may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or Copyright Clearance Center be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or Copyright Clearance Center for denied permissions.

LIMITED LICENSE

The following terms and conditions apply only to specific license types:

15. **Translation**: This permission is granted for non-exclusive world **English** rights only unless your license was granted for translation rights. If you licensed translation rights you may only translate this content into the languages you requested. A professional translator must perform all translations and reproduce the content word for word preserving the integrity of the article.

16. **Posting licensed content on any Website**: The following terms and conditions apply as follows: Licensing material from an Elsevier journal: All content posted to the web site must maintain the copyright information line on the bottom of each image; A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx or the Elsevier homepage for books at http://www.elsevier.com; Central Storage: This license does not include permission for a

scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.
Licensing material from an Elsevier book: A hyper-text link must be included to the Elsevier homepage at http://www.elsevier.com . All content posted to the web site must maintain the copyright information line on the bottom of each image.

Posting licensed content on Electronic reserve: In addition to the above the following clauses are applicable: The web site must be password-protected and made available only to bona fide students registered on a relevant course. This permission is granted for 1 year only. You may obtain a new license for future website posting.
17. **For journal authors:** the following clauses are applicable in addition to the above:
Preprints:
A preprint is an author's own write-up of research results and analysis, it has not been peer-reviewed, nor has it had any other value added to it by a publisher (such as formatting, copyright, technical enhancement etc.).
Authors can share their preprints anywhere at any time. Preprints should not be added to or enhanced in any way in order to appear more like, or to substitute for, the final versions of articles however authors can update their preprints on arXiv or RePEc with their Accepted Author Manuscript (see below).
If accepted for publication, we encourage authors to link from the preprint to their formal publication via its DOI. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help users to find, access, cite and use the best available version. Please note that Cell Press, The Lancet and some society-owned have different preprint policies. Information on these policies is available on the journal homepage.
Accepted Author Manuscripts: An accepted author manuscript is the manuscript of an article that has been accepted for publication and which typically includes author-incorporated changes suggested during submission, peer review and editor-author communications.
Authors can share their accepted author manuscript:

- immediately
    - via their non-commercial person homepage or blog
    - by updating a preprint in arXiv or RePEc with the accepted manuscript
    - via their research institute or institutional repository for internal institutional uses or as part of an invitation-only research collaboration work-group
    - directly by providing copies to their students or to research collaborators for their personal use
    - for private scholarly sharing as part of an invitation-only work group on commercial sites with which Elsevier has an agreement
- After the embargo period
    - via non-commercial hosting platforms such as their institutional repository
    - via commercial sites with which Elsevier has an agreement

In all cases accepted manuscripts should:

- link to the formal publication via its DOI
- bear a CC-BY-NC-ND license - this is easy to do
- if aggregated with other manuscripts, for example in a repository or other site, be shared in alignment with our hosting policy not be added to or enhanced in any way to appear more like, or to substitute for, the published journal article.

Published journal article (JPA): A published journal article (PJA) is the definitive final record of published research that appears or will appear in the journal and embodies all value-adding publishing activities including peer review co-ordination, copy-editing, formatting, (if relevant) pagination and online enrichment.

Policies for sharing publishing journal articles differ for subscription and gold open access articles:

Subscription Articles: If you are an author, please share a link to your article rather than the full-text. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help your users to find, access, cite, and use the best available version. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

If you are affiliated with a library that subscribes to ScienceDirect you have additional private sharing rights for others' research accessed under that agreement. This includes use for classroom teaching and internal training at the institution (including use in course packs and courseware programs), and inclusion of the article for grant funding purposes.

Gold Open Access Articles: May be shared according to the author-selected end-user license and should contain a CrossMark logo, the end user license, and a DOI link to the formal publication on ScienceDirect.

Please refer to Elsevier's posting policy for further information.

18. **For book authors** the following clauses are applicable in addition to the above: Authors are permitted to place a brief summary of their work online only. You are not allowed to download and post the published electronic version of your chapter, nor may you scan the printed edition to create an electronic version. **Posting to a repository:** Authors are permitted to post a summary of their chapter only in their institution's repository.

19. **Thesis/Dissertation**: If your license is for use in a thesis/dissertation your thesis may be submitted to your institution in either print or electronic form. Should your thesis be published commercially, please reapply for permission. These requirements include permission for the Library and Archives of Canada to supply single copies, on demand, of the complete thesis and include permission for Proquest/UMI to supply single copies, on demand, of the complete thesis. Should your thesis be published commercially, please reapply for permission. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

Elsevier Open Access Terms and Conditions

You can publish open access with Elsevier in hundreds of open access journals or in nearly 2000 established subscription journals that support open access publishing. Permitted third party re-use of these open access articles is defined by the author's choice of Creative Commons user license. See our open access license policy for more information.

Terms & Conditions applicable to all Open Access articles published with Elsevier:

Any reuse of the article must not represent the author as endorsing the adaptation of the article nor should the article be modified in such a way as to damage the author's honour or reputation. If any changes have been made, such changes must be clearly indicated.

The author(s) must be appropriately credited and we ask that you include the end user license and a DOI link to the formal publication on ScienceDirect.

If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source it is the responsibility of the user to ensure their reuse complies with the terms and conditions determined by the rights holder.

Additional Terms & Conditions applicable to each Creative Commons user license:

CC BY: The CC-BY license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article and to make commercial use of the Article (including reuse and/or resale of the Article by commercial entities), provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by/4.0.
CC BY NC SA: The CC BY-NC-SA license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article, provided this is not done for commercial purposes, and that the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. Further, any new works must be made available on the same conditions. The full details of the license are available at http://creativecommons.org/licenses/by-nc-sa/4.0.
CC BY NC ND: The CC BY-NC-ND license allows users to copy and distribute the Article, provided this is not done for commercial purposes and further does not permit distribution of the Article if it is changed or edited in any way, and provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, and that the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by-nc-nd/4.0.
Any commercial reuse of Open Access articles published with a CC BY NC SA or CC BY NC ND license requires permission from Elsevier and will be subject to a fee.
Commercial reuse includes:

- Associating advertising with the full text of the Article
- Charging fees for document delivery or access
- Article aggregation
- Systematic distribution via e-mail lists or share buttons

Posting or linking by commercial companies for use by customers of those companies.

20. **Other Conditions**:

Terms and Conditions

INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.

3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:

"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."

4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.

5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions, deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com). No modifications can be made to any Lancet figures/tables and they must be reproduced in full.

6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.

7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.

8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either

by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.

9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.

10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.

11. No Transfer of License: This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person without publisher's written permission.

12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).

13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.

14. Revocation: Elsevier or Copyright Clearance Center may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or Copyright Clearance Center be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or Copyright Clearance Center for denied permissions.

LIMITED LICENSE

The following terms and conditions apply only to specific license types:

15. **Translation**: This permission is granted for non-exclusive world **English** rights only unless your license was granted for translation rights. If you licensed translation rights you may only translate this content into the languages you requested. A professional translator must perform all translations and reproduce the content word for word preserving the integrity of the article.

16. **Posting licensed content on any Website**: The following terms and conditions apply as follows: Licensing material from an Elsevier journal: All content posted to the web site must maintain the copyright information line on the bottom of each image; A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx or the Elsevier homepage for books at http://www.elsevier.com; Central Storage: This license does not include permission for a scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.

Licensing material from an Elsevier book: A hyper-text link must be included to the Elsevier homepage at http://www.elsevier.com . All content posted to the web site must maintain the copyright information line on the bottom of each image.

Posting licensed content on Electronic reserve: In addition to the above the following clauses are applicable: The web site must be password-protected and made available only to bona fide students registered on a relevant course. This permission is granted for 1 year only. You may obtain a new license for future website posting.
17. **For journal authors:** the following clauses are applicable in addition to the above:
Preprints:
A preprint is an author's own write-up of research results and analysis, it has not been peer-reviewed, nor has it had any other value added to it by a publisher (such as formatting, copyright, technical enhancement etc.).
Authors can share their preprints anywhere at any time. Preprints should not be added to or enhanced in any way in order to appear more like, or to substitute for, the final versions of articles however authors can update their preprints on arXiv or RePEc with their Accepted Author Manuscript (see below).
If accepted for publication, we encourage authors to link from the preprint to their formal publication via its DOI. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help users to find, access, cite and use the best available version. Please note that Cell Press, The Lancet and some society-owned have different preprint policies. Information on these policies is available on the journal homepage.
Accepted Author Manuscripts: An accepted author manuscript is the manuscript of an article that has been accepted for publication and which typically includes author-incorporated changes suggested during submission, peer review and editor-author communications.
Authors can share their accepted author manuscript:

- immediately
    - via their non-commercial person homepage or blog
    - by updating a preprint in arXiv or RePEc with the accepted manuscript
    - via their research institute or institutional repository for internal institutional uses or as part of an invitation-only research collaboration work-group
    - directly by providing copies to their students or to research collaborators for their personal use
    - for private scholarly sharing as part of an invitation-only work group on commercial sites with which Elsevier has an agreement
- After the embargo period
    - via non-commercial hosting platforms such as their institutional repository
    - via commercial sites with which Elsevier has an agreement

In all cases accepted manuscripts should:

- link to the formal publication via its DOI
- bear a CC-BY-NC-ND license - this is easy to do
- if aggregated with other manuscripts, for example in a repository or other site, be shared in alignment with our hosting policy not be added to or enhanced in any way to appear more like, or to substitute for, the published journal article.

Published journal article (JPA): A published journal article (PJA) is the definitive final record of published research that appears or will appear in the journal and embodies all value-adding publishing activities including peer review co-ordination, copy-editing, formatting, (if relevant) pagination and online enrichment.
Policies for sharing publishing journal articles differ for subscription and gold open access articles:
<u>Subscription Articles:</u> If you are an author, please share a link to your article rather than the full-text. Millions of researchers have access to the formal publications on ScienceDirect,

and so links will help your users to find, access, cite, and use the best available version. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

If you are affiliated with a library that subscribes to ScienceDirect you have additional private sharing rights for others' research accessed under that agreement. This includes use for classroom teaching and internal training at the institution (including use in course packs and courseware programs), and inclusion of the article for grant funding purposes.

Gold Open Access Articles: May be shared according to the author-selected end-user license and should contain a CrossMark logo, the end user license, and a DOI link to the formal publication on ScienceDirect.

Please refer to Elsevier's posting policy for further information.

18. **For book authors** the following clauses are applicable in addition to the above: Authors are permitted to place a brief summary of their work online only. You are not allowed to download and post the published electronic version of your chapter, nor may you scan the printed edition to create an electronic version. **Posting to a repository:** Authors are permitted to post a summary of their chapter only in their institution's repository.

19. **Thesis/Dissertation**: If your license is for use in a thesis/dissertation your thesis may be submitted to your institution in either print or electronic form. Should your thesis be published commercially, please reapply for permission. These requirements include permission for the Library and Archives of Canada to supply single copies, on demand, of the complete thesis and include permission for Proquest/UMI to supply single copies, on demand, of the complete thesis. Should your thesis be published commercially, please reapply for permission. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

Elsevier Open Access Terms and Conditions

You can publish open access with Elsevier in hundreds of open access journals or in nearly 2000 established subscription journals that support open access publishing. Permitted third party re-use of these open access articles is defined by the author's choice of Creative Commons user license. See our open access license policy for more information.

Terms & Conditions applicable to all Open Access articles published with Elsevier:

Any reuse of the article must not represent the author as endorsing the adaptation of the article nor should the article be modified in such a way as to damage the author's honour or reputation. If any changes have been made, such changes must be clearly indicated.

The author(s) must be appropriately credited and we ask that you include the end user license and a DOI link to the formal publication on ScienceDirect.

If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source it is the responsibility of the user to ensure their reuse complies with the terms and conditions determined by the rights holder.

Additional Terms & Conditions applicable to each Creative Commons user license:

CC BY: The CC-BY license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article and to make commercial use of the Article (including reuse and/or resale of the Article by commercial entities), provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by/4.0.

CC BY NC SA: The CC BY-NC-SA license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article, provided this is not done for commercial purposes, and that the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the

work. Further, any new works must be made available on the same conditions. The full details of the license are available at http://creativecommons.org/licenses/by-nc-sa/4.0.
CC BY NC ND: The CC BY-NC-ND license allows users to copy and distribute the Article, provided this is not done for commercial purposes and further does not permit distribution of the Article if it is changed or edited in any way, and provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, and that the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by-nc-nd/4.0.
Any commercial reuse of Open Access articles published with a CC BY NC SA or CC BY NC ND license requires permission from Elsevier and will be subject to a fee.
Commercial reuse includes:

- Associating advertising with the full text of the Article
- Charging fees for document delivery or access
- Article aggregation
- Systematic distribution via e-mail lists or share buttons

Posting or linking by commercial companies for use by customers of those companies.

20. **Other Conditions**:

Terms and Conditions

Springer Nature Terms and Conditions for RightsLink Permissions

Springer Nature Customer Service Centre GmbH (the Licensor) hereby grants you a non-exclusive, world-wide licence to reproduce the material and for the purpose and requirements specified in the attached copy of your order form, and for no other use, subject to the conditions below:

1. The Licensor warrants that it has, to the best of its knowledge, the rights to license reuse of this material. However, you should ensure that the material you are requesting is original to the Licensor and does not carry the copyright of another entity (as credited in the published version).

   If the credit line on any part of the material you have requested indicates that it was reprinted or adapted with permission from another source, then you should also seek permission from that source to reuse the material.

2. Where **print only** permission has been granted for a fee, separate permission must be obtained for any additional electronic re-use.

3. Permission granted **free of charge** for material in print is also usually granted for any electronic version of that work, provided that the material is incidental to your work as a whole and that the electronic version is essentially equivalent to, or substitutes for, the print version.

4. A licence for 'post on a website' is valid for 12 months from the licence date. This licence does not cover use of full text articles on websites.

5. Where **'reuse in a dissertation/thesis'** has been selected the following terms apply: Print rights of the final author's accepted manuscript (for clarity, NOT the published version) for up to 100 copies, electronic rights for use only on a personal website or institutional repository as defined by the Sherpa guideline (www.sherpa.ac.uk/romeo/).

6. Permission granted for books and journals is granted for the lifetime of the first edition and does not apply to second and subsequent editions (except where the first edition permission was granted free of charge or for signatories to the STM Permissions Guidelines http://www.stm-assoc.org/copyright-legal-affairs/permissions/permissions-guidelines/), and does not apply for editions in other languages unless additional translation rights have been granted separately in the licence.

7. Rights for additional components such as custom editions and derivatives require additional permission and may be subject to an additional fee. Please apply to Journalpermissions@springernature.com/bookpermissions@springernature.com for these rights.

8. The Licensor's permission must be acknowledged next to the licensed material in print. In electronic form, this acknowledgement must be visible at the same time as the figures/tables/illustrations or abstract, and must be hyperlinked to the journal/book's homepage. Our required acknowledgement format is in the Appendix below.

9. Use of the material for incidental promotional use, minor editing privileges (this does not include cropping, adapting, omitting material or any other changes that affect the meaning, intention or moral rights of the author) and copies for the disabled are permitted under this licence.

10. Minor adaptations of single figures (changes of format, colour and style) do not require the Licensor's approval. However, the adaptation should be credited as shown in Appendix below.

Development of an Acute and Highly Pathogenic Nonhuman Primate Model of Nipah Virus Infection

Abstract

Nipah virus (NiV) is an enigmatic emerging pathogen that causes severe and often fatal neurologic and/or respiratory disease in both animals and humans. Amongst people, case fatality rates range between 40 and 75 percent and there are no vaccines or treatments approved for human use. Guinea pigs, hamsters, cats, ferrets, pigs and most recently squirrel monkeys (New World monkey) have been evaluated as animal models of human NiV infection, and with the exception of the ferret, no model recapitulates all aspects of NiV-mediated disease seen in humans. To identify a more viable nonhuman primate (NHP) model, we examined the pathogenesis of NiV in African green monkeys (AGM). Exposure of eight monkeys to NiV produced a severe systemic infection in all eight animals with seven of the animals succumbing to infection. Viral RNA was detected in the plasma of challenged animals and occurred in two of three subjects as a peak between days 7 and 21, providing the first clear demonstration of plasma-associated viremia in NiV experimentally infected animals and suggested a progressive infection that seeded multiple organs simultaneously from the initial site of virus replication. Unlike the cat, hamster and squirrel monkey models of NiV infection, severe respiratory pathology, neurological disease and generalized vasculitis all manifested in NiV-infected AGMs, providing an accurate reflection of what is observed in NiV-infected humans. Our findings demonstrate the first consistent and highly pathogenic NHP model of NiV infection, providing a new and critical platform in the evaluation and licensure of either passive and active immunization or therapeutic strategies for human use.

Introduction

Nipah virus (NiV) is a recently recognized viral zoonotic pathogen of the family *Paramyxoviridae* that is distinguished by its ability to cause fatal disease in both animal and human hosts. NiV along with Hendra virus (HeV) comprise the new genus *Henipavirus* (reviewed [1,2]). NiV was first identified during an outbreak of severe encephalitis in Malaysia and Singapore in 1998–99 that involved hundreds of people and more than 100 deaths, with pigs serving as the intermediate amplifying host [3,4]. Since 1998 there have been more than a dozen recognized occurrences of human NiV infection, primarily in Bangladesh and India (reviewed [5]) with the two most recent outbreaks in March 2008 [6] and January 2010 [7]. In the majority of subsequent spillover events, the mortality rate among humans has been higher (~75%) along with evidence of multiple rounds of person-to-person transmission [8].

Several species of fruit bats of the *Pteropus* genus (flying foxes) appear to be the principle natural reservoirs of both NiV and HeV (reviewed [5]) but serological evidence of NiV or Nipah-like virus infection has recently been reported in several additional frugivorous and insectivorous bats [9,10]. NiV has been isolated from bat urine and partially eaten fruit [11,12] and direct transmission of NiV from flying foxes to humans from contaminated food sources has been suggested [13,14]. The Centers for Disease Control and Prevention (CDC) and the National Institute of Allergy and Infectious Diseases (NIAID) have classified NiV as a select agent with the potential for causing significant morbidity and mortality in humans and major economic and public health impacts. Consequently, work with live virus requires Biosafety Level 4 (BSL-4) containment.

Host cell infection by NiV requires two membrane-anchored envelope glycoproteins; the attachment glycoprotein (G) which binds receptor and the fusion (F) glycoprotein which facilitates virus-host cell membrane fusion [2]. NiV G lacks hemagglutinin and neuraminidase activities and F is a typical class I fusion glycoprotein [15]. Recently, ephrin-B2 and ephrin-B3 ligands

Terms and Conditions

Introduction

The publisher for this copyrighted content is Massachusetts Medical Society ("MMS"). By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your RightsLink account and that are available at any time at http://myaccount.copyright.com).

Scope of License

1. MMS hereby grants to you a non-exclusive license to reproduce the aforementioned content subject to the terms and conditions indicated within the RightsLink transaction. Licenses are for one-time use only. Web posting is limited to the time period selected within your transaction - beginning on the date of this license.
2. This grant of permission is for the content to be used without alteration, as originally published by MMS. However, minor formatting and stylistic changes are permitted, provided that any explanatory material or figure legend that you use accurately reflects the content as originally published by MMS. MMS does not approve adaptations or modifications.
3. MMS's copyrighted content may not be used in any manner that implies endorsement, sponsorship, or promotion of any entity, product or service by the MMS or its publications. MMS cannot and does not authorize the use of any author's name on promotional materials; such approval must be obtained directly from the author.
4. This permission is granted for English language rights only unless your license specifically grants translation rights. If translation rights are granted, the content must be reproduced word for word with the integrity and original meaning of the content preserved.
5. If your license specifically grants "expanded rights," permission is granted to reproduce the aforementioned content in a primary work and related materials created to supplement or add value to it, such as: ancillaries, instructor guides, testing materials, and student resource materials.
6. MMS reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.

Acknowledgement

7. This permission requires suitable acknowledgement of the source, either as a footnote, in a reference list, or adjacent to where the MMS content appears. The credit line should read as follows:
"From [Publication Title, Author(s), Title of Article, Volume No., Page No. Copyright © (notice year) Massachusetts Medical Society. Reprinted with permission from Massachusetts Medical Society."

General Terms

8. Warranties. MMS makes no representations or warranties with respect to the licensed content.
9. Indemnity. You hereby indemnify and agree to hold harmless the MMS and CCC, and their respective officers, directors, employees, members and agents, from and against any and all claims arising out of your use of the licensed content other than as specifically authorized by this license.
10. No Transfer of License. This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person or entity without permission from MMS.
11. No Amendment Except in Writing. This license may not be amended except in a writing signed by both parties.

12. Objection to Contrary Terms. MMS hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.

13. License Contingent on Payment. While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either by MMS or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of content as described in a revoked license, as well as any use of the content beyond the scope of an unrevoked license, may constitute copyright infringement and MMS reserves the right to take any and all action to protect its copyright in the content.

14. This license transaction shall be governed by and construed in accordance with the laws of the Commonwealth of Massachusetts. You hereby agree to submit to the jurisdiction of the federal and state courts located in Boston, MA for purposes of resolving any dispute that may arise in connection with this licensing transaction.

Restrictions

15. This permission applies only to content of the MMS, and not to copyrighted content from any other source. If content appears in our work with credit to another source, you must also obtain permission from that source.

16. This permission does not apply to and is not valid for photographs depicting identifiable individuals.

Terms and Conditions

INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.
3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:
"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."
4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.
5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions, deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com). No modifications can be made to any Lancet figures/tables and they must be reproduced in full.
6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.
7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event

that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.
9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.
10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.
11. No Transfer of License: This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person without publisher's written permission.
12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).
13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.
14. Revocation: Elsevier or Copyright Clearance Center may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or Copyright Clearance Center be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or Copyright Clearance Center for denied permissions.

LIMITED LICENSE

The following terms and conditions apply only to specific license types:
15. **Translation**: This permission is granted for non-exclusive world **English** rights only unless your license was granted for translation rights. If you licensed translation rights you may only translate this content into the languages you requested. A professional translator must perform all translations and reproduce the content word for word preserving the integrity of the article.
16. **Posting licensed content on any Website**: The following terms and conditions apply as follows: Licensing material from an Elsevier journal: All content posted to the web site must maintain the copyright information line on the bottom of each image; A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx or the Elsevier homepage for books at http://www.elsevier.com; Central Storage: This license does not include permission for a scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.
Licensing material from an Elsevier book: A hyper-text link must be included to the Elsevier homepage at http://www.elsevier.com . All content posted to the web site must maintain the copyright information line on the bottom of each image.

Posting licensed content on Electronic reserve: In addition to the above the following clauses are applicable: The web site must be password-protected and made available only to

bona fide students registered on a relevant course. This permission is granted for 1 year only. You may obtain a new license for future website posting.
17. **For journal authors:** the following clauses are applicable in addition to the above:
Preprints:
A preprint is an author's own write-up of research results and analysis, it has not been peer-reviewed, nor has it had any other value added to it by a publisher (such as formatting, copyright, technical enhancement etc.).
Authors can share their preprints anywhere at any time. Preprints should not be added to or enhanced in any way in order to appear more like, or to substitute for, the final versions of articles however authors can update their preprints on arXiv or RePEc with their Accepted Author Manuscript (see below).
If accepted for publication, we encourage authors to link from the preprint to their formal publication via its DOI. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help users to find, access, cite and use the best available version. Please note that Cell Press, The Lancet and some society-owned have different preprint policies. Information on these policies is available on the journal homepage.
Accepted Author Manuscripts: An accepted author manuscript is the manuscript of an article that has been accepted for publication and which typically includes author-incorporated changes suggested during submission, peer review and editor-author communications.
Authors can share their accepted author manuscript:

- immediately
  - via their non-commercial person homepage or blog
  - by updating a preprint in arXiv or RePEc with the accepted manuscript
  - via their research institute or institutional repository for internal institutional uses or as part of an invitation-only research collaboration work-group
  - directly by providing copies to their students or to research collaborators for their personal use
  - for private scholarly sharing as part of an invitation-only work group on commercial sites with which Elsevier has an agreement
- After the embargo period
  - via non-commercial hosting platforms such as their institutional repository
  - via commercial sites with which Elsevier has an agreement

In all cases accepted manuscripts should:

- link to the formal publication via its DOI
- bear a CC-BY-NC-ND license - this is easy to do
- if aggregated with other manuscripts, for example in a repository or other site, be shared in alignment with our hosting policy not be added to or enhanced in any way to appear more like, or to substitute for, the published journal article.

Published journal article (JPA): A published journal article (PJA) is the definitive final record of published research that appears or will appear in the journal and embodies all value-adding publishing activities including peer review co-ordination, copy-editing, formatting, (if relevant) pagination and online enrichment.
Policies for sharing publishing journal articles differ for subscription and gold open access articles:
<u>Subscription Articles:</u> If you are an author, please share a link to your article rather than the full-text. Millions of researchers have access to the formal publications on ScienceDirect, and so links will help your users to find, access, cite, and use the best available version.
Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal

publications on ScienceDirect.
If you are affiliated with a library that subscribes to ScienceDirect you have additional private sharing rights for others' research accessed under that agreement. This includes use for classroom teaching and internal training at the institution (including use in course packs and courseware programs), and inclusion of the article for grant funding purposes.
Gold Open Access Articles: May be shared according to the author-selected end-user license and should contain a CrossMark logo, the end user license, and a DOI link to the formal publication on ScienceDirect.
Please refer to Elsevier's posting policy for further information.
18. **For book authors** the following clauses are applicable in addition to the above: Authors are permitted to place a brief summary of their work online only. You are not allowed to download and post the published electronic version of your chapter, nor may you scan the printed edition to create an electronic version. **Posting to a repository:** Authors are permitted to post a summary of their chapter only in their institution's repository.
19. **Thesis/Dissertation**: If your license is for use in a thesis/dissertation your thesis may be submitted to your institution in either print or electronic form. Should your thesis be published commercially, please reapply for permission. These requirements include permission for the Library and Archives of Canada to supply single copies, on demand, of the complete thesis and include permission for Proquest/UMI to supply single copies, on demand, of the complete thesis. Should your thesis be published commercially, please reapply for permission. Theses and dissertations which contain embedded PJAs as part of the formal submission can be posted publicly by the awarding institution with DOI links back to the formal publications on ScienceDirect.

Elsevier Open Access Terms and Conditions

You can publish open access with Elsevier in hundreds of open access journals or in nearly 2000 established subscription journals that support open access publishing. Permitted third party re-use of these open access articles is defined by the author's choice of Creative Commons user license. See our open access license policy for more information.
Terms & Conditions applicable to all Open Access articles published with Elsevier:
Any reuse of the article must not represent the author as endorsing the adaptation of the article nor should the article be modified in such a way as to damage the author's honour or reputation. If any changes have been made, such changes must be clearly indicated.
The author(s) must be appropriately credited and we ask that you include the end user license and a DOI link to the formal publication on ScienceDirect.
If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source it is the responsibility of the user to ensure their reuse complies with the terms and conditions determined by the rights holder.
Additional Terms & Conditions applicable to each Creative Commons user license:
CC BY: The CC-BY license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article and to make commercial use of the Article (including reuse and/or resale of the Article by commercial entities), provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by/4.0.
CC BY NC SA: The CC BY-NC-SA license allows users to copy, to create extracts, abstracts and new works from the Article, to alter and revise the Article, provided this is not done for commercial purposes, and that the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, indicates if changes were made and the licensor is not represented as endorsing the use made of the work. Further, any new works must be made available on the same conditions. The full details of the license are available at http://creativecommons.org/licenses/by-nc-sa/4.0.

CC BY NC ND: The CC BY-NC-ND license allows users to copy and distribute the Article, provided this is not done for commercial purposes and further does not permit distribution of the Article if it is changed or edited in any way, and provided the user gives appropriate credit (with a link to the formal publication through the relevant DOI), provides a link to the license, and that the licensor is not represented as endorsing the use made of the work. The full details of the license are available at http://creativecommons.org/licenses/by-nc-nd/4.0.
Any commercial reuse of Open Access articles published with a CC BY NC SA or CC BY NC ND license requires permission from Elsevier and will be subject to a fee.
Commercial reuse includes:

- Associating advertising with the full text of the Article
- Charging fees for document delivery or access
- Article aggregation
- Systematic distribution via e-mail lists or share buttons

Posting or linking by commercial companies for use by customers of those companies.

20. **Other Conditions**:

Highlights

- Advanced antivirals against Nipah and Hendra are a Hendra-sG subunit vaccine and a human monoclonal antibody, m102.4.
- The Hendra-sG vaccine was launched in Australia for equine use and is the first BSL-4 agent vaccine for public use.

- m102.4 has been used in people on a compassionate use basis in Australia and is presently in pre-clinical development.
- A structural model of the Hendra-sG vaccine and its complex with the neutralizing human monoclonal antibody is shown.

Abstract

Hendra virus and Nipah virus are bat-borne paramyxoviruses that are the prototypic members of the genus *Henipavirus*. The henipaviruses emerged in the 1990s, spilling over from their natural bat hosts and causing serious disease outbreaks in humans and livestock. Hendra virus emerged in Australia and since 1994 there have been 7 human infections with 4 case fatalities. Nipah virus first appeared in Malaysia and subsequent outbreaks have occurred in Bangladesh and India. In total, there have been an estimated 582 human cases of Nipah virus and of these, 54% were fatal. Their broad species tropism and ability to cause fatal respiratory and/or neurologic disease in humans and animals make them important transboundary biological threats. Recent experimental findings in animals have demonstrated that a human monoclonal antibody targeting the viral G glycoprotein is an effective post-exposure treatment against Hendra and Nipah virus infection. In addition, a subunit vaccine based on the G glycoprotein of Hendra virus affords protection against Hendra and Nipah virus challenge. The vaccine has been developed for use in horses in Australia and is the first vaccine against a Biosafety Level-4 (BSL-4) agent to be licensed and commercially deployed. Together, these advances offer viable approaches to address Hendra and Nipah virus infection of livestock and people.

Hendra virus; Nipah virus; Vaccine; Monoclonal antibody; G glycoprotein; Horse

1. Introduction

Hendra virus and Nipah virus are recently recognized bat-borne paramyxoviruses, each of which have repeatedly emerged causing significant morbidity and mortality in both animal and human populations since the mid to late 1990's. Hendra virus was isolated in Australia from fatal cases of severe respiratory disease in horses and one person in the Brisbane suburb of Hendra in September, 1994, and was shown to be distantly related to measles virus and other morbilliviruses (Murray et al., 1995). The same virus had also caused fatal infections in horses a month prior in Mackay, Australia, but this emergence was only recognized when one individual who was unknowingly exposed to the infected horses at that time developed a recrudescence of fatal meningoencephalitis 13 months later (O'Sullivan et al., 1997, Wong et al., 2009). Hendra virus' close relative, Nipah virus, emerged in peninsular Malaysia in 1998–99, in a large outbreak of respiratory disease in pigs along with numerous cases of encephalitis among pig farmers, eventually resulting in more than 100 human fatalities. Genetic and serological studies revealed the relatedness of this new virus to Hendra virus (Chua et al., 2000). Hendra virus and Nipah virus now represent the prototype species of the new genus *Henipavirus* within the paramyxovirus family (Wang et al., 2013).

Since their discovery, both Hendra virus and Nipah virus have continued to repeatedly cause spillover events into animals and/or people. Hendra virus infection among horses in Australia has occurred annually since 2006 and in total there have now been 7 human cases of which 4 have been fatal (Anonymous, 2009b, Playford et al., 2010). In all 7 human cases, Hendra virus was transmitted from infected horses to humans. Of note, in 2011 from the months of June to October, a significant increase in the number of Hendra virus spillovers occurred with 18 separate episodes of infection in horses in Australia, including the first recognized case of infection in a dog (reviewed in (Broder, 2012)). There were 8 cases of Hendra virus spillovers into horses in 2012 (Anonymous, 2012b) and a further two cases of Hendra virus infection in horses in early 2013 (Anonymous, 2013b). In all, a total of 42 Hendra virus spillover events have occurred since 1994 and 28 of these have occurred in just the past 2 years. Likewise, following the Malaysian outbreak in 1998, nearly annual outbreaks of Nipah virus infection, occurring primarily in Bangladesh but also India have occurred since 2001. The most recent outbreak occurred in early 2013, with apparently 10 fatalities of 12 cases (Anonymous, 2013c). Compared to the original Malaysian outbreak, these Nipah virus spillovers have been smaller in case number, however the fatality rates in people overall have been notably higher, ranging from 75–100%. Importantly, direct transmission of Nipah virus from bats to humans and significant human-to-human transmission have also been documented during outbreaks in India and

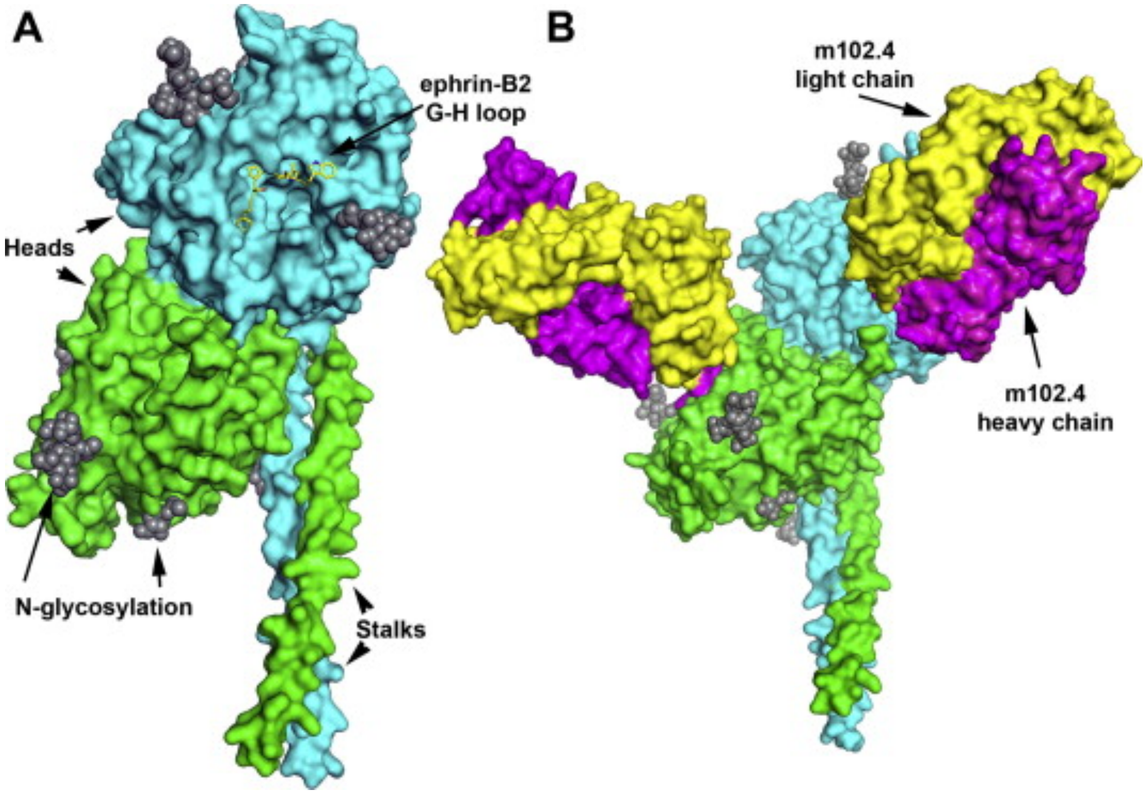
Bangladesh. The epidemiological details of the spillovers of both Hendra virus and Nipah virus into people since their emergence and recognition have recently been reviewed and summarized in detail (Luby and Gurley, 2012). There have been an estimated 582 cases of Nipah virus infection with 315 human fatalities (Anonymous, 2013c, Luby and Gurley, 2012, Luby et al., 2009, Pallister et al., 2011a).

2. The henipavirus transboundary threat

The natural reservoir hosts of Hendra virus and Nipah virus are several species of pteropid fruit bats among which they are not known to cause disease (Halpin et al., 2011). However, Hendra and Nipah viruses possess an exceptionally broad species tropism and both natural and experimental infections have demonstrated their capacity to cause disease which can often be fatal in horses, pigs, cats, dogs, ferrets, hamsters, guinea pigs, monkeys, and humans, spanning 6 mammalian Orders (reviewed in (Geisbert et al., 2012)). In disease susceptible animal hosts and people, Nipah virus and Hendra virus cause a systemic infection that is characterized as a wide-spread vasculitis and endothelial cell tropism. Though this pathology is not unique to these henipaviruses, an understanding of Hendra and Nipah virus cellular tropism on the molecular level has provided an explanation to this disease feature which includes the appearance of syncytia, thrombosis, ischemia and necrosis, with parenchymal cell infection and associated pathology in many major organ systems, and prominently in the brain and lung (reviewed in (Weingartl et al., 2009, Wong and Ong, 2011)). The major involvement of the lung and brain in Hendra and Nipah virus infection often manifests as an acute severe respiratory syndrome, encephalitis or a combination of both. Disturbingly however, infection in people can also have longer term consequences, and in addition to an acute symptomatic infection, Hendra and Nipah virus infection can also take a protracted course following recovery from an initial infection. Individuals in these cases can later undergo a recrudescence of virus replication in the central nervous system (CNS) causing a relapse of encephalitis, a process that was first noted in the second fatal case of Hendra virus human infection (O’Sullivan et al., 1997, Wong et al., 2009). Quite remarkably, relapsed-encephalitis caused by Nipah virus has been reported in people from several months to as long as 11 years following infection (Abdullah et al., 2012) (reviewed in (Wong, 2010)). How the henipaviruses survive immune-mediated clearance and can later cause a recrudescence of replication in the CNS is unknown, but this virological feature clearly has important implications for anti-henipavirus therapeutics development.

Given the virulence of Hendra and Nipah virus and the increase in their spillover occurrences over the past decade, strategies to mitigate the risk of Hendra and Nipah virus exposure have become paramount. Both Hendra virus and Nipah virus reside in large wild bat populations, which make controlling virus in the reservoir host or influencing the reservoir host population dynamics difficult to impossible. In extreme instances, bat culling has been proposed to minimize exposure; however, the ecological importance of bats as a whole makes this an unrealistic option. In Malaysia and Australia efforts have been made to reduce livestock interactions with bats; for example, restricting livestock access to areas under fruit trees, covering water and feed containers to prevent contamination and not placing water and feed under fruit trees (Anonymous, 2013a). However, the significant numbers of fruit trees and roosting flying foxes on or near properties containing livestock makes complete separation of the wildlife and livestock populations near impossible. In Bangladesh, measures have been employed to prevent flying foxes access to date palm sap collectors in hopes of preventing contamination with Nipah virus (Luby and Gurley, 2012). Unfortunately, Nipah outbreaks continue to occur every year reflecting the difficulty of implementing a new practice culturally to prevent such a disease that is still considered to be rare. Developing vaccines and antiviral therapies for Hendra and Nipah virus are also viable alternatives for mitigating disease risk. As livestock have been identified as intermediate hosts for both Hendra and Nipah virus, antiviral therapies seem less attractive given the size of horses and pigs and the significant costs associated with producing large quantities of any possible drug. Conversely, vaccination of livestock populations is a highly attractive mitigation strategy since both disease in the target species as well as secondary transmission of virus to humans would be prevented. In areas such as Bangladesh, where no intermediate host has been definitively identified, there is a real need for the development of effective therapies and vaccine strategies to prevent infection. Similarly, for individuals who have potential occupational exposure to Hendra and Nipah virus infection, such as pig farmers and equine veterinarians, therapeutic agents and/or a vaccine to prevent infection would significantly reduce morbidity and mortality associated with Hendra and Nipah viruses.

Hendra and Nipah virus attach to host cell-surface displayed ephrin-B2 or -B3 proteins and infect host cells by the coordinated activity of their attachment (G) and fusion (F) glycoproteins (reviewed in (Aguilar and Iorio, 2012, Lee and Ataman, 2011)). The G glycoprotein monomer consists of a stalk and globular head (Fig. 1) and the atomic structures of both the Nipah and Hendra virus G glycoprotein's globular head domain have been determined alone and in complex with ephrin proteins (reviewed in (Xu et al., 2012a)). The F glycoprotein mediates the membrane fusion process between the viral and host cell membranes by a Class I fusion mechanism that is initiated following the G glycoprotein engagement of ephrin receptor (Lee and Ataman, 2011). The susceptible host species and associated cellular tropism and pathology of Hendra and Nipah virus has in large part been explained by their use of the highly conserved ephrin-B2 and -B3 proteins as entry receptors (reviewed in (Pernet et al., 2012, Wong and Ong, 2011)). In addition and of importance to countermeasure development, the henipavirus G and F envelope glycoprotein spikes are major targets of virus-neutralizing antibodies and as discussed below, the development of potential vaccines have largely focused on these important structural components of the virion (reviewed in (Broder, 2010)).



Download full-size image

Fig. 1. Model of the Hendra virus soluble G glycoprotein subunit vaccine (HeV-sG) and its complex with the henipavirus-neutralizing human monoclonal antibody m1024. (A) The HeV-sG glycoprotein subunit vaccine is composed of the entire ectodomain (amino acids 76–604) of the HeV G glycoprotein. Here, HeV-sG is shown as dimer with one monomer colored green and the other cyan. The secondary structure elements of the two globular head domains are derived from the crystal structure of the HeV G head domain (Colgrave et al., 2011, Xu et al., 2012b), and the stalk regions of each G monomer (residues 77–136) are modeled (Kelley and Sternberg, 2009). N-linked glycosylation sites shown as gray spheres. The ephrin-binding face of the cyan globular head is facing forward with an overlay of the interacting ephrin-B2 G-H loop residues

in yellow. (B) The HeV-sG dimer shown in complex with two m102.4 Fab antibody fragments. The two HeV-sG monomers are colored green and cyan as in panel A and rotated slightly to the right. The two Fab m102.4 molecules are shown with their heavy chains colored in magenta and light chain – in yellow, each binding one globular head domains of G. (Xu, K. et al., submitted). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.).

The development of medical countermeasures for use in humans is a time-consuming process, especially for highly pathogenic BSL-4 agents like Hendra and Nipah virus where human efficacy trials are not feasible. Demonstrated efficacy in two animal models of disease is required to support possible licensure. In recent years monoclonal antibodies (mAbs) have attracted considerable attention as viable antiviral and antibacterial therapies, and the Food and Drug Administration (FDA) has approved both humanized and fully human monoclonal antibody (mAb) for use in preventing or treating infectious diseases in humans (Dolgin, 2013, Zhu et al., 2013). The development of human monoclonal antibodies (humAbs) against Hendra and Nipah virus infection has been highly successful and as discussed below, a viable post-exposure mAb therapy is currently in development. In addition, a recombinant subunit vaccine candidate has been successfully trialed in several animal challenge models of Hendra and Nipah virus infection, and has recently been deployed as an effective equine vaccine in Australia; potentially breaking the chain of Hendra virus transmission and a practical cost effective way to mitigate human Hendra virus infection.

3. Antiviral treatment

There are no approved or licensed therapeutics for treating henipavirus infection or disease in people, and antiviral approaches against the henipaviruses that have been tested in animal models are few (reviewed in (Broder, 2012)). Ribavirin is a well-known first line treatment strategy for suspected viral infections of unknown etiology. Ribavirin exhibits antiviral activity against a wide variety of both RNA and some DNA viruses (Sidwell et al., 1972) and is an accepted or approved treatment for several viral infections including respiratory syncytial virus and arenaviral hemorrhagic-fevers (reviewed in (Snell, 2001)). *In vitro* studies have shown that ribavirin is effective against both Hendra and Nipah virus replication (Aljofan et al., 2009, Wright et al., 2005). Also, the anti-malarial drug chloroquine was shown earlier to block the critical proteolytic processing needed for the maturation and function of the Hendra virus F glycoprotein (Pager et al., 2004), and not surprisingly cholorquine was later shown to inhibit

Nipah and Hendra virus infection in cell culture (Porotto et al., 2009).

An open label ribavirin treatment trial was carried out during the outbreak of Nipah virus in Malaysia in 1998 and was reported to reduce mortality by 36% in treated patients when compared to those patients who presented before ribavirin availability or who refused treatment (Chong et al., 2001). Of the recorded human Hendra virus cases, three individuals were treated with ribavirin, and of these, two succumbed to disease and one survived (Playford et al., 2010). Chloroquine was administered along with ribavirin to one HeV-infected individual in 2009 (Anonymous, 2009c) with no apparent clinical benefit. Three additional people received ribavirin treatment in combination with chloroquine after suspected exposure to Hendra virus contaminated secretions from infected horses. While all three individuals survived, infection was not confirmed and therefore it remains unknown whether the treatment had any effect (Anonymous, 2009a). In the absence of other therapies, ribavirin may be an option for treatment of henipavirus infections. However, more recent animal studies have revealed no therapeutic benefit of either drug. Two studies in hamsters and one study in nonhuman primates (African green monkey (AGM)) showed that ribavirin treatment only delayed but did not prevent death after Nipah or Hendra virus infection (Freiberg et al., 2010, Georges-Courbot et al., 2006, Rockx et al., 2010) and AGMs treated with ribavirin following Hendra virus infection had marked increases of neurological symptoms. Similarly, chloroquine was unable to prevent Nipah infection or disease in ferrets (Pallister et al., 2009).

4. A passive immunotherapy for people

In contrast, passive immunotherapy with polyclonal or monoclonal antibody specific for the viral envelope glycoproteins has proved successful from initial proof-of-concept findings from several studies carried out in hamsters (Guillaume et al., 2004, Guillaume et al., 2006). Presently, the only reported and effective post-exposure therapy against Hendra or Nipah virus infection and one that could likely be approved in the near future for use in people has been a human monoclonal antibody (mAb) known as m102.4 which was isolated from a recombinant naïve human phage-displayed Fab library (Zhu et al., 2008).

The m102.4 mAb has exceptionally potent neutralizing activity against both Nipah and Hendra viruses and its epitope maps to the ephrin receptor binding site (Fig. 1). Testing of m102.4 has confirmed its neutralization activity against several isolates; NiV-Malaysia, HeV-1994, HeV-Redlands, NiV-Bangladesh (Bossart et al., 2009). Effective post-exposure efficacy with m102.4 has now been demonstrated in both ferrets and nonhuman primates (African green monkey

(AGM)) infected with either Hendra virus or Nipah virus (Table 1). The successful m102.4 passive immunotherapy in the AGM was recently reported in a study designed to reflect a possible real life scenario requiring mAb as a post-exposure treatment, and was a follow-up from the initial successful m102.4 post-exposure therapy carried out in ferrets (Bossart et al., 2009). Fourteen monkeys were challenged intratracheally with Hendra virus and 12 animals were infused twice with a 100 mg dose (~20 mg/kg) of m102.4 beginning at 10 h, 24 h or 72 h p.i. with the second infusion ~48 h later. All 12 animals that received m102.4 survived infection; whereas the untreated control subjects succumbed to severe systemic disease by day 8 (Bossart et al., 2011). There was no evidence of Hendra virus mediated pathology in any of the m102.4-treated animals and no infectious Hendra virus could be recovered from any tissues from any m102.4-treated subjects.

Table 1. Evaluation of post-exposure therapy with the henipavirus G glycoprotein-specific human monoclonal antibody m102.4 against lethal henipavirus challenge in laboratory animals.

Virus	Animal model	Experimental design and results[a]	Reference
Hendra	AGM	A 10, 24, or 72 h post-exposure use of m102.4 could protect against a 10-fold lethal intratracheal virus challenge	(Bossart et al., 2011)
	Ferret	A 10 or 24 h post-exposure dose of m102.4 could protect against a 10-fold lethal oronasal virus challenge	(Pallister J., unpublished)
Nipah	Ferret	A 10 h post-exposure dose of m102.4 could protect against a 10-fold lethal oronasal virus challenge	(Bossart et al., 2009)
	AGM	A 24, 72, or 120 h post-exposure use of m102.4 could protect against a 10-fold lethal intratracheal virus challenge	(Geisbert T., unpublished)

[a] The administration of m102.4 mAb was performed by infusion in all studies with the exception of one ferret in one study were it had to be administered by intraperitoneal injection (Bossart et al., 2009). All studies to date have reported that all animals receiving m102.4 post-exposure therapy have survived virus challenge, some with varying levels of mild to moderate illness.

In May of 2010, an instance of possible Hendra virus infection in two individuals was reported on the Sunshine Coast, north of Brisbane, Australia. Both individuals had extensive close contact with a horse just prior to and during the development of clinical illness in the animal. Following a diagnosis of Hendra virus infection in the horse, both individuals were considered to have had high-risk exposure to Hendra virus (Anonymous, 2010). A request was made by Australian health authorities to obtain m102.4 as a possible compassionate use therapeutic option even though clinical trials in human had not been undertaken and safety data of the mAb in humans was lacking. These two individuals were administered the m102.4 mAb (Miles, 2010). Both individuals ultimately did not develop detectable Hendra virus infection but whether this was due to the mAb therapy could not be determined. In 2010, the cell line expressing the human m102.4 mAb was provided to the Queensland Government, Queensland Health, to allow health authorities to manufacture m102.4 for its potential use on a compassionate basis in future cases of high-risk human exposure. In 2012, a third asymptomatic individual who experienced high-risk Hendra virus exposure was also given m102.4 mAb therapy (Anonymous, 2012a, Guest, 2012). There have been no adverse effects observed or reported in these cases.

5. A one-health solution – vaccination

Initial immunization strategies using the henipavirus G or F viral glycoproteins were first evaluated using recombinant vaccinia viruses providing evidence that complete protection from disease was achievable by eliciting an immune response to the Nipah virus envelope glycoproteins (Guillaume et al., 2004). Other studies using recombinant canarypox-based vaccine candidates for potential use in pigs have also been carried out (Weingartl et al., 2006). To date, the most widely evaluated henipavirus vaccine antigen has been a subunit, consisting of a recombinant soluble and oligomeric form of the G glycoprotein (sG) of Hendra virus (HeV-sG) (Bossart et al., 2005). The HeV-sG subunit vaccine (Fig. 1) is a secreted version of the molecule in which the transmembrane and cytoplasmic tail domains have been deleted from the coding sequence. HeV-sG is produced in mammalian cell culture expression systems and is properly N-linked glycosylated and retains many native characteristics including its oligomerization into dimers and tetramers, ability to bind ephrin receptors and elicit potent cross-reactive (Hendra and Nipah virus) neutralizing antibody responses (reviewed in (Broder et al., 2012)) Table 2.

Table 2. Evaluation of the protective efficacy of henipavirus sG vaccines against lethal henipavirus challenge in laboratory animals.

Virus	Animal model	Experimental design and results[a]	Reference
Hendra	Ferret	Hendra-sG used to immunize followed by 10-fold lethal oronasal virus challenge	(Pallister et al., 2011b)
	AGM	Hendra-sG used to immunize followed by 10-fold lethal intratracheal virus challenge	(Bossart et al., 2012)
	Horse	Hendra-sG is used to immunize horses followed by lethal oronasal virus challenge	(Balzer, 2011) (Middleton D., et al., submitted)
Nipah	Cat	Hendra-sG or Nipah-sG used to immunize followed by 10-fold lethal subcutaneous virus challenge; Hendra-sG used to immunize followed by 100-fold lethal oronasal virus challenge	(McEachern et al., 2008, Mungall et al., 2006)
	Ferret	Hendra-sG used to immunize followed by 10-fold lethal oronasal virus challenge	(Pallister J., unpublished)
	AGM	Hendra-sG used to immunize followed by 10-fold lethal intratracheal virus challenge	(Geisbert T., unpublished)

[a] All studies to date have reported that all Hendra-sG immunized animals can be completely protected from infection and disease following either a Hendra or Nipah virus challenge. No evidence of virus replication or shedding has been reported in the majority of challenged subjects.

Studies showing the HeV-sG subunit immunogen as a successful vaccine against lethal Hendra virus or Nipah virus challenge have been carried out in the cat (McEachern et al., 2008, Mungall et al., 2006), ferret (Pallister et al., 2011b) and nonhuman primates (Bossart et al., 2012) (Table 2), and details of the results from these studies have been reviewed elsewhere (Broder et al., 2012). The success of the HeV-sG vaccine-mediated protection observed in multiple animal challenge models led to the consideration of the HeV-sG as a safe and effective vaccine for horses against Hendra virus infection in Australia following a human fatality in 2009 and the human exposure cases in 2010 discussed above. The adopted equine vaccination strategy was to both prevent infection in horses and thus ameliorate the risk of Hendra virus transmission to people. A series of horse HeV-sG vaccination and Hendra virus challenge studies have been carried out in Australia; at the high containment biological safety level 4 (BSL-4) facilities of the Animal Health Laboratories (AAHL), Commonwealth Scientific and Industrial Research Organisation (CSIRO), in Geelong. The development of HeV-sG as an equine vaccine against Hendra virus was a collaborative research program between the Uniformed Services University of the Health Sciences, the Henry M. Jackson Foundation, the AAHL and Pfizer Animal Health (now Zoetis, Inc.). Findings from these initial studies were reported at Australian Veterinary Association, Annual Conference in Adelaide, in May 2011 (Balzer, 2011). The HeV-sG subunit glycoprotein was used to vaccinate horses (a 2 dose regime with a 3 week interval) and both a high and a low dose of HeV-sG antigen was examined. Following a high dose oronasal challenge with Hendra virus, all vaccinated horses remained clinically disease-free, and there was no evidence of virus replication or virus shedding in any of the immunized horses. On November 1, 2012, the vaccine called Equivac HeV® was released for use in Australia, and it is the first vaccine licensed and commercially deployed against a BSL-4 agent and currently is the only licensed prophylactic treatment for henipaviruses.

6. Concluding remarks

The Nipah virus and Hendra virus are zoonotic paramyxoviruses that can infect and cause lethal disease across a broad range of vertebrate species including humans. They are present in a variety of bat reservoirs, can be isolated and propagated and because of their associated high morbidity and mortality they pose a risk from natural outbreaks, laboratory accidents or deliberate misuse. For all of these reasons, the development of effective prevention and treatment strategies has been pursued. Over the past decade a considerable amount of research has focused on the henipavirus envelope glycoproteins and their roles in the virus attachment and infection process. These efforts have now led to the development and testing of both passive and active immunization strategies applicable to both human and animal use. Presently, a cross-reactive human mAb (m102.4) has been demonstrated as an exceptionally efficacious post-exposure therapy in protecting both ferrets and nonhuman primates from lethal henipavirus disease, and its effectiveness led to its application in people as a compassionate use post-exposure prophylaxis in Australia. Also, as an active vaccination strategy for preventing Hendra virus infection and disease in horses in Australia and thus blocking potential transmission to people, a recombinant subunit vaccine, HeV-sG, which has been shown to provide protection against henipavirus challenge in cats, ferrets, monkeys and now horses, has been licensed and deployed for use in Australia.

To date, henipavirus antivirals have only been deployed in Australia in the fight against Hendra virus. As Nipah virus causes significantly more instances of human disease, increased efforts are needed to advance Nipah-targeted countermeasures in endemic regions. Animal models have demonstrated that both the HeV-sG vaccine and the m102.4 human antibody can prevent both Nipah virus infection and/or disease. Efforts are currently under way to develop HeV-sG for human use as well as for use in pigs. However, the cost of the vaccine per animal and uptake of the vaccine in the absence of repeated outbreaks or disease will be critical factors influencing the feasibility of its application in Southeast Asia. The pre-clinical development of recombinant HeV-sG for use in people is only a first step and the acquisition of further support for manufacture and clinical trials will certainly be challenging. Clinical trials will also be needed for the m102.4 human antibody therapy, and both the United States and Australia are developing the m102.4 antibody for human use as a Nipah and Hendra virus countermeasure. Nipah virus has not occurred in Malaysia since 1998 and requests for compassionate use of the m102.4 antibody in India or Bangladesh following high-risk Nipah virus exposure or cases of infection have not occurred and may be difficult to orchestrate. Whether the antibody could be pre-positioned in Nipah virus endemic areas will largely depend on international cooperation and financial support.

RE: Chapter 14 by Professor Benhur Lee for Field's Virology: Emerging Viruses

Dear Benhur Lee,

Your submission entitled "Chapter 14" has been received by the editorial office.

You may check on the progress of your submission at any time by logging in to Editorial Manager as an author.

https://www.editorialmanager.com/wkmedprac/

Your username is: (b) (6)

You will be notified of the reference number assigned to your submission in due course. Please note that we have the following information on file for you and any coauthors on file. Please verify if this information is correct. If this is not correct, please respond and provide the correct information.

1. Professor Benhur Lee, MD
Secondary Name:

E-mail Address: benhur.lee@mssm.edu
Position: Ward-Coleman Chair in Microbiology
Institution: Icahn School of Medicine at Mount Sinai
Department: Microbiology
Street Address: One Gustave L. Levy Place #1124
City: New York
State: NY
Zip or Postal Code: 10001
Country or Region: UNITED STATES

2. Professor Christopher C. Broder, PhD
Secondary Name:
E-mail Address: christopher.broder@usuhs.edu
Position: Professor and Chair
Institution: Uniformed Services University of the Health Sciences
Department: Microbiology and Immunology

<H1>History

Hendra virus (HeV), the first known member of the genus *Henipavirus* in the family *Paramyxoviridae*, came to light in September 1994 as the causative agent of a sudden outbreak of acute respiratory disease in thoroughbred horses at a stable in Brisbane, Australia. A total of 21 horses and 2 humans (a horse trainer and a stable hand) became infected. The horse trainer and 14 horses died, and 7 horses with mild or subclinical infection were euthanized.[1,2] A virus was isolated, initially called *Equine Morbillivirus* but later re-named *Hendra virus* after the Brisbane suburb where the outbreak occurred. A second person died from HeV infection 13 months after the Brisbane outbreak, a farmer from Mackay, nearly 1000 km north of Brisbane. Unlike the first case, however, the man succumbed to encephalitis caused by HeV infection.[3] A forensic retrospective investigation found that the farmer had suffered a mild meningitic illness 14 months earlier after assisting at the necropsy of two horses that had died of severe respiratory distress—later found to have been caused by HeV[4]—and that he became infected at that time. After initial serologic evidence suggested that fruit bats (flying foxes) of the genus *Pteropus* in the suborder Yinpterochiroptera were the reservoir hosts.[5] HeV was isolated from two species of flying fox.[6] In total, there have been 60 recognized occurrences of HeV in Australia between 1994–2018, with at least one occurrence per year since 2006 (Table 14.1A-online).[7] Every occurrence of HeV has involved horses as the initial infected host, causing lethal respiratory disease and encephalitis, along with a total of seven human cases arising from exposure to infected horses, among which four have been fatal and the most recent in 2009 (Table 14.1B-online).[8]

Nipah virus (NiV), the second known member of the genus *Henipavirus*, emerged as the cause of an outbreak of disease in pigs and humans in Peninsular Malaysia in 1998 through 1999. The epidemic started in Perak State as clusters of cases of encephalitis among pig farmers. It was initially believed to be caused by Japanese encephalitis virus; however, various features of the outbreak, including a high proportion of cases in direct contact with pigs and illness and deaths in pigs, differed from those expected with Japanese encephalitis.[9] Indeed, respiratory illness and encephalitis in pigs preceded human cases in the same district.[10] The epidemic spread south to the intensive pig-farming areas of Negeri Sembilan in December 1998 and subsequently peaked between February and April 1999. More than 1 million pigs were destroyed to halt the spread of the epidemic, and by late May, 265 human cases of acute encephalitis with 105 deaths were recorded.[9,11] A cluster of 11 cases with 1 death occurred among abattoir workers in Singapore.[12] In early March 1999, a virus was isolated from the cerebrospinal fluid (CSF) of a patient with encephalitis and identified as the etiologic agent.[9,11] Named *Nipah virus* after the village from which the patient had come, it was shown to be closely related to HeV. NiV was subsequently isolated from the urine of Malaysian flying foxes.[13] A highly related NiV emerged in Bangladesh in 2001,[14] and outbreaks of NiV-related encephalitis have occurred in people from that country almost every year since, along with three reports of NiV encephalitis in India[15,16], albeit in Bangladesh adjacent regions. However, the most recent outbreak of NiV occurred in 2018 in Kerala (India), more than 2,500 km south-west of NiV-endemic Bangladesh counties. This outbreak claimed 21 lives out of 23 infected human cases.[17] In 2014, a NiV outbreak occurred in the Province of Sultan Kudarat, the Phillipines, which resulted in the death of 9 humans from 11 which showed an acute encephalitis syndrome.[18] The human case fatality rate of these NiV outbreaks averages around 60% (Table 14.1C). So far human NiV oubreaks have been documented in a total of five countries: Malaysia, Singapore, Bangladesh, India and the Philippines. Sero-epidemiological evidence for henipavirus spillover events from bats into high-risk human populations have also been reported in Cameroon.[19]

<TAB14.1C>

<H1>Infectious Agent

<H2>Classification

When HeV was first isolated in 1994, partial sequencing of the matrix gene (M) revealed that it most closely resembled members of the genus *Morbillivirus* in the subfamily *Paramyxovirinae.*[2] Subsequent characterization of the full-length genome, however, revealed that many of the genetic features of HeV were unique among paramyxoviruses and that the virus did not fit within any of the three genera existing at that time, *Morbillivirus, Respirovirus*, and *Rubulavirus.*[20,21] When NiV was isolated in 1999, it was initially described as Hendra-like on the basis of its strong reactivity with anti-HeV antibodies. Later it was shown that sera raised against HeV were able to neutralize NiV and vice versa, and that both viruses shared a high degree of similarity in genome organization and protein size and sequence.[11,22-24] In 2002, the genus *Henipavirus* was created to accommodate these novel paramyxoviruses, and HeV was designated the type species.[25] Since 1994, there have been 38 isolations of HeV or NiV from humans, bats, horses, and pigs over a wide geographic area and spanning a period of approximately 20 years (Table 14.2-online). The susceptibility of humans, the virulence of the viruses, and absence of therapeutics and vaccines led to classification of HeV and NiV as biosafety level 4 (BSL4) pathogens. In the latest report from the paramyxovirus study group under the order Mononegavirales, the genus *Henipavirus* has been expanded to include three new species,[26,27] they are *Cedar henipavirus* (Cedar virus, CedV) isolated from bats in Australia, [28] *Ghanaian bat henipavirus* (Ghana virus, GhV) detected in bats from Ghana, [29] and *Mojiang henipavirus* (Mòjiāng, MojV) detected in rats in China.[30] These three new species are highly divergent from NiV and HeV, and only CedV has been isolated. GhV and MojV are only known from sequence information. *Henipavirus* is now classified as one of the seven ICTV-approved genera in the family *Paramyxoviridae*.

Commented [BHL1]: Nomenclature will change pending official ICTV ratification in March 2019

<H2>Propagation in Cell Culture and Cytopathic Effect

The ultrastructural characteristics of henipavirus-infected cells resemble those found in cells infected by other members of the *Paramyxoviridae.* Shared features include generation of large syncytia and the presence of viral nucleocapsids in cytoplasmic inclusion bodies and underlying electron-dense areas of the plasma membrane.[31,32] In Vero cells, NiV-induced syncytia are significantly larger than those generated by HeV and nuclei and nucleocapsids are frequently located at the cell periphery, compared with HeV-induced syncytia, where they tend to be more centrally located or distributed randomly throughout the cytoplasm (Fig. 14.1). Henipavirus-infected cells also contain structures that are not seen with other paramyxoviruses—specifically a network of membrane-like reticular structures in the cytoplasm and long tubules that appear to be continuous with the plasma membrane in NiV-infected cells. Tubules can also be observed in NiV virions (Fig. 14.2A). *In situ* hybridization suggests that these reticular structures contain viral RNA and may play a role in viral transcription.[31]

<FIG14.1><FIG14.2>

<H2>Virus Morphology

Henipavirus particles are pleomorphic, varying from spherical to filamentous and ranging in size from 40 to 1,900 nm. [2,31,32] Nucleocapsids have a diameter of 18 to 19 nm with an average pitch of 5 nm. When examined by electron microscopy (EM), HeV has a unique double-fringed appearance, caused by the presence of surface projections 15 ± 1 nm and 8 ± 1 nm in length (see Fig. 14.2B). Approximately 95% of virions contain the double fringe, and the remaining 5% display a uniform fringe length of 15 ± 1 nm. Unlike HeV, NiV possesses a single layer of surface projections with an average length of 17 ± 1 nm, and NiV particles released into the culture medium are difficult to image because they are routinely penetrated by negative stains. This suggests that the viruses may differ in the physical nature of their envelope.[32]

<H2>Genome Length and Organization

In the family *Paramyxoviridae*, the genome length of all characterized viruses is divisible by six, an observation caused by the requirement of each N protein in the viral ribonucleoprotein to bind 6 nucleotide (nt) residues (see Chapter 13). This is also true for HeV and NiV despite their much larger genome sizes.[24] The genomes of the Malaysian (MY) and Bangladesh (BD) strains of NiV differ by 6 nt because of a 6-nt increase in the 3′ untranslated region of the *F* gene in NiV-BD.[33] A minigenome replicon study confirms that NiV complies with the rule of six.[34] When the complete genome sequence of HeV was determined, its length (18,234 nt) was more than 2,700 nt, or 15% longer than the genomes of all other paramyxoviruses known at that time.[21] The size of NiV genomes at 18,246 nt to 18,252 nt are slightly larger than that of HeV.[22,23,33] These large genome sizes of >18 kb is a conserved feature of henipaviruses as even the recently discovered and more divergent CedV, GhV, and MojV all have genomes between 18,162 nt (CedV) to ~18,430 nt (GhV). Given the caveat that there is wide variation amongst individual species of the other paramyxovirus genera, the extra length of the henipavirus genome is primarily due to the longer 3’ untranslated regions (3’UTRs) at the end of several of its six genes, and a larger *P* gene relative to the other paramyxovirus genera. A comparison of genome length and gene organisation of representative members of the *Paramyxoviridae* is shown in Fig. 14.3A. The nomenclature of each of the six major genes common to all paramyxoviruses have been updated to reflect the latest ICTV convention.[35] An analysis of the 3’ UTR lengths between extant henipaviruses and representative species from each paramyxovirus genera that infects mammals is presented in Fig. 14.3B. The most significant differences are in the 3’UTRs of *N*, *P*, and *RBP* genes even given the wide variance seen within each genus. The significance of long 3’ UTRs, especially in HeV and NiV, is generally unknown. However, the N gene 3’UTR of NiV appears to play a role in the downregulation of N mRNAs via specific interactions with hnRNP D.[36]

<FIG14.3A><FIG14.3B>

The genome organization of henipaviruses resembles that in the genera *Respirovirus* and *Morbillivirus*. The first 12 nt of the 3′ and 5′ genomic terminal sequences of paramyxoviruses are highly conserved and complementary, containing promoter elements for replication and transcription (see Chapter 13). The first 3 nt of the henipavirus genome termini are 5′-ACC-3′—a sequence that is absolutely conserved in members of the family *Paramyxoviridae* and different from that found in the family *Pneumoviridae.*

<H2>Virus Proteins and Their Properties

Analysis of purified viruses by polyacrylamide gel electrophoresis reveals RdRP (L), P, RBP (G), F_0, N, F_1, M, and F_2 proteins[20,24] where F_0 is the uncleaved and F_1 and F_2 the cleaved products of the *F* gene (Fig. 14.4A). Interestingly, F_0 is more readily detected in HeV compared with other paramyxoviruses, including NiV,[24,37] which may suggest that HeV-F is less efficiently cleaved. Overall, the proteins of henipaviruses are typical of those of *Paramyxoviridae*, with the exception of the P protein, which is significantly larger than cognate proteins in this virus family.[26] The P protein is translated from messenger RNA (mRNA) that is co-linear with genomic RNA. For most henipaviruses, the *P* gene also encodes V and W proteins, produced from mRNA in which one and two nontemplated G residues, respectively, are inserted at the RNA editing site during transcription. The P, V, and W proteins, therefore, are identical for the first 405 amino acid residues. A C protein is encoded by the 5′ end of the gene in an overlapping reading frame and is produced by an internal translational initiation mechanism, which is common to other members of *Paramyxoviridae*, except for rubulaviruses (see Chapter 13). The *P*-derived V, W, and C proteins are present in HeV-infected and/or NiV-infected cells.[24,38] It is worth noting that Cedar virus lacks both the RNA editing and expression of the V protein.[28] Similar to other paramyxoviruses, P itself and its derived proteins (V, W and C in the case of most

Commented [BHL2]: **LFW:** I obtained (free) permission/license to use this figure from your review in *Microbes & Infection*, 2001. It shows all the NiV and HeV proteins on the same PAGE gel in the order listed. Fig.14.4**A** complements (now) Fig. 14.4**B** (HNV life cycle) very well. It illustrates your point beautifully about HeV-F_0 being more detectable, and it technically does not add a figure.

BTW, matrix wasn't mentioned at all, so I did it at the end of this section. Our instructions were to talk about the *unique* aspects of the HNV life cycle in this infectious agent section. I referred to Fig. 14.4B quite a bit at the end of this section because F cleavage and matrix is relatively unique.

henipaviruses), all antagonize innate immune responses via a diverse set of mechanisms.[39,40] The C protein also interacts with the host cell ESCRT machinery and the virus matrix (M) protein itself to facilitate virus budding (see Pathogenesis section for more details on function of these P-derived proteins).[41]

<FIG14.4A><FIG14.4B>

Paramyxovirus N, P, and RdRP proteins are necessary and sufficient for replication of viral RNA both *in vitro* and *in vivo* as discussed in chapter 13. This has been confirmed for henipaviruses by reverse genetics. Using a minigenome replicon containing leader and trailer sequences of the NiV genome with its entire coding region replaced with a reporter gene, it was shown that efficient genome replication was achieved only when all three proteins were expressed in the same cell.[34,42] NiV N, P, and RdRP proteins were also able to rescue a minigenome constructed from the leader and trailer sequences of the HeV genome, demonstrating the close genetic relationship between the viruses. Full-length recombinant NiV bearing the matrix (M), fusion (F) and receptor binding protein (RBP) genes from HeV, singly or in combination, can also be functionally rescued. These chimeric but isogenic rNiVs replicate well in primary human endothelial and neuronal cells, further underscoring the genetic relatedness of NiV and HeV that allows for heterotypic complementation between their major structural proteins.[43] These henipavirus structural proteins contribute to unique aspects of the henipavirus life cycle (Fig. 14.4B), and play different roles in the spread and virulence of henipaviruses (as discussed in the Pathogenesis section).

The RdRP protein of nonsegmented, negative-stranded RNA (NNR) viruses in the order *Mononegavirales* contains a highly conserved GDNQ motif, believed to be important for polymerase activity.[44] Henipaviruses were the first NNR viruses in which GDNQ was replaced by GDNE. It was speculated that this motif might be unique to paramyxoviruses with relatively large genomes[21,24]; however, the GDNE motif has since been found in the

RdRP protein of Mossman virus that has a genome length of 16,650 nt.[45] Conversely, other henipaviruses of both Asiatic (CedV) and African lineages (GhV) also have the GDNQ motif that is common to most other NNR viruses. High-resolution cryo-EM structures of VSV-RdRP (another NNR virus, family *Rhabdoviridae*) suggest that GDN is the truly conserved catalytic motif essential for the polymerase function of RdRP.[46]

The receptor binding proteins (RBPs) of the *Paramyxoviridae* display hemagglutination (H) and neuraminidase (N) activities in a predominantly genus-specific manner. Viruses in *Respirovirus, Avulavirus*, and *Rubulavirus* genera possess both activities, hence their RBPs were formerly termed HN proteins[47] whereas viruses in the genus *Morbillivirus* do not behave uniformly and only some possess hemagglutination activity, but nonetheless their RBPs were formerly termed H.[48] This is an unfortunate misnomer. Paramyxoviruses with RBPs bearing HN activity genuinely use sialic acid based receptors for entry whereas "H" activity of some morbilliviruses arise from the ability of their RBPs to bind CD46 expressed on some non-human primate (NHP) red blood cells.[49] In contrast, henipavirus RBPs have neither of these activities[24,50]; rather, they utilize at least ephrin-B2, and in many cases, also ephrin-B3 expressed on host cell surfaces as attachment and entry receptors [51-54,28,55]. The exception is MojV, which does not appear to use any known paramyxovirus receptors.[56]

Recent solution structures of various henipavirus RBPs alone and in complex with the ephrin-B2 and/or ephrin-B3 receptors have revealed the details of the virus–host cell binding process, distinguishing it from other paramyxoviruses's receptor binding strategies.[57-59, 49,55,56] (Fig. 14.5)

Commented [BHL3]: **Note to Co-authors:** I added this structural phylogeny figure which shows all published HNV-RBPs in relation to RBPs from each of the other PMV genera. It highlights that MojV is an outlier.

<FIG14.5>

Proteolytic processing of paramyxovirus F proteins is essential for the generation of a fusogenic form of the protein. For most paramyxoviruses that generate systemic infections, furin-like proteases in the secretory pathway cleave their F proteins at a multibasic cleavage site.[60] Surprisingly, henipavirus F proteins are cleaved without the involvement of furin and, although cleavage occurs at a single basic residue—lysine for HeV and arginine for NiV.[37]—activation of the NiV F protein does not require a basic amino acid at the cleavage site.[61] Instead, endosomal/lysosomal cysteine proteases such as cathepsins L and B are responsible for the cleavage of henipavirus F proteins.[62-65] To access cathepsins L/B, henipavirus F proteins are endocytosed upon initially reaching the cell surface in an uncleaved form, and subsequently have to traffic back to the cell surface once they are cleaved into a fusion-competent form (Fig. 14.4B). [55,57] Classical endocytic YXXØ motifs [66,67] in the cytoplasmic tails of henipavirus F proteins and specific residues in the transmembrane domain of at least HeV-F regulate this trafficking behaviour through the early/sorting (S490) and recycling endosomal (Y498) compartments.[68] Henipavirus F proteins also have the ability to bud by themselves forming F-only particles in the absence of M.[69,70]

The matrix protein (M) plays a major role in the efficient assembly and budding of infectious paramyxoviruses.[71,72] M interacts specifically with N, the cytoplasmic tail of F, as well as cognate lipid ligands along the vesicular trafficking pathway. These orchestrated interactions help to co-ordinate the envelopment of encapsidated viral genomes (RNPs) and the budding of infectious virions bearing a relatively high density of viral envelope glycoprotein spikes. General details on the role that matrix plays in paramyxovirus assembly and budding are given in the previous chapter 13.

Henipavirus M exhibits some relatively unique behaviours and functions. For example, NiV and HeV M have classical nuclear localization and export sequences (NLS, NES) that when mutated give the relevant nuclear exclusion and nuclear retention phenotypes, respectively.[73] Time-course monitoring of M trafficking during live NiV and HeV infection indicates that M first appears in the nucleus, localizes to subnuclear compartments, including the nucleolus, before exiting into the cytoplasm and trafficking to the plasma membrane to coordinate virus assembly and budding (Fig. 14.4B).[73,74] This nuclear transit is regulated by ubiquitination and is critical for M to acquire its budding functionality.[73,75] Henipavirus M is multi-mono and poly-ubiquitinated; a lysine to arginine mutation of a key residue in its bipartite NLS is sufficient to dysregulate ubiquitination of M and abrogate its budding function.[73,75] The latter is true not only in HeV and NiV, but also in divergent henipaviruses (GhV, CedV, MojV), albeit to varying degrees.[76] Matrix interactome studies have identified many nuclear interacting factors, including importins and exportins, consistent with the nuclear-cytoplasmic trafficking phenotype of M.[75,77].

<H2>Host Range

For most paramyxoviruses, host range is limited and interspecies transmission is rare. In contrast, henipaviruses display a broad species tropism. In addition to a large number of bat hosts at various geographic locations (see more detail in Epidemiology section), NiV has naturally infected pigs, humans, dogs, horses, and cats,[10,11,78-80] whereas HeV infects all four Australian flying fox species and has naturally infected humans, horses and dogs.[2,81-83] Confirmation of the wide host range of these henipaviruses and the identical cell tropism of HeV and NiV were obtained early using an *in vitro* cell fusion system that relies on vaccinia virus–mediated cell surface expression of G and F glycoproteins.[84-86] Bats, guinea pigs, hamsters, ferrets, squirrel monkeys, and African green monkeys are also susceptible to experimental NiV infection.[87-91] Laboratory studies have added cats, guinea pigs, hamsters, ferrets, dogs and African green monkeys to the list of HeV-susceptible species.[83,92-96] CedV, isolated from flying foxes (*Pteropus sp.*) in Cedar Grove, Australia, can establish transient but non-pathogenic infections in laboratory challenged guinea pigs and ferrets. GhV and MojV, known only from sequence information, were identified from bats[29] and rats,[30] respectively.

<H1>Pathogenesis and Pathology

<H2>Entry into the host

Epidemiological and experimental studies generally support an oronasal [8,97,98] or oropharygeal[99-101] route of entry. This occurs directly or indirectly via saliva, urine, or oronasal scerections that are contaminated with relatively high levels of HeV or NiV.[83,95,97,102-113] Fig. 14.6 summarizes what is known about how NiV is transmitted to humans either directly from their pteropid reservoir hosts—fruit bats or flying foxes—or indirectly via a secondary amplifying host such as pigs, horses and humans. Direct bat-to-human transmission has been associated with consuming contaminated fruit or liquid (e.g. date palm sap) [99-101]. Human-to-human transmission of NiV has been well-documented, especially in Bangladesh[107,114-116] and the most recent outbreak in Kerala (India).[17] However, all 7 known cases of HeV infections in humans have resulted from contact with sick horses already exhibiting symptoms of respiratory distress,[117] likely after being exposed to food or water contaminated with saliva and urine/droppings from HeV-infected flying foxes.[118] While patients that succumb to henipavirus infections eventually die from encephalitic complications that often involve brainstem neuronal dysfunction,[98,119] there is diversity of clinical presentations.[120] For example, NiV-MY infected patients in Malaysia present less often with respiratory involvement (~40%) than the vast majority of NiV-BD infected patients in Bangladesh and India, including the latest outbreak in Kerala (India). The handful of HeV infected humans have also presented with encephalitic illness with or without a respiratory component (see Clinical Features section). To better understand the pathogenesis and pathology associated with henipavirus disease in humans, many relevant animal models have been developed that either represent natural amplifying hosts (pigs and horses) or that reproduce well the respiratory and encephalitic disease seen in humans (hamsters, ferrets and African green monkeys (AGMs)). [121,122] Despite the broad host range mentioned in the prior section, other animal challenge models (guinea pigs, cats, dogs) either do not represent the full spectrum of disease seen in humans, or are relatively asymptomatic when challenged with NiV and/or HeV.[83,121]

<FIG14.6>

<H2>Site of primary replication, virus spread, and cell and tissue tropism

The clinical and pathological data from humans (see Clinical Features section), relevant animal models, and cell tropism studies (Table 14.3) indicate that the initial site of replication is within the respiratory system, likely involving cells lining the oro-/naso-pharyngeal epithelium as well as bronchiolar epithelial cells, type I pneumocytes, alveolar macrophages or pulmonary airway dendritic cells (DCs).[40,122-125] The distribution and time of appearance of lesions throughout the vasculature and in the brain and lung in NiV encephalitis suggest that secondary infection probably arises via hematogenous spread of the virus, with secondary replication occurring in vascular endothelium.[126] Inflammation of blood vessels (vasculitis) occurs in most organs but is particularly prominent in the brain, lung, heart, kidney and spleen.[9,126,127]Vasculitis is limited to small arteries, arterioles, and capillaries where NiV antigen is found in both endothelial cells and the smooth muscle of the tunica media. The pattern and time of appearance of vasculitis and viral antigen distribution are consistent with endothelial cell infection occurring before infection of the smooth muscle. The 5-day interval between maximal vasculitis in the brain and parenchymal infection in acute NiV encephalitis suggests that virus replication occurs first in endothelial cells, with infection of neurons occurring as a result of vascular damage and breakdown of the blood-brain barrier (BBB). In humans as well as in pigs and hamsters, viral antigen positive brain microvascular endothelial cells can be observed in areas of compromised BBB integrity.[126,128,129] The presence of inclusion bodies and viral antigen in neurons, along with widespread histologic and radiologic lesions, suggests that neurologic impairment in NiV (and HeV) encephalitis may be caused by both the effects of ischemia and infarction and viral infection of neurons.[12,97,126]

<TAB14.3>

In addition to the systemic vasculitis, NiV antigen is clearly present in the parenchyma of multiple organs mentioned above. The same pathology has been reported for a fatal case of acute HeV encephalitis.[130] Similar widespread infection and multiorgan vasculopathy has been demonstrated in relevant animal models with the highest viral antigen load consistently seen in the lung and brain (Fig. 14.7). [121,122] Interestingly, intranasal inoculation in pigs, hamsters, and ferrets suggests that NiV can also directly invade the central nervous system (CNS) through the olfactory epithelium (OE). NiV antigen positive neurons or olfactory nerves can be found extending through the cribiform plate or in the nasal turbinate into the olfactory bulb.[123,129,131] While primary human OE cells are susceptible to henipavirus infection[132], the olfactory route is unlikely to be the major mode of CNS invasion in humans (and the AGM model). Primates have a relatively smaller area of OE compared to hamsters, pigs, or ferrets where the majority of evidence regarding the olfactory route of entry has been gathered.[87,129,131] In addition, NiV antigen was not detected in the olfactory bulbs of at least nine infected patients from the autopsy series reported from the Malaysian outbreak.[126]

<FIG14.7>

The widespread cell and tissue tropism of NiV and HeV seen in humans and the various animal models is determined by the expression pattern of the henipavirus receptors, ephrin-B2 and ephrin-B3.[51-54] The ephrinB ligands and their cognate EphB receptors are both receptor tyrosine kinases that mediate bidirectional cell–cell signaling events upon engaging each other. They are critical modulators of cell remodeling events, especially within the nervous and vascular systems.[133,134] They are also highly conserved among vertebrates, which explains, at least in part, the unusually broad species tropism of henipaviruses. Ephrin-B2 is found in arteries, arterioles, and capillaries in multiple organs, and is more broadly distributed across multiple tissues and cell types (Fig. 14.8), including neurons, arterial smooth muscle and human bronchiolar epithelial cells [133,135-137] but is absent from venous components of the vasculature.[138,139] In contrast, ephrin-B3 is essentially restricted to the brain[134] where it is expressed higher than ephrin-B2 (Fig. 14.8). Its relative absence from organs such as lung, kidney, and spleen, as well as from arterial endothelium suggest that the systemic vasculitis, respiratory distress, and other end-organ pathologies seen in henipavirus infections is largely a consequence of ephrin-B2-mediated entry. Conversely, ephrin-B3 mediated entry may play a larger role in the spread of HeV and NiV within the CNS.

<FIG14.8>

Human lymphocytes (mainly T- and B- cells), and monocytes, despite being non-permissive for NiV infection[140] or HeV-F/RBP induced fusion[84], can bind and transfer NiV to permissive microvascular endothelial cells *in vitro*. [140] This trans-infection phenotype, thought to be mediated by heparan sulfates,[141] may be an efficient form of hematogenous spread in addition to the free form viruses that make up the plasma viremia seen in acute NiV and HeV infections in humans. This acute but transient viremia appears about 4-7 days post-onset of illness (POI) and in survivors, is usually undetectable within 2-4 weeks POI depending on severity of the disease course.[17,142-144] A similar course of plasma viremia can also be detected in AGMs challenged intratracheally and orally with NiV.[88] The next section on the Immune Response will discuss possible mechanisms by which viremia is cleared in survivors.

<H2>Immune Response

Viral antagonism of innate immune responses

HeV and NiV have a broad host range that is uncommon in paramyxoviruses. This ability to replicate, spread, and cause acutely lethal disease amongst multiple species suggest that these viruses have evolved effective means to antagonize or evade innate antiviral responses that might otherwise keep them in check until adaptive immune responses develop. In henipaviruses, as in other paramyxoviruses, [40] the major anti-interferon (IFN) activities are encoded by the *P* gene and *in vitro* studies indicate that *P* gene products inhibit both IFN induction and signalling (Fig. 14.9). [39] In IFN induction, various forms of viral double-stranded RNA (dsRNA) are detected by cytoplasmic RNA helicases[145-147] such as RIG-I and MDA-5, and by toll-like receptor-3 (TLR-3). [147,148] Both of these dsRNA signaling pathways, via a cascade of signaling events depicted in Fig. 14.9 (left) lead to activation and nuclear translocation of interferon regulatory factor (IRF)-3, or if present, IRF-7, and nuclear factor kappa B (NF-kB); transcription factors that induce the expression of IFN-α/β proteins. HeV and NiV inhibit dsRNA signaling via its V protein, which binds to MDA-5 and prevents downstream signaling[145,149,150] but does not abrogate dsRNA signaling through TLR-3.[151] Recent evidence suggest that NiV-V also binds RIG-I and its regulator (TRIM25), disrupting downstream signalling. [152] In an additional strategy unique to henipaviruses, the W protein, by virtue of a NLS located in the unique carboxy terminal, inhibits induction of IFN-α/β expression in the nucleus by targeting a process that is part of both helicase-dependent and TLR-3–dependent signaling pathways.[153] Unexpectedly, the NiV M protein, can also inhibit IFN-α/β induction by indirectly antagonizing the activity of IKKε, the kinase responsible for IRF-3 activation.[154]

<FIG14.9>

In the IFN signaling pathway (Fig. 14.9, right), IFN binds to the IFN-α/β receptor (IFNAR) on cells and initiates a signaling sequence that leads to activation of members of a family of proteins called *signal transducers and activators of transcription* (STAT).[155,156] Henipaviruses inhibit IFN signaling by sequestering STAT proteins in high molecular weight complexes and preventing their phospho-activation .[157,158] The anti-IFN signaling activity is a property of the V protein, as has been observed for other paramyxoviruses, but also of the W and P proteins,[151,157,158] [159]The P, V, and W proteins of henipaviruses have an N-terminal extension of 100 to 200 amino acids compared with cognate proteins in the subfamily,[20,23] and the STAT binding domain of NiV V maps to this region.[151,160,161] The V and P proteins bind STAT in the cytoplasm, whereas the W protein, which is imported into the nucleus via specific interactions of its NLS with importin α-3, [162] likely sequesters unactivated STAT1 in the nucleus.[151,153] Recently, NiV and HeV N proteins were also found to antagonize IFN-signaling by interfering with formation of activated phospho-(p)STAT1 complexes. This NiV-N mediated antagonism of pSTAT1 nuclear accumulation does not rely on direct binding to or inhibiting phosphorylation of STAT1 itself. [163] NiV C has also been demonstrated to interfere with IFN-signaling.[164,165] However, its mechanism and true function remains unclear. Antagonizing IFN-signaling is unlikely to be the main function of the C protein since recombinant C-deficient NiVs have an attenuated replication phenotype even in Vero cells, [41,159,166]which are genetically deficient in IFN production.

There is little doubt that inhibition of IFN-α/β production is one major contributor to the acute virulence of HeV and NiV *in vivo*. Daily administration of poly(I)-poly(C(12)U), a potent IFN-inducer, results in >80% survival in a lethal challenge hamster model for NiV infections. [167] Most of the studies described previously were carried out *in vitro* using single-gene transfection expression systems. Understanding the true function(s) of these proteins requires assessing their impact in the context of a live virus infection or the phenotype of viruses deficient in the cognate protein(s). For example, IFN signaling apparently remains functional during live HeV and NiV infection of human cell lines, whereas IFN production was inhibited.[168] However, henipaviruses also clearly antagonize both IFN production and signaling in bat cells derived from *Pteropus sp*. that serve as their natural hosts. [169]

The diverse phenotypes observed in the various animal models when challenged with recombinant viruses deficient in the various P-derived accessory proteins makes interpretation difficult. The clearest phenotype comes from rNiVs engineered to be V-deficient. rNiV-ΔV are extremely attenuated in both hamster and ferret challenge models.[166,170] Each model re-capitulates the respiratory and neurological disease seen in human infections when infected with wt NiV, albeit in different ways and in a dose-dependent fashion.[93,121,171] However, challenge with V-deficient rNiV under conditions where their wt counterparts effectuate 100% mortality always results in 100% survival, and almost never results in any overt respiratory or neurological signs. [166,170] On the other hand, C-deficient rNiVs give a variety of phenotypes that range from strong attenuation in the hamster model, [172] to 100% mortality in the ferret model, albeit with less severe histological lesions in the lung. [173] Similarly, W-deficient rNiVs did not show significant attenuation compared to their wild-type counterparts in both the hamster[166] and ferret models, although the disease symptomology appeared to be more neurologic in the latter. [170,173] Interestingly, a rNiV lacking both C and W still resulted in 60% mortality with reduced respiratory disease but markedly increased neurological disease. [173]

Adaptive immune responses.

In patients with encephalitis, anti-NiV antibodies were observed more frequently in the serum than the CSF. Immunoglobulin M (IgM) antibodies occurred more frequently than immunoglobulin G (IgG) antibodies in both locations. [9,12,126]The appearance of specific IgM antibodies in serum preceded their appearance in the CSF, a sequence consistent with viremia preceding central nervous system (CNS) infection. Anti-NiV antibodies were present in most patients with clinical NiV encephalitis; however, no difference was observed in clinical features, laboratory results, or mortality between seropositive and seronegative patients. [98,174] Seroconversion of IgG against HeV was seen in two human cases of HeV infection in 2008, with one progressing to fatal encephalitis. [8] From these cases, seroconversion in acute henipavirus disease may have diagnostic but no apparent prognostic value. Conversely, in the most recent NiV outbreak in Kerala involving 23 cases, careful monitoring of humoral and cellular immune responses in the 2 survivors revealed that there was a dramatic increase in activated (Ki67+) CD8+ T-cells with an acute effector phenotype (CD38+/HLA-DR+/Granzyme B+ /PD1+), suggesting that virus-specific naïve T-cells were actively proliferating in response to the virus. Interestingly, clearance of viremia coincided with the peak of proliferating Ki67+ CD8+ T-cells, and occurred before peak IgG titers. [142] Increases in activated CD8+ T-cells in lethal (NHP)[175] and non-lethal (Swine) animal models of NiV infection have also been observed; [176] in the latter, prevention of virus shedding appears correlated with such T-cell responses. However, most animal studies do not monitor adaptive immune responses with the requisite precision and sophistication in order to make definitive statements regarding the relative importance of T- or B- cell responses in protective immunity against acute henipavirus infections.[177]

The high CFR associated with the acute nature of henipavirus infections already suggests that the virus interferes with the timely generation of effective T- or B- cell responses during the *natural* history of the disease in the majority of infected individuals. Indeed, although NiV replicates poorly in DCs (Table 14.3), [140,178] *in vitro* NiV-infected DCs induces an inflammatory pro-apoptotic milieu (TNF-a, IL-1β, IL-8) that leads not only to defective T-cell priming, but apoptosis of cognate T-cells and DCs. [178] This in vitro phenomenon, if recapitulated *in vivo* by NiV-infected DCs that traffic to lymph nodes, may account for the lymphoid depletion and lymphoid necrotic lesions seen in humans[126], and various relevant animal models. [179,180] [170]

<H2>Release from host and transmission

Transmission is generally accepted to occur via the oronasal route[8,97,98]or liquid/food (palm sap/fruit),[99-101] with transmissibility of HeV (horse-human or human-to-human) [181,182] being much less efficient than that of NiV transmission (pig-to-human or human-to-human).[9,15,17,98,105,107,116,183,184] Infectious NiV can be recovered from urine and the tracheal and nasopharyngeal secretions of infected patients in the early phase of their illness in the original Malaysian outbreak. [3,97,98] Nonetheless, human-to-human transmission in the Malaysian outbreak was extremely rare[185], although it has been reported in the more recent outbreak in the Philippines. In contrast, person-to-person transmission in Bangladesh has been well-documented and typically occurs during the final stages of disease in the index patient when not only symptoms of respiratory involvement are most prominent, but also more frequent and closer contact with familial caretakers occurs. [115,183,184]

Replication in the respiratory epithelium and shedding in oronasal secretions is most likely responsible for virus release and transmission. Ferrets have been used to model the respiratory transmission of henipaviruses[102,180] as their respiratory symptoms (cough, serous nasal discharge, dyspnea) mimic the human disease.[87] Despite shedding relatively large amounts of virus in their oronasal secretions (4-5 log10 $TCID_{50}$ equivalents/ml at peak titers), passively cohoused naïve ferrets never got infected, regardless of whether the index ferrets were infected with HeV, NiV-MY, or NiV-BD.[102,180] However, following assisted or direct exposure to infectious oronasal fluids from the index ferrets, all the naïve ferrets developed acute infections, regardless of virus strain used. [102] Thus, the efficiency of NiV transmission appears low, and likely requires direct and repeated oro- or naso-mucosal exposure to infectious oronasal secretions. This is consistent with epidemiological investigations into the many recurrent outbreaks in Bangladesh where despite chains of person-to-person transmission, the estimated basic reproductive number R_0 of NiV-BD strains that have spilled over in Bangladesh have averaged 0.48.[183]

<H2>Virulence

Infection with HeV appears more severe than infection with NiV-MY and NiV-BD in the hamster[128,186] and AGM model.[187] The dose-dependent disease symptomology in the hamster model[128,188] makes it difficult to make generalize statements about any intrinsic pathogenic difference between these three genetically distinct henipaviruses. However, the intratracheal and intranasal AGM challenge model appears to recapitulate the clinical pathologies seen in human patients more robustly.[88,93] Interestingly, it is also in this model that NiV-BD is shown to be more pathogenic than NiV-MY,[187] which reflects the observed differences in pathogenicity between NiV-MY and NiV-BD.   Previous studies comparing NiV-MY and NiV-BD in hamsters[186] and in ferrets[102] gave conflicting and confusing results. But more careful comparisons of fully-sequenced NiV-MY and NiV-BD strains in the AGM model provides support that NiV-BD is more pathogenic than NiV-MY,[187] which is consistent with the higher mortality rates associated with NiV-Bang (see Table 14.1C). Under identical experimental conditions, NiV-BD is not only shown to be more pathogenic in terms of viral load in lungs, spleen, and blood, but also that the therapeutic window for post-exposure prophylaxis using human monoclonal antibody (m102.4) is significantly shorter in NiV-BD infected AGMs.[187] m102.4 is a potent neutralizing mAb previously shown to rescue NiV-MY and HeV infected AGMs even when administered up to 7 days post-infection.[189,190]

CedV lacks the editing site in the *P* gene and does not make the V protein,[28] a potent type I IFN antagonist required for henipavirus virulence *in vivo*.[39] Not surprisingly, CedV, which is naturally V-deficient, also does not induce any overt disease in ferrets and guinea pigs.[28] Reactive hyperplasia of oropharyngeal lymphoid tissues and detection of viral RNA in select bronchial associated lymphoid tissue (BALT) accompanied by increasing neutralizing Ab titers suggests that CedV likely replicates transiently in the upper and lower respiratory tracts of the challenged animals.[28] While recent evidence suggests that the CedV P protein itself is also a less efficient antagonizer of IFN-α signaling compared to HeV-P,[191] whether CedV is truly non-pathogenic in humans or horses remains to be seen. Given the fact that CedV does not appear to use ephrin-B3 as receptor, one might also predict CedV to be less encephalopathic even in more susceptible animals.

<H2>Persistence

A small percentage of NiV-infected patients (3-7%) experience late-onset or relapse encephalitis months to years after the initial NiV infection; the former describes patients with initially mild or asymptomatic NiV infections while the latter are survivors of acute NiV encephalitis.[98,119,192,193] One case of fatal late-onset HeV encephalitis has also been reported. [3,130] These cases suggest that NiV and HeV can persist in sanctuary sites like the brain especially since virus has never been isolated from oronasal secretions of relapsed encephalitis cases.[9,97,126,192-194] (see Clinical Features section for details). There is one report of NiV RNA being detected in the semen of a NiV survivor 4 weeks post-onset of illness, but this was gone 2 weeks later. Longitudinal studies on 2 HeV survivors shows no evidence of viral shedding by RT-qPCR, up to 6 years post-symptom onset.[144] It is unlikely that NiV and HeV in humans can persist in infectious forms. Thus, relapse henipavirus encephalitis might resemble measles virus associated subacute sclerosing panencephalitis, which can occur years after recovery from measles virus infection.[195,196]

<H1>Epidemiology

<H2>Age

The age of patients with encephalitis in the Malaysian outbreak ranged from 9 to 76 years, with almost 50% of cases occurring in those 40 to 44 years.[98,126,143,174,197] The male-to-female ratio was approximately 3:1, and more than 80% of the patients were Chinese, with statistics reflecting the increased risk to those working with infected pigs.[98,197] In Bangladesh, the age of patients ranged from 4 to 60 years, and males constituted 47% and 67% of the cases in the 2001 and 2003 outbreaks, respectively.[14,198] The outbreak in early 2011 in Bangladesh claimed at least 35 lives, including many children and infants, with ages ranging from 2 to 56 years.[117,199] Among the 18 suspected patients in the 2014 oubreak in the Phillipines, the age distribution is between 21-60 years old.[18] In the most recent NiV outbreak in Kerala, India, the age distribution ranged from a 17 year old male to a 75 year old female among a total of 23 human cases.[17]

<H2>Morbidity and Mortality

In Malaysia, between September 1998 and June 1999, 256 patients who developed acute NiV encephalitis were admitted to Malaysian hospitals and 105 died, a mortality rate of approximately 40%.[9,197] The rate of subclinical infection in households and farms where cases of NiV encephalitis occurred was calculated to be 8% and 11%, respectively.[192,197] In Singapore, where 11 patients were confirmed to have acute NiV encephalitis, a further 2 asymptomatic abattoir workers were serologically positive, representing a rate of subclinical infection of 15%.[200] Subsequently, 89 individuals were identified on the basis of positive serology as having experienced either an asymptomatic or mildly symptomatic NiV infection.[119] This increases the number of people infected with NiV to 345 and decreases the mortality rate to approximately 30%.[127] In Bangladesh, 98 of 135 patients died in eight outbreaks from 2001 to 2008, giving a combined case fatality rate of 73%.[107,184,198] In the Philippines outbreak, the case mortality is 53% out of all the suspected cases or 81% for those with encephalitic clinical signs.[18] The case mortality is 94% for the 2018 Kerala outbreak in India.[17] There have only been seven known human cases of HeV infection in

Australia in the past 16 years, four of which have been fatal (three acute and one case of relapsed encephalitis).[2,3,8]

<H2>Origin and Spread of Epidemics

Fruit bats (flying foxes) in the genus *Pteropus*, family *Pteropodidae*, suborder *Megachiroptera* are main reservoir hosts of HeV and NiV.[5,6,13,79,201] In Australia, HeV has been shown to occur in all four flying fox species, with the crude seroprevalence of 47%, indicating an endemic pattern of infection throughout Australia.[81] Serologic tests show that NiV or NiV-related virus is widely dispersed in bats from Malaysia to the west border of Africa (Fig. 14.10). NiV was first isolated from the urine of Island flying foxes and from the saliva on partially eaten fruit[13] and has since been isolated from Lyle's flying foxes (*Pteropus lylei*) in Cambodia[79] and *Pteropus medius* in Bangladesh.[202] The Indian flying fox (*Pteropus giganteus*) is the main pteropid species throughout Bangladesh and the Indian subcontinent with a high seroprevelence of henipavirus-specific antibody.[14,100,183,203] Additional serologic and limited nucleic acid evidence has suggested that related henipaviruses are circulating in other regions, including Thailand, Indonesia, Vietnam, China, Madigascar, and several countries and regions in Africa (Fig. 14.10 and Table 14.4-online).

<FIG14.10>

Neither HeV nor NiV appear to cause clinical disease in flying foxes infected naturally,[81,198,201,204] and experimental infection with doses of HeV, consistently shown to be lethal in horses, generates only sporadic vasculitis in the lung, spleen, meninges, kidney, and gastrointestinal tract and only in a proportion of infected bats.[95] Viral antigen is detected in the tunica media rather than endothelial cells, a fact that may spare the flying fox from the clinical effects associated with vasculitis.[205] In infected pregnant flying foxes, antigen was observed in similar locations and in the placenta.[206] The mode of transmission between flying foxes is unknown. Transplacental transmission has also been observed experimentally without apparent harm to the fetus.[206] Experimental infection of flying foxes with NiV produced a subclinical infection with a transient presence of virus within selected viscera along with periodic viral excretion in bat urine and seroconversion with neutralizing antibody present.[90]

The spillover and epidemic hosts of HeV and NiV were horses in Australia and pigs in Malaysia. All human infections with HeV in Australia and NiV in Malaysia have only occurred through transmission from these domestic animal hosts.[9,197] No evidence exists of direct transmission from pteropid bats to humans in Australia or Malaysia, despite many opportunities in Australia for transmission to bat carers.[192,207] In contrast, flying foxes apparently play a direct role in the transmission of NiV to humans in the many recent outbreaks of disease in Bangladesh, where epidemiologic evidence in support of a role for an intermediate host was lacking.[14,198] Three pathways of NiV transmission from bats to people have been identified based on epidemiologic investigations in Bangladesh.[107] Consumption of fresh date palm sap appears to be the predominant risk factor, and infrared camera studies have confirmed that *P. giganteus* bats frequently visit date palm sap trees and consume sap during collection.[208] In the 2005 NiV outbreak in Tangail District, Bangladesh, drinking raw date palm sap was the only activity significantly associated with illness (64% among cases vs. 18% among controls).[100] Another route of transmission for NiV from bats to people in Bangladesh could be via domestic animals. Contact with a sick cow in Meherpur, Bangladesh, in 2001 was strongly associated with NiV infection,[14] and contact with pigs and diseased goats have also been implicated in other occurrences of NiV in Bangladesh.[107] Although NiV has never been isolated in domestic livestock animals, serological evidence was reported for antibodies to NiV or NiV-related viruses in cattle, goats and pigs in Bangladesh.[209] Transmission via direct contact with NiV-infected bat secretions also appears possible from evidence in the Goalando outbreak in 2004, where individuals who climbed trees were more likely to develop NiV infection than controls.[210]

The mode of transmission from bats to spillover hosts in Australia and Malaysia remains to be determined. Three principal hypotheses exist. One is that masticated pellets of virus-contaminated, residual fruit pulp spat out by flying foxes are ingested by horses or pigs.[201] The second is that urine from infected animals contaminates pastures or pigsties. The third is that infected fetal tissues or fluids contaminate pastures or sties and are ingested. The latter is based largely on the fact that the HeV outbreaks have occurred during the birthing period of some species of flying fox and is supported by the isolation of virus from a pregnant flying fox and its fetus.[6]

HeV has been transmitted from horse to man on seven occasions from 1994 to 2009, twice during the initial outbreak in Brisbane,[1,2] twice during necropsy of horses that died in the field,[1,4] twice during either daily nasal cavity lavage and participating in a necropsy,[8] and once from performing an endoscopy on an infected horse.[8,211] HeV is rarely found in the bronchi or bronchioles of infected horses, which suggests that aerosol transmission to either man or horses is less likely[212] and horse-to-horse transmission of HeV has not been demonstrated.[95] The presence of HeV in equine saliva, however, suggests that close contact with infected horses, such as might occur during manual feeding of the animals, may facilitate horse-to-human transmission.[1] The presence of virus in a wide range of tissues and in the nasal discharge commonly found at the terminal stage of infection offers a range of sources for virus transmission during necropsy.[2,213] As shown in Fig. 14.6A, high level of viral antigen can be detected in the nasal cavity of HeV-infected horses.

In the Malaysian NiV outbreak, contact with pigs or fresh pig products was required for transmission of the virus to humans, with greater likelihood of transfer to those in direct contact with sick or dying pigs on farms or in abattoirs.[9,197] The presence of NiV in the respiratory epithelium of naturally and experimentally infected pigs (Fig. 14.6B) indicated that virus probably spread to humans and within the pig population by aerosol or by direct contact with oropharyngeal or nasal secretions.[10,111,129] The presence of the virus in a wide range of organs indicates that humans may also have been infected during processes such as slaughtering or farrowing. In Bangladesh, pigs were excluded as potential sources of NiV on epidemiolog grounds, and human-to-human transmission was observed.[116,184] The virus may have been transmitted to human index cases directly through contact with fruit bat secretions in contaminated fruit or date palm sap before circulation in the human population.[13,14,107,198] Nosocomial transmission has been detected in some of the Bangladesh and India outbreaks.[15,107,214] In the Philippines NiV outbreak, Of the 17 case-patients, a total of 7 (41%) had participated in horse slaughtering and horse meat consumption; 3 (18%) had only consumed horse meat and but had no history of slaughtering or meat preparation; 5 (29%) case-patients had been exposed to other human casepatients but not to any horses. So it is possible that both horse-to-human and human-to-human transmission might have occurred.[18] For the Kerala NiV outbreak, while it remains undefined how the index case was exposed to NiV, it was evident that human-to-human transmission was the main driver for the spread of the virus in both family/community and hospital settings.[17]

<H2>Genetic Diversity

Genome sequencing revealed that HeV isolated from equine and human sources during the outbreak in Brisbane appears identical and differs little from HeV isolated from flying foxes 2 years later.[2,6] Sequencing of five additional horse isolates from five different locations from the 2006 to 2008 HeV occurrences has also demonstrated a very high genetic similarity.[215] Similar observations were made in Malaysia, where it was demonstrated that NiV isolated from pigs at the height of the outbreak and at its geographic focus were essentially identical to human isolates made at that time and isolates obtained from flying foxes several years later.[13,22,23,216]

In Bangladesh, four human isolates obtained in 2004 demonstrate significant genetic heterogeneity, which might suggest multiple spillovers of NiV from flying foxes into the human population.[33] The NiV sequences detected from human patients in India from 2001 to 2018 were more related to NiV from Bangladesh than NiV from Malaysia.[15,17,214] A recently whole genome sequencing study of ten NiV isolates obtained from bats in 2013 in Bangladesh at two different geographic locations revealed that the isolated viruses were very similar in sequences. This suggests that multiple strains were not co-circulating in the bat population at the time.[202] Furthermore, none of the bat NiV isolate sequences was identical with any previously detected human NiV isolate sequences, suggesting that NiV spillover into humans is a rare event and more intensive surveillance is required to appreciate the full genetic diversity of NiV in bats in an area with frequent spillover events into human populations.[202] NiV isolated from the flying fox *Pteropus lylei* in Cambodia[79] represents an evolutionary lineage that is separated from the Malaysia or Bangladesh/India cluster . Partial *N* gene sequences detected in *Pteropus lylei* in Thailand indicate the circulation of at least two lineages of NiV—one related to the Bangladesh NiV and the other more related to the Malaysian NiV.[109] On the other hand, NiV sequences detected in *Pteropus hypomelanus* in southern Thailand are clearly more related to the Malaysian NiV.[217] As the RNA-dependent RNA polymerase (RdRP), also known as the L protein, is the most highly conserved protein for paramyxoviruses, it has been used as a more reliable indicator of evolutionary relationship among different paramyxoviruses. Shown in Fig. 14.11 is phylogenetic tree based on RdRP proteins of prototype species of each genera in the family *Paramyxoviridae* with major members of the genus *Henipavirus*, selected to represent major species origin, geographic location and time of isolation.

<FIG14.11>

The presence of henipavirus-reactive (but not neutralizing) antibodies and viral RNA in bats from other regions of the world (Fig. 14.10 and Table 14.4-online) predicts that a much greater genetic diversity of henipaviruses exists in different bat populations. This also suggests the existence of henipaviruses with different transmissibility and pathogenicity in non-bat hosts.

<H1>Clinical Features

<H2>Incubation Period

Based on the time interval between the last exposure to pigs and onset of disease, the incubation period for NiV ranged from 2 to 45 days; however, for 90% of patients, it was 2 weeks or less.[98,143,174] An estimate of 2 to 3 weeks was made based on the time interval between importation of pigs from NiV-affected areas of Malaysia and development of human disease at a Singaporean abattoir.[200] A mean incubation period of 9.4 days was calculated for four patients who had a fixed period of exposure.[174] The NiV outbreak in Kerala, India, 2018, revealed a median incubation period was 9.5 days among 23 cases, 22 of which were nosocomial.[17] In the occurrence of HeV in Australia in 2008, a detailed examination of exposure histories from two infected patients (one fatal) suggested a likely incubation period of 9 to 16 days, with exposure occurring some 3 days before the onset of symptoms of HeV infection in the horse.[8]

<H2>Acute Clinical Features

The first two patients infected with HeV presented with fever, myalgia, headaches, lethargy, and vertigo. One patient recovered; however, the other developed pneumonitis, respiratory failure, renal failure, and arterial thrombosis, and died of cardiac arrest 7 days after admission to the hospital. Findings at autopsy were consistent with a viral infection; both lungs were congested, hemorrhagic, and filled with serous fluid, and the histology revealed focal necrotizing alveolitis with many giant cells, some syncytial formation, and viral inclusions.[1] Although the predominant clinical features of NiV encephalitis derived from CNS involvement in the initial Malaysia outbreak, a proportion (40%) of patients displayed pulmonary involvement, which presented as an atypical pneumonia with fever, cough, and headache.[12,98,126,174] In the Kerala, India NiV outbreak, 19 cases (83%) presented with acute respiratory distress syndrome (ARDS) and shortness of breath, and 20 cases (87%) had respiratory symptoms.[17] The clinical presentation of NiV infections in Bangladesh also shows severe respiratory disease involvement.[218] A chest X-ray of an acute NiV-infected human case showing diffuse bilateral opacities of the lung fields consistent with ARDS (Fig. 14.12A) and a similar presentation was reported in the first fatal human HeV case.[1] Chest X-ray images of NiV and HeV-infected AGMs have also demonstrated severe respiratory disease (Fig. 14.12B). Case definitions for suspected NiV infection in Bangladesh[218] and India[15,17] generally included individuals residing in an outbreak area who presented with fever, headache, vomiting or altered mental status or with history of cough or shortness of breath and fever.

<FIG14.12>

With NiV in Malaysia, most patients presented with acute encephalitis characterized by fever, headache, drowsiness, dizziness, myalgia, and vomiting, and more than 50% had a reduced level of consciousness.[9,12,98,174] The major clinical signs included drowsiness, areflexia, segmental myoclonus, tachycardia, hypertension, pinpoint pupils, and an abnormal doll's eye reflex. Such clinical features as these suggested involvement of the brain stem and upper cervical spinal cord, and were observed more frequently in patients with a reduced level of consciousness.[98,219]In Kerala, India, 2018, NiV-infected patients presented with altered sensorium (74%), along with myalgia, headache, vomiting, and seizures.[17] Patients in the NiV-Malaysia outbreak who retained normal levels of consciousness throughout their illness recovered fully; however, only 15% with reduced levels of consciousness survived. Figure 14.13 shows magnetic resonance imaging (MRI) images of human cases of acute NiV encephalitis (India, 2018 and Malaysia, 1999). Such neurologic manifestations are consistent with vasculitis-induced thrombosis in the brain and the direct infection of neurons.[9,11,12,126] The multiple discrete lesions 1 to 5 mm in diameter in the cerebral white matter detected by MRI may be the site of such microinfarctions and are distinct from lesions caused by other viruses.[9,12,130,192,220] A third case of HeV infection presented first with meningitis and a 12-day history of sore throat, headache, drowsiness, vomiting, and neck stiffness. After an apparent full recovery, this patient developed fatal encephalitis 13 months later and was admitted to the hospital with a generalized tonic-clonic seizure after 2 weeks of irritable mood and low back pain. Recurrent focal motor seizures occurred over the next 7 days, as did secondarily generalized seizures and low-grade fever, followed by dense right hemiplegia, signs of brain stem involvement, and depressed consciousness requiring intubation. The patient remained comatose and died 25 days after admission.[3] Two patients in 2008[8] presented with initial influenza-like illness, although soon after apparent clinical improvement and an absence of fever, encephalitis developed in both. MRI revealed widespread cortical, subcortical, and deep white matter involvement, similar to the previous late-onset case of HeV encephalitis[3] and to NiV encephalitis cases (Fig. 14.13B).[98,192,221]

<FIG14.13>

<H2>Outcome of Infection

Most patients who survived acute NiV encephalitis in Malaysia made a full recovery; however, approximately 20% had residual neurologic deficits.[98,174,222] Neurologic sequelae included cognitive difficulties, tetraparesis, cerebellar signs, nerve palsies, and clinical depression. A few patients remained in a vegetative state. In patients with encephalitis who recovered, most brain lesions revealed by MRI disappeared or became smaller over a period of 12 to 18 months, although some remained unchanged during this period.[222] Approximately 7.5% of patients who recovered from acute encephalitis and 3.4% of those who experienced nonencephalitic or asymptomatic infection developed late neurologic disease (Fig. 14.13).[98,119,192,193] Relapse encephalitis and late-onset encephalitis presented several months to 4 years after the initial infection, with the longest reported case 11 years after an initial acute infection.[223] Relapsed cases had elevated IgG, but not IgM, and no vasculitis, and unlike the situation in acute encephalitis, virus was not isolated from throat and nasal secretions.[9,97,126,192-194]

The clinical features associated with relapse and late-onset encephalitis resembled those found with acute NiV encephalitis, although decreased incidence was seen of fever, coma, segmental myoclonus, and meningism and an increased occurrence of seizures and focal cortical signs compared with the acute manifestation of the disease.[119] The clinical, radiologic, and pathologic features of relapse NiV encephalitis resembled those of the patient who became infected with HeV, suffered mild, transient aseptic meningitis, and recovered but died of a fatal meningoencephalitis 13 months later.[3,130] Most patients with relapse and late-onset encephalitis had only one neurologic episode, although some patients experienced two episodes separated by a mean of 7.6 months (6 weeks to 1 year).[119] The mortality rate associated with relapse and late-onset encephalitis at 18% was lower than that associated with acute encephalitis, at 30% to 40%. However, 61% of patients with relapse and late onset had further neurologic sequelae compared with 22% after acute encephalitis. Among NiV survivors in Bangladesh, some 30% have moderate to severe persistent neurologic dysfunction for years following acute infection.[192]

The demographics, clinical features, serology, and MRI of patients with relapsed and late-onset encephalitis were similar, suggesting that the two diseases have identical pathogenesis[119] and that the initial infection in late-onset encephalitis patients may not have been sufficiently severe to cause neurologic symptoms. MRI abnormalities similar to those observed in patients with acute encephalitis were also seen in 16% of asymptomatic patients, although the lesions were fewer in number. [219] The involvement of the cortex in relapse and late-onset encephalitis suggests a different pathologic mechanism compared with acute encephalitis. Relapse and late-onset encephalitis are considered to be caused by the recrudescence and rapid replication of virus that had persisted following acute or asymptomatic NiV infection.[119] NiV, however, was not isolated from CSF and brain tissue of patients with relapse and late-onset encephalitis.[119]

<FIG14.14>

The generalized understanding of the infection process along with the clinical features of human NiV and HeV infection is diagrammed in Fig. 14.14. Transmission is likely via the oronasal route as described the above section on Pathogenesis. The initial site of replication in humans is likely within the respiratory system and disease onset is characterized by fever, myalgia, shortness of breath, cough, which may progress to ARDS. Possible invasion into the CNS via the olfactory bulb has also been suggested and has been demonstrated in animal models. [224]Virus replication and hematogenous systemic spread occurs (cell-free or cell-associated viremia) and established infection is characterized by a widespread vasculitis with endothelial and smooth muscle cell tropism resulting in multinucleated syncytial cells.[126] CNS infection and encephalitis results in altered sensorium, headache, vomiting, and seizures along with fever and other systemic symptoms. Infection of other organs in addition to lung and brain in human cases occurs and has been reported in kidney, heart, spleen and lymphoid

Commented [BHL4]: Chris: I took 2-3 sentences out from here and put it into my pathogenesis section on “transmission”. Hope you don’t mind.

tissues,[126] and similar widespread infection has been demonstrated in multiple animal models.[121]

<H1>Diagnosis

Virus isolation, EM, immuno-EM, immunohistochemistry (IHC), serology, and polymerase chain reaction (PCR) played key roles in the initial discovery of HeV[2] and NiV,[11] and they remain essential elements in a repertoire of procedures for the rapid and specific diagnosis of henipavirus infections in humans and animals.

During investigation of a suspected disease outbreak, attempts to grow henipaviruses may be initiated in a BSL3 laboratory. However, if a cytopathic effect (CPE) is observed and the growth of henipavirus is confirmed by PCR or immune staining, infected cultures should be handled under BSL4 conditions and subsequent work with live virus restricted to BSL4. Both HeV and NiV replicate in various cell lines—a feature that contributed to the efficiency with which they were isolated during the initial disease outbreak investigations.[2,11] Vero cells are commonly used, generating titers of virus as high as 10^8 infectious virions per milliliter.[143,225] In fatal cases, attempts should be made to isolate virus from brain, lung, kidney, and spleen.[225] For tissue specimens containing a high virus load, direct examination by immuno-EM and IHC can be very useful in providing early diagnosis. Various antibody reagents have been developed for this purpose, including polyclonal antisera, monospecific antibodies raised against recombinant antigens,[20] and monoclonal antibodies (mAb) raised against whole virions or vaccinia virus–expressed viral proteins.[226-229] Using HeV- or NiV-specific mAb, it is possible to differentiate between the two viruses.[228,229] Quantitative real-time PCR (TaqMan assay) has been the method of choice to detect viral materials in infected tissues because of its speed, specificity, and sensitivity. The first-generation henipavirus TaqMan assays are either HeV specific[230] or NiV specific.[231] Since then, several consensus henipavirus real-time PCR assays have been developed that target different conserved regions of the viral genome.[232] It should be cautioned that the current PCR tests may not work with new henipaviruses yet to be discovered, especially those from African bats, owing to expected greater genetic divergence than those detected in Australia and Asia.

For henipaviruses, serologic tests are important both during outbreak investigation and for disease surveillance. The virus neutralization test (VNT) is accepted as the reference standard.[225] Few laboratories, however, can conduct neutralization tests because of the requirement to handle live virus at BSL4. For surveillance and diagnostic purposes, three types of tests that do not require BSL4 containment have been developed:

1. *Enzyme-linked immunosorbent assay (ELISA):* Several ELISA-based tests have been reported for the detection of henipavirus antibodies.[225,233,234] For diagnosis of human infections, two different ELISA tests have been applied: an IgM capture ELISA for early diagnosis of infection and an indirect ELISA for detection of IgG antibodies.[225]
2. *Liquid protein array multiplex test:* A Luminex-based test based on recombinant soluble G proteins of HeV and NiV was developed that is capable of mimicking VNT with great sensitivity and differentiating between antibody responses of HeV versus NiV infection.[235]
3. *Pseudotype virus:* Different pseudotype systems carrying the henipavirus F and G proteins have been developed as a surrogate VNT for detecting henipavirus-specific antibodies.[18,236-238] Incorporation of reporter genes in these systems resulted in greater sensitivity and reproducibility.

<H1>Prevention, and Control

<H2>Drugs and Small molecules

Ribavirin, which inhibits replication of HeV *in vitro*,[239] was used during the NiV outbreak in Malaysia in an open-label study in which 140 patients with encephalitis were given the drug, and 54 patients who presented before ribavirin became available or who refused treatment acted as controls.[240] Mortality in the treated group was 32% compared with 54% in the control group, representing a 35% reduction ($P = 0.011$). Duration of ventilation and total hospital stay were both significantly shorter in the ribavirin group ($P = 0.0002$ and <0.0001, respectively). In the absence of other therapies, ribavirin may be an option for treatment of henipavirus infections. However, two HeV-infected patients in 2008[8] were given a high-dose intravenous regimen of ribavirin, although basal concentrations appeared inadequate given the results of *in vitro* susceptibility testing of HeV, and the efficacy of ribavirin as therapy or prophylaxis in people remains at best uncertain. Chloroquine, an antimalarial drug, was first demonstrated to block the critical proteolytic processing needed for HeV F maturation and function.[241] Not surprisingly, the drug was later shown to inhibit NiV and HeV infection in cell culture experiments.[242] Chloroquine was administered along with ribavirin to one HeV-infected individual in 2009[243] with no apparent clinical benefit. Remdesivir (GS-5734) is a nucleotide analog prodrug that showed therapeutic efficacy in a nonhuman primate model of Ebola virus infection.[244] GS-5734 has been administered under compassionate use to Ebola virus infected patients and is currently in Phase 2 clinical development for treatment of Ebola virus disease. The antiviral activities of GS-5734 has been demonstrated to be broad showing *in vitro* activity against viruses in the *Coronaviridae, Filoviridae* and the *Paramyxoviridae* including NiV and HeV.[245]

In vivo, ribavirin only delayed but did not prevent deaths caused by NiV and had no effect on HeV infection in a hamster model.[167,246] Ribavirin treatment also only delayed disease onset by 1 to 2 days in African green monkeys challenged with HeV with no significant benefit for disease progression or outcome.[93] Chloroquine administration, either alone or in combination with ribavirin, had no therapeutic benefit in ferrets challenged with NiV or hamsters challenged with either NiV or HeV.[246,247] Poly(I)-poly(C12U), which induces IFN-α and -β production and can completely block NiV replication *in vitro*, displayed some protective activity in the hamster model of lethal NiV infection.[167]

<H2>Peptide Fusion Inhibitors

The first potential henipavirus-specific therapeutic was shown to be a heptad peptide-based fusion inhibitor,[85] analogous to HIV-1-specific peptide, enfuvirtide (Fuzeon) approved by the Food and Drug Administration (FDA) in March 2003. The henipavirus F_1 glycoprotein resembles other fusion glycoproteins in having α-helical heptad repeat (HR) domains proximal to both the fusion peptide at the amino (N) terminus and the transmembrane domain near the carboxy (C) terminus of the protein. The HR domains are involved in the formation of a trimer-of-hairpins structure during the membrane fusion and virus infection process. Addition of exogenous peptide from either HR domain blocks formation of the trimer-of-hairpins and abrogates membrane fusion and virus infection.[84,85,248] These observations were followed up with testing cholesterol tagged HR-derived peptides in the hamster model of NiV infection providing the first evidence of *in vivo* effectiveness of a fusion inhibiting peptide against NiV.[249]

<H2>Vaccines

A wide variety of immunization strategies have been developed for NiV and HeV prevention and include live-recombinant virus platforms, protein subunit, virus-like particles and DNA vaccines, however many of these approaches have only been examined for HeV- or NiV-specific neutralizing antibody induction.[250] A more limited number of vaccine candidates have been examined for both immune response and efficacy using a variety of animal challenge models (Table 14.5). Attenuated vaccinia virus strain NYVAC recombinants encoding either the NiV F or G glycoproteins used to immunize hamsters provided complete protection from NiV-mediated disease following challenge and demonstrated that an immune response to the viral envelope glycoproteins were an important immunogen in protection.[251] A second poxvirus-based approach was developed as a potential livestock vaccine using recombinant canarypox virus with the NiV F and G genes inserted into ALVAC vectors (Table 14.5). ALVAC vectors expressing either NiV F or NiV G were tested individually and in combination by vaccination of piglets, and animals were challenged intranasally with NiV. Piglets were protected from NiV-mediated illness by either ALVAC vector alone or in combination and immunized animals shed only low levels of nucleic acid detectable virus and no recoverable virus was evident.[252] Three other viral vector-based NiV vaccines have been examined in animal challenge studies (Table 14.5). An adeno-associated virus (AAV) platform using the NiV G glycoprotein was tested in the hamster model using NiV challenge, showing complete protection against NiV, but only low level cross-protection (3 of 6 animals) against a HeV challenge.[253] A recombinant measles virus vector encoding the NiV G glycoprotein was examined using two different vectors; the HL (rMV-HL-G) and Edmonston (rMV-Ed-G) measles virus strains[254] (Table 14.5). Here, complete protection from NiV disease was achievable in the hamster challenge model following vaccination with either rMV-HL-G or rMV-Ed-G, and the rMV-Ed-G was tested in the nonhuman primate model demonstrating 2 of 2 AGMs were protected against NiV challenge. Several groups have tested the vesicular stomatitis virus (VSV) based platform using the NiV F or G glycoproteins (Table 14.5). In the ferret model, a single immunization with VSV encoding either NiV F or NiV G could afford complete protection from NiV challenge.[255] Similarly, NiV G or F glycoproteins in VSV vectors were successful in protection from NiV challenge in the hamster model,[256,257] and a single immunization of NiV G encoding VSV was protective in the AGM model.[258,259]

<TAB14.5>

The most extensively tested vaccine against NiV and HeV has been a recombinant protein subunit strategy because of the inherent safety of such an approach. Soluble, secreted, oligomeric forms of the G glycoprotein (sG) from both NiV and HeV were developed and tested as possible vaccine candidates and the HeV-sG was show capable of eliciting a more potent cross-reactive polyclonal antibody response and also a better cross-protective response[260,261] (Table 14.5). HeV-sG is a soluble and secreted version of the molecule with a genetically deleted transmembrane and cytoplasmic tail that is produced in mammalian cell culture systems and is properly N-linked glycosylated[262] (Fig. 14.15). HeV-sG has been shown to retain many native characteristics including oligomerization and ability to bind ephrin receptors,[52,260] and is capable of eliciting potent cross-reactive (HeV and NiV) neutralizing antibody responses in a variety of animals including mice, rabbits, cats, ferrets, monkeys and horses.[250] The HeV-sG vaccine in the cat model provided complete protection against a lethal NiV challenge[261] and suggested a single subunit vaccine (HeV-sG) could be effective against both HeV and NiV. Further studies in the cat model revealed that antibody titers as low as 1:32 could protect against NiV-Malaysia challenge[263] (Table 14.5). Studies in the ferret model with low vaccine doses of HeV-sG formulated in CpG and Allhydrogel™ could completely protect against high dose HeV challenge.[96] Immunization and challenge studies in ferrets with the NiV-Bangladesh strain also demonstrated complete protection.[264] In addition, good durable immunity was shown in other ferrets challenged 434 days post-vaccination.[264] However, preliminary studies with HeV-sG as a vaccine in the pig model was less effective against HeV and un-protective against NiV, and both humoral and cellular immune responses were required for protection of swine against henipaviruses in that challenge model.[176]

<FIG14.15>

The HeV-sG vaccine has also been extensively evaluated in nonhuman primates (AGMs). Monkeys immunized with HeV-sG formulated in Allhydrogel^{TM} and CpG were completely protected against intratracheal challenge with NiV-Malaysia, some with pre-challenge neutralizing titers as low as 1:28, and no evidence of clinical disease, virus replication, or pathology was observed in any vaccinated monkeys.[265] Similarly, HeV-sG vaccination and protection from a HeV challenge in AGMs has also been shown, including HeV-sG formulated in Allhydrogel^{TM} alone.[266] The inherent safety and effectiveness of the HeV-sG vaccine led to its development as an equine vaccine to prevent not only HeV infection of horses but also as the means to reduce the risk of HeV transmission to people (Figure 14.16A). HeV-sG was licensed by Zoetis™ Inc., (formerly Pfizer Animal Health) and developed as an equine vaccine for use in Australia. Horse HeV-sG vaccination and HeV challenge studies were conducted at the BSL-4 facilities of the Animal Health Laboratories (AAHL) in Geelong[267] (Table 14.5). HeV-sG was formulated in an approved equine adjuvant (Zoetis, Inc.) and two initial efficacy studies in horses tested 50 µg and 100 µg doses of the same HeV-sG used in published animal studies was used to immunize horses. Additional studies used a 100 µg dose of HeV-sG produced in CHO cells (Zoetis, Inc.). Immunizations were two doses given intramuscularly 3-weeks apart. All horses in these efficacy studies were challenged oronasally with 2×10^6 $TCID_{50}$ of HeV. Seven horses were challenged at 28 days, and 3 horses were challenged 194 days, after the second immunization. All vaccinated horses remained clinically healthy following challenge, demonstrating protection with pre-challenge HeV neutralizing titers as low as 1:16.[267] There was no gross or histologic evidence of HeV infection in any of the vaccinated horses at study completion, and all tissues examined were negative for HeV antigen by immunohistochemistry, with no viral genome detected in any tissue. In 9 of 10 vaccinated horses, HeV nucleic acid was not detected in daily nasal, oral, or rectal swab specimens or from blood, urine, or feces samples collected before euthanasia, and no recoverable virus was present.[267]

<FIG14.16>

Equivac® HeV was launched in November 2012 on a Minor Use Permit by the regulatory authority, the Australian Pesticides and Veterinary Medicines Authority (APVMA), and is the first commercially developed and deployed vaccine against a BSL-4 agent and is currently the only licensed antiviral approach for henipavirus infection. All vaccinated horses receive a microchip and database is maintained, and in August, 2015 Equivac® HeV received full registration by the APVMA. To date, >640,000 doses of Equivac® HeV vaccine has been administered to >153,000 unique horses (Fig. 14.16B). Since vaccine release, laboratory confirmed HeV infections in horses (n=21) have only occurred in unvaccinated horses. The HeV-sG recombinant subunit vaccine for NiV and HeV is now in clinical development with support from the Coalition for Epidemic Preparedness Innovations (CEPI)[268] and Phase I clinical trials set to commence in 2019. Recent vaccination and challenge studies in nonhuman primates have shown that a single immunizing dose of HeV-sG in Allhydrogel™ can protect against HeV and NiV-Bangladesh challenge (Geisbert and Broder, unpublished) and together with the results of recombinant VSV-based NiV vaccines, these findings highlight their potential usefulness in an emergency-use or outbreak scenario.

<H2>Passive immunization

Initial passive immunization studies using either NiV G and F-specific polyclonal antiserums, or mouse monoclonal antibodies (mAbs) specific for the NiV or HeV G or F glycoproteins were shown to be protective in the hamster model.[92,251,269] HeV- and NiV-neutralizing human mAbs reactive to the G glycoproteins of both HeV and NiV have been developed using recombinant antibody technology.[270] One mAb, m102.4, possessed strong cross-reactive neutralizing activity against HeV and NiV and was later produced in an IgG1 format in a CHO-K1 cell line.[271] The m102.4 mAb epitope maps to the receptor binding site of G and engages G in a similar fashion as the ephrin receptors[272] (Figure 14.5). The m102.4 mAb can neutralize all HeV and NiV isolates tested, including HeV-1994, HeV-Redlands, NiV-Malaysia and NiV-Bangladesh.[87,273] NiV challenge experiments in the ferret demonstrated complete protection was possible by a single dose of m102.4 mAb administered by intravenous infusion 10 hrs following a lethal virus challenge.[87] The therapeutic efficacy of mAb m102.4 has also been examined in nonhuman primates against both NiV and HeV challenge as a post-exposure therapeutic reflective of a potential real life virus exposure scenario[189,190] (Table 14.5). In one study, AGMs were challenged intratracheally with HeV and following virus administration they were infused twice with m102.4 (~15 mg/kg) beginning at 10 hrs, 24 hrs or 72 hrs post-infection followed by a the second infusion ~48 hrs after the first. In this study, all subjects became infected following challenge, and all animals that received m102.4 survived whereas all controls succumbed to severe systemic disease 8 days following virus challenge. Animals in a 72 hrs treatment group did exhibit neurological signs but all recovered by day 16, but there was no evidence of HeV-specific pathology in any of the m102.4-treated animals, and no infectious HeV could be recovered from any tissues from any m102.4-treated subjects. A later study evaluated the efficacy of m102.4 against NiV-Malaysia challenge in AGMs, at several time points after virus exposure by intratracheal challenge including as late as the onset of clinical illness.[190] Here, animals were infused twice with m102.4 (15 mg/kg) beginning at either 1, 3, or 5 days following NiV-Malaysia challenge and again 48 hrs after the first dose. All animals became infected following virus exposure, and again all subjects that received m102.4 therapy survived the infection, whereas the untreated control subjects succumbed to disease between days 8 and 10 following virus challenge. The m102.4 mAb was also shown to be effective the nonhuman primate model against NiV-Bangladesh infection, although its therapeutic window was much shorter as compared to NiV-Malaysia infected subjects.[187] Taken together, these studies have shown that m102.4 mAb therapy can prevent HeV or NiV lethal disease in exposed subjects is the only effective post-exposure therapeutic tested *in vivo* in nonhuman primates. The mAb m102.4 has since been used by emergency protocol in 13 people in Australia and one in the U.S. because of significant risk of HeV or NiV infection.[250] The m102.4 antibody has completed a Phase I clinical trial in Australia, and has recently been supplied to Government of India and included in an international Nipah treatment protocol sponsored by the Indian Council of Medical Research (ICMR) with support from the NIAID, NIH, USA.

<H1>Perspective and Geographic Considerations

Commented [BHL5]: Have to write this together. Haven't updated this at all.

The high virulence of the henipaviruses and the requirement for BSL-4 facilities have hampered investigations into the biology and pathogenesis of these novel paramyxoviruses. Recent investigations into the structure and function of henipavirus proteins expressed from cloned genes have provided insight into the functions of many henipavirus proteins in infected cells. It remains to be determined if all of the functional characteristics of the henipavirus proteins determined *in vitro* accurately reflect the role that they play in the cells of both terrestrial and chiropteran hosts.

Although significant strides and an expanded understanding of the henipaviruses have been made during the past two decades, many questions relating to the ecology and biology of henipaviruses remain unanswered. It is clear that Pteropus species of fruit bats are the major reservoir host of these viruses, but new studies have suggested that an even wider group of chiropteran species may host the known henipaviruses and certainly yet to be identified new henipavirus species. With the wide geographic range of Pteropus species as overlapping populations, extending from islands in the South Pacific through Australia, and southern Asia to Pakistan, and with additional species on islands off the eastern coast of Africa, together with the cross-reactive serologic evidence of henipavirus presence,(61),(81) it would seem that many other related viruses remain to be identified.(43),(56) The emergence of these and related viruses is probably associated with the destruction of the flying fox native habitats, driving the animals to seek food from orchards and ornamental trees in urban and periurban areas. Thus, with continued deforestation, undoubtedly further outbreaks of HeV, NiV, and novel related members of the genus will occur. The mechanisms by which henipaviruses are transmitted between fruit bats and maintained within their colonies, as well as the pathways leading to the infection of spillover hosts, remain to be elucidated.

Figure legends

Figure 14.1. Syncytia induced in vero cells 24 hours after infection by Hendra virus (HeV) (A) and Nipah virus (NiV) (B). Methanol-fixed infected cells were labeled with rabbit monospecific antiserum to the HeV P protein and fluorescein-conjugated goat antirabbit immunoglobulin G. P protein is detected in extensive perinuclear ribonucleoprotein complexes (*small arrow*) and in discrete regularly shaped arrays (*large arrow*) distributed throughout the cytoplasm and believed to be sites of virus egress from the cell. Nuclei are indicated by *chevrons.*

Figure 14.2. A: Electron micrograph of Nipah virus (NiV)-infected Vero cells showing tubule-like structures, both in the cytoplasm and in a maturing virus particle (*arrows*). **B:** Electron micrograph of negatively stained Hendra virus (HeV) displaying the double fringe at the virus envelope (*small arrow*) and the herringbone nucleocapsids (*large arrow*). (Courtesy of Dr. Alex Hyatt, CSIRO Australian Animal Health Laboratory.)

Figure 14.3. Genome size and organization of Hendra virus in comparison with the type species in each of the other six genera in the family *Paramyxoviridae*. A: Genome length (in nucleotides) are given in brackets after each virus. Color coding: blue, proteins for the inner most nucleocapsid responsible for replication and transcription; green, envelope proteins. **B:** 3'UTR of certain genes in henipaviruses (N, P and G) are longer than their counterparts from representative members of paramyxovirus genera that infect mammals. The 3'UTR length (number of nucleotides) of each gene from representative members of the indicated genera is compared separately in box-and-whisker plots (N, P, M, F, RBP, and RdRP). P values are calculated based on one-tailed t-test (*Henipavirus* vs all other genera); five virus species from *Henipavirus* (HeV, NC_001906; NiV, NC_002728; CedV, NC_025351.1; GhV, NC_025256.1; MojV,

NC_025352.1), and three each from *Morbillivirus,* (MeV, NC_001498.1; CDV, NC_001921.1; FeMV, NC_039196.1), *Rubulavirus* (MuV, NC_002200.1; HPIV-2, NC_003443.1; PIV-5, NC_006430.1) and *Respirovirus* (SeV, NC_001552; HPIV-1, NC_003461; HPIV-3, NC_001796.2). Courtesy of Satoshi Ikegame and Christian Stevens, Icahn School of Medicine at Mount Sinai, New York.

Figure 14.4. The major proteins of Hendra virus and Nipah virus and their roles in the henipavirus life cycle. A: Viruses were purified and analyzed as described in Wang LF et al.[1] Major virus proteins and the molecular weights of standard marker proteins are shown on the right and left, respectively. Reproduced with permission from Wang LF et al, Molecular biology of Hendra and Nipah viruses. *Microbes Infect* 2001; 3:279-87**. B:** Henipavirus replication cycle is depicted. The virus receptor binding protein (RBP, deep blue lollipops) attaches the virus to the cell via its cognate receptor, typically ephrinB2/B3 **(1)**, and triggers virus-cell membrane fusion mediated by the viral fusion protein (F, filled orange trapezoids) **(2)**. Fusion delivers the nucleoprotein (N) encapsidated negative-sense virus RNA genome [vRNA(−), cyan] to the cytosol **(3).** The vRNA(-) serves as template for viral transcripts made by the transcriptase complex comprised of the phosphoprotein (P) and the large RNA-dependent RNA-polymerase (RdRP) (P-RdRP, transparent hexagons) **(4).** Viral transcripts are made following a 3′ to 5′ attenuation gradient. The vRNA(-) is also the template for making full-length antigenomic cRNA(+) **(5),** which in turn is a template for vRNA(−) synthesis during virus genome replication **(6).** Henipavirus genome replication mediated by the N-P-RdRP replicase complex is similar to the details described for the *Paramyxoviridae* in chapter 13. However, some aspects of henipavirus assembly are relatively unique. The matrix protein (M, green octagons) needs to transit through the nucleus **(7)** in a ubiquitin-regulated manner **(8),** in order to traffic properly to

the plasma membrane. This nuclear sojourn involves shuttling through subnuclear compartments such as nucleoli **(9).** Proper trafficking is required for M to orchestrate the assembly of the viral RNPs with the viral envelope glycoproteins into budding infectious virions bearing the vRNA(-) **(10).** Matrix also has non-structural functions such as antagonizing type-I IFN responses **(11);** see Fig. 14.8 and text for details. Additionally, in order for the henipavirus F protein to be cleaved and become fusion-competent, it needs to access cathepsins L/B in the endosomal compartment. To do this, F first reaches the plasma membrane via the secreory pathway in an uncleaved form (open orange trapezoids) **(12).** Subsequent endocytosis and recycling back to the plasma membrane **(12a)** is required to form infectious virions where cleaved fusion-competent F (filled orange trapezoids) **(12b)** is complexed with the RBP in its proper oligomeric state. Where this occurs along the vesicular trafficking pathway and/or the plasma membrane is unresolved **(13).** F protein cleavage is seldom complete and uncleaved F can be detected in budded virions **(14)** (Adapted from Aguilar HC and Lee B. Emerging paramyxoviruses: molecular mechanisms and antiviral strategies. *Expert Rev Mol Med* 2011;13:e6)

Figure 14.5. A structure-based phylogeny of paramyxoviral receptor binding proteins. Structure-based phylogenetic analysis on extant structures of all henipavirus RBPs and representative RBPs from at least one virus in other paramyxovirus genera for which structural data is available. RBPs are shown besides the tree and are rendered as surface representation (grey). All receptor-binding proteins, with the exception of the MojV-G, are shown in complex with their respective receptor molecules (yellow), with the receptor-binding interface colored red. Analysis was performed and produced as described in Rissanen et al.[2] Paramyxoviral RBPs generally cluster according to their respective genera and cellular receptor usage with the

exception MojV-RBP, which is almost equidistant to all structurally studied genera. Courtesy of Dr. Thomas Bowden, University of Oxford, U.K.

Figure 14.6. Nipah virus transmission. Major pathways of human Nipah virus infection are summarized for Malaysia (blue arrows), Bangladesh (red arrows), the Philippines (green arrows), and the latest outbreak in Kerala, India (orange arrows). (Adapted from Clayton BA. Nipah virus: transmission of a zoonotic paramyxovirus. *Curr Opin Virol* 2017; 22:97-104)

Commented [BHL1]: May need professional rendering, but also O.K. as is depending on Editor's opinion.

Figure 14.7. Immunohistochemistry detection of Nipah virus (NiV) and Hendra virus (HeV) antigen in henipavirus-infected tissues. A-D: Hendra virus infected tissues. **A:** Staining of HeV antigen (N protein-specific rabbit antibody) within the wall of superficial arteriole in the sub-mucosa of the nasal cavity in a HeV-infected horse. **B:** Immmunolabeling (N protein-specific rabbit antibody) of the endothelium of medium caliber vessels and alveolar septae in lung of a HeV-infected African green monkey (AGM) (10x). **C:** Immunolabeling of HeV antigen (N protein-specific rabbit antibody) within neurons in the brainstem of a HeV-infected AGM (40x). **D:** Immunolabeling of HeV antigens (mouse anti-HeV polyclonal antibody) in neurons of acute HeV-infected human case (40x). **E:** Positive immunolabelling (using anti-Nipah virus rabbit serum) within the lung of a NiV-infected pig. Involvement of bronchial epithelium and airway debris is noted. **F:** Immunolabeling (N protein-specific antibody) of the endothelium of medium caliber vessels and alveolar septae in lung of a NiV-infected AGM (20x). **G:** Immunolabeling of NiV antigen (N protein-specific antibody) within neurons in the brainstem of a NiV-infected AGM (40x). **H:** Immunolabeling of NiV antigens (hyperimmune anti-NiV mouse ascitic fluid) in the cytoplasm and nuclei of neurons, and neuronal processes in the brain of acute NiV-infected human case (158x). A and E, courtesy of Dr. Deborah Middleton, CSIRO Australian Animal Health Laboratory. B, C, F and G, courtesy of Dr. Karla Fenton, University of

Texas Medical Branch at Galveston, Texas. D, courtesy of Dr. Kum Thong Wong, University of Malaya; H, from Wong et al.[3]

Figure 14.8. Ephrin-B2 and ephrin-B3 RNA-seq expression data across representative human non-disease tissues. Shown here are ephrin-B2 (upper) and ephrin-B3 (lower) expression data obtained from the Genotype-Tissue Expression (GTEx) Portal. The GTEx project is a public resource where up to 53 non-disease tissue sites obtained from nearly 1,000 individuals are subjected to RNA-seq by next-generation sequencing amongst other assays. Details on datasets can be found on https://gtexportal.org. Data from all available brain regions are shown. The non-brain tissues are chosen for illustrative purposes based on their relevance to henipavirus pathogenesis. Expression data in transcripts per million are plotted as box plots with the medians and 25th and 27th percentiles shown; points are displayed as outliers if they are above or below 1.5 times the interquartile range. 1a Artery – Aorta; 1b Artery – Coronary; 2a Brain – Amygdala; 2b Brain - Anterior cingulate cortex (BA24); 2c Brain - Caudate (basal ganglia); 2d Brain - Cerebellar Hemisphere; 2e Brain – Cerebellum; 2f Brain – Cortex; 2g Brain - Frontal Cortex (BA9); 2h Brain – Hippocampus; 2i Brain – Hypothalamus; 2j Brain - Nucleus accumbens (basal ganglia); 2k Brain - Putamen (basal ganglia); 2l Brain - Spinal cord (cervical c-1); 2m Brain - Substantia nigra; 3 Breast - Mammary Tissue; 4 Colon – Transverse; 5 Esophagus - Gastroesophageal Junction; Esophagus – Mucosa; 6 Heart - Left Ventricle; 7 Kidney – Cortex; 8 Liver; 9 Lung; 10 Minor Salivary Gland; 11 Spleen; 12 Whole Blood.

Figure 14.9. Innate immune evasion mechanisms of the Nipah virus N, P, V, W and M proteins. Left: The V and W proteins (green diamonds) block IFN-α/β expression by different mechanisms. Depicted are simplified versions of the RIG-I-like receptor (RLR) signaling (blue

arrows) and TLR3 signaling (black arrows) pathways. Both lead to activation of interferon regulatory factors 3 and 7 (IRF-3 and IRF-7) (dashed arrow). RIG-I, MDA5 and TLR3 can sense RNAs produced during viral infection. Activation of RIG-I or MDA5 leads to their interaction with the mitochondria-associated adapter protein MAVS (1). This leads to activation of the kinases IKKε and/or TBK-1 (2), which phosphorylate and activate IRF-3 and, when present, IRF-7 (3). For clarity, MAVS activation of NF-κB is not shown. Activated IRF-3 and IRF-7 translocate into and accumulate in the nucleus; both contribute to IFN-α/β gene transcription (4). TLR3 signals through adaptor protein TRIF to activate IKKε/TBK-1 (5). The cytoplasmic NiV and HeV V proteins interact with and inhibit MDA5, thereby inhibiting the induction of IFN-α/β expression early on in the pathway (a); however NiV V does not appear to inhibit TLR3 signaling. The nucleo-cytoplasmic shuttling NiV M protein (green hexagon), while it is in the cytoplasm, antagonizes induction of type-I IFNs by blocking IKKε activation (b). This prevents downstream phosphorylation and nuclear translocation of IRF3, which also leads to a failure of IFN-α/β induction. The nuclear W protein (green trapezoid) effectively blocks RLR and TLR3 activation of the IFN-β promoter by preventing the accumulation of phosphorylated IRF-3 (c). This function requires the nuclear localization of W. **Right:** The Nipah virus N, P, V and W proteins each block IFN signaling pathways at distinct steps (red arrows), ultimately leading to reduced expression of interferon- stimulated (antiviral) genes (ISGs). The P, V and W proteins can each inhibit the phosphorylation and activation of STAT1 and STAT2 in response to IFN-α/β (6) and block the phosphorylation and activation of STAT1 in response to IFN-γ. The inhibition of the IFN-α/β signaling pathway is depicted. The cytoplasmic P and V proteins interact with and inhibit STAT1 (d). The V protein also interacts with STAT2, in a STAT1-dependent manner. P and V prevent nuclear accumulation of pSTAT1 /pSTAT2 following IFN-α/β addition to cells and cause the STAT proteins to accumulate in a high molecular weight complex. The NiV and HeV N proteins (green oval) were recently reported to disrupt phospho-STAT1 complex formation (7), though not phosphorylation of STAT1 itself (e). Nonetheless, this N-mediated disruption of STAT complexes reduces nuclear accumulation of the activated STAT complexes required to stimulate ISG expression (8). The nuclear W protein relocalizes non-phosphorylated STAT1 from its typically cytoplasmic localization to the nucleus (f). STAT1 relocalized to the nucleus by W remains unphosphorylated and does not activate transcription of ISGs in response to IFN-α/β addition. (Adapted from Basler CF. Nipah and Hendra virus interactions with the innnate immune system. *Curr Top Microbiol Immunol* 2012; 359: 123-52)

Figure 14.10. Brain MR scans of acute Nipah (A) and relapsing Nipah encephalitis (B) showing hyperintense discrete and more confluent lesions, respectively, corresponding to discrete pathological lesions (C) and confluent lesions (D). H&E stains (C, D). Magnification, objective x4 (Reproduced with permission from Wong KT and Tan CT. Clnical and Pathological manifestations of human henipavirus infection. *Curr Top Microbiol Immunol* 2012; 359: 95-104).

Figure 14.11. Distribution of frugivorous bats belonging to various genera in the *Pteropodidae* family where evidence of henipavirus presence have been detected. The presence of henipavirus is graded into four levels with known outbreak (red), virus isolation (pink), molecular detection (blue), and antibody detection (green).

Figure 14.12: Phylogenetic tree based on L-proteins of selected henipaviruses and type species of the other six genera in the family *Paramyxoviridae.* Tree was constructed by using Neighbor-Joining approach with 1,000 bootstrap replicates. Numbers at the nodes represent

bootstrap values. Scale bar indicates amino acid substitutions per site. Sequences are labelled with the following ordination when all relative information is available for any given genome sequence: Virus/Country/Host/Year/Strain (GenBank accession number). For example, NiV/BD/Human/2010/Faridpur(JN808864) represents a Nipah virus isolated in Bangladesh from humans in 2010 with Faridpur as its isolate name and JN808864 as its Genbank accession number. (Two accession numbers still missing from figure, pending Genbank release)

Figure 14.13. Chest radiographs of a Nipah virus (NiV) infected patient and Nipah virus (NiV) and Hendra virus (HeV) infected African green monkeys. A: Chest X-ray of patient infected with Nipah virus (Nipah-Bangladesh clade) from Kerala, India, 2018, at 6 days following onset of symptoms showing diffuse bilateral opacities covering the majority of the lung fields, consistent with acute respiratory distress syndrome (ARDS). **B:** Top, comparison of pre-challenge to Nipah virus (Nipah-Malaysia clade) infected African green monkey at 11 days post-challenge showing congestion and pneumonia with infiltrates on the lung fields. Bottom, comparison of pre-challenge to Hendra virus infected African green monkey at 8 days post-challenge showing diffuse interstitial infiltrates and pulmonary consolidation and severe respiratory distress. Panel A, courtesy of Prof. Govindakarnavar Arunkumar, Manipal Centre for Virus Research, Manipal Academy of Higher Education (deemed to be University), Karnataka State, India and Dr. Suresh Kumar. E.K, Malabar Institute of Medical Sciences, Kerala State, India. Panel B, top, from Geisbert et al.[4], bottom, from Rockx et al.[5] (reproduced with permission)

Figure 14.14. Magnetic resonance imaging scans of patients with Nipah virus (NiV) or Hendra virus (HeV) encephalitis. A: Left, patient with NiV encephalitis (Nipah-Bangladesh clade) from Kerala, India, 2018, at 6 days following onset of symptoms showing cortical and

subcortical hyperintense foci (arrow heads). Middle, patient with acute NiV encephalitis (Nipah-Malaysia clade) from Malaysia, 1999, showing multiple discrete hyperintense lesions in the grey and white matter. Right, patient with relapsed NiV encephalitis from Malaysia, 1999, showing confluent lesions involving primarily the cortical grey matter. **B:** Left, acute HeV encephalitis in a patient on day 18 of illness, showing cortical and subcortical hyperintense foci. Right, relapsed HeV encephalitis in a patient on day 14 following symptoms onset showing widespread multifocal neocortical involvement. Panel A, left (India), courtesy of Prof. Govindakarnavar Arunkumar, Manipal Centre for Virus Research, Manipal Academy of Higher Education (deemed to be University), Karnataka State, India and Dr. Suresh Kumar. E.K, Malabar Institute of Medical Sciences, Kerala State, India. Figure 14.15. Generalized understanding of infection and clinical features of human Nipah virus (NiV) and Hendra virus (HeV) infection. **A:** Transmission is generally accepted to occur via the oronasal route presumably by virus contaminated respiratory secretions or droplets from infected animals or people, or liquid/food (palm sap/fruit); **B:** The initial site of replication in humans is ill-defined but is thought to occur within the respiratory system and disease onset is characterized by fever, myalgia, shortness of breath, cough, which may progress to an acute respiratory distress syndrome (ARDS); **C:** Possible invasion into the central nervous system (CNS) via the olfactory bulb has also been suggested and has been demonstrated in animal models; **D:** Virus replication and hematogenous systemic spread occurs (cell-free or cell-associated viremia) and established infection is characterized by a widespread vasculitis with endothelial and smooth muscle cell tropism resulting in multinucleated syncytial cells; **E:** CNS infection and encephalitis results in altered sensorium, headache, vomiting, and seizures along

Commented [BHL3]: Needs professional rendering. Submitted to Dave Murphy via email on Feb 18 at 1:58 AM EST.

with fever and other systemic symptoms; **F:** Infection of other organs in addition to lung and brain in human cases occurs and has been reported in kidney, heart, spleen and lymphoid tissues, and similar widespread infection has been demonstrated in multiple animal models.

Figure 14.16. Model of the Hendra virus soluble G glycoprotein subunit vaccine (HeV-sG) and its complex with the Hendra and Nipah virus neutralizing human monoclonal antibody m102.4. A: The HeV-sG glycoprotein subunit vaccine is composed of the entire ectodomain (amino acids 76-604) of the HeV G glycoprotein. HeV-sG is shown as dimer with one monomer colored green and the other cyan. The secondary structure elements of the two globular head domains are derived from the crystal structure of the HeV G head domain, the stalk regions of each G monomer (residues 77-136) are modeled, and N-linked glycosylation sites shown as gray spheres. The ephrin-binding face of the cyan globular head is facing forward with an overlay of the interacting ephrin-B2 G-H loop residues in yellow. **B:** The HeV-sG dimer is modeled in complex with two m102.4 Fab antibody fragments. The two HeV-sG monomers are colored green and cyan as in panel A and rotated slightly to the right, and the two Fab molecules are shown with their heavy chains colored in magenta and light chain – in yellow, each binding one globular head domains of G. Modified from Broder et al.[9]

Figure 14.17. One Health Vaccine strategy. A: The known modes of henipavirus transmission in different countries. In Australia, all seven human cases were infected via contacting infected horses. A One Health vaccine strategy was developed for immunization of horses with the dual purposes of saving horses from lethal Hendra virus infection and prevention of transmission from bats to humans via horses. **B:** Location densities of Equivac® HeV vaccine administered to horses around Australia, courtesy of Dr. Richard L'Estrange, Zoetis Inc.

Platform	Viral antigen target or immunogen	Animal challenge model

Active vaccination		
Recombinant vaccinia virus	Nipah F and/or G glycoprotein	Hamster[a] (NiV) Pig[b] (NiV)
Recombinant canarypox virus	Nipah F and/or G glycoprotein	Ferret[c] (NiV), Hamster[d] (NiV), nonhuman primate[e] (NiV)
Recombinant VSV	Nipah F and/or G glycoprotein	Hamster[f] (NiV, HeV) Hamster[g], Nonhuman primate (NiV, HeV)
Recombinant AAV		
Recombinant measles virus	Nipah G glycoprotein Nipah G glycoprotein	Cat[h] (NiV), Ferret[i] (HeV, NiV), nonhuman primate[j] (HeV, NiV)
Recombinant subunit	Hendra soluble G glycoprotein	Horse[k] (HeV)
Passive immunization		
Human monoclonal antibody m102.4	Hendra / Nipah G glycoprotein	Ferret[l] (NiV) Nonhuman primate[m] (HeV, NiV)

[a] Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vaccinia viruses were protected against disease following intraperitoneal challenge with 10^3 PFU of NiV.[65]

[b] Pigs immunized with NiV F and/or G glycoprotein encoding recombinant canarypox viruses were protected against intranasal challenge with $2.5x10^5$ PFU of NiV.[66].

[c] Ferrets immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intranasal challenge with $5x10^3$ PFU of NiV.[67]

[d] Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intraperitoneal challenge with 10^5 $TCID_{50}$ of NiV;[68] or $6.8x10^4$ $TCID_{50}$ of NiV.[69]

[e] African green monkeys immunized with a NiV G encoding recombinant VSV vector were protected against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV.[70,71]

[f] Hamsters immunized with a NiV G encoding recombinant adeno-associated virus (AAV) vector were protected against lethal intraperitoneal with 10^4 PFU of NiV.[72]

[g] Hamsters and African green monkeys immunized with a NiV G encoding recombinant measles virus vector were protected against lethal intraperitoneal challenge with 10^3 $TCID_{50}$ of NiV (hamsters) or 10^5 $TCID_{50}$ of NiV (AGMs).[73]

[h] Hendra virus soluble G glycoprotein (HeV-sG) used to immunize cats protects against lethal subcutaneous (500 $TCID_{50}$)[74] or oronasal ($5x10^4$ $TCID_{50}$) NiV challenge.[75]

[i] HeV-sG used to immunize ferrets protects against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of HeV[76] or $5x10^3$ $TCID_{50}$ of NiV challenge.[77]

[j] HeV-sG used to immunize African green monkeys protects against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV[78] or $5x10^5$ PFU of HeV.[79]

[k] HeV-sG used to immunize horses protects against lethal oronasal challenge with $2x10^6$ $TCID_{50}$ of HeV[80].

[l] A NiV and HeV cross-reactive G glycoprotein specific neutralizing human mAb (m102.4) protects ferrets against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of NiV[81] or $5x10^3$ $TCID_{50}$ of HeV (J. Pallister and C. Broder, unpublished) by post-exposure infusion.

[m] Human mAb m102.4 protects African green monkeys by post-exposure infusion following lethal intratracheal challenge with $4x10^5$ $TCID_{50}$ of HeV[82] or lethal intratracheal challenge with $5x10^5$ PFU of NiV.[83,84]

HNV_Fields Ref.enlp.zip
Henipavirus Tables 14.1-14.5-V10-190226.docx

HI Folks,

This is the final draft for now. I think it's still way too long by my counting, but at least everyone can see how everything hangs together.

The only edits and comments you see are new ones I added, mostly to LinFa's section, but I also took a couple sentences from Chris's section to put into my pathogenesis part to avoid duplication. I clearly indicated where.

I removed two old figures and replace with two new ones.

Attached is the (1) Master Excel Spread sheet to keep everything straight, (2) the text manuscript file, (3) Figure Legend text file, (4) Master endnote file., (5) Final Table Text file

I will send you a Googlelink to the ppt file with all the figures. The tiff files are individually exported, can share them in a dropbox if you want.

Anyway, I'm happy to take out anything in my section - it's just too long, and I already cut out so much. Let me know what you think is important.

Thanks. (LinFa, maybe you can tell Sean we'll be uploading soon. I'm afraid to talk to him!) Gottta go and get some sleep now.

Benhur

> Hi Guys,
>
> The reason why I wanted things earlier on to put together is because . . . I just got (b) (6) [redacted]. But my schedule is not your problem.
>
> I am also here at a GRC in Ventura (on Bioterrorism but speaking on CRISPR delivery, NOT NiV). Basically have been continuously working till 5 am or so every day since last week (except for flying here and on my (b) (6) [redacted] day).
>
> This chapter is such a bear to put together. Reading the instructions, they really want the subsections constructed as in the outline, so the whole book has the same organization. I had re-do my original sections almost completely, and have to keep referring to both your sections (that's why I need your sections to fully complete mine) to make everything consistent and avoid duplication.
>
> I've added substantial new matter for LinFa's into section on viral proteins properties, etc. To keep up with advances, I made an entirely original figure on B2/B3 expression across tissues using the original NGS data from the GTEx Portal. Then converting every figure into a high resolution tiff file for those that i don't have already is a nightmare.
>
> I'm going to send what I have even if the length is too long . . . to all of you by early am (Mar 7 EST). I may be upload it as well. We all have to revise the manuscript anyway, after review, and also after the substantial nomenclature changes are adopted later this month by ICTV.
>
> (b) (6) [redacted]. all week and we are taking off for the weekend, so if I still have to work on this chapter this weekend, this will be (b) (6) [redacted]. I can already tell the uploading process is a bear.
>
> So, I apologize. It's so much work than I thought! You see what I mean when i send everything. Thank you for your patience.

<H1>History

Hendra virus (HeV), the first known member of the genus *Henipavirus* in the family *Paramyxoviridae*, came to light in September 1994 as the causative agent of a sudden outbreak of acute respiratory disease in thoroughbred horses at a stable in Brisbane, Australia. A total of 21 horses and 2 humans (a horse trainer and a stable hand) became infected. The horse trainer and 14 horses died, and 7 horses with mild or subclinical infection were euthanized.(130) A virus was isolated, initially called *Equine Morbillivirus* but later re-named *Hendra virus* after the Brisbane suburb where the outbreak occurred. A second person died from HeV infection 13 months after the Brisbane outbreak, a farmer from Mackay, nearly 1000 km north of Brisbane. Unlike the first case, however, the man succumbed to encephalitis caused by HeV infection.(107) A forensic retrospective investigation found that the farmer had suffered a mild meningitic illness 14 months earlier after assisting at the necropsy of two horses that had died of severe respiratory distress—later found to have been caused by HeV(125)—and that he became infected at that time. After initial serologic evidence suggested that fruit bats (flying foxes) of the genus *Pteropus* in the suborder Yinpterochiroptera were the reservoir hosts,(165) HeV was isolated from two species of flying fox.(56) In total, there have been 60 recognized occurrences of HeV in Australia between 1994–2018, with at least one occurrence per year since 2006 (Table 14.1A). (5)·(10) Every occurrence of HeV has involved horses as the initial infected host, causing lethal respiratory disease and encephalitis, along with a total of seven human cases arising from exposure to infected horses, among which four have been fatal and the most recent in 2009 (Table 14.1B).(6)·(10)·(115)

Commented [L1]: Can we cite webpage? https://www.business.qld.gov.au/industries/service-industries-professionals/service-industries/veterinary-surgeons/guidelines-hendra/incident-summary

BHL REPLY: I have added the web-page into my Endnote database and cited it. Green highlighted Ref 1

Commented [BHL2]: Does this mean you still want to keep **Ref 5 and 10**, Please make the decision and add/delete ref accordingly. **PLEASE USE the Endnote File I sent you. All these (refs) from the original document Publisher sent (Knipe XXXXx) CANNOT be formatted – I DON'T have the time to go through every single one and do it myself.**

Commented [BHL3]: **TABLE 14.1A and 14.1B** should be moved to online materials**. TABLE 14.1C** (below) should be kept in the print version.

Nipah virus (NiV), the second known member of the genus *Henipavirus*, emerged as the cause of an outbreak of disease in pigs and humans in Peninsular Malaysia in 1998 through 1999. The epidemic started in Perak State as clusters of cases of encephalitis among pig farmers. It was initially believed to be caused by Japanese encephalitis virus; however, various features of the outbreak, including a high proportion of cases in direct contact with pigs and illness and deaths in pigs, differed from those expected with Japanese encephalitis.(30) Indeed, respiratory illness and encephalitis in pigs preceded human cases in the same district.(97) The epidemic spread south to the intensive pig-farming areas of Negeri Sembilan in December 1998 and subsequently peaked between February and April 1999. More than 1 million pigs were destroyed to halt the spread of the epidemic, and by late May, 265 human cases of acute encephalitis with 105 deaths were recorded.(29)·(30) A cluster of 11 cases with 1 death occurred among abattoir workers in Singapore.(114) In early March 1999, a virus was isolated from the cerebrospinal fluid (CSF) of a patient with encephalitis and identified as the etiologic agent.(29)·(30) Named *Nipah virus* after the village from which the patient had come, it was shown to be closely related to HeV. NiV was subsequently isolated from the urine of Malaysian flying foxes.(33) A highly related NiV emerged in Bangladesh in 2001,(68) (7) and outbreaks of NiV-related encephalitis have occurred in people from that country almost every year since, along with three reports of NiV encephalitis in India (23), albeit in Bangladesh adjacent regions. However, the most recent outbreak of NiV occurred in 2018 in Kerala (India), more than 2,500 km south-west of NiV-endemic Bangladesh counties.

This outbreak claim~~ing~~ed 21 lives out of 23 infected human cases. [2](60) In 2014, a NiV outbreak occurred in the Province of Sultan Kudarat, the Phillipines, which resulted in the death of 9 humans from 11 which showed an acute encephalitis syndrome.[3] The human case fatality rate of these NiV outbreaks averages around 60% (Table 14.1C).(68),(85) So far human NiV oubreaks have been documented in a total of five countries, Malaysia, Singapore, Bangladesh, India and the Philippines.

<H1>Infectious Agent

<H2>Classification ~~refs~~

When HeV was first isolated in 1994, partial sequencing of the matrix gene (M) revealed that it most closely resembled members of the genus *Morbillivirus* in the subfamily *Paramyxovirinae.*(104) Subsequent characterization of the full-length genome, however, revealed that many of the genetic features of HeV were unique among paramyxoviruses and that the virus did not fit within any of the three genera existing at that time, *Morbillivirus, Respirovirus*, and *Rubulavirus.*(147),(148) When NiV was isolated in 1999, it was initially described as Hendra-like on the basis of its strong reactivity with anti-HeV antibodies. Later it was shown that sera raised against HeV were able to neutralize NiV and vice versa, and that both viruses shared a high degree of similarity in genome organization and protein size and sequence.(29),(58),(59),(146) In 2002, the genus *Henipavirus* was created to accommodate these novel paramyxoviruses, and HeV was designated the type species.(75) Since 1994, there have been 38 isolations of HeV or NiV from humans, bats, horses, and pigs over a wide geographic area and spanning a period of approximately 20 years (Table 14.2). The susceptibility of humans, the virulence of the viruses, and absence of therapeutics and vaccines led to classification of HeV and NiV as biosafety level 4 (BSL4) pathogens. In the latest report from the paramyxovirus study group under the order Mononegavirales, the genus *Henipavirus* has been expanded to include three new species,[4,5] they are *Cedar henipavirus* (Cedar virus, CedV) isolated from bats in Australia, [6] *Ghanaian bat henipavirus* (Ghana virus, GhV) detected in bats from Ghana,[7] and *Mojiang henipavirus* (Mòjiāng, MojV) detected in rats in China.[8] *Henipavirus* is now classified as one of the seven ICTV-approved genera in the family *Paramyxoviridae*.

<TAB14.2>

<H2>Propagation in Cell Culture and Cytopathic Effect

The ultrastructural characteristics of henipavirus-infected cells resemble those found in cells infected by other members of the *Paramyxoviridae*. Shared features include generation of large syncytia and the presence of viral nucleocapsids in cytoplasmic inclusion bodies and underlying electron-dense areas of the plasma membrane.(49),(69) In Vero cells, NiV-induced syncytia are significantly larger than those generated by HeV and nuclei and nucleocapsids are frequently located at the cell periphery, compared with HeV-induced syncytia, where they tend to be more centrally located or distributed randomly throughout the cytoplasm (Fig.

Commented [L9]: Hi Benhur, for the time being, I am using the Arch Virol taxonomy. I am not sure when the new Taxonmy will be officially published. This will have a major impact on everything we do, including Figures 14.3 and 14.4
BHL: Understood. We'll have to see what Bob Lamb uses in his chapter on *Paramyxoviridae*. I already told Sean– we should be ready to change nomenclature during revisions, etc.

Commented [BHL10]: **Please delete this "CALL-OUT" if you agree with my suggestion for moving TABLE 14.2 to online materials.**

14.1). Henipavirus-infected cells also contain structures that are not seen with other paramyxoviruses—specifically a network of membrane-like reticular structures in the cytoplasm and long tubules that appear to be continuous with the plasma membrane in NiV-infected cells. Tubules can also be observed in NiV virions (Fig. 14.2A). *In situ* hybridization suggests that these reticular structures contain viral RNA and may play a role in viral transcription.(49)

<FIG14.1><FIG14.2>

<H2>Virus Morphology

Commented [BHL11]: Note to self: Do we want to talk about the superresolution NiV-F/G study in Nat Commun here, later in pathogenesis section, or at all ?

Henipavirus particles are pleomorphic, varying from spherical to filamentous and ranging in size from 40 to 1,900 nm.(49)·(69)·(104) Nucleocapsids have a diameter of 18 to 19 nm with an average pitch of 5 nm. When examined by electron microscopy (EM), HeV has a unique double-fringed appearance, caused by the presence of surface projections 15 ± 1 nm and 8 ± 1 nm in length (see Fig. 14.2B). Approximately 95% of virions contain the double fringe, and the remaining 5% display a uniform fringe length of 15 ± 1 nm. Unlike HeV, NiV possesses a single layer of surface projections with an average length of 17 ± 1 nm, and NiV particles released into the culture medium are difficult to image because they are routinely penetrated by negative stains. This suggests that the viruses may differ in the physical nature of their envelope.(69)

<H2>Genome Length and Organization

In the family *Paramyxoviridae*, the genome length of all characterized viruses is divisible by six, an observation caused by the requirement of each N protein in the viral ribonucleoprotein to bind 6 nucleotide (nt) residues.(76) This is also true for HeV and NiV despite their much larger genome sizes.(146) The genomes of the Malaysian and Bangladesh strains of NiV differ by 6 nt because of a 6-nt increase in the 3′ untranslated region of the *F* gene.(57) A minigenome replicon study confirms that NiV complies with the rule of six.(55) When the complete genome sequence of HeV was determined, its length (18,234 nt) was more than 2,700 nt, or 15% longer than the genomes of all other paramyxoviruses known at that time.(148) The size of NiV genomes at 18,246 nt to 18,252 nt are slightly larger than that of HeV.(57)(–)(59) These large genome sizes of >18 kb is a conserved feature of henipaviruses as even the recently discovered and more divergent CedV, GhV, and MojV all have genomes between 18,162 nt (CedV) to ~18,430 nt (GhV). Given the caveat that there is wide variation amongst individual species of the other paramyxovirus genera, the extra length of the henipavirus genome is primarily due to the longer 3' untranslated regions (3'UTRs) at the end of several of its six genes, and a larger *P* gene relative to the other paramyxovirus genera. A comparison of genome length and gene organisation of representative members of the *Paramyxoviridae* is shown in Fig. 14.3A. The nomenclature of each of the six major genes common to all paramyxoviruses havs been updated to reflect the latest ICTV convention. An analysis of the 3' UTR lengths between extant henipaviruses and representative species from each paramyxovirus genera that infects mammals is presented in Fig. 14.3B. The most significant differences are in the 3'UTRs of *N*, *P*, and *RBP* genes even given the wide variance seen within each genera. The significance of long 3’ UTRs, especially in HeV and NiV, is generally unknown. However, the N gene 3’UTR of NiV appears to play a role in the downregulation of N mRNAs via specific interactions with hnRNP D. [9]

<FIG14.3A><FIG14.3B>

The genome organization of henipaviruses resembles that in the genera *Respirovirus* and *Morbillivirus.* The first 12 nt of the 3′ and 5′ genomic terminal sequences of paramyxoviruses are highly conserved and complementary, containing promoter elements for replication and transcription.(76) The first 3 nt of the henipavirus genome termini are 5′-ACC-3′—a sequence that is absolutely conserved in members of the family*Paramyxoviridae* and different from that found in the family *Pneumoviridae.*

<H2>Genetic Diversity

Genome sequencing revealed that HeV isolated from equine and human sources during the outbreak in Brisbane appears identical and differs little from HeV isolated from flying foxes 2 years later.(56),(104) Sequencing of five additional horse isolates from five different locations from the 2006 to 2008 HeV occurrences has also demonstrated a very high genetic similarity.(90) Similar observations were made in Malaysia, where it was demonstrated that NiV isolated from pigs at the height of the outbreak and at its geographic focus were essentially identical to human isolates made at that time and isolates obtained from flying foxes several years later.(2),(24),(33),(58),(59)

In Bangladesh, four human isolates obtained in 2004 demonstrate significant genetic heterogeneity, which might suggest multiple spillovers of NiV from flying foxes into the human population.(57) The NiV sequences detected from human patients in India from 2001 to 2018 were more related to NiV from Bangladesh than NiV from Malaysia.(9),(23) [2] A recently whole genome sequencing study of ten NiV isolates obtained from bats in 2013 in Bangladesh at two different geographic locations revealed that the isolated viruses were very similar in sequences. This suggests that multiple strains were not co-circulating in the bat population at the time.[10] Furthermore, none of the bat NiV isolate sequences was identical with any previously detected human NiV isolate sequences, suggesting that NiV spillover into humans is a rare event and more intensive surveillance is required to appreciate the full genetic diversity of NiV in bats in an area with frequent spillover events into human populations. [10] NiV isolated from the flying fox *Pteropus lylei* in Cambodia(120) represents an evolutionary lineage that is separated from the Malaysia or Bangladesh/India cluster . Partial *N* gene sequences detected in *Pteropus lylei* in Thailand indicate the circulation of at least two lineages of NiV—one related to the Bangladesh NiV and the other more related to the Malaysian NiV.(144) On the other hand, NiV sequences detected in *Pteropus hypomelanus* in southern Thailand are clearly more related to the Malaysian NiV. [11] As the RNA-dependent RNA polymerase (RdRP), also known as the L protein, is the most highly conserved protein for paramyxoviruses, it has been used as a more reliable indicator of evolutionary relationship among different paramyxoviruses. Shown in Fig. 14.4 is

Commented [BHL12]: **LINFA: I** am confused. I thought Genetic Diversity has been moved to Section D.5. (Under Epidemiology) according to the new outline you gave us and the figure numbering we agreed on. Please see comments below aboujt Figh. 14.4 which should be Fig. 14.11 in Section D5.

Commented [L13]: Arunkumar et al (2018) JID. DOI: 10.1093/infdis/jiy612
BHL: I have added the new 2018 Kerala ref 2. Please retain/delete old reference as you deem appropriate. But please do it using the Endnote file.

Commented [L14]: Anderson et al (2019) EID 25:166
BHL: I have added the Anderson 2019 as ref 10. All my added references are from my endnote file and follows numbering different from the original 2012 text.

Commented [L15]: Wacharapluesadee et al. Virology Journal (2016) 13:53
BHL: I have added Wacharapluesadee **2016 as ref 11. All my added references are from my endnote file and follows numbering different from the original 2012 text.**

Commented [BHL16]: **LINFA:** This is supposed to be **Fig. 14.11** if moved to Section D5 (under Epidemiology) according to the new outline we agreed on. Please clarify- see above – if this whole genetic diversity section should be moved to Section D5.

phylogenetic tree based on RdRP proteins of prototype species of each genera in the family *Paramyxoviridae* with major members of the genus *Henipavirus*, selected to represent major species origin, geographic location and time of isolation.

<FIG>

The presence of henipavirus-reactive (but not neutralizing) antibodies and viral RNA in bats from other regions of the world (see Epidemiology section below) predicts that a much greater genetic diversity of henipaviruses exists in different bat populations. This also suggests the existence of henipaviruses with different transmissibility and pathogenicity in non-bat hosts.

<H2>Virus Proteins and Their Properties

Analysis of purified viruses by polyacrylamide gel electrophoresis reveals RdRP (L), P, RBP (G), F_0, N, F_1, and F_2 proteins,(146),(147) where F_0 is the uncleaved and F_1 and F_2 the cleaved products of the *F* gene. Interestingly, F_0 is more readily detected in HeV compared with other paramyxoviruses, including NiV,(93),(146) which may suggest that HeV-F is less efficiently cleaved. Overall, the proteins of henipaviruses are typical of those of ~~*the subfamily Paramyxovirinae*~~*Paramyxoviridae*, with the exception of the P protein, which is significantly larger than cognate proteins in ~~the~~ this virus ~~sub~~family.(147) The P protein is translated from messenger RNA (mRNA) that is co-linear with genomic RNA. For most henipaviruses, the *P* gene also encodes V and W proteins, produced from mRNA in which one and two nontemplated G residues, respectively, are inserted at the RNA editing site during transcription. The P, V, and W proteins, therefore, are identical for the first 405 amino acid residues. A C protein is encoded by the 5′ end of the gene in an overlapping reading frame and is produced by an internal translational initiation mechanism, which is common to other members of ~~*Paramyxovirinae*~~*Paramyxoviridae*, except for rubulaviruses.(76) The P, V, and the C proteins predicted from the coding regions in the *P* gene are present in HeV-infected cells.(146) The functional expression of W in NiV-infected cells has recently been demonstrated.(84) It is worth to note that Cedar virus lacks both the RNA editing and expression of the V protein. 6

Paramyxovirus N, P, and RdRP proteins are necessary and sufficient for replication of viral RNA both *in vitro* and *in vivo*,(76) and this has been confirmed for henipaviruses by reverse genetics. Using a minigenome replicon containing leader and trailer sequences of the NiV genome with its entire coding region replaced with a reporter gene, it was shown that efficient genome replication was achieved only when all three proteins were expressed in the same cell.(55)12 NiV N, P, and RdRP proteins were also able to rescue a minigenome constructed from the leader and trailer sequences of the HeV genome, further demonstrating the close genetic relationship between the viruses. (BHL might want to expand more on reverse genetics of HNVs if space permits-BHL)

The RdRP protein of nonsegmented, negative-stranded RNA (NNR) viruses in the order *Mononegavirales* contains a highly conserved GDNQ motif, believed to be important for polymerase activity.(116) Henipaviruses were the first NNR viruses in which GDNQ was replaced by GDNE. It was speculated that this motif might be unique to paramyxoviruses with relatively large genomes(146),(148); however, the GDNE motif has since been found in the RdRP protein of Mossman virus that has a genome length of 16,650 nt.(96). Conversely, other henipaviruses of both Asiatic (CedV) and African lineages (GhV) also have the GDNQ motif that is common to most other NNR viruses. High-resolution cryo-EM structures of VSV-RdRP (another NNR virus, family *Rhabdoviridae*) suggest that GDN is the truly conserved catalytic motif essential for the polymerase function of RdRP.[13]

The receptor binding proteins (RBPs) of the *Paramyxovirinae* display hemagglutination (H) and neuraminidase (N) activities in a predominantly genus-specific manner. Viruses in the genera *Respirovirus, Avulavirus*, and *Rubulavirus* possess both activities, hence their RBPs were formerly termed HN proteins (76) whereas viruses in the genus *Morbillivirus* do not behave uniformly and only some possess hemagglutination activity, but nonetheless their RBPs were formerly termed H. (77) This is an unfortunate misnomer. Paramyxoviruses with RBPs bearing HN activity genuinely use sialic acid based receptors for entry whereas "H" activity of some morbilliviruses arise from their RBPs ability to bind CD46 expressed on some non-human primate red blood cells. [14] In contrast, henipavirus RBPs have neither of these activities(146),(166); rather, they utilize the host cell expressed ephrin-B2 and ephrin-B3 molecules as attachment and entry receptors (11),(13),(105),(106) [15] with the exception of MojV, which does not appear to use any known paramyxovirus receptors.[16] Recent solution structures of various henipavirus RBPs alone and in complex with the ephrin-B2 and/or ephrin-B3 receptors have revealed the details of the virus–host cell binding process, distinguishing it from other paramyxoviruses's receptor binding strategies.(20),(21),(163)[15] [14]

Proteolytic processing of paramyxovirus F proteins is essential for the generation of a fusogenic form of the protein. For most paramyxoviruses that generate systemic infections, cleavage is catalyzed by the cellular protease furin at a multibasic cleavage site.(76) Surprisingly, henipavirus F proteins are cleaved without the involvement of furin and, although cleavage occurs at a single basic residue—lysine for HeV and arginine for NiV(98)—activation of the NiV F protein does not require a basic amino acid at the cleavage site.(93) It has been shown that the lysosomal cysteine protease cathepsin L is responsible for the cleavage of the HeV F protein.(108) The cytoplasmic tails of henipavirus F proteins contain the endocytosis consensus motif YXX ø.(92),(143) Endocytosis is required for cleavage activation of the F protein,(35),(92) consistent with identification of cathepsin L as the enzyme responsible for cleavage.

<H2>Host Range

For most paramyxoviruses, host range is limited and interspecies transmission is rare. In contrast, henipaviruses display a broad species tropism. In addition to ~~at least three flying fox species, two nonpteropid fruit bat species, and an insectivorous species~~a large number of bat hosts at various geographic locations (see more detail in Epidemiology section), NiV has naturally infected pigs, humans, dogs, horses, and cats,(29),(63),(97),(120),(164) whereas HeV infects all four Australian flying fox species and has naturally infected humans,~~ and~~ horses and dogs.(42),(104) Confirmation of the wide host range of henipaviruses and the identical cell

Commented [L17]: Benhur, I forgot whether we agreed for you to include a discussion on the RBP structure evolution story here?! If so, pls insert here.

BHL: I'm stoopping here. It's 7:30 am and I need to get some sleep before resuming. Potentially the "extra:" Fig. 14.7B (Structural phylogeny of different paramyxovirus RBPs will go well here).

Commented [L18]: This is obviously HeV and NiV dominating. But I don't think there is anything new to add for the other henipaviruses?!

tropism of HeV and NiV were obtained early using an *in vitro* cell fusion system that relies on vaccinia virus–mediated cell surface expression of G and F glycoproteins.(17)·(18)·(136) Guinea pigs, hamsters, ferrets, squirrel monkeys, and African green monkeys are also susceptible to experimental NiV infection.(19)·(46)·(88)·(94)·(157) Laboratory studies have added cats, guinea pigs, hamsters, ferrets, and African green monkeys to the list of HeV-susceptible species,(53)·(121)·(151)·(156). ~~along with ferrets (J. Pallister and L. F. Wang, unpublished results).~~Mojiang virus was isolated from rats ().

<H1>Pathogenesis and Pathology

<H2>Cell and Tissue Tropism

The primary site of NiV replication and the dynamics of virus spread in humans are unknown. However, the distribution and time of appearance of lesions throughout the vasculature and in the brain and lung in NiV encephalitis suggest that secondary infection probably arises via hematogenous spread of the virus, with secondary replication occurring in vascular endothelium.(159) Inflammation of blood vessels occurs in most organs but is particularly prominent in the brain, lung, heart, and kidney.(30)·(159)·(160) Vasculitis is limited to small arteries, arterioles, and capillaries where NiV antigen is found in both endothelial cells and the smooth muscle of the tunica media. The pattern and time of appearance of vasculitis and viral antigen distribution are consistent with endothelial cell infection occurring before infection of the smooth muscle. Syncytial endothelial cells are present in blood vessels of various organs and represent a pathognomonic but insensitive feature of henipavirus infections found in only 25% of human NiV infections.(159) Syncytial endothelial cells were also observed in the single human case of encephalitis caused by HeV.(107) NiV antigen is also found in neurons and, less frequently, in bronchiolar and renal epithelial cells. The 5-day interval between maximal vasculitis in the brain and parenchymal infection in acute NiV encephalitis suggests that primary virus replication occurs in endothelial cells, with infection of neurons occurring as a result of vascular damage. The presence of inclusion bodies and viral antigen in neurons suggests that neurologic impairment in encephalitis may be caused by both the effects of ischemia and infarction and viral infection of neurons.(30)·(114)·(159) Human HeV encephalitis has been described as widespread cortical, subcortical, and deep white matter involvement in two cases in 2008(115) and similar to those described in a previous HeV encephalitis case(82)·(107) and NiV encephalitis cases.(82)·(127)

Although NiV antigen is found less frequently in bronchiolar and renal epithelial cells compared with vascular and neuronal locations, replication in epithelial locations may play a role in virus dissemination, because NiV is found in urine and in tracheal and nasopharyngeal secretions of infected patients in the early phase of their illness.(31)·(48) Despite this, human-to-human transmission in Malaysia was extremely rare.(100)

The identification of ephrin-B2 and ephrin-B3 as functional receptors for henipaviruses in cultured cells provides an explanation for the observed distribution of viral antigen in arterial endothelial cells, smooth muscle, neurons, and some epithelial cells.(11)·(13)·(105)·(106) Ephrin-B2 is found in arteries, arterioles, capillaries in multiple organs, and tissues including arterial smooth muscle and human bronchiolar epithelial cells(135) but is absent from venous components of the vasculature.(45) Ephrin-B3 is found predominantly in the nervous system as well as the vasculature.(113) The ephrins engage Eph receptors and mediate bidirectional cell–cell signaling events and are modulators of cell remodeling events, especially within the nervous and vascular systems.(113)

<H2>Immune Response

In patients with encephalitis, anti-NiV antibodies were observed more frequently in the serum than the CSF. Immunoglobulin M (IgM) antibodies occurred more frequently than immunoglobulin G (IgG) antibodies in both locations.(30),(114),(159) The appearance of specific IgM antibodies in serum preceded their appearance in the CSF, a sequence consistent with viremia preceding central nervous system (CNS) infection. Anti-NiV antibodies were present in most patients with clinical NiV encephalitis; however, no difference was observed in clinical features, laboratory results, or mortality between seropositive and seronegative patients.(27),(48) Seroconversion of IgG against HeV was seen in two human cases of HeV infection, one fatal, in 2008,(115) following an influenza-like illnesses and before progressing to encephalitis.

<H2>Inhibition of the Interferon Response

In henipaviruses, as in other paramyxoviruses,(66) anti-interferon (IFN) activities are encoded by the *P* gene and *in vitro* studies indicate that *P* gene products inhibit both IFN induction and signaling.(37) In IFN induction, viral double-stranded RNA (dsRNA) is detected by intracellular RNA helicase enzymes(3),(79) and by toll-like receptor 3 (TLR-3).(12) Both of these dsRNA signaling pathways lead to activation of the pre-existing transcription factors interferon regulatory factor 3 (IRF-3) and nuclear factor kappa B (NF-kB),(50) and the synthesis of IFN-α and a subset of IFN-β proteins.(89) HeV inhibits dsRNA signaling by using a strategy adopted by other paramyxoviruses in which the V protein binds to the intracellular RNA helicase sensor and prevents downstream signaling(3) but does not abrogate dsRNA signaling through TLR-3.(132) In an additional strategy unique to henipaviruses, the W protein, by virtue of a nuclear localization signal located in the unique carboxy terminal, inhibits dsRNA signaling in the nucleus by targeting a process that is part of both helicase-dependent and TLR-3–dependent signaling pathways.(132)

In the IFN signaling pathway, IFN binds to cell surface receptors in a paracrine manner and initiates a signaling sequence that leads to activation of members of a family of proteins called *signal transducers and activators of transcription* (STAT).(1),(50) Henipaviruses inhibit IFN signaling by sequestering STAT proteins in high molecular weight complexes.(123),(124) The anti-IFN signaling activity is a property of the V protein, as has been observed for other paramyxoviruses, but also of the W and P proteins.(123),(124),(133) The P, V, and W proteins of henipaviruses have an N-terminal extension of 100 to 200 amino acids compared with cognate proteins in the subfamily,(59),(147) and the STAT binding domain of NiV V maps to this region.(122) The V and P proteins bind STAT in the cytoplasm, whereas the W protein, with its nuclear localization signal, co-localizes with STAT in the nucleus.(132),(133) The W protein is the most and P protein the least efficient IFN antagonist.(112) The NiV C protein also displays a modest inhibition of IFN signaling, although the mechanism and target are unknown.(112)

It should be noted that most, if not all, studies described previously were carried out *in vitro* using single-gene transfection expression systems. A recent study conducted using live virus infection indicated that IFN signaling remains functional during henipavirus infection of human cell lines, whereas IFN production was inhibited.(142)

<H2>Infections of Animals

Only limited data are available on the minimal lethal and infectious doses of henipaviruses. In golden hamsters (*Mesocricetus auratus*), the NiV lethal dose 50% (LD$_{50}$) following intraperitoneal and intranasal administration was 270 and 47,000 plaque-forming units (pfu), respectively,(157) and was calculated to be 12 pfu for HeV by intraperitoneal injection.(53) The NiV minimal infectious dose in hamsters is 100 pfu if the intraperitoneal route is used and 10^3 pfu if the virus is administered intranasally. Guinea pigs and pigs are also more resistant to infection by HeV and NiV, respectively, when the viruses are administered by the oronasal route compared with the subcutaneous route.(95),(154) In contrast, both HeV and NiV appear to be equally infectious for cats following either parenteral (5,000 tissue culture infectious dose 50% [TCID$_{50}$] virus) or oronasal (50,000 TCID$_{50}$ virus) administration.(64),(91),(95),(101),(151)

Experimental infection of horses with HeV by parenteral or oronasal routes is almost uniformly fatal, with death or euthanasia usually occurring 5 to 10 days after infection. Several horses in the original outbreak in Hendra survived infection, however, some asymptomatically.(103),(104),(156) In horses, HeV displays a predominantly respiratory tropism, and infection is characterized by pulmonary edema and congestion.(64),(104),(156) In field cases, the airways are often filled with a blood-tinged frothy exudate. Neurologic signs do exist, but they have been observed infrequently in terminally ill horses and in horses that recovered from respiratory infection.(125),(156) Infection is associated with virus replication and with the appearance of viral antigen in endothelial cells in a wide variety of organs, including lungs, lymph nodes, kidneys, spleen, bladder, and meninges. The subsequent degeneration of small blood vessels is accompanied by the appearance of syncytial endothelial cells.(63) Virus can be recovered from several internal organs, including lung, and from saliva and urine.(64),(156)

In contrast, NiV infection of pigs is frequently asymptomatic, particularly following natural infection and after experimental administration of the virus by the ocular and oronasal route.(95),(97),(150) When symptoms are present, they vary according to the age of the pig, with older animals presenting primarily with a neurologic syndrome, whereas a respiratory syndrome predominates in young animals. The virus manifests respiratory and neurologic tropisms in both asymptomatic and clinical infections.(95),(149) Neurologic signs include trembling and neurologic twitches, muscle spasms, and uncoordinated gait.(97) After experimental NiV infection of young pigs by the ocular and oronasal routes, virus replication occurs in the oropharynx and spreads sequentially to the upper respiratory tract and submandibular lymph nodes, the lower respiratory tract, and additional lymphoid tissues.(149) Here, viral antigen is widespread and syncytia are common in clinically affected animals as a result of replication in the endothelial and smooth muscle cells of medium to large veins as well as in the arteries of the central nervous, lymphoid, and respiratory systems.(63),(95),(149) NiV invades the CNS via the cranial nerves and by crossing the blood–brain barrier.(149) Virus is recovered from a range of tissues, including tonsil, nasal, and throat swabs and lung, but is recovered infrequently from urine.(34),(95),(149) Experimental HeV infection of pigs (Landrace and Gottingen minipig breeds) via oronasal or nasal inoculations has shown both to be susceptible to infection,(80) with virus detected mainly in tissues from respiratory and lymphoid systems, and could be isolated from nasal, oral, and rectal swabs, indicating the possible routes for virus shedding.

<H2>Laboratory Animal Models

In hamsters, the pathologic features following NiV infection resemble those found in humans.(157) Hamsters die 5 to 9 days after intraperitoneal administration of 100 to 10,000 infectious particles and 24 hours after the appearance of tremors and limb paralysis. In contrast, hamsters inoculated intranasally with doses as high as 10^3 to 10^6 infectious particles die between 9 and 15 days later, displaying progressive deterioration with limb paralysis, lethargy, limb twitching, and breathing difficulties. Vascular pathology is observed in a range of organs, including brain, lung, liver, kidney, and heart, and viral antigen and genome are found in endothelial cells. The brain is the most severely affected organ, with the vascular and parenchyma lesions consistent with CNS-mediated clinical signs.(159) HeV infection of hamsters also resembled the pathology seen in acute human cases, including both respiratory and brain pathology.(53) HeV-induced pathology in the hamster was similar to that of NiV(157) and consisted of endothelial infection and vasculitis with thrombosis and microinfarction, with evidence of direct parenchymal cell infection, notably in the CNS.

In cats, the first clinical signs, which are observed on days 4 to 8 after parenteral or oronasal administration of HeV and NiV, include depression, fever, and an increased rate of respiration.(65),(101),(151),(152) Most infected animals die 1 day after the appearance of respiratory distress. The disease caused by HeV and NiV in cats closely resembles that seen in HeV-infected horses, with copious frothy sanguineous fluid in the bronchi and hemorrhage or congestion of the tracheal epithelium.(64) Vaculitis affects both arteries and arterioles, and syncytial cells are observed in endothelia, predominantly in the lungs but also in gastrointestinal, spleen, and lymphoid organs. A major difference between NiV and HeV infection of cats is the extensive degree to which NiV, but not HeV, infects the respiratory epithelium.(95) Henipaviruses are found in the urine and bladder of experimentally infected cats, and NiV can transplacentally infect and replicate in fetal tissues with high levels of recoverable virus from the placenta and uterine fluid.(102)

In guinea pigs, the clinical response to henipavirus infection is frequently mild and often variable, ranging from inapparent to sudden death, with only a proportion of animals displaying signs such as transient weight loss, depression, ataxia, lethargy, and twitching.(154),(157) The vascular tropism of HeV in guinea pigs is evident in many organs.(65)

Death appears to result from vascular disease in a variety of organs.(65) Only a proportion of infected animals develop encephalitis with virus observed in blood vessels and neurons.(154)

A ferret model of henipavirus infection and pathogenesis has also been developed.(19),(110) The ferret exhibits both severe respiratory and neurologic disease as well as generalized vasculitis following an oronasal challenge with NiV with doses as low as 500 $TCID_{50}$ within 6 to 10 days postinfection. Clinical signs in affected ferrets included various combinations of severe depression, cough, serous nasal discharge, dyspnea, subcutaneous edema of the head, cutaneous ecchymoses, and obtundation with tremor and hind limb paresis depending on the challenge dose. Clinical disease in the ferret included vascular fibrinoid necrosis in multiple organs, necrotizing alveolitis, and syncytia of endothelium and alveolar epithelium. Histopathologic lesions included severe focal necrotizing alveolitis, vasculitis, degeneration of glomerular tufts, and focal necrosis in a wide range of other tissues. High levels of viral antigen were noted in blood vessel walls, and syncytial cells were frequently present. Viral antigen was present in neurons, and infectious NiV was isolated from multiple organs including the brain. Overall, NiV-mediated disease observed in the ferret model manifested with all the hallmarks seen among NiV-infected humans, and essentially identical results have been observed with HeV infection of ferrets (J. Pallister and L.-F. Wang, unpublished results).

A nonhuman primate model of henipavirus infection has been developed using the African green monkey,(46),(121) which yields a uniformly lethal disease with doses as low as approximately 2×10^4 pfu (NiV) or 4×10^5 $TCID_{50}$ of HeV. Monkeys, following intratracheal inoculation with either NiV or HeV, reveal a rapid spread of the virus (3–4 days postinfection) to numerous organ systems. NiV-infected monkeys developed a severe acute respiratory distress syndrome (ARDS)-like disease, associated with copious amounts of sanguineous fluid and froth. The lungs are enlarged with multifocal areas of congestion and hemorrhage, and immunohistochemical and histopathologic examination revealed significant amounts of polymerized fibrin and NiV antigen.(46) Endothelial syncytial cells were prominent in most of the tissues, and vasculitis was widespread. NiV antigen was present in endothelial and arterial smooth muscle cells in most examined tissues. Respiratory disease development could be seen within 7 days postinfection with either NiV or HeV following intratracheal inoculation by radiologic examination(46),(121) progressing to severe congestion and infiltration in the lung fields.

NiV and HeV could be found in virtually every organ system sampled at the time of death in the African green monkey. Immunohistochemical and histopathologic analysis revealed the presence of NiV antigen, predominantly in endothelial cells and smooth muscle cells, along with associated pathology. Most animals showed evidence of henipavirus-induced neurologic disease,(46),(121) with severe congestion and evidence of meningeal hemorrhaging and edema. NiV and HeV antigen was detected in endothelial cells in brain, with infection of neurons often widespread in the brain stem.(46),(121) NiV infection of squirrel monkeys has also been examined.(88) Although some animals demonstrated limited similarities to NiV pathogenesis in humans, only 50% of challenged animals exhibited any clinical signs, with most remaining well even following intranasal or intravenous delivery of doses as high as 10^7 pfu of NiV.

Unlike the cat, guinea pig, hamster, and squirrel monkey models of NiV or HeV infection, severe respiratory pathology, neurologic disease, and generalized vasculitis all occur in henipavirus-infected African green monkeys, providing an accurate reflection of what is observed in henipavirus-infected humans.

<H1>Epidemiology

<H2>Age

The age of patients with encephalitis in the Malaysian outbreak ranged from 9 to 76 years, with almost 50% of cases occurring in those 40 to 44 years.(27)·(28)·(48)·(111)·(159) The male-to-female ratio was approximately 3:1, and more than 80% of the patients were Chinese, with statistics reflecting the increased risk to those working with infected pigs.(48)·(111) In Bangladesh, the age of patients ranged from 4 to 60 years, and males constituted 47% and 67% of the cases in the 2001 and 2003 outbreaks, respectively.(43)·(68) The ~~recent~~ outbreak in early 2011 in Bangladesh claimed at least 35 lives, including many children and infants, with ages ranging from 2 to 56 years.(8) Among the 18 suspected patients in the 2014 oubreak in the Phillipines, the age distribution is between 21-60 years old (). In the most recent NiV outbreak in Kerala, India, the age distribution ranged from a 17 year old male to a 75 year old female among a total of 23 human cases ()

<H2>Morbidity and Mortality

In Malaysia, between September 1998 and June 1999, 256 patients who developed acute NiV encephalitis were admitted to Malaysian hospitals and 105 died, a mortality rate of approximately 40%.(30)·(111) The rate of subclinical infection in households and farms where cases of NiV encephalitis occurred was calculated to be 8% and 11%, respectively.(111)·(139) In Singapore, where 11 patients were confirmed to have acute NiV encephalitis, a further 2 asymptomatic abattoir workers were serologically positive, representing a rate of subclinical infection of 15%.(25) Subsequently, 89 individuals were identified on the basis of positive serology as having experienced either an asymptomatic or mildly symptomatic NiV infection.(138) This increases the number of people infected with NiV to 345 and decreases the mortality rate to approximately 30%.(160) In Bangladesh, 98 of 135 patients died in eight outbreaks from 2001 to 2008, giving a combined case fatality rate of 73%.(43)·(62)·(85) In the Philippines outbreak, the case mortality is 53% out of all the suspected cases or 81% for those with encephalitic clinical signs.() The case mortality is 94% for the Kerala outbreak in India ()There have only been seven known human cases of HeV infection in Australia in the past 16 years, four of which have been fatal (three acute and one case of relapsed encephalitis).(6)·(104)·(107)·(115)

<H2>Origin and Spread of Epidemics

Fruit bats (flying foxes) in the genus *Pteropus*, family *Pteropodidae*, suborder *Megachiroptera* are main reservoir hosts of HeV and NiV.(33)·(56)·(164)·(165) In Australia, HeV has been shown to occur in all four flying fox species, with the crude seroprevalence of 47%, indicating an endemic pattern of infection throughout Australia.(42) Serologic tests show that

NiV or NiV-related virus is widely dispersed in ~~pteropid~~ bats ~~in~~ from Malaysia~~,~~ to the west border of Africa (Fig. 14.10). ~~especially the Island flying fox (*Pteropus hypomelanus*) and the Malayan flying fox (*Pteropus vampyrus*).(~~164) NiV was first isolated from the urine of Island flying foxes and from the saliva on partially eaten fruit(33) and has since been isolated from Lyle's flying foxes (*Pteropus lylei*) in Cambodia~~.~~(120) and *Pteropus medius* in Bangladesh() The Indian flying fox (*Pteropus giganteus*) is the ~~only~~ main pteropid species throughout Bangladesh and the Indian subcontinent with a high seroprevelence of henipavirus-specific antibody.(39),(68),(86),(87) Additional serologic and limited nucleic acid evidence has suggested that related henipaviruses are circulating in other regions, including Thailand, Indonesia, Vietnam, China, Madigascar, and several countries and regions in ~~West~~ Africa.(36),(61),(70),(81),(131),(145)

Formatted: Font: Italic

Neither HeV nor NiV appear to cause clinical disease in flying foxes infected naturally,(42),(43),(119),(164) and experimental infection with doses of HeV, consistently shown to be lethal in horses, generates only sporadic vasculitis in the lung, spleen, meninges, kidney, and gastrointestinal tract and only in a proportion of infected bats.(156) Viral antigen is detected in the tunica media rather than endothelial cells, a fact that may spare the flying fox from the clinical effects associated with vasculitis.(37) In infected pregnant flying foxes, antigen was observed in similar locations and in the placenta.(155) The mode of transmission between flying foxes is unknown. Transplacental transmission has also been observed experimentally without apparent harm to the fetus.(155) Experimental infection of flying foxes with NiV produced a subclinical infection with a transient presence of virus within selected viscera along with periodic viral excretion in bat urine and seroconversion with neutralizing antibody present.(94)

The spillover and epidemic hosts of HeV and NiV were horses in Australia and pigs in Malaysia. All human infections with HeV in Australia and NiV in Malaysia have only occurred through transmission from these domestic animal hosts.(30),(111) No evidence exists of direct transmission from pteropid bats to humans in Australia or Malaysia, despite many opportunities in Australia for transmission to bat carers.(127),(129) In contrast, flying foxes apparently play a direct role in the transmission of NiV to humans in the many recent outbreaks of disease in Bangladesh, where epidemiologic evidence in support of a role for pigs was lacking.(43),(68) Three pathways of NiV transmission from bats to people have been identified based on epidemiologic investigations in Bangladesh.(85) Consumption of fresh date palm sap appears to be the predominant risk factor, and infrared camera studies have confirmed that *P. giganteus* bats frequently visit date palm sap trees and consume sap during collection.(126) In the 2005 NiV outbreak in Tangail District, Bangladesh, drinking raw date palm sap was the only activity significantly associated with illness (64% among cases vs. 18% among controls).(87) Another route of transmission for NiV from bats to people in Bangladesh could be via domestic animals. Contact with a sick cow in Meherpur, Bangladesh, in 2001 was strongly associated with NiV infection,(68) and contact with pigs and diseased goats have also been implicated in other occurrences of NiV in Bangladesh.(85) Although NiV has never been isolated in domestic livestock animals, serological evidence was reported for antibodies to NiV or NiV-related viruses in cattle, goats and pigs in Bangladesh. ()

Commented [L24]: Chowdhury et al., 2014 PloS NTD

Transmission via direct contact with NiV-infected bat secretions also appears possible from evidence in the Goalando outbreak in 2004, where individuals who climbed trees were more likely to develop NiV infection than controls.(99)

The mode of transmission from bats to spillover hosts in Australia and Malaysia remains to be determined. Three principal hypotheses exist. One is that masticated pellets of virus-contaminated, residual fruit pulp spat out by flying foxes are ingested by horses or pigs.(164) The second is that urine from infected animals contaminates pastures or pigsties. The third is that infected fetal tissues or fluids contaminate pastures or sties and are ingested. The latter is based largely on the fact that the HeV outbreaks have occurred during the birthing period of some species of flying fox and is supported by the isolation of virus from a pregnant flying fox and its fetus.(56)

HeV has been transmitted from horse to man on seven occasions from 1994 to 2009, twice during the initial outbreak in Brisbane,(4) twice during necropsy of horses that died in the field,(125),(130) twice during either daily nasal cavity lavage and participating in a necropsy,(115) and once from performing an endoscopy on an infected horse.(6) HeV is rarely found in the bronchi or bronchioles of infected horses, which suggests that aerosol transmission to either man or horses is less likely(64) and horse-to-horse transmission of HeV has not been demonstrated.(156) The presence of HeV in equine saliva, however, suggests that close contact with infected horses, such as might occur during manual feeding of the animals, may facilitate horse-to-human transmission.(130) The presence of virus in a wide range of tissues and in the nasal discharge commonly found at the terminal stage of infection offers a range of sources for virus transmission during necropsy.(103),(104) As shown in Fig.~~ure~~ ~~37.5~~14.1xA, high level of viral antigen can be detected in the nasal cavity of HeV-infected horses.

<FIG>

In the Malaysian NiV outbreak, contact with pigs or fresh pig products was required for transmission of the virus to humans, with greater likelihood of transfer to those in direct contact with sick or dying pigs on farms or in abattoirs.(30),(111) The presence of NiV in the respiratory epithelium of naturally and experimentally infected pigs (Fig. ~~37.5~~14.1xB) indicated that virus probably spread to humans and within the pig population by aerosol or by direct contact with oropharyngeal or nasal secretions.(95),(97),(149) The presence of the virus in a wide range of organs indicates that humans may also have been infected during processes such as slaughtering or farrowing. In Bangladesh, pigs were excluded as potential sources of NiV on epidemiolog grounds, and human-to-human transmission was observed.(54),(62) The virus may have been transmitted to human index cases directly through contact with fruit bat secretions in contaminated fruit or date palm sap before circulation in the human population.(33),(43),(68),(85) Nosocomial transmission has been detected in some of the Bangladesh and India outbreaks.(9),(23),(85) In the Philippines NiV outbreak, Of the 17 case-patients, a total of 7 (41%) had participated in horse slaughtering and horse meat consumption; 3 (18%) had only consumed horse meat and but had no history of slaughtering or meat preparation; 5 (29%) case-patients had been exposed to other human casepatients but not to any horses. So it is possible that both horse-to-human and human-to-human transmission might have occurred. () For the Kerala NiV outbreak, while it remains undefined how the index case was exposed to NiV, it was evident that human-to-human transmission was the main driver for the spread of the virus in both family/community and hospital settings. ()

Commented [L26]: Arunkumar et al., 2018, JID

<H1>Clinical Features

<H2>Incubation Period

Based on the time interval between the last exposure to pigs and onset of disease, the incubation period for NiV ranged from 2 to 45 days; however, for 90% of patients, it was 2 weeks or less.(27),(28),(48) An estimate of 2 to 3 weeks was made based on the time interval between importation of pigs from NiV-affected areas of Malaysia and development of human disease at a Singaporean abattoir.(25) A mean incubation period of 9.4 days was calculated for four patients who had a fixed period of exposure.(27) In the occurrence of HeV in Australia in 2008, a detailed examination of exposure histories from two infected patients (one fatal) suggested a likely incubation period of 9 to 16 days, with exposure occurring some 3 days before the onset of symptoms of HeV infection in the horse.(115)

<H2>Acute Clinical Features

The first two patients infected with HeV presented with myalgia, headaches, lethargy, and vertigo. One patient recovered; however, the other developed pneumonitis, respiratory failure, renal failure, and arterial thrombosis, and died of cardiac arrest 7 days after admission to the hospital. Findings at autopsy were consistent with a viral infection; both lungs were congested, hemorrhagic, and filled with serous fluid, and the histology revealed focal necrotizing alveolitis with many giant cells, some syncytial formation, and viral inclusions.(130) A third case of HeV infection presented first with meningitis and a 12-day history of sore throat, headache, drowsiness, vomiting, and neck stiffness. After an apparent full recovery, this patient developed fatal encephalitis 13 months later and was admitted to the hospital with a generalized tonic-clonic seizure after 2 weeks of irritable mood and low back pain. Recurrent focal motor seizures occurred over the next 7 days, as did secondarily generalized seizures and low-grade fever, followed by dense right hemiplegia, signs of brain stem involvement, and depressed consciousness requiring intubation. The patient remained comatose and died 25 days after admission.(107) Two patients in 2008(115) presented with initial influenza-like illness, although soon after apparent clinical improvement and an absence of fever, encephalitis developed in both. Magnetic resonance imaging (MRI) revealed widespread cortical, subcortical, and deep white matter involvement, similar to the previous late-onset case of HeV encephalitis(107) and to NiV encephalitis cases.(78),(127)

With NiV, the mean duration of illness from the onset of symptoms to the nadir was 3 to 31 days, with an average of 6.9 days.(48) Most patients presented with acute encephalitis characterized by fever, headache, drowsiness, dizziness, myalgia, and vomiting, and more than 50% had a reduced level of consciousness.(27),(30),(48),(114) The major clinical signs included drowsiness, areflexia, segmental myoclonus, tachycardia, hypertension, pinpoint pupils, and an abnormal doll's eye reflex. Such clinical features as these suggested involvement of the brain stem and upper cervical spinal cord, and were observed more frequently in patients with a reduced level of consciousness.(48),(139) Patients who retained normal levels of consciousness throughout their illness recovered fully; however, only 15% with reduced levels of consciousness survived. Such neurologic manifestations are consistent with vasculitis-induced thrombosis in the brain and the direct infection of neurons.(29),(30),(114),(159) The multiple discrete lesions 1 to 5 mm in diameter in the cerebral white matter detected by MRI may be the site of such microinfarctions and are distinct from lesions caused by other viruses.(30),(82),(114),(127),(159) Although the predominant clinical features of NiV encephalitis derive from CNS involvement, a proportion of patients displayed pulmonary involvement, which presented as an atypical pneumonia with fever, cough, and headache.(27),(48),(114) The clinical presentation of NiV infections in Bangladesh is also predominantly a severe respiratory disease.(67)

<H2>Outcome of Infection

Most patients who survived acute NiV encephalitis made a full recovery; however, approximately 20% had residual neurologic deficits.(27),(48),(83) Neurologic sequelae included cognitive difficulties, tetraparesis, cerebellar signs, nerve palsies, and clinical depression. A few patients remained in a vegetative state. In patients with encephalitis who recovered, most brain lesions revealed by MRI disappeared or became smaller over a period of 12 to 18 months, although some remained unchanged during this period.(83) Approximately 7.5% of patients who recovered from acute encephalitis and 3.4% of those who experienced nonencephalitic or asymptomatic infection developed late neurologic disease.(48),(127),(138),(161) Relapse encephalitis and late-onset encephalitis presented several months to 4 years after the initial infection. Relapsed cases had elevated IgG, but not IgM, and no vasculitis, and unlike the situation in acute encephalitis, virus was not isolated from throat and nasal secretions.(30)(–)(32),(127),(159),(161)

The clinical features associated with relapse and late-onset encephalitis resembled those found with acute NiV encephalitis, although decreased incidence was seen of fever, coma, segmental myoclonus, and meningism and an increased occurrence of seizures and focal cortical signs compared with the acute manifestation of the disease.(138) The clinical, radiologic, and pathologic features of relapse NiV encephalitis resembled those of the patient who became infected with HeV, suffered mild, transient aseptic meningitis, and recovered but died of a fatal meningoencephalitis 13 months later.(107),(158) Most patients with relapse and late-onset encephalitis had only one neurologic episode, although some patients experienced two episodes separated by a mean of 7.6 months (6 weeks to 1 year).(138) The mortality rate associated with relapse and late-onset encephalitis at 18% was lower than that associated with acute encephalitis, at 30% to 40%. However, 61% of patients with relapse and late onset had further neurologic sequelae compared with 22% after acute encephalitis. Among NiV survivors in Bangladesh, some 30% have moderate to severe persistent neurologic dysfunction for years following acute infection.(128)

The demographics, clinical features, serology, and MRI of patients with relapsed and late-onset encephalitis were similar, suggesting that the two diseases have identical pathogenesis(138) and that the initial infection in late-onset encephalitis patients may not have been sufficiently severe to cause neurologic symptoms. MRI abnormalities similar to those observed in patients with acute encephalitis were also seen in 16% of asymptomatic patients, although the lesions were fewer in number.(139) The involvement of the cortex in relapse and late-onset encephalitis suggests a different pathologic mechanism compared with acute encephalitis. Relapse and late-onset encephalitis are considered to be caused by the recrudescence and rapid replication of virus that had persisted following acute or asymptomatic NiV infection.(138) NiV, however, was not isolated from CSF and brain tissue of patients with relapse and late-onset encephalitis.(138)

<H1>Diagnosis

Commented [L27]: I don't think there is anything new and worthwhile to add here.

<H2>Laboratory Diagnosis

Virus isolation, EM, immuno-EM, immunohistochemistry (IHC), serology, and polymerase chain reaction (PCR) played key roles in the initial discovery of HeV(104) and NiV,(29) and they remain essential elements in a repertoire of procedures for the rapid and specific diagnosis of henipavirus infections in humans and animals.

During investigation of a suspected disease outbreak, attempts to grow henipaviruses may be initiated in a BSL3 laboratory. However, if a cytopathic effect (CPE) is observed and the growth of henipavirus is confirmed by PCR or immune staining, infected cultures should be handled under BSL4 conditions and subsequent work with live virus restricted to BSL4. Both HeV and NiV replicate in various cell lines—a feature that contributed to the efficiency with which they were isolated during the initial disease outbreak investigations.(29)·(104) Vero cells are commonly used, generating titers of virus as high as 10^8 infectious virions per milliliter.(28)·(34) In fatal cases, attempts should be made to isolate virus from brain, lung, kidney, and spleen.(34) For tissue specimens containing a high virus load, direct examination by immuno-EM and IHC can be very useful in providing early diagnosis. Various antibody reagents have been developed for this purpose, including polyclonal antisera, monospecific antibodies raised against recombinant antigens,(147) and monoclonal antibodies (mAb) raised against whole virions or vaccinia virus–expressed viral proteins.(71)·(140)·(141)·(153) Using HeV- or NiV-specific mAb, it is possible to differentiate between the two viruses.(141)·(153) Quantitative real-time PCR (TaqMan assay) has been the method of choice to detect viral materials in infected tissues because of its speed, specificity, and sensitivity. The first-generation henipavirus TaqMan assays are either HeV specific(134) or NiV specific.(52) Recently, several consensus henipavirus real-time PCR assays have been developed that target different conserved regions of the viral genome.(41) It should be cautioned that the current PCR tests may not work with new henipaviruses yet to be discovered, especially those from African bats, owing to expected greater genetic divergence than those detected in Australia and Asia.

For henipaviruses, serologic tests are important both during outbreak investigation and for disease surveillance. The virus neutralization test (VNT) is accepted as the reference standard.(34) Few laboratories, however, can conduct neutralization tests because of the requirement to handle live virus at BSL4. For surveillance and diagnostic purposes, three types of tests that do not require BSL4 containment have been developed:

1. *Enzyme-linked immunosorbent assay (ELISA):* Several ELISA-based tests have been reported for the detection of henipavirus antibodies.(34),(40),(73) For diagnosis of human infections, two different ELISA tests have been applied: an IgM capture ELISA for early diagnosis of infection and an indirect ELISA for detection of IgG antibodies.(34)
2. *Liquid protein array multiplex test:* A Luminex-based test based on recombinant soluble G proteins of HeV and NiV was developed that is capable of mimicking VNT with great sensitivity and differentiating between antibody responses of HeV versus NiV infection.(15)
3. *Pseudotype virus:* Different pseudotype systems carrying the henipavirus F and G proteins have been developed as a surrogate VNT for detecting henipavirus-specific antibodies.(72),(74),(137) Incorporation of reporter genes in these systems resulted in greater sensitivity and reproducibility.(72),(137)

<H1>Prevention and Control

<H2>Treatment

Ribavirin, which inhibits replication of HeV *in vitro*,(162) was used during the NiV outbreak in Malaysia in an open-label study in which 140 patients with encephalitis were given the drug, and 54 patients who presented before ribavirin became available or who refused treatment acted as controls.(26) Mortality in the treated group was 32% compared with 54% in the control group, representing a 35% reduction ($P = 0.011$). Duration of ventilation and total hospital stay were both significantly shorter in the ribavirin group ($P = 0.0002$ and <0.0001, respectively). In the absence of other therapies, ribavirin may be an option for treatment of henipavirus infections. However, two HeV-infected patients in 2008(115) were given a high-dose intravenous regimen of ribavirin, although basal concentrations appeared inadequate given the results of *in vitro* susceptibility testing of HeV, and the efficacy of ribavirin as therapy or prophylaxis in people remains at best uncertain. Chloroquine, an antimalarial drug, was first demonstrated to block the critical proteolytic processing needed for HeV F maturation and function.(109) Not surprisingly, the drug was later shown to inhibit NiV and HeV infection in cell culture experiments.(117) Chloroquine was administered along with ribavirin to one HeV-infected individual in 2009(6) with no apparent clinical benefit.

In vivo, ribavirin only delayed but did not prevent deaths caused by NiV and had no effect on HeV infection in a hamster model.(44),(47) Ribavirin treatment also only delayed disease onset by 1 to 2 days in African green monkeys challenged with HeV with no significant benefit for disease progression or outcome.(121) Chloroquine administration, either alone or in combination with ribavirin, had no therapeutic benefit in ferrets challenged with NiV or hamsters challenged with either NiV or HeV.(44),(110)

<H2>Vaccines and Passive Immunotherapy

No henipavirus vaccines are available at this time; however, studies suggest that vaccination may offer several viable anti-henipavirus strategies.(22),(38) NiV F and G glycoproteins expressed from vaccinia virus elicit neutralizing antibodies in mice and hamsters,(51),(136) with higher antibody titers generated in response to the G glycoprotein compared with the F glycoprotein. Hamsters were protected from lethal challenge with NiV following vaccination with vaccinia virus expressing either NiV F or G glycoprotein.(51) The challenge virus was capable of hyperimmunizing vaccinated animals, indicating that although the virus replicated, the presence of neutralizing antibodies ameliorated replication to an extent that limited infection and prevented clinical disease. Further, the protection afforded hamsters by passive transfer of anti-G and anti-F antibodies before a lethal NiV or HeV challenge confirmed both the importance of a humoral protective immune response to NiV.(51),(53)

HeV G glycoprotein has been expressed in a soluble form (sG-HeV) that retains many native characteristics and can elicit a potent cross-reactive neutralizing antibody response in rabbits.(14) Rabbit anti-HeV G antibodies neutralize both HeV and NiV in cell culture, displaying a slightly higher titer against the homologous virus. The nature and location of the neutralizing epitopes on the F glycoprotein have not been reported, although preliminary information is available for the HeV G glycoprotein.(153) Four neutralizing epitopes have been mapped on the globular head of the HeV G protein. Two are located on the base of the head and two on the top, in locations resembling those identified as neutralizing sites in other paramyxoviruses.

Immunization and challenge studies using recombinant sG-HeV in the cat model have demonstrated that the protein can illicit a completely protective immune response against NiV challenge,(101) even at a low-dose formulation with CpG and Alhydrogel and a two-dose protocol followed by oronasal challenge with 50,000 TCID$_{50}$ of NiV.(91) Further sG-HeV immunization studies have been completed in the ferret with a HeV challenge (J. Pallister and L-F. Wang, in submission) and in the African green monkey with a NiV challenge (T. Geisbert and C. Broder, in submission). In both of these investigations, complete protection from henipavirus-induced disease was achieved. The potential application of sG-HeV as an equine vaccine is being evaluated in Australia (D. Middleton, personal communication). These data suggest that a single vaccine (sG-HeV) may be effective against both HeV and NiV. Analysis of the antibody responses in sera from naturally infected or immunized sources has also shown that HeV-infected sources had high levels of NiV G cross-reactive antibodies, whereas NiV-infected individuals had limited cross-reactive antibodies to HeV G. Together, these data suggested that the HeV G stimulates a more cross-reactive immune response.(15)

The sG-HeV glycoprotein was also used to isolate HeV G-specific human mAbs. One human mAb (m102.4) was HeV and NiV cross-reactive and possessed extremely potent virus neutralizing activity.(167),(168) *In vivo* studies have demonstrated that m102.4 can protect animals from a lethal challenge with henipavirus as a postexposure application in the ferret model with NiV(19) and in the African green monkey model with HeV (T. Geisbert and C. Broder, in submission). In August 2009, m102.4 was used on a compassionate basis to save the life of an HeV-infected individual while in a coma (G. Playford, personal communication). Unfortunately, delivery and intravenous administration of only 100 mg of available antibody occurred after the onset of encephalitis, and the individual died shortly thereafter. During the 2010 HeV emergence, 11 people had potential exposure and 2 individuals considered at high risk. In this instance, the m102.4 antibody was given to 2 individuals prior to HeV diagnosis or the onset of clinical disease(5) at doses sufficient to achieve a high serum concentration. Both individuals have remained healthy. Altogether, these findings highlight the therapeutic potential of antibody-based passive transfer modalities for treating henipavirus exposure.

<H2>Peptide Inhibitors

The first potential henipavirus-specific therapeutic was shown to be a heptad peptide-based fusion inhibitor(17) analogous to the human immunodeficiency virus type 1 (HIV-1)-specific peptide, enfuvirtide (Fuzeon) approved by the Food and Drug Administration (FDA) in March 2003. The henipavirus F_1 glycoprotein resembles other fusion glycoproteins in having α-helical heptad repeat (HR) domains proximal to both the fusion peptide at the amino (N) terminus and the transmembrane domain near the carboxy (C) terminus of the protein. The HR domains are involved in the formation of a trimer-of-hairpins structure during or immediately following the fusion of virus and cell membranes that occurs during infection. Addition of exogenous peptide from either HR domain blocks formation of the trimer-of-hairpins and abrogates membrane fusion and entry of the viral genome into the cell.(16)·(17)·(38) These observations were followed up with testing cholesterol tagged HR-derived peptides in the hamster model of NiV infection.(118) The *in vivo* efficacy of peptide fusion inhibitors of henipavirus infection merits further investigation.

<H1>Perspective and Geographic Considerations

The high virulence of the henipaviruses and the requirement for BSL4 facilities have hampered investigations into the biology and pathogenesis of these novel paramyxoviruses. Recent investigations into the structure and function of henipavirus proteins expressed from cloned genes have provided insight into the functions of many henipavirus proteins in infected cells. It remains to be determined if all of the functional characteristics of the henipavirus proteins determined *in vitro* accurately reflect the role that they play in the cells of both terrestrial and chiropteran hosts.

Many questions relating to the ecology and biology of henipaviruses remain unanswered. Little doubt exists that *Pteropus* species of fruit bats are the major reservoir host of these viruses. With the wide geographic range of *Pteropus* species as overlapping populations, extending from islands in the South Pacific through Australia, and southern Asia to Pakistan, and with additional species on islands off the eastern coast of Africa, together with the cross-reactive serologic evidence of henipavirus presence,(61)·(81) it would seem that several other related viruses may remain to be identified.(43)·(56) The emergence of these and related viruses is probably associated with the destruction of the flying fox native habitats, driving the animals to seek food from orchards and ornamental trees in urban and periurban areas.

Thus, with continued deforestation, undoubtedly further outbreaks of HeV, NiV, and novel related members of the genus will occur. The mechanisms by which henipaviruses are transmitted between fruit bats and maintained within their colonies, as well as the pathways leading to the infection of spillover hosts, remain to be elucidated.

Figure 37.1. Syncytia induced in vero cells 24 hours after infection by Hendra virus (HeV) (A) and Nipah virus (NiV) (B). Methanol-fixed infected cells were labeled with rabbit monospecific antiserum to the HeV P protein and fluorescein-conjugated goat antirabbit immunoglobulin G. P protein is detected in extensive perinuclear ribonucleoprotein complexes (*small arrow*) and in discrete regularly shaped arrays (*large arrow*) distributed throughout the cytoplasm and believed to be sites of virus egress from the cell. Nuclei are indicated by *chevrons.*

Figure 37.2. A: Electron micrograph of Nipah virus (NiV)-infected Vero cells showing tubule-like structures, both in the cytoplasm and in a maturing virus particle (*arrows*). **B:** Electron micrograph of negatively stained Hendra virus (HeV) displaying the double fringe at the virus envelope (*small arrow*) and the herringbone nucleocapsids (*large arrow*). (Courtesy of Dr. Alex Hyatt, CSIRO Australian Animal Health Laboratory.)

Figure 37.3. Genome size and organization of Hendra virus compared with type species of each of the other four classified genera in the subfamily *Paramyxovirinae.* Genome lengths (in nucleotides) are given in brackets after each virus.

Figure 37.4. Phylogenetic relationship between the N protein sequences of henipavirus isolates from different geographic locations. The virus nomenclature abbreviation follows the following format: virus/country origin/host/year/isolate name. For example, NiV/KH/BA/2004/KHM represents a Nipah virus isolated from bats in Cambodia in 2004 with KHM as its isolate name.

Figure 37.5. Immunoperoxidase detection of viral antigen in henipavirus-infected tissues. **A:** Staining of Hendra virus (HeV) antigen (N protein-specific antibody) within the wall of superficial arteriole in the submucosa of the nasal cavity in a HeV-infected horse. **B:** Immunolabeling (using anti–Nipah virus rabbit serum) within the lung of a pig infected with Nipah virus. Involvement of bronchial epithelium and airway debris is noted. (Courtesy of Dr. Deborah Middleton, CSIRO Australian Animal Health Laboratory.)

Table 37.1. Summary of Henipaviruses Isolated from Different Species and Geographic Locations

		Isolation details

HNV_Fields Ref.enlp.zip

Dear LinFa,

I started reading through your sections and adding/editing what I could but ran into some problems and inconsistencies with our agreed upon outline, I had to stop. I simply can’t do everything myself - I also have meetings to chair and conferences to go to.

For now, I’m sending back to you what I have done and ask for your help in giving me back a document that I can deal with more easily. I almost finished everything up to my own section on Pathogenesis _ I can't add my own section yet because of the **referencing conflicts** - in fact I hardly have had time for my own section.

(1) I have added all the new references you requested and then some more (these are are highlighted in GREEN in the main text). This was easy using my endnote file.

- The most important thing is that all the old references in big brackets/parentheses (ref)(ref)(ref)(ref) are not linked to the master endnote file I sent out. So, when I configure my bibliography, I can only see the new refs I added in, which is about 16 for now.
- I simply do **not** have the time or energy to go through 168 (ref)(ref)(ref)(ref) by myself and individually replace them with linked citations from my endnote file (I’m sure you weren't expecting me to).
- When Chris gave me his section, I could easily format and configure the bibliography, which will help when I put everything together. That was the plan.
- PLEASE replace all the (ref) (ref) (ref) (ref) in the main text with the refs from my Endnote file. Or have someone do it for you. You and Chris will see what I mean when you open the document and see my comments/notes.

(2) To make things easier to see, I have accepted all your comments (on the side column) but left your original changes (it appears orange/peach colored in my word document. My changes/edits are dark red/maroon. It’ll be obvious. I added the most text about the 3’IUTR and on the RBP section. Then, I ran out of steam. It’s extremely distracting and hard not to be able to format all those (ref) (ref) (ref) (ref) !

(3) I made some suggestions about what Tables to put online, etc.

(4) Finally, parts of what you wrote does not conform to the section outline you sent us, and which I painstakingly clarified and confirmed multiple times by sending out clearly color coded outline and Figure/Table numbering. For example, I thought the genetic diversity section was suppose to be in Section D5 (Epidemiology), so your **Fig. 14.4 in the text** is actually **Fig. 14.11** in my master powerpoint. I thought we al agreed to the figure and Table numbering and order.

Basically, I was a bit frustrated and confused to continue. I felt like all my efforts in organizing the figures and sticking to your outline have been wasted. I am more than happy to edit and compile, but we must all agree to the same rules and do our parts.

I am sending back **(A)** your doc which I edited so far, and **(B)** the latest master endnote file, which you should use to replace all (ref) (ref) (ref) (ref) in your document. Chris, I hope you understand what I mean when you open the document.

There is no way I can compile the final documents unless everyone uses the same endnote file. I had no problems with compilingeveryone's Tables, so I was surprised at receiving your doc where all the (ref) (ref) (ref) (ref) have not been replaced.

Benhur **(One word doc and one Endnote file attached).**

[a] Expression inferred from (1) transcriptional data (microarray, next-generation sequencing, RT-PCR, etc.) provided in the cited references, or (2) indepedently verified through the Gene Expression Omnibus (GEO) Database (https://www.ncbi.nlm.nih.gov/geo/), or (3) competition with soluble ephrinB ligands or interference with cognate henipavirus receptor binding proteins. [b] For clarity and uniformity, only infection-permissive (not fusion-permissive) data are indicated; infection includes use of live virus and/or pseudotyped virus. [c] References cited support expression, infection data, or cell-type origin where relevant, and are representative, not comprehensive. [d] Indicates >10-100-fold below positive control when quantitative data is avialable. ND, not determined; (?), not specifically mentioned.

TABLE 14.5 Summary of Advanced Henipavirus Vaccination Development Initiatives Evaluated in Animal Challenge Models

Platform	Viral antigen target or immunogen	Animal challenge model
Active vaccination		
Recombinant vaccinia virus	Nipah F and/or G glycoprotein	Hamster[a] (NiV)
Recombinant canarypox virus	Nipah F and/or G glycoprotein	Pig[b] (NiV)
Recombinant VSV	Nipah F and/or G glycoprotein	Ferret[c] (NiV), Hamster[d] (NiV), nonhuman primate[e] (NiV)
Recombinant AAV	Nipah G glycoprotein	Hamster[f] (NiV, HeV)
Recombinant measles virus	Nipah G glycoprotein	Hamster[g], Nonhuman primate (NiV, HeV)
Recombinant subunit	Hendra soluble G glycoprotein	Cat[h] (NiV), Ferret[i] (HeV, NiV), nonhuman primate[j] (HeV, NiV) Horse[k] (HeV)
Passive immunization		
Human monoclonal antibody m102.4	Hendra / Nipah G glycoprotein	Ferret[l] (NiV) Nonhuman primate[m] (HeV, NiV)

[a] Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vaccinia viruses were protected against disease following intraperitoneal challenge with 10^3 PFU of NiV.[1]

[b] Pigs immunized with NiV F and/or G glycoprotein encoding recombinant canarypox viruses were protected against intranasal challenge with $2.5x10^5$ PFU of NiV.[2].

[c] Ferrets immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intranasal challenge with $5x10^3$ PFU of NiV.[3]

[d] Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intraperitoneal challenge with 10^5 $TCID_{50}$ of NiV;[4] or $6.8x10^4$ $TCID_{50}$ of NiV.[5]

[e] African green monkeys immunized with a NiV G encoding recombinant VSV vector were protected against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV.[6,7]

[f] Hamsters immunized with a NiV G encoding recombinant adeno-associated virus (AAV) vector were protected against lethal intraperitoneal with 10^4 PFU of NiV.[8]

[g] Hamsters and African green monkeys immunized with a NiV G encoding recombinant measles virus vector were protected against lethal intraperitoneal challenge with 10^3 $TCID_{50}$ of NiV (hamsters) or 10^5 $TCID_{50}$ of NiV (AGMs).[9]

[h] Hendra virus soluble G glycoprotein (HeV-sG) used to immunize cats protects against lethal subcutaneous (500 $TCID_{50}$)[10] or oronasal ($5x10^4$ $TCID_{50}$) NiV challenge.[11]

[i] HeV-sG used to immunize ferrets protects against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of HeV[12] or $5x10^3$ $TCID_{50}$ of NiV challenge.[13]

[j] HeV-sG used to immunize African green monkeys protects against lethal intratracheal challenge with 10^5 $TCID_{50}$ of NiV[14] or $5x10^5$ PFU of HeV.[15]

[k] HeV-sG used to immunize horses protects against lethal oronasal challenge with $2x10^6$ $TCID_{50}$ of HeV[16].

[l] A NiV and HeV cross-reactive G glycoprotein specific neutralizing human mAb (m102.4) protects ferrets against lethal oronasal challenge with $5x10^3$ $TCID_{50}$ of NiV[17] or $5x10^3$ $TCID_{50}$ of HeV (J. Pallister and C. Broder, unpublished) by post-exposure infusion.

[m] Human mAb m102.4 protects African green monkeys by post-exposure infusion following lethal intratracheal challenge with $4x10^5$ $TCID_{50}$ of HeV[18] or lethal intratracheal challenge with $5x10^5$ PFU of NiV.[19,20]

Subject: Table 14.3 Henipavirus Cell Tropism and Receptor Expression
Date: Sunday, February 17, 2019 12:07:46 AM
Attachments: Table 14.3.Henipavirus Cell Tropism.docx
TABLE 14-5-Formatted-Broder.docx
HNV Fields Ref.enlp.zip

Hi Folks,

I forgot to send you my completed **Table 14.3** on HNV Cell tropism and Receptor Expression.

Please check the Table if you have time. Refs have been formatted. I will remove the name/date when we are ready to put everything together (since only Ref numbers are allowed in the Tables).

- Please see the **footnotes (a, b, c, d)** to the Table for an explanation of how to interpret the various items in the Table.
- It's obviously not comprehensive. I had to make judgement calls about what to put in and what to leave out. My criteria is for the table to be useful, so there is a combination of positive and negative data.
- It's divided into human and non-human cell lines/primary cell types, and then listed alphabetically.
- Let me know if I missed anything major.

LinFa, can you put the reference number in (or ask your asst to do it ;-) for your tables. It'll take me too much time to replace all the (name/date) references that you have in your Tables by myself.

Chris, I was so pleased that I could format your Table 14.5 with no problems using the Master endnote file (**HNV_Fields Ref.enlp**). So, the system works! I have attached your formatted Table 14.5. Hopefully everything looks correct.

Finally, I have added the refs you all have asked me to. The Master endnote file I'm attaching to this email has **1,208 references**.

Thanks!

Benhur

Subject: Master Endnote file
Date: Friday, February 15, 2019 4:17:30 PM
Attachments: HNV Fields Ref.enlp.zip

O.K, I hope this is what you are asking for.

This is the Endnote "Package" file (i.e. it is self-contained **".enlp"** that does not require accompanying "Endnote Library.Data Folders", rdg, tdb, etc.). It is NOT the default ",enl" endnote file which Endnote generates.

Feel free to search directly from this **.enlp** file to add anything that is not here. Right now, it has 1,193 ref with no duplications and contains PubMed Refs with Nipah OR Hendra in any field.

Thanks!

benhur

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (*Pteropus* species and several other bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species (including horses, cats, and dogs) were found to be infected with NiV on the farms involved in the outbreak. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India. Some differences have been noted in the clinical features of infection, with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiV infection is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Ready availability and accessibility of r~~R~~obust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) ~~that are readily available and accessible~~ for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research represents a substantial challenge, since economic incentives to invest in Nipah research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions, which can increase the cost of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- While ferrets, Syrian hamsters, and interferon-alpha/beta receptor knockout (IFNAR-KO) mice are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major

challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures.
- Obtaining additional prospective serosurveillance data of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk should be explored as a strategy to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure.
- Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains for R&D of MCMs for NiV infection. Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
- Clear criteria for downselection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or other regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.

- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species.
- Additional research is needed to optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) for promoting development and evaluation of MCMs, particularly if investigators are required to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurologic sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development.

- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole-genome sequencing of NiV are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains to facilitate R&D of NiV MCMs.

2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and that may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.
- **Generate** research tools to promote R&D of MCMs for NiV infection (e.g., standardized and validated assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for downselection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.

- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific, and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and investigation into the cause of infection is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.

- Owing to the biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the rapid disease progression of NiV infection.
- Currently, no approved tests for diagnosis of NiV infection are commercially available.
- *Pteropus* species (and perhaps other bat species) appear to carry other henipaviruses in addition to NiV and HeV, some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate using serologic assays which henipaviruses are in circulation. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests. As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature), and have a high sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

- Improved diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, particularly given the costs of regulatory approval.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotype neutralization assays and antigen-capture enzyme-linked immunosorbent assays [ELISAs]) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries: Bangladesh and India.

2. By 2021, identify funding and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.

Priority Areas/Activities

Research

- **Create** a virtual repository of clinical reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- **Develop and evaluate** point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons.
- In NiV-endemic areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis but do not have NiV infection. Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore, accurate and rapid diagnosis is critical.
- Studies in animals often evaluate the usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control–programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.
- A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that are detected annually.

Key needs

- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas, particularly during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).
- A transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials, given the limited number of cases that could potentially be enrolled in trials each year.

Knowledge gaps

- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to further assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection and strengthen the therapeutic pipeline.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
3. By 2019, identify an approach for downselecting promising therapeutic candidates for further study in clinical trials, given limited annual case numbers for enrollment.
4. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
5. By 2020, generate a reliable source of m102.4 (or other promising agent[s] or agent combinations) to be ~~used~~ assessed in clinical trials.

Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4 and favipiravir) for treating and preventing NiV infection, including conducting studies in animal models and clinical trials as appropriate and feasible.
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Generate** a reliable source of m102.4 to be used in clinical trials.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development, and few companies are willing to invest in the generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could diminish the acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptance and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen, and therefore multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed involving target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- Additional sociological research is needed to explore perceptions and concerns of at-risk populations regarding NiV vaccine implementation.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the need for licensure and future use of NiV vaccines. This consultation should include representatives from in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.

- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Evaluate** the feasibility of generating multivalent vaccines (i.e., that protect against more than one disease) and determine whether or not such vaccines would be useful in future NiV control efforts.

Product development

- **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Introduction

Nipah virus (NiV), a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chua 1999, Chew 2000, Parashar 2000). At least 265 human cases of encephalitis were identified in Malaysia and most had close contact with pigs (Chua 2010, Parashar 2000). In addition, 11 abattoir workers in Singapore became ill following contact with pigs imported from Malaysia; eight patients presented with signs of encephalitis and three presented with atypical pneumonia (one of which later also had evidence of encephalitis) (Paton 1999). No new outbreaks have been reported in these countries since May 1999; however, NiV infection was subsequently recognized in Bangladesh in 2001 (Hsu 2004) and nearly annual outbreaks have occurred in that country since then (WHO 2018). Outbreaks also have been recognized in eastern India and, in 2018, an outbreak occurred in the southern Indian state of Kerala (Arunkumar 2018, Sharma 2018, Chattu 2018). To date, nearly 350 cases of NiV infection have been identified in Bangladesh and India (WHO 2018). Possible emergence of NiV in a third geographic area is evidenced by an outbreak of an unidentified henipavirus that occurred among horses and humans in the Philippines in 2014 (Ching 2015). Although detailed genomic information for the virus is limited, experts agree that the causative agent was either NiV or a virus closely related to NiV. The Henipavirus genus includes another pathogen, Hendra virus, which predominantly causes infection in horses in Australia and can also lead to human disease, usually following contact with infected horses (Ksiazek 2011).

The most common clinical syndrome associated with NiV infection is severe, rapidly progressive encephalitis (Goh 2000, Hossain 2008). The main presenting features include fever, headache, dizziness, vomiting, and altered mental status. NiV infection may result in late-onset

encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Tan 2002, Goh 2000). Some patients also have respiratory involvement or respiratory illness alone, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The overall case-fatality rate for the Malaysia outbreak was approximately 40%, whereas case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 65% to 100% (Hossain 2008, WHO 2018). Genomic sequencing has demonstrated that there are multiple strains of NiV, which may account for the differences noted in clinical features and outcomes between Malaysia and Bangladesh (Mire 2016).

Fruit bats of the Pteropus genus are considered the primary natural reservoir for NiV. In the Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and possibly limited human-to-human NiV transmission (Chua 2010). Additionally, several other domestic animal species in the outbreak area (including horses, cats, and dogs) were found to be infected with NiV (Chua 2000). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap (Islam 2016, Luby 2006, Rahman 2012) and subsequent person-to-person transmission. While person-to-person transmission was apparently minimal in the Malaysia outbreak, it has played a larger role in amplifying outbreaks in Bangladesh and India (Gurley 2007, Luby 2009, Chadha 2006, Arunkumar 2018). This may, in part, be related to the greater propensity toward respiratory disease in NiV strains found in South Asia and transmission via droplet spread (Spiropoulou 2018). A recent study demonstrated that hamsters could be infected when exposed to NiV via a small-particle aerosol; however, the epidemiologic significance of this remains unclear (Escaffre 2018). Given the potential for respiratory transmission of NiV and the recent experience with

Ebola in West Africa, some have raised concerns about the possibility of larger NiV outbreaks if the virus takes hold in a crowded or urban area (Donaldson 2018) or about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Pteropus fruit bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Other fruit bats of the Pteropodidae family also may harbor NiV, and such bats can be found across Africa and parts of the Middle East. Evidence of NiV infection (via virus isolation, serologic testing, or nucleic acid detection using real-time polymerase chain reaction [RT-PCR]) has been found in Pteropus bat species and other bat species in geographically diverse regions, including South Asia (Bangladesh and India); Southeast Asia (Cambodia, Indonesia, Malaysia, the Philippines, Thailand, and Vietnam); the Western Pacific region (Papua New Guinea); and Africa (Madagascar and Ghana) (Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2018, Yob 2001). This wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

WHO has determined that Nipah virus is a priority disease for epidemic preparedness (WHO 2018). To improve epidemic response for this infection, in the fall of 2017, WHO embarked on development of a research and development (R&D) roadmap for NiV disease; this report provides a summary of the key elements of that roadmap, including important challenges and barriers that need to be addressed to ensure that diagnostics, therapeutics, and vaccines are

developed, manufactured, and readily available when needed *[provide link to full roadmap here when available]*.

The NiV R&D roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one medical countermeasure category), diagnostics, therapeutics, and vaccines. The strategic goals and milestones identified in each section are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updates to the roadmap as needed. The roadmap is specific to R&D for disease in humans; however, further research of NiV in animal species, including development of appropriate medical countermeasures targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV in humans and virus transmission can occur at the human-animal interface.

Cross-Cutting Issues

A major challenge for development of diagnostics, therapeutics, and vaccines for NiV is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Advocacy to policy makers in affected countries and to global stakeholders is needed to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures. As part of this process, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate human populations in areas of predicted risk. Human health, animal health, and wildlife officials should be engaged in these efforts as part of a long-term collaborative One Health approach (Chattu 2018, Kulkarni 2013).

Another important issue is the need to optimize relevant animal challenge models for promoting development and evaluation of medical countermeasures for NiV infection, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval (Rockx 2014). For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for therapeutic or vaccine development; (3) determine when after challenge medical countermeasures should be administered in animal models to best mimic realistic timing of such use in humans; (4) bridge data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human doses; and (5) identify the best models for studying chronic (relapsing) infection (Dhondt 2013, Johnston 2015, Mathieu 2015). Currently, the African green monkey is regarded as the most relevant animal model for evaluating candidate therapeutics and vaccines intended for use in humans (Bossart 2012, Geisbert 2010, Johnston 2015), and studies involving nonhuman primates may be required for licensure of therapeutics and vaccines via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns, however, constrain the use of this animal model. In addition to optimizing animal models, standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains are needed to move R&D of medical countermeasures for NiV infection forward (Satterfield 2016).

To inform development of optimal NiV medical countermeasures, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals.

This includes issues such as evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection.

To respond to these challenges, the strategic goals and milestones for cross-cutting issues in the NiV R&D roadmap focus primarily on developing a sustainable value proposition and identifying funding sources to promote R&D, availability, and accessibility of NiV medical countermeasures, optimizing animal models for research, and generating standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains to facilitate R&D of NiV medical countermeasures (Table 1).

Diagnostics

Currently, no approved tests for diagnosis of NiV infection are commercially available. The most commonly used methods for diagnosing NiV infection include virus isolation, enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies, and real time-polymerase chain reaction (RT-PCR) nucleic acid testing. Virus isolation requires biosafety level 4 (BSL-4) capabilities and is generally only performed in reference laboratories for specific purposes, such as to confirm a new outbreak or to identify the virus in new host species (Wang 2012). During the Malaysia outbreak, the US Centers for Disease Control and Prevention (CDC) developed a capture ELISA for detection of IgM antibodies and an indirect ELISA for detection of IgG antibodies (Daniels 2001); since then, additional ELISA tests have been developed (Wang 2012) and serologic testing is often used for case confirmation during outbreaks (Chadha 2006, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009). RT-PCR, which can be performed on throat and nasal swabs, cerebrospinal fluid, urine, and blood, is also often used for diagnostic testing (Chadha 2006, Guillaume 2004, Lo 2012). Quantitative RT-qPCR tests have been developed for quantifying viral replication; such tools can be used to measure viral load reduction when screening vaccine candidates and potential therapeutics (Jensen 2018). More recently, pseudotyped-based serum neutralization assays for NiV detection that use vesicular stomatitis virus systems have been developed; these assays potentially can be used under BSL2 conditions in laboratories with limited diagnostic capabilities and appear to offer improved sensitivity and specificity (Kaku 2009, Kaku 2012, Tamin 2009). Antigen-capture ELISAs using monoclonal antibodies also have been developed, which could result in more rapid diagnosis (Chiang 2010). These newer technologies hold promise; however, more information is needed regarding their performance characteristics, particularly under field conditions. Development and validation of immunohistochemical staining tests can facilitate studies on pathogenesis of NiV infections and may also be useful for primary diagnosis in low-resource settings.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation, which can delay outbreak detection and implementation of infection control measures. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. To address these issues, rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes, once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of such a repository requires addressing the following: (1) determining what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outlining the purposes of sample collection; (3) determining what organizations will be responsible for activities related to creating and maintaining the repositories; (4) establishing standardized protocols for sample collection and maintenance; (5) establishing an appropriate governance structure; (6) identifying who would have access to the samples; (7) prioritizing use of samples and sample distribution; and (8) ensuring that material transfer agreements are in place. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

To address these issues, the strategic goals and milestones for diagnostic testing outlined in the NiV R&D roadmap focus on creation of a virtual reference repository, development of highly sensitive and specific point-of-care or near-patient NiV diagnostic tests, and enhancement of laboratory diagnostic preparedness to promote early detection of NiV in areas of known or potential spillover risk (Table 2).

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients; findings from treated patients were compared to those of 54 historical controls who became ill before ribavirin was available or who refused treatment (Chong 2001).

Results demonstrated a significantly lower mortality (36%) among treated patients; however, the use of historical controls may have biased this finding. No additional clinical studies using ribavirin have been conducted, and limited studies in animal models have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Rockx 2010, Georges-Courbot 2006). Chloroquine also has been studied in animal models, but has not shown any therapeutic benefit, either alone or in combination with ribavirin (Freiberg 2010, Pallister 2009). Based on these findings, these approaches are not considered viable options for treatment of NiV infection.

A more promising therapeutic option is the development of monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). Therapy with anti-NiV mAbs may be appropriate for early treatment and for post-exposure prophylaxis (PEP) to prevent illness in exposed persons, such as healthcare workers, family caregivers, and persons exposed to infected livestock. Researchers have demonstrated that the human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009), and it has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Recently, a phase 1 clinical trial of m102.4 with 40 human participants was completed in Australia, but results are not yet available (ANZCTR). M102.4 was deployed for use during the 2018 NiV outbreak in Kerala, India, but was not used because the outbreak was brought under control quickly (Spiropoulou 2018). One recent study in nonhuman primates showed that the therapeutic window for m102.4 may vary by virus strain, which is a consideration for further preclinical and clinical study of this agent (Mire 2016). It may also be worthwhile to explore development of alternate mAbs against NiV or to evaluate cocktails of mAbs.

Other potential options for NiV treatment include favipiravir (a small-molecule antiviral that inhibits RNA-dependent RNA polymerase), fusion inhibitory peptides (peptides that inhibit virus-mediated membrane fusion), and remdesivir (also known as GS-5734, which is a monophosphoramidate prodrug of an adenosine analogue). Researchers recently demonstrated efficacy of favipiravir in hamsters challenged with a lethal dose of NiV (Dawes 2018), supporting proof-of-concept for favipiravir as a possible therapy against NiV infection. Studies in animal models also have been conducted for fusion inhibitory peptides; for example, investigators recently reported that lipopeptides delivered via the respiratory route can prevent lethal NiV infection in hamsters and nonhuman primates (Mathieu 2018). Remdesivir is a small-molecule antiviral that is currently being evaluated in clinical studies as a therapeutic option for treating Ebola virus disease. Investigators recently demonstrated in vitro inhibition by remdesivir against a number of different viruses, including paramyxoviruses (Lo 2017). While these agents are promising, further preclinical data are needed to assess their utility. In addition, efforts are needed to expand the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents that may be more aligned with optimal and desired characteristics for anti-NiV therapy.

Key additional considerations for moving NiV therapeutics forward include: (1) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising novel treatments for NiV disease; (2) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (3) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in both endemic and at-risk areas. A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that are detected each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources. Additionally, clinicians in endemic areas need to maintain high vigilance for cases of acute febrile encephalitic syndrome, particularly in association with respiratory symptoms, to facilitate early diagnosis and case identification. Additional training of clinicians along with effective and appropriate risk communication strategies need to be implemented in endemic areas.

To address these issues, the goals and milestones for therapeutics in the NiV R&D roadmap focus on continuing to move promising agents forward into clinical trials and on enhancing preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks (Table 3).

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Satterfield 2016). A Hendra virus subunit vaccine involving soluble glycoprotein (sG) has been developed and is commercially available for use in horses (Middleton 2014), which supports this option as a promising approach for developing a human NiV vaccine.

The Coalition for Epidemic Preparedness Innovations (CEPI), which is a partnership of government agencies, industry, academia, philanthropy, and intergovernmental institutions aimed at providing funding for R&D of new vaccines against pathogens with epidemic potential, has recently provided financial support to promote the development of several NiV candidate vaccines. In May 2018, CEPI awarded a US$ 25 million contract to Profectus BioSciences, Inc. and Emergent BioSolutions Inc. to develop a human NiV vaccine that is based on the same technology as that used for the Hendra virus vaccine for horses (CEPI 2018). In September 2018, CEPI announced plans to award approximately US$ 2 million to the Jenner Institute at the University of Oxford and Janssen Vaccines & Prevention BV for preclinical development of a replication-deficient simian adenoviral-vectored vaccine, derived from an adenovirus originally isolated from chimpanzees (CEPI 2018). These efforts, and potentially additional future efforts funded by CEPI, will support preclinical and early clinical development of NiV vaccines.

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research in this area should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

The immediate goals and milestones in the vaccine section of the NiV R&D roadmap focus on moving vaccine candidates forward into clinical trials and promoting development of guidance on requirements for clinical trials, regulatory pathways, and other considerations relevant to licensure of a vaccine against NiV (Table 4).

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures forward. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Tables

Table 1: Goals and Milestones for NiV Infection Cross-Cutting Issues

Goals and Milestones for NiV Infection Cross-Cutting Issues	
STRATEGIC GOALS	**MILESTONES**
1. Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas. 2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
2. Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.	1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation. 2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.
3. Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and NiV challenge strains to facilitate R&D of NiV MCMs. 2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.
Abbreviations: NiV, Nipah virus; MCM, medical countermeasure; R&D, research and development.	

Table 2: Goals and Milestones for NiV Diagnostics

Goals and Milestones for NiV Diagnostics	
STRATEGIC GOALS	**MILESTONES**
1. Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India). 2. By 2021, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.

2. Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.	1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays. 2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays. 3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP. 4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
3. Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.	1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.
Abbreviations: NiV, Nipah virus; NRA, national regulatory authority; TPP, target product profile.	

Table 3: Goals and Milestones for NiV Therapeutics

Goals and Milestones for NiV Therapeutics	
STRATEGIC GOALS	**MILESTONES**
1. Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. 2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. 3. By 2019, identify an approach for downselecting promising therapeutic candidates for further study in clinical trials, given limited annual case numbers for enrollment. 4. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. 5. By 2020, generate a reliable source of m102.4 (or other promising agent[s] or agent combinations) to be assessed in clinical trials.

2. Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.	1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates. 2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection. 3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
Abbreviations: NiV, Nipah virus; PEP, post-exposure prophylaxis.	

Table 4: Goals and Milestones for NiV Vaccines

Goals and Milestones for NiV Vaccines	
STRATEGIC GOALS	**MILESTONES**
1. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.	1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure. 2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as the FDA or the EMA), national and international public health agencies and organizations, and local and international researchers.
2. Develop and evaluate NiV vaccines for prevention of NiV disease in humans.	1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates. 2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines. 3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.
Abbreviations: FDA, US Food and Drug Administration; EMA, European Medicines Agency; NiV, Nipah virus; NRA, national regulatory authority; WHO, World Health Organization.

Subject:	Nipah virus R&D roadmap and manuscript as submitted to WHO for final clearance
Date:	Friday, January 11, 2019 8:05:42 PM
Attachments:	Nipah RD Roadmap.January2019.docx Nipah Roadmap manuscript.20190111.docx

Dear Nipah virus R&D taskforce members:

First, thanks to all of you who reviewed the manuscript and roadmap and provided input. We very much appreciate your thoughtful comments and time.
We have incorporated your feedback and have sent the documents to WHO for their final review. I have attached them here as an FYI. The roadmap contains track changes so our WHO colleagues can see the edits and make final decisions regarding the content.

We hope that that the roadmap will be published in the next few weeks and that we can submit the manuscript for publication soon. We're currently planning to submit to Lancet ID, but the final decision and next steps rest with WHO. We will likely need you to sign off on the manuscript once it is accepted for publication.

We'll keep you posted as this effort progresses.

Again, thank you for your time and support.

Kind regards,

Kris

Introduction

Nipah virus (NiV), a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chua 1999, Chew 2000, Parashar 2000). At least 265 human cases of encephalitis were identified in Malaysia and most had close contact with pigs (Chua 2010, Parashar 2000). In addition, 11 abattoir workers in Singapore became ill following contact with pigs imported from Malaysia; eight patients presented with signs of encephalitis and three presented with atypical pneumonia (one of which later also had evidence of encephalitis) (Paton 1999). No new outbreaks have been reported in these countries since May 1999; however, NiV infection was subsequently recognized in Bangladesh in 2001 (Hsu 2004) and nearly annual outbreaks have occurred in that country since then (WHO 2018). Outbreaks also have been recognized in eastern India and, in 2018, an outbreak occurred in the southern Indian state of Kerala (Arunkumar 2018, Sharma 2018, Chattu 2018). To date, nearly 350 cases of NiV infection have been identified in Bangladesh and India (WHO 2018). Possible emergence of NiV in a third geographic area is evidenced by an outbreak of an unidentified henipavirus that occurred among horses and humans in the Philippines in 2014 (Ching 2015). Although detailed genomic information for the virus is limited, experts agree that the causative agent was either NiV or a virus closely related to NiV. The Henipavirus genus includes another pathogen, Hendra virus, which predominantly causes infection in horses in Australia and can also lead to human disease, usually following contact with infected horses (Ksiazek 2011).

The most common clinical syndrome associated with NiV infection is severe, rapidly progressive encephalitis (Goh 2000, Hossain 2008). The main presenting features include fever, headache, dizziness, vomiting, and altered mental status. NiV infection may result in late-onset

encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Tan 2002, Goh 2000). Some patients also have respiratory involvement or respiratory illness alone, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The overall case-fatality rate for the Malaysia outbreak was approximately 40%, whereas case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 65% to 100% (Hossain 2008, WHO 2018). Genomic sequencing has demonstrated that there are multiple strains of NiV, which may account for the differences noted in clinical features and outcomes between Malaysia and Bangladesh (Mire 2016).

Fruit bats of the Pteropus genus are considered the primary natural reservoir for NiV. In the Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and possibly limited human-to-human NiV transmission (Chua 2010). Additionally, several other domestic animal species in the outbreak area (including horses, cats, and dogs) were found to be infected with NiV (Chua 2000). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap (Islam 2016, Luby 2006, Rahman 2012) and subsequent person-to-person transmission. While person-to-person transmission was apparently minimal in the Malaysia outbreak, it has played a larger role in amplifying outbreaks in Bangladesh and India (Gurley 2007, Luby 2009, Chadha 2006, Arunkumar 2018). This may, in part, be related to the greater propensity toward respiratory disease in NiV strains found in South Asia and transmission via droplet spread (Spiropoulou 2018). ~~The potential for droplet spread is supported by a~~ A recent study ~~that~~ demonstrated that hamsters could be infected when exposed to NiV via a small-particle aerosol; however, the epidemiologic significance of this remains unclear (Escaffre 2018). Given the potential for respiratory transmission of NiV and the recent experience with Ebola in West Africa, some have raised concerns about the possibility of larger NiV outbreaks if the virus takes hold in a crowded or urban area (Donaldson 2018) or about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Pteropus fruit bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Other fruit bats of the Pteropodidae family also may harbor NiV, and such bats can be found across Africa and parts of the Middle East. Evidence of NiV infection (via virus isolation, serologic testing, or nucleic acid detection using real-time polymerase chain reaction [RT-PCR]) has been found in Pteropus bat species and other bat species in geographically diverse regions, including South Asia (Bangladesh and India); Southeast Asia (Cambodia, Indonesia, Malaysia, the Philippines, Thailand, and Vietnam); the Western Pacific region (Papua New Guinea); and Africa (Madagascar and Ghana) (Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2018, Yob 2001). This wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

WHO has determined that Nipah virus is a priority disease for epidemic preparedness (WHO 2018). To improve epidemic response for this infection, in the fall of 2017, WHO embarked on development of a research and development (R&D) roadmap for NiV disease; this report provides a summary of the key elements of that roadmap, including important challenges and barriers that need to be addressed to ensure that diagnostics, therapeutics, and vaccines are developed, manufactured, and readily available when needed *[provide link to full roadmap here when available]*.

The NiV R&D roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one medical countermeasure category), diagnostics, therapeutics, and vaccines. The strategic goals and milestones identified in each section are focused on key achievements for the next 5 years; ~~the roadmap milestones will be tracked over time,~~ the roadmap milestones will be tracked over time, with periodic assessment of progress and updates to the roadmap as needed. The roadmap is specific to R&D for disease in humans; however, further research of NiV in animal species, including development of appropriate medical countermeasures targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV in humans and virus transmission can occur at the human-animal interface.

Cross-Cutting Issues

A major challenge for development of diagnostics, therapeutics, and vaccines for NiV is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Advocacy to policy makers in affected countries and to global stakeholders is needed to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures. As part of this process, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species (e.g., bats, swine, and equids) and proximate human populations in areas of predicted risk. Human health, animal health, and wildlife officials should be engaged in these efforts as part of a long-term collaborative One Health approach (Chattu 2018, Kulkarni 2013).

Another important issue is the need to optimize relevant animal challenge models for promoting development and evaluation of medical countermeasures for NiV infection, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval (Rockx 2014). For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for therapeutic or vaccine development; (3) determine when after challenge medical countermeasures should be administered in animal models to best mimic realistic timing of such use in humans; (4) bridge data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human doses; and (5) identify the best models for studying chronic (relapsing) infection ~~(Bossart 2012, Debuysscher 2013, ~~(Dhondt 2013, Johnston 2015, Mathieu 2015~~, Satterfield 2016~~). Currently, the African green monkey is regarded as the most relevant animal model for evaluating candidate therapeutics and vaccines intended for use in humans (Bossart 2012, Geisbert 2010, Johnston 2015), and studies involving nonhuman primates may be required for licensure of therapeutics and vaccines via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns, however, constrain the use of this animal model. In addition to optimizing animal models, standardized and well-characterized assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains are needed to move R&D of medical countermeasures for NiV infection forward (Satterfield 2016).

To inform development of optimal NiV medical countermeasures, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. This includes issues such as evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection.

To respond to these challenges, the strategic goals and milestones for cross-cutting issues in the NiV R&D roadmap focus primarily on developing a sustainable value proposition and identifying funding sources to promote R&D, availability, and accessibility of NiV medical countermeasures, optimizing animal models for research, and generating standardized and well-characterized assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains to facilitate R&D of NiV medical countermeasures (Table 1).

Diagnostics

Currently, no approved tests for diagnosis of NiV infection are commercially available. The most commonly used methods for diagnosing NiV infection include virus isolation, enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies, and real time-polymerase chain reaction (RT-PCR) nucleic acid testing. Virus isolation requires biosafety level 4 (BSL-4) capabilities and is generally only performed in reference laboratories for specific purposes, such as to confirm a new outbreak or to identify the virus in new host species (Wang 2012). During the Malaysia outbreak, the US Centers for Disease Control and

Prevention (CDC) developed a capture ELISA for detection of IgM antibodies and an indirect ELISA for detection of IgG antibodies (Daniels 2001); since then, additional ELISA tests have been developed (Wang 2012) and serologic testing is often used for case confirmation during outbreaks (Chadha 2006, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009). RT-PCR, which can be performed on throat and nasal swabs, cerebrospinal fluid, urine, and blood, is also often used for diagnostic testing (Chadha 2006, Guillaume 2004, Lo 2012). Quantitative RT-qPCR tests have been developed for quantifying viral replication; such tools can be used to measure viral load reduction when screening vaccine candidates and potential therapeutics (Jensen 2018). More recently, pseudotyped-based serum neutralization assays for NiV detection that use vesicular stomatitis virus systems have been developed; these assays potentially can be used under BSL2 conditions in laboratories with limited diagnostic capabilities and appear to offer improved sensitivity and specificity (Kaku 2009, Kaku 2012, Tamin 2009). Antigen-capture ELISAs using monoclonal antibodies also have been developed, which could result in more rapid diagnosis (Chiang 2010). These newer technologies hold promise; however, more information is needed regarding their performance characteristics, particularly under field conditions. Development and validation of immunohistochemical staining tests can facilitate studies on pathogenesis of Nipah infections and may also be useful for primary diagnosis in low-resource settings.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation, which can delay outbreak detection and implementation of infection control measures. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. To address these issues, rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes, once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of such a repository requires addressing the following: (1) determining what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outlining the purposes of sample collection; (3) determining what organizations will be responsible for activities related to creating and maintaining the repositories; (4) establishing standardized protocols for sample collection and maintenance; (5) establishing an appropriate governance structure; (6) identifying who would have access to the samples; (7) prioritizing use of samples and sample distribution; and (8) ensuring that material transfer agreements are in place. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

To address these issues, the strategic goals and milestones for diagnostic testing outlined in the NiV R&D roadmap focus on creation of a virtual reference repository, development of highly sensitive and specific point-of-care or near-patient NiV diagnostic tests, and enhancement of laboratory diagnostic preparedness to promote early detection of NiV in areas of known or potential spillover risk (Table 2).

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients; findings from treated patients were compared to those of 54 historical controls who became ill before ribavirin was available or who refused treatment (Chong 2001). Results demonstrated a ~~statistically~~ significantly lower mortality ~~reduction in mortality~~ among treated patients (36%); however, the use of historical controls may have biased this finding. No additional clinical studies using ribavirin have been conducted, and limited studies in animal models have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Rockx 2010, Georges-Courbot 2006). Chloroquine also has been studied in animal models, but has not shown any therapeutic benefit, either alone or in combination with ribavirin (Freiberg 2010, Pallister 2009). Based on these findings, these approaches are not considered viable options for treatment of NiV infection.

A more promising therapeutic option is the development of monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). Therapy with anti-NiV mAbs may be appropriate for early treatment and for post-exposure prophylaxis (PEP) to prevent illness in exposed persons, such as healthcare workers, family caregivers, and persons exposed to infected livestock. Researchers have demonstrated that the human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009), and it has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Recently, a phase 1 clinical trial of m102.4 with 40 human participants was completed in Australia, but results are not yet available (ANZCTR). M102.4 was deployed for use during the 2018 NiV outbreak in Kerala, India, but was not used because the outbreak was brought under control quickly

(Spiropoulou 2018). One recent study in nonhuman primates showed that the therapeutic window for m102.4 may vary by virus strain, which is a consideration for further preclinical and clinical study of this agent (Mire 2016). It may also be worthwhile to explore development of alternate mAbs against NiV or to evaluate cocktails of mAbs.

Other potential options for NiV treatment include favipiravir (a small-molecule antiviral that inhibits RNA-dependent RNA polymerase), fusion inhibitory peptides (peptides that inhibit virus-mediated membrane fusion), and remdesivir (also known as GS-5734, which is a monophosphoramidate prodrug of an adenosine analogue). Researchers recently demonstrated efficacy of favipiravir in hamsters challenged with a lethal dose of NiV (Dawes 2018), supporting proof-of-concept for favipiravir as a possible therapy against NiV infection. Studies in animal models also have been conducted for fusion inhibitory peptides; for example, investigators recently reported that lipopeptides delivered via the respiratory route can prevent lethal NiV infection in hamsters and nonhuman primates (Mathieu 2018). Remdesivir is a small-molecule antiviral that is currently being evaluated in clinical studies as a therapeutic option for treating Ebola virus disease. Investigators recently demonstrated in vitro inhibition by remdesivir against a number of different viruses, including paramyxoviruses (Lo 2017). While these agents are promising, further preclinical data are needed to assess their utility. In addition, efforts are needed to expand the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents that may be more aligned with optimal and desired characteristics for anti-NiV therapy.

Key additional considerations for moving NiV therapeutics forward include: (1) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising novel treatments for NiV disease; (2)

ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (3) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in both endemic and at-risk areas. A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that are detected each year. To address this concern, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how to best allocate scarce resources. Additionally, clinicians in endemic areas need to maintain high vigilance for cases of acute febrile encephalitic syndrome, particularly in association with respiratory symptoms, to facilitate early diagnosis and case identification. Additional training of clinicians, along with effective and appropriate risk communication strategies need to be implemented in endemic areas.

To address these issues, the goals and milestones for therapeutics in the NiV R&D roadmap focus on continuing to move promising agents forward into clinical trials and on enhancing preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Satterfield 2016). A Hendra virus subunit vaccine involving soluble glycoprotein (sG) has been developed and is commercially available for use in horses (Middleton 2014), which supports this option as a promising approach for developing a human NiV vaccine.

The Coalition for Epidemic Preparedness Innovations (CEPI), which is a partnership of government agencies, industry, academia, philanthropy, and intergovernmental institutions aimed at providing funding for R&D of new vaccines against pathogens with epidemic potential, has recently provided financial support to promote the development of several NiV candidate vaccines. In May 2018, CEPI awarded a US$ 25 million contract to Profectus BioSciences, Inc. and Emergent BioSolutions Inc. to develop a~~n~~ human NiV vaccine that is based on the same technology as that used for the Hendra virus vaccine for horses (CEPI 2018). In September 2018, CEPI announced plans to award approximately US$ 2 million to the Jenner Institute at the University of Oxford and Janssen Vaccines & Prevention BV for preclinical development of a replication-deficient simian adenoviral-vectored vaccine, derived from an adenovirus originally isolated from chimpanzees (CEPI 2018). These efforts, and potentially additional future efforts funded by CEPI, will support preclinical and early clinical development of NiV vaccines.

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012, Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research in this area should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

The immediate goals and milestones in the vaccine section of the NiV R&D roadmap focus on moving vaccine candidates forward into clinical trials and promoting development of guidance on requirements for clinical trials, regulatory pathways, and other considerations relevant to licensure of a vaccine against NiV.

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures forward. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Tables

Table 1: Goals and Milestones for NiV Infection Cross-Cutting Issues

Goals and Milestones for NiV Infection Cross-Cutting Issues Nipah Virus Roadmap	
STRATEGIC GOALS	**MILESTONES**
1. Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
	2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
2. Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
	2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Table 2: Goals and Milestones for NiV Diagnostics

Goals and Milestones for NiV Diagnostics Nipah Virus Roadmap	
STRATEGIC GOALS	**MILESTONES**
1. Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).
	2. By 2021, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.
2. Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are	1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.
	2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
	3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.	4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
3. Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.	1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.

Table 3: Goals and Milestones for NiV Therapeutics

Goals and Milestones for NiV Therapeutics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. 2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. 3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol. ~~3.~~4. By 2019, identify an approach for downselecting promising therapeutic candidates for further study in clinical trials, given limited annual case numbers for enrollment. ~~4.~~5. By 2020, generate a reliable source of m102.4 (or other promising agent[s] or agent combinations) to be assessed in clinical trials.
2. Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.	1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
	2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
	3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Table 4: Goals and Milestones for NiV Vaccines

Goals and Milestones for NiV Vaccines **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.	1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
	2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.
2. Develop and evaluate NiV vaccines for prevention of NiV disease in humans.	1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
	2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
	3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

December 2018

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (*Pteropus* species and several other bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species (including horses, cats, and dogs) were found to be infected with NiV on the farms involved in the outbreak. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India. Some differences have been noted in the clinical features of infection, with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiV infection is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Ready availability and accessibility of r~~R~~obust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) ~~that are readily available and accessible~~ for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research represents a substantial challenge, since economic incentives to invest in Nipah research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions, which can increase the cost of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- While ferrets, Syrian hamsters, and interferon-alpha/beta receptor knockout (IFNAR-KO) mice are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major

challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures.
- Obtaining additional prospective serosurveillance data of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk should be explored as a strategy to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure.
- Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains for R&D of MCMs for NiV infection. Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
- Clear criteria for downselection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or other regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.

- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species.
- Additional research is needed to optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) for promoting development and evaluation of MCMs, particularly if investigators are required to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurologic sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development.

- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole-genome sequencing of NiV are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains to facilitate R&D of NiV MCMs.

2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and that may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.
- **Generate** research tools to promote R&D of MCMs for NiV infection (e.g., standardized and validated assays, reagents, antibodies, nucleic acids, and ~~stocks of~~ NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for downselection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.

- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an "affordable and fair" price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific, and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and investigation into the cause of infection is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.

- Owing to the biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the rapid disease progression of NiV infection.
- Currently, no approved tests for diagnosis of NiV infection are commercially available.
- *Pteropus* species (and perhaps other bat species) appear to carry other henipaviruses in addition to NiV and HeV, some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate using serologic assays which henipaviruses are in circulation. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests. As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature), and have a high sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

- Improved diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, particularly given the costs of regulatory approval.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotype neutralization assays and antigen-capture enzyme-linked immunosorbent assays [ELISAs]) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries: Bangladesh and India.
2. By 2021, identify funding and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.

Priority Areas/Activities

Research

- **Create** a virtual repository of clinical reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- **Develop and evaluate** point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons.
- In NiV-endemic areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis but do not have NiV infection. Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore, accurate and rapid diagnosis is critical.
- Studies in animals often evaluate the usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control–programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.
- A limiting constraint to assessing the effectiveness of promising therapies is the number of patients with NiV infection who can be enrolled in clinical trials, given the small number of cases that are detected annually.

Key needs

- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas, particularly during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.

- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).
- A transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials, given the limited number of cases that could potentially be enrolled in trials each year.

Knowledge gaps

- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to further assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection and strengthen the therapeutic pipeline.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
4. By 2019, identify an approach for downselecting promising therapeutic candidates for further study in clinical trials, given limited annual case numbers for enrollment.
5. By 2020, generate a reliable source of m102.4 (or other promising agent[s] or agent combinations) to be ~~used~~ assessed in clinical trials.

Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4 and favipiravir) for treating and preventing NiV infection, including conducting studies in animal models and clinical trials as appropriate and feasible.
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Generate** a reliable source of m102.4 to be used in clinical trials.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development, and few companies are willing to invest in the generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could diminish the acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac HeV from Zoetis).
- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA's Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen, and therefore multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed involving target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- Additional sociological research is needed to explore perceptions and concerns of at-risk populations regarding NiV vaccine implementation.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the need for licensure and future use of NiV vaccines. This consultation should include representatives from in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.

- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.
- **Evaluate** the feasibility of generating multivalent vaccines (i.e., that protect against more than one disease) and determine whether or not such vaccines would be useful in future NiV control efforts.

Product development

- **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Subject:	Next version of the Nipah virus R&D roadmap and manuscript--please review changes by January 7
Date:	Wednesday, December 19, 2018 12:57:13 PM
Attachments:	Nipah Roadmap manuscript.V2.docx Nipah RD Roadmap.December2018.docx
Importance:	High

Dear Nipah virus R&D taskforce members: Thank you to those who submitted comments on the versions that were sent earlier. I have attached a revised manuscript and a slightly revised roadmap; both incorporate feedback that we received.

Please take another look, if you have time. IF WE DON'T HEAR FROM YOU BY JANUARY 7, WE WILL ASSUME THAT THESE VERSIONS ARE ACCEPTABLE TO YOU.

After that date, I will forward the manuscript and roadmap to WHO for their final review and approval process. Any changes to the roadmap will be at the discretion of WHO. They will also be moving the manuscripts forward. We'll keep you posted on that process. I assume that, at some point, we'll need to obtain an authorship form from you, but that can wait for now.

Thank you again for your time and effort regarding this important work!

Happy holidays to all of you!

Warm regards,

Kris

CEPI New vaccines for a safer world

Application for funding from CEPI (CEPI-CfP-001)

Project description template step 2

1. Project summary

1.1. Project Title

A Subunit Vaccine (HeV-sG) to Protect Against Nipah and Hendra Diseases

1.2. Project summary (500 words)

*Please give a summary of the proposed project, including rationale, technology, vaccine candidate, objectives, expected outcomes and **total project costs***

Nipah virus (NiV) and Hendra virus (HeV) are closely related paramyxoviruses associated with significant morbidity and mortality in both animals and humans. Outbreaks of NiV (Malaysia, Bangladesh, India) and HeV (Australia) lead to death in 40 to 90% of infected subjects. There are currently no approved products that prevent or treat NiV or HeV infections in humans. A recombinant subunit vaccine derived from the ectodomain of HeV attachment G glycoprotein (HeV-sG) has demonstrated complete protection against lethal NiV and HeV disease in three animal species, including African Green Monkeys (AGM). In addition, a horse vaccine composed of the same HeV-sG has been marketed in Australia by Zoetis since 2012. We and the cooperating partners are currently developing the HeV-sG vaccine to protect humans against both NiV and HeV disease. To date, a Master Cell Bank (MCB) has been manufactured and released, a cGMP process for vaccine manufacture has been developed, a GLP toxicology study is nearing completion, a study in AGMs to confirm protective efficacy against lethal challenge has been completed, and stability studies of the development/toxicology HeV-sG candidate vaccine are in progress. Here we propose to advance development of this dually protective vaccine to the point of establishing an emergency use stockpile by:

- Producing and releasing drug substance (DS) and drug product (DP) under cGMPs.
    - Production at 1,000L scale is calculated to yield approximately 120 gm of purified product
    - 1,000 vials will be filled to support phase 1 evaluation
    - 50,000 vials at optimum dose filled to support phase 2 evaluation and investigational vaccine stockpiling
- Submitting an IND.
- Performing Phase 1 and 2 clinical studies to demonstrate human safety and immunogenicity.

Total project cost to this point in the proposal is estimated to be $XXXX

Optional activities that could be performed to accelerate licensure:

- Performing challenge studies under the “animal rule” to bridge human immune responses to protective responses in AGMs.
- Producing and releasing two additional at-scale Lots of vaccine to demonstrate manufacturing and clinical consistency.
- Submitting a BLA.

1.3. Development status

NiV and HeV must be handled under biological safety level 4 (BSL-4) conditions due to the severe disease they cause in humans, and the US NIH and US CDC list them as Category C biothreat agents. Only NiV is included in the current CEPI call for proposals, however, the ability of HeV-sG to protect against both NiV and HeV disease provides an additional benefit. These emerging viruses, unlike other Category A biothreat viral agents such as Smallpox or Ebola virus, can easily be isolated from their natural reservoir, grown in cell culture to high titer (1-5), and spread in livestock that are known to transmit these viruses to humans, where subsequent person-to-person transmission can facilitate an outbreak (6-8). Transmission via aerosol and a high rate of lethality heighten their potential as biothreat agents.

Currently, there is no approved human prophylactic or therapeutic against NiV or HeV, disease. During the 2009 outbreak of HeV in Australia, four people exposed at a Queensland horse nursery were offered treatment with Ribavirin (The Sydney Morning Herald, August 12, 2009). Unfortunately, the Ribavirin treatment had no impact on disease presentation or progression, and the infected veterinarian died on September 1, 2009. The other three individuals were later found negative for HeV. Chloroquine and Ribavirin will delay disease progression to death in NiV infected hamsters by approximately five days, but do not show any effect in HeV-infected hamsters (9) or AGMs (10). Vaccination, on the other hand, offers a viable anti-henipavirus strategy (4, 11) that could provide significant public health benefit against natural outbreak or deliberate misuse as a bio-weapon. A HeV-sG vaccine for veterinary use (Equivac® HeV), which is identical to the vaccine proposed here for human use, has been marketed by Zoetis in Australia since November 2012 under the authority of the Australian Pesticides and Veterinary Medicines Authority (APVMA). This is the first commercialized vaccine against any BLS-4 agent. The APVMA granted full registration of Equivac® HeV in August 2015. Of note, the human immune response to accidental inoculation (N=2) with the veterinary vaccine has been shown to be potent and to cross-neutralize both NiV and HeV (I. Smith and C. Broder, unpublished).

Profectus BioSciences, Inc. is a vaccine developer with the personnel and resources to manage HeV-sG vaccine manufacture, clinical evaluation, and regulatory approval. The company possesses intellectual property and expertise in the fields of live replication competent recombinant vaccines based on attenuated vesiculoviruses, vaccines and molecular adjuvants based on plasmid DNA vectors, as well as soluble subunit vaccines. Profectus performs GMP, GLP, and GCP activities through outsourcing, and has the personnel and key quality system policies and procedures needed to support the manufacture, testing, and conduct of human clinical trials utilizing GMP, GLP and GCP-compliant contract service providers. Development of the HeV-sG vaccine as well as a human monoclonal anti-NiV/HeV antibody (m102.4) for post-exposure treatment have been supported by two NIAID RO1 awards under the Partnerships for Biodefense program that include Drs. Broder (Uniformed Services University) and Geisbert (University of Texas Medical Branch at Galveston) as essential personnel. In the case of HeV-sG, the RO1 funding supports development of this vaccine through MCB production, upstream process development (USP), downstream process development (DSP), and toxicology testing, but does not support manufacture under cGMPs. Therefore, this application proposes the manufacture of a GMP Lot of HeV-sG of sufficient size to support phase 1 clinical testing, phase 2 clinical testing, and the stockpiling of approximately 150,000 doses of investigational vaccine for emergency use. Manufacturing will be performed with Profectus operational and quality oversight using Profectus-approved CMOs. The clinical trials will be performed in partnership with PATH, using PATH clinical research, operations, and data management infrastructure and the Profectus clinical assay laboratory.

Should CEPI choose to support the most expedient path to licensure, two additional at-scale Lots of candidate vaccine could be produced and released to demonstrate manufacturing and clinical consistency. In addition, “animal rule” studies designed in consultation with the US FDA to bridge the human immune response to the protective response in AGMs could be conducted in partnership with Dr. Geisbert at the BSL-4 laboratories at UTMB.

2. About the applicant organisation/consortium

2.1. About the applicant organization and cooperating partner(s)

Profectus BioSciences, Inc. The Profectus Vaccines Group was spun-out of Wyeth Vaccines Research in 2008 with the mission of developing and commercializing vaccines to treat and prevent chronic viral diseases (HIV, HCV, HPV, HSV), and viral infections of biodefense and public health importance (filoviruses, arenaviruses, alphaviruses, henipaviruses), areas outside the immediate focus of Wyeth (now Pfizer). To enable Profectus, Wyeth transferred:

- A broad intellectual property (IP) portfolio in vectored and subunit vaccines.
- The experienced senior staff essential for the research, development, and cGMP manufacture of vaccines. These individuals each possess 10 or more years of experience in a major pharma environment and include:
    - John H. Eldridge, Ph.D., Chief Scientific Officer
    - David Clarke, Ph.D., Senior Director of Virology/Vector Design
    - Rong Xu, Ph.D., Director of Immunology
    - Susan Sciotto-Brown, Senior Director Regulatory Affairs
    - Tracy Chen, Ph.D., Executive Director of Outsourcing and Operations
    - Marc Tremblay, M.S., Senior Director of Quality
    - Alan Gordon, Esq., Corporate Counsel
    - Also on staff at Profectus is Dr. Antony Dimitrov, subject matter expert on NiV and HeV, and Project Leader
- Proprietary and patented manufacturing methods, equipment, and certified cell banks needed to manufacture vaccines for human use.

Profectus performs GMP, GLP, and GCP activities through outsourcing, and has the personnel, key quality systems, policies and procedures needed to support the manufacture, testing, and conduct of human clinical trials utilizing GMP, GLP and GCP-compliant contract service providers. Over the past 8 years Profectus has successfully produced/maintained 6 vaccine components under cGMPs, written 8 INDs, and conducted 7 clinical trials in the US and EU. Partners and collaborators include, the Galveston National Laboratory at UTMB, Yale University, the Institute of Human Virology, the Center for HIV/AIDS Vaccine Immunology, the National Cancer Institute, the NIH Division of AIDS, the Bill and Melinda Gates Foundation, the International AIDS Vaccine Initiative, the HIV Vaccines Trials Network, and the AIDS Clinical Trials Group.

University of Texas Medical Branch, Galveston National Laboratory (UTMB). Dr. Thomas Geisbert at UTMB has extensive experience conducting experiments utilizing small animals and nonhuman primates (NHPs) in high biocontainment, with over 28 years' biosafety-level 4 (BSL-4) experience at USAMRIID and at the Galveston National Laboratory (GNL). He has experience managing large research programs, including a current US National Institutes of Health-funded Center of Excellence for Translational Research grant. Dr. Geisbert's research interests have focused on the study of haemorrhagic fever viruses and he has published extensively in this area. His research group was the first to demonstrate complete protection of NHPs against Ebola, Marburg, and Lassa viruses using a novel vaccine based on recombinant vesicular stomatitis virus (VSV). In addition, Dr. Geisbert has extensive experience with developing appropriate animal models that mimic human pathology, including the ferret and AGM models for NiV and HeV.

PATH. For more than 20 years, PATH has successfully developed and delivered lifesaving vaccines for the most vulnerable children and communities around the world, spanning the spectrum of discovery to development to delivery. PATH's Center for Vaccine Innovation and Access (CVIA) brings together global expertise across every stage of the long and complex vaccine process, from early discovery and clinical testing of vaccine candidates, to regulatory approval and manufacturing, to introduction and delivery. PATH has led numerous global partnerships to advance vaccine development, including the Malaria Vaccine Initiative, which helped develop the first malaria vaccine candidate recommended for pilot implementation, and the award-winning Meningitis Vaccine Project, which developed the first vaccine tailor-made for use in sub-Saharan Africa. CVIA's current portfolio encompasses more than two dozen vaccines either in development or already in use to protect against 16 different diseases.

Catalent: Catalent Pharma Solutions (Catalent) is located at 726 Heartland Trail, Madison, WI and is a contract manufacturer of Master Cell Banks and Bulk Drug Substance (BDS) such as monoclonal, fusion and recombinant mammalian derived proteins for clinical Phase I and II use. These proteins are produced utilizing aseptic processing to minimize bioburden and cross contamination during the biological manufacturing processes.

GRAM: Grand Rapid Aseptic Manufacturing (GRAM) is located 140 Front Avenue SW, Suite 3, Grand Rapids, MI and is founded in 2010. It is a full-service parenteral contract manufacturing organization supporting new product development and cGMP manufacturing. GRAM is currently approved by FDA to manufacture 4 commercial drug products with the first approval granted in 2013. The current portfolio is 57% biologics and 43% small molecules with 80% being sterilized by aseptic filtration and 20% by terminal sterilization. GRAM manufactures drug products in vials and syringes to support clinical trial from Phase 1 to Phase 3.

Uniformed Services University, Henry M. Jackson Foundation (USU-HMJF). The mission of the Uniformed Services University of Health Sciences is to educate, train, and comprehensively prepare uniformed services health professionals, scientists, and leaders to support the Military and Public Health Systems, the National Security and National Defense Strategies of the United States, and the readiness of our Uniformed Services. The mission of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc. is to advance military medical research and improve health worldwide.

Duke-NUS Medical School. SingHealth Investigational Medicine Unit, Singapore General Hospital, Block 7 Level 7, Outram Road, Singapore 169608. & Duke-NUS Medical School, 8 College Road, Singapore 169857. Dr. Low is a senior consultant infectious disease physician at the Singapore General Hospital and a Associate Professor of Emerging Infectious Diseases at the Duke-NUS Medical School. Her research addresses translational therapeutics and vaccinology for acute viral diseases, focusing primarily on dengue and influenza in the first instance. She has been the clinical PI for 5 vaccine trials, 2 of which were first-in-man trials, as well as the clinical PI for a therapeutic trial for acute dengue. Importantly, she co-led the trial that authenticated antibody-dependent enhancement of yellow fever vaccination in those with cross-reactive flaviviral antibodies, the findings of which were published last year in Nature Microbiology.

2.2. The experience and track record of applicant organisation, principal investigator and cooperating partner(s)

Pre-clinical studies

In the interest of brevity, the pre-clinical R&D experience of the Profectus, UTMB, USU-HMJF collaborators relevant to this proposal is presented in **Table 1**.

Table 1. Relevant PBS, UTMB, USU-HMJF Pre-Clinical Experience

Field	Animal Model	Vaccine Type			Challenge	Immune Measures

The UTMB Galveston National Laboratory (GNL). The GNL provides BSL-4, BSL-3 and BSL-2 laboratories designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism to develop vaccines, diagnostics, and therapeutics against them. The seven-story GNL and the adjacent Keiller Building together offer 14,330 square feet of BSL-4 space, 29,713 square feet of BSL-3 facilities and 51,903 square feet for BSL-2 level laboratories. Additionally, there are BSL-3 and BSL-4 aerobiology facilities.

The GNL's mission is fulfilled through a system of specialized research cores providing the following services: aerosolization studies of BSL-3 and BSL-4 level pathogens in small animals and NHPs; animal model development; host-pathogen studies; screening methodology development through *in vitro* studies; technical assistance in histological and tissue processing methods; and diagnostic expertise in the event of disease outbreaks or bioterrorism. The GNL also provides a national resource for studying and developing protocols against arthropod vectors; state-of-the-art equipment, particularly that available via an Imaging Core having expertise in the analysis of human and animal tissues and *in vivo* whole-animal imaging; plus, a full-service immunology core in which knockout and transgenic mouse models are developed for immunological studies. Other cores provide administrative and regulatory (GLP) oversight, as well as ensure security, safety and efficient operation of the GNL. In addition, the GNL features full-service animal care procedural and maintenance facilities, including laminar flow isolator caging systems, sterilization equipment, procedure rooms, cage-washing and autoclaving.

The GNL BSL-4 laboratory consists of approximately 12,000 square feet of space equally divided between wet space and ABSL-4 facilities. The BSL-4 laboratory consists of three modules that can be operated in concert or independently. Each module consists of a wet lab (~1,000 square feet), a necropsy room (approximately 250 square feet), a virus storage and centrifuge room (approximately 250 square feet) and one to three animal rooms. Animal housing can accommodate rodents, ferrets, and nonhuman primates (NHPs). CDC inspections and select agent permits are current. The first NHP studies were performed in the GNL BSL-4 laboratories in April 2011. Seven different viruses, including Lassa, Nipah and Hendra viruses, have been used, and Dr. Geisbert's team is adept at performing procedures on animals that involve inoculating filoviruses, monitoring animals for signs of disease, collecting specimens, and evaluating clinical data during the disease course.

Phase I/II clinical vaccine trials

Profectus phase I/II clinical trials relevant to the current proposal are presented in **Table 2**, PATH phase I/II clinical trials are presented in **Table 3**, and Duke-NUS phase I/II clinical trials are listed in **Table 4**.

PATH has expertise in early and late stage clinical development of vaccine candidates for use in resource-limited settings. Over the past 15 years, PATH has overseen the conduct of approximately 70 Phase I and II trials, including approximately 40 in high-income countries and approximately 30 in low- and middle-income countries. The following is an illustrative list highlighting PATH's diverse early-stage clinical trial experience.

Table 3. Select PATH Phase I/II Clinical Vaccine Trials – All Countries

Short Title	Indication	Phase	Number of Subjects	Population	Countries	Clinical Trial Registry Number
Multivalent Inactivated Enterotoxigenic Escherichia Coli (ETEC) ETVAX (ETVAX/dmLT)	Enterotoxigenic E Coli	I	495	Adults, Toddlers, Infants	Bangladesh	NCT02531802
Shigella Sonnei 53G Challenge	Shigella	II	45	Adults	USA	NCT02816346
Serum Institute of India's 10-valent Pneumococcal Conjugate Vaccine (SIILPCV10)	Pneumococcal	I	30	Adults	India	CTRI/2013/09/003961
Malaria Vaccine in Healthy Adults (Ad35.CS.01 + RTS,S prime-boost)	Malaria	I	168	Adults	USA	NCT01366534
Monovalent Live attenuated H7N3 Influenza vaccine (A/17/Mallard/Netherlands/00/95	Influenza	I	40	Adults	Russia	NCT01511419
Influenza A/H5N1 Vaccine Clinical Trial (IVACFLU-A/H5N1) - Phase 1	Influenza	I	76	Adults	Vietnam	NCT02171819
Trivalent Split, Inactivated Influenza Vaccine	Influenza	I	60	Adults	Serbia	NCT02585700
Needle-free Jet Injection of Reduced-dose, Intradermal, Influenza Vaccine in >= 6 to < 24-month-old Children	Influenza	I/IIa	450	Children	Dominican Republic	NCT00386542
Live Attenuated Shigella Vaccine (WRSS1)	Shigella	I/II	103	Toddlers	Bangladesh	NCT01813071
S.Pneumoniae Whole Cell Vaccine (PATH-wSP)	Pneumococcal	I/II	304	Adults, Toddlers	Kenya	NCT02097472
Monovalent P2VP8 Subunit Parenteral Rotavirus Vaccine	Rotavirus	I/II	204	Toddlers, infants	South Africa	NCT02109484
10-Valent Pneumococcal Conjugate Vaccine (SIILPCV10)	Pneumococcal	I/II	346	Adults, Toddlers, Infants	The Gambia	NCT02308540
Trivalent P2-VP8 Subunit Parenteral Rotavirus Vaccine	Rotavirus	I/II	660	Adults, Toddlers, Infants	South Africa	NCT02646891
Live attenuated Shigella Vaccine (WRSS1)	Shigella	I/II	64	Toddlers	Bangladesh	NCT02934178
Meningococcal A conjugate vaccine (MenAfriVac®)	Meningitis	II	1200	Infants	Ghana	ISRCTN No. 82484612
Polyvalent ACYW Conjugate Meningococcal Vaccine	Meningitis	II	601	Toddlers	Mali, The Gambia	ISRCTN No. 78147026
GSK Biologicals' Malaria Vaccine 257049	Malaria	II	480	Infants	Malawi	NCT01231503
GSK Biologicals' 2189242A Vaccine (Nasopharyngeal Carriage, Safety & Immunogenicity)	Pneumococcal	II	1320	Children	The Gambia	NCT01262872
Intranasal Seasonal Trivalent Live-Attenuated Influenza Vaccine	Influenza	II	300	Children	Bangladesh	NCT01625689

Vaccine for Pneumonia in Adults and Toddlers in Kenya (Dose-finding)	Pneumococcal	II	147	Adults, Toddlers	Kenya	NCT02543892
Inactivated Whole Cell Shigella Flexneri 2a Vaccine With and Without dmLT	Shigella	II	120	Adults	USA	NCT03038243

Phase III clinical efficacy vaccine trials

Over the past 15 years, PATH has conducted more than 30 Phase III and/or IV clinical trials, all in low- and middle-income countries, in support of licensure of vaccines against influenza, Japanese encephalitis, malaria, meningitis A, polio, and rotavirus. This experience has included establishing and managing clinical trial sites in Africa and Asia, including investments in clinical and laboratory facilities, as well as training in Good Clinical Practice (GCP), communications, and financial management, among other skills. **Table 5** is an illustrative list highlighting PATH's diverse late-stage clinical trial experience.

Table 5. Select PATH Phase III/IV Clinical Vaccine Trials – All Countries

Short Title	Indication	Phase	Number of Subjects	Population	Countries	Clinical Trial Registry Number
Efficacy of GSK Biologicals' Candidate Malaria Vaccine 257049	Malaria	III	15459	Infants, Toddlers	Burkina Faso, Gabon, Ghana, Kenya, Malawi, Mozambique, Tanzania	NCT00866619
Immunogenicity and Safety of Beijing TiantanBio Liquid Bivalent Oral Poliomyelitis Vaccine in Comparison to a WHO Prequalified Comparator	Polio	III	750	Infants	Kenya	NCT02434770
Efficacy Trial to Evaluate the Protective Efficacy of Three Doses of Oral Rotavirus Vaccine (ORV) 116E (ROTAVAC)	Rotavirus	III	6800	Infants	India	NCT01305109
Efficacy and Safety of Live-Attenuated Influenza Vaccine (LAIV)	Influenza	III	1761	Children	Bangladesh	NCT01797029
Clinical Efficacy of Trivalent Live-Attenuated Influenza Vaccine (LAIV) Among Children in Senegal	Influenza	III	1761	Children	Senegal	NCT01854632
Efficacy of Serum Institute of India's Rotavirus Vaccine (ROTASIIL)	Rotavirus	III	7500	Infants	India	NCT02133690
Safety of meningococcal A conjugate vaccine	Meningitis	III	6000	Adults, Children, Toddlers	Mali	PACTR 2010030001913177
Antibody persistence after MenAfriVac®	Meningitis	III/IV	950	Children	Ghana	ISRCTN No. 10763234
Long-term follow-up of children who participated in PsA-TT-007 in Mali	Meningitis	III/IV	825	Children	Mali	ISRCTN No. 37623829

Long-term immunogenicity of JE vaccine and response to a booster	Japanese Encephalitis	III/IV	561	Children	Bangladesh	NCT02514746
Japanese Encephalitis Vaccine administered with Measles-Mumps-Rubella Vaccine	Japanese Encephalitis	III/IV	628	Infants	Philippines	NCT02880865

Technology transfer

PATH facilitates technology transfer to developing-country manufacturers and provides ongoing support to help those manufacturers develop, introduce, and scale-up vaccine products that will be accessible and affordable for use in low-income countries. **Table 6** is an illustrative list of successful technology transfer activities.

Table 6. Select PATH Vaccine Technology Transfer Experience

Product	Technology Transferred	Source	Recipient	PATH Role
MenAfriVac®	Conjugation method	US Food and Drug Administration, Center for Biologics Evaluation and Research	Serum Institute of India Ltd. (SIIL)	Identified source and recipient, provided technical support as a core partner in the Meningitis Vaccine Project.
Polyvalent bovine rotavirus vaccine	Wuhan (China), SIIL (India), Shanta (India) and Butantan (Brazil) licensed the live attenuated bovine-human reassortant rotavirus vaccine (BRV) from the US NIH, and PATH provided enabling technology for the vaccine development program	US National Institutes of Health	Wuhan, SIIL, Shanta, Butantan	Provided funding, reagents and technical assistance.
Pneumococcal whole cell vaccine	Master cell bank and associated processes, methods and assays	Children's Hospital Boston and PATH	PT Bio Farma (Indonesia)	PATH collaborated with CHB on the preclinical development of this vaccine candidate and led the conduct of early stage clinical trials to demonstrate its potential, then transferred the technology for the vaccine candidate to PT Bio Farma for manufacturing and further development.
Non-replicating rotavirus vaccine (NRRV)	Materials and know how for the purification and characterization of NRRV proteins at commercial scale	US National Institutes of Health	SK Chemicals (South Korea)	PATH developed the vaccine candidate and completed both preclinical and early stage clinical trials for this vaccine candidate, then transferred the technology for the vaccine candidate to SK Chemicals for manufacturing and further development. PATH is also providing funding to SK. (Press release attached)

Bringing vaccines through a regulatory pathway over the past 10 years

Profectus. Since the Profectus Vaccines Group was spun out of Wyeth Vaccines Research in 2008, the regulatory activities have been restricted to those required to initiate and conduct the phase 1 clinical trials outlined in **Table 2**. However, as described above, the senior leadership of Profectus has extensive major pharma experience and contributed to the approval of several vaccines, including a series of paediatric combination vaccines, Prevnar®, Prevnar 13®, FluMist®, and Rotashield®.

PATH has partners closely with manufacturers, including both multinational pharmaceutical companies and emerging-market manufacturers, to achieve licensure of 6 products in Africa and Asia. PATH also supports manufacturers in achieving WHO prequalification for their vaccines, including supporting the first vaccines from China and India to be WHO prequalified. In the field of malaria, our partnership with GSK has resulted in the first malaria vaccine candidate to be assessed by a stringent regulatory agency, which received a positive scientific opinion from the European Medicines Agency (EMA) under the agency's Article 58 procedure. **Table 7** is a list of products on which PATH has partnered closely with manufacturers to achieve licensure over the past 10 years:

Table 7. PATH Vaccine Regulatory Approval Experience

Product	Indication	Manufacturer	Primary regulatory authority	Alternative pathway (if applicable)	WHO PQ	Additional regulatory authorities
MenAfriVac®	Meningitis A	Serum Institute of India, Ltd.	Drugs Controller General of India (DCGI)/ Central Drugs Standard Control Organization (CDSCO)	N/A	June 2010	Benin, Burkina Faso, Cameroon, Central African Republic, Chad, Côte d'Ivoire, Ethiopia, Ghana, Mali, Niger, Nigeria, Togo
MenAfriVac® 5 micrograms	Meningitis A (pediatric)	Serum Institute of India, Ltd.	DCGI/CDSCO	N/A	Dec. 2014	Benin, Burkina Faso, Cameroon, Central African Republic, Chad, Côte d'Ivoire, Ethiopia, Ghana, Mali, Niger, Nigeria, Togo
RTS,S (Mosquirix™)	Malaria (*P. falciparum*)	GSK	European Medicines Agency	Article 58	Pending	
Rotavac®	Rotavirus	Bharat Biotech	DCGI/CDSCO	N/A	PQ submission pending review	
SA 14-14-2	Japanese encephalitis	Chengdu Institute of Biological Products	China Food and Drug Administration	N/A	August 2013	Cambodia, the Democratic People's Republic of Korea (North Korea), India, Laos, Nepal, Sri Lanka
Rotasiil®	Rotavirus	Serum Institute of India, Ltd.	DCGI/CDSCO	N/A	PQ submission pending review	

Infrastructures and facilities in-house,

Profectus Research and Development Laboratories: Profectus Biosciences currently leases over 40,000 square feet of laboratory and office space in Building 205 on the IRG campus in Pearl River, NY. The facility is state-of-the-art, newly renovated with secure key-card access, central air, a newly installed purified deionized (DI) water system, centrally distributed CO_2, and uninterrupted power provided by a 600-gallon diesel generator. Air within the laboratories is single pass and all laboratories, with one exception, are under negative pressure with respect to common and office areas. The Compliant Laboratory, used to rescue viral vectors under conditions suitable for initiating cGMP manufacture, is under positive pressure relative to the hallway. Laboratories include a Bioreactor suite; a Common Equipment area; a laboratory dedicated to Molecular Biology/Virology; a Flow Cytometry/ Sequencing Room; a laboratory dedicated to Immunology; a laboratory dedicated to clinical assays; a self-contained keypad restricted access Compliant Rescue Laboratory; a walk-in 4°C cold room; a glass wash, autoclave, and drying oven area, and; other support areas such as Millipore Elix 20 deionized water room, storage, utility, and IT rooms.

UTMB GNL Facilities: Dr. Thomas Geisbert has dedicated BSL-2 laboratory space in the GNL totaling over 1,500 square feet. He also has access to the BSL-4 facilities in the GNL and the adjacent Robert E. Shope, MD Laboratory that together offer 14,330 square feet of BSL-4 space. The facility is unique in that it is the only currently operational BSL-4 facility in the United States that is located on an academic campus. This unique location benefits the proposed studies in several ways. Regarding physical resources, the GNL has many specialized assets that are essential for the proposed work. In addition, being located on an academic campus, Dr. Geisbert is a faculty member in the Department of Microbiology and Immunology and currently supports four graduate students in his laboratory. Faculty from several academic Departments at UTMB are located within the GNL. This academic environment fosters creativity and collaboration. In particular, having many investigators with diverse areas of expertise housed within the GNL is particularly advantageous in promoting collaborative efforts that are invaluable to the success of many research projects. It is anticipated that this environment with a cadre of faculty with areas of expertise including molecular biology, immunology, pathology and pathogenesis, structural biology, genomics, and many other disciplines will be highly beneficial to this proposal.

Dr. Geisbert's BSL-2 laboratory and the BSL-4 facilities at UTMB contain sufficient cell culture incubators, laminar flow hoods, chemical hoods, centrifuges, and other equipment required to conduct the proposed research. Clinical pathology instruments including hematology, clinical chemistry, and blood coagulation analyzers are available in both the BSL-2 laboratories and in the BSL-4 facilities at UTMB. In addition, multiplex machines, microscopes, and an array of other equipment for monitoring and processing samples are available. Dedicated BSL-2 and BSL-4 animal rooms contain appropriate rodent and/or NHP cages necessary for the proposed work. Dedicated BSL-4 necropsy rooms contain downdraft tables and specialized equipment for performing necropsies. In addition to standard light and fluorescence microscopy, the GNL offers a range of specialized imaging equipment, including combined confocal and multiphoton microscopy imaging systems at the BSL-2 level for molecular imaging of thick specimens and intravital microscopy. An IVIS 200 system for *in vivo* small animal molecular optical imaging, a microPET/CT whole animal imaging system, digital X-ray, and ultrasound equipment are available in the GNL BSL-4 laboratory. The GNL also has a full complement of gel imaging capabilities as well as a traditional x-ray film processor. In addition, the campus has *in situ* confocal microscopy and endoscopic optical coherence tomography equipment.

The **UTMB Animal Resource Center** (ARC) is responsible for housing and care to all animals on campus. The ARC encompasses 89,694 square feet in nine facilities across the UTMB campus. UTMB is a registered Research Facility under the Animal Welfare Act. It has a current Letter of Assurance on file with the Office for Protection from Research Risks. The Geisbert laboratory and the ARC have a documented ability to conduct work in accordance with guidelines for *Biosafety in Microbiological and Biomedical Laboratories* (Fifth Edition, December 2009) and the *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (Revised 2015). The Department of Defense, CDC, and USDA have approved our laboratories for work with select agents and AAALAC (Association for the Assessment and Accreditation of Laboratory Animal Care International) has certified our animal facilities (Accreditation #000870). UTMB follows the:

- *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (2015 reprint)
- *Guide for the Care and Use of Laboratory Animals*, Eighth Edition (2011)
- US Government Principles for the Utilization and Care of Vertebrate Animals Used in Testing, Research, and Training
- USDA-administered Animal Welfare Act (Public Law [PL] 89-544 as amended by PL 91-579 [1970], PL 94-279 [1976], and PL 99-198 [1985]) and published in 9 CFR Parts 1-3 on Final Rules regarding Animal Welfare
- Health Research Extension Act of 1985 (PL 99-158) regarding "Animals in Research"; and
- PL 103-43 regarding the "Plan for Use of Animals in Research" (1993).

UTMB's ARC follows all standards for AAALAC and Institutional Animal Care and Use Committee compliance. Depending on space availability, animals may be housed in ARC facilities with animal care provided by the ARC staff including two full-time veterinarians. These facilities are capable of housing NHPs, rats, mice, hamsters and guinea pigs under BSL2/3 biohazard containment, and encompass 72,847 square feet. All facilities feature full-service animal care procedural and maintenance facilities, including laminar flow isolator caging systems, sterilization equipment, procedure rooms, cage-washing, and autoclaving.

USU-HMJF Facilities. Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. The PI is a tenured Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. A major focus of the PI's Department is virology and viral Immunology, and the PI has many talented and productive colleagues with whom to interact, in addition to his multiple international collaborative research activities. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators, including the PI's chair, Dr. Alison O'Brien, who was the 2008-9 President of the American Society for Microbiology (ASM). The PI has had and is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development (with Dr. Joseph Mattapallil and Dr. Brian Schaefer). USU is also physically located directly across from the main NIH campus in Bethesda, and within a short distance from Frederick, MD, and the PI maintains a very active collaboration with NCI, NIH, investigators (Dr. Dimiter Dimitrov and his group) which has been in place for over 27 years since the PIs postdoctoral work began at NIH in 1989. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI has often uses these resources to his advantage, both for his research objectives and interests, but also in his role as the Director of the Emerging Infectious Diseases Graduate Program (for the Ph.D.) because he has activity recruited adjunct faculty appointments within the EID graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Dr. Broder submits such appointments requests through the Office of Dean of the Medical School (USU). The USU/EID program can accept 5 fully supported student positions per academic year, for 3 years, at which time the student's mentor begins support, and there is no tuition or fees associated with the EID program. The PI has been well-supported by both the Department of Microbiology and Immunology and the USU Office of Research. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional.

Laboratory: The PI's laboratories are divided into 3 rooms totaling 1,440 sf, and are equipped with eight CO2 incubators for tissue culture, 4 inverted and 1 bright field microscopes, high speed and ultracentrifuges, four biological safety cabinets, 2 -20°C, 3 -80°C freezers, 4 liquid nitrogen freezers 6 refrigerator/freezers, 4 PCR machines, 2 ELISA plate reader, and various small equipment items (gel electrophoresis, circulating adjustable water baths, heat blocks). 2 complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus.

Animal: Animals if applicable are maintained in the University's laboratory animal facilities under the supervision of a full-time veterinarian. These facilities are a modern AAALC accredited, central animal tract of about 50,000 sq. ft. The animal care and use program is managed by the Department of Laboratory Animal Medicine which is directed by a veterinarian who is an ACLAM Diplomat and staffed with one other veterinarian, a graduate animal husbandryman, and about 30 technicians.

Computers: A pentium computer, scanners and two laser jet printers in the PI's office and 9 pentium computers in the laboratories/offices are connected to a departmental server and hardwired to the central VAXC computer.

Office: The PI has an office separate from, but across from the laboratory. Three full-time secretaries are available to provide support within the department.

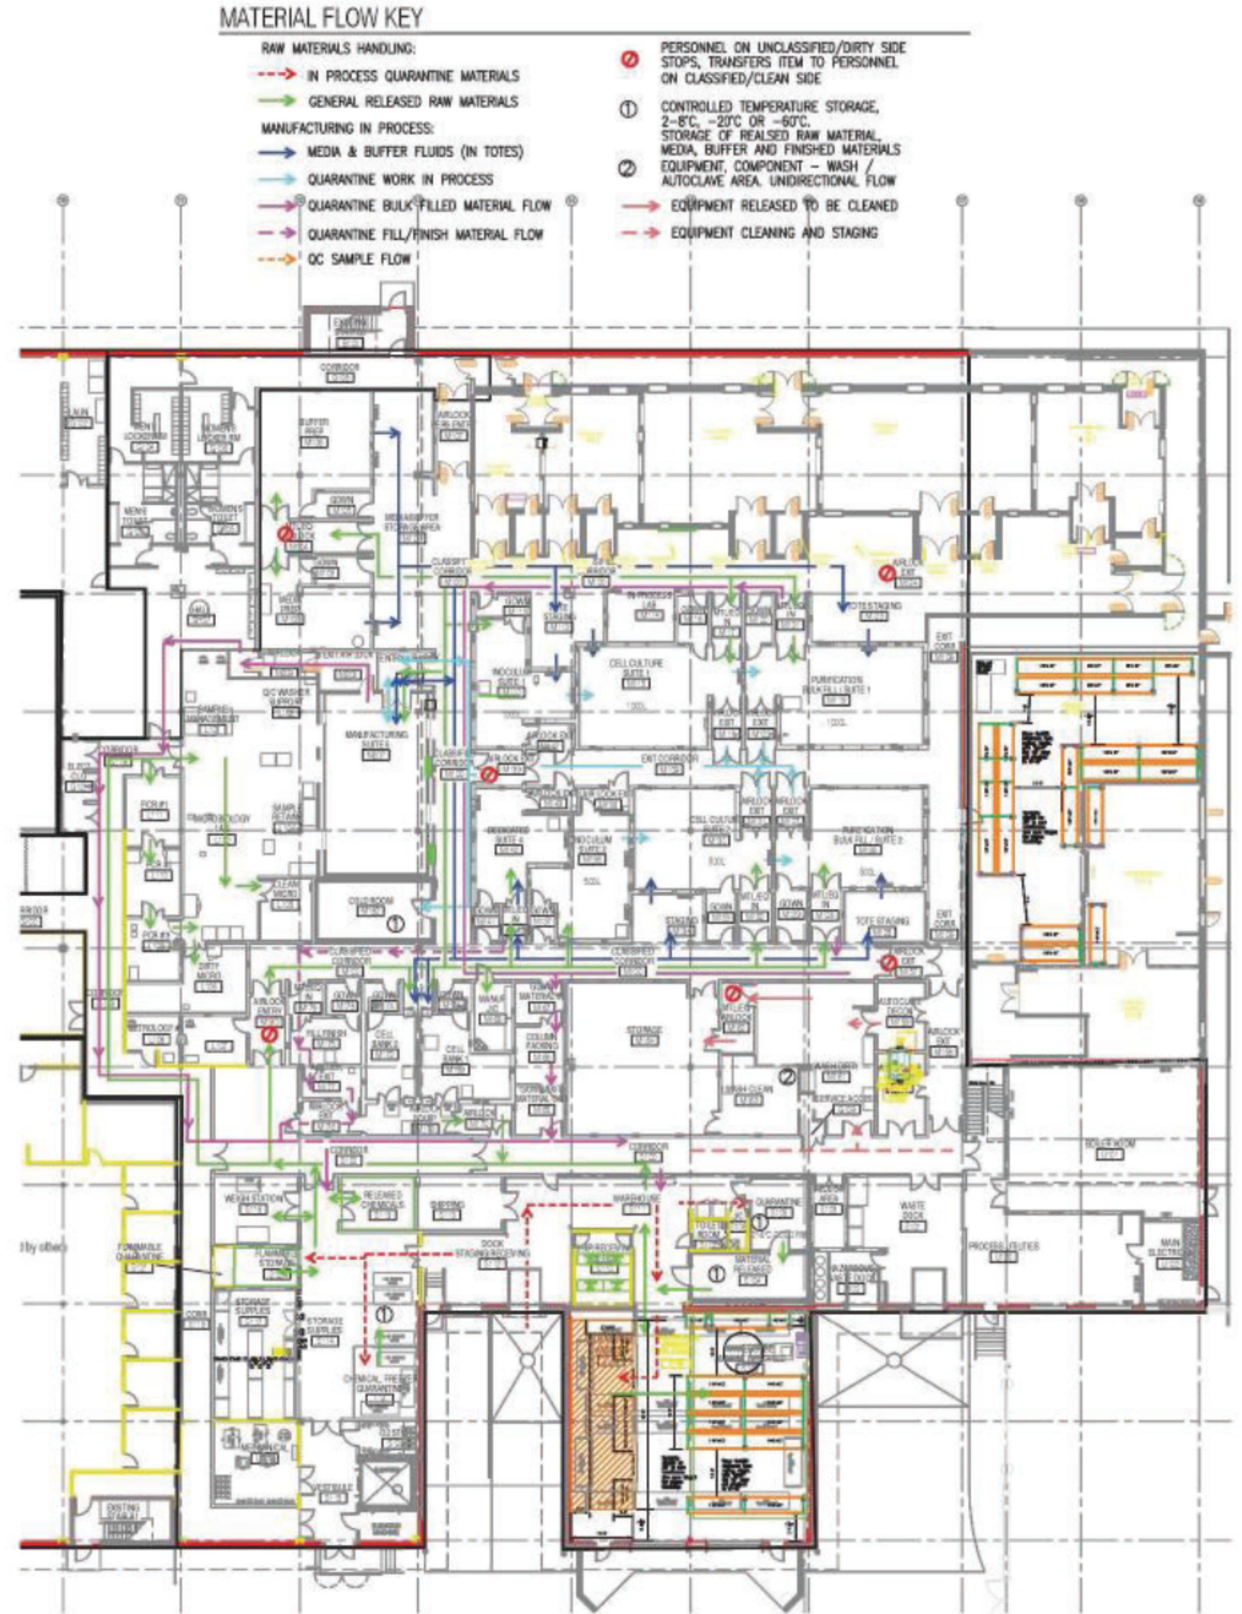
Catalent Facilities. Catalent is a contract manufacturer of Master Cell Banks and Bulk Drug Substance (BDS) which as monoclonal, fusion and recombinant mammalian derived proteins for clinical Phase I and II use. Pharmaceutical manufacturing activities of the site. GMP compliance begins with the Master Cell Bank production. BDS is manufactured following ICH Q7, Good Manufacturing Practice Guidance for Active Pharmaceutical Ingredients and EU GMP Annex 2, Manufacture of Biological Active Substances and Medicinal Products for Human Use Suitable for Phase I/II Clinical Studies. Catalent is committed to the manufacturing, processing, packaging and holding of Bulk Drug Substances in full compliance with cGMPs to assure that they consistently meet the safety, identity, strength, quality, and purity characteristics they are purported to meet. All procedures are clearly defined and are checked systematically. Protocols are created for equipment qualifications, assay qualifications, stability, and experimental design, where appropriate. Specifications are maintained for all raw materials and GMP product. The measures of Catalent's systems are implemented by a corporate Quality Manual, a GMP Site Master File (SMF), a validation Master Plan (VMP), Standard Operating Procedures (SOPs), Batch Production Records (BPRs), Job Aids (JA), protocols, specifications, and forms.

Floor Diagram: The GMP Manufacturing layout is shown in below.

cGMP Manufacturing System, process flow and description: Suites for two (2) separate manufacturing trains are provide; one for 500L and the other for 1000L of cell culture volume. Each train is comprised of three (3) separate rooms with separate air handling; an inoculation suite, a cell culture suite, and a purification suite. An additional suite will be fitted to accommodate a future line to manufacture smaller volumes of cell culture broth up to 50 L of volume. Manufacturing operations utilize single use technology where possible. All primary doors separating the labs and manufacturing from the remainder of the facility and the office areas utilize card readers for access control as defined by Catalent.

Inoculation Suites: Each inoculation suite is configured to allow for scale-up of cell mass from a frozen vial to approximately 20% of the production scale bioreactor volume (100 L or 250L) for a 500 L or 1000 L Single Use Bioreactors (SUB), respectively. Each outfitted inoculation suite is setup with a biosafety cabinet, incubator, wave bioreactor(s), appropriately sized SUB, and all supporting equipment to allow scale-up from amp thaw to 100 L or 250 L (as applicable). These vessels may also be used as production vessels as business requires. Drains from the inoculation suites are tied to a process drain system. Any biocontaminated waste is collected and inactivated within the suite prior to release.

Cell Culture Suites: The 500 L and 1000 L cell culture suites are provided with a SUB capable of operating at the respective volume. These production bioreactors are inoculated by the final seed bioreactor in the respective inoculation suite by passing tubing through a wall pass-through and aseptically fusing the tubing at the other end. The production bioreactors are fed with initial media, feed media, and bicarbonate solution (for pH control) from corridor alcoves next to the suites. The bioreactor skids are equipped with peristaltic pumps to provide controlled feed of the aforementioned solutions. Load cells measure the weight of the contents of the bioreactors. Near each of the production single-use bioreactors, there are utility panels with process compressed air, instrument air, carbon dioxide, and oxygen. Two (2) additional utility panels in each suite are positioned to support product recovery and viral inactivation unit operations. Process compressed air, instrument air, chilled water (supply and return) and temperature controlled water (supply and return) are provided at these panels. At the end of a production run, samples are drawn from the bioreactor for quality assays and manufacture of End of Production Cells (EPC), as required. Processing takes place through the use of closed bag/tubing systems and transferred from room to room through tube pass-throughs. All pre-viral purification steps are also conducted in these suite with a complete segregation to minimize contamination.



Purification Suites: The purification processes are unit operation driven. Depending upon the process, a sequence of operational steps consisting of column chromatography and tangential flow filtration (TFF) is normally required. The purification suites are therefore flexibly configured. The cell culture and purification suites are physically isolated to ensure separation of equipment and materials pre and post-viral inactivation. Procedural controls are utilized to ensure personnel fully re-gown before entering the purification suites after working in the inoculation or cell culture suites. Utility panels are strategically positioned within the purification suites and are adjacent to the corridor alcove for buffer delivery. There are three (3) utility panels in each of the purification suites to support the various unit operations. Process compressed air, instrument air, and chilled water are provided at each panel. One of the panels also contains temperature controlled water (supply and return) for re-warming of materials.

Cold Storage Room: A 2-8°C cold storage room is located within the manufacturing space for storage of in-process raw materials, buffers, and drug substances waiting for final bulk filtration/sampling.

Bulk Filtration: Concentrated active drug in appropriate buffer system in bag(s) is brought to the bulk filtration suite. Under a HEPA-filtered laminar air flow hood, the concentrate is filtered with 0.2 µm filters into either a bulk container or smaller containers. The product is appropriately sampled and remaining filled container(s) are taken to the product warehouse for quarantine storage at the appropriate temperature. Process compressed air is provided in this processing area.

Cell Banking/EPC: The cell banking/EPC laboratories are provided with carbon dioxide. Two (2) airlocks at the exit of the labs are provided with liquid nitrogen service to fill liquid nitrogen Dewars and a controlled rate freezer. Proper ventilation and oxygen monitoring is provided in these rooms. Drains from the lab are tied to the process drain system. Any biocontaminated waste is collected and inactivated within the suite or transferred to the waste autoclave area for treatment prior to release.

Media Preparation Suite: A weighing and dispensing booth, located in the warehouse, is utilized to create batch quantities of components for addition to the mixing bag systems prior to entry into the manufacturing area. Raw materials are brought into the suite through a material air lock after wipe down. There are four (4) media preparation bag systems: one (1) at 650 L and three (3) mixtainers, one (1) at 200 L, one (1) at 100 L, and one (1) at 50 L. Only one (1) Lev mixer is provided, so one media preparation can be done at a time using the disposable bag mixing systems. Smaller scale mixing equipment is shared with the buffer preparation suite. A utility panel with instrument air and process air is installed between the two preparation units. A point of use heat exchanger is provided to cool USP Water-for-Injection (WFI) for use in the preparation of media. The heat exchanger is a U-tube shell and tube heat exchanger with double tube sheet construction. Tubes and bonnet is fully drainable and constructed of polished, 316L stainless steel. Flow through the sub-loop and the heat exchanger is hot, except when cold WFI is requested. The heat exchanger is cooled with the HVAC chilled water system. The heat exchanger is insulated and has white PVC jacketing. The heat exchanger is located in the interstitial space above the room. A single user drop point is provided near the utility panel. Media prepared in the media preparation suite is transferred and filtered into bag systems in mobile plastic containers in the corridor alcove adjacent to the suite.

Buffer Preparation Suite: The buffer preparation suite operates similarly to media preparation suite described in the previous section. A weighing and dispensing booth, located in the warehouse, is utilized to control these operations. Two (2) buffer preparation disposable bag mixing tanks systems are provided: one (1) at 1000 L and one (1) at 500 L capacity. Two (2) Lev mixers are provided. Therefore, two buffer preparations can take place at a given time. Smaller scale mixing equipment is shared with the media preparation suite. Two (2) utility panels with instrument air, and process compressed air, are installed. As with media preparation, prepared buffers are transferred via peristaltic pump through inline filters to bag systems in mobile plastic containers located in the corridor alcove adjacent to the suite. The same heat exchanger that supports media prep is used for the buffer prep area. Two (2) user drop points off of the heat exchanger sub-loop are provided near the utility panels. These user points can also be used by manufacturing personnel to fill bags with WFI.

Wash Area: The wash area is divided into two (2) distinct functions: rinsing/wash area and the cleaning and sterilization of small components (e.g. stir rods, flasks). Soiled mixing systems and smaller components enter the area at a common point and are staged in different areas. When needed, mixing systems rinsing is done with USP purified water through a hose or a spray nozzle. Compressed air is used to blow excess liquid from the unit. Cleaned mixing systems are staged on the opposite side of the cleaning station and conveyed to the media or buffer preparation alcove for filling, or to a suite for use. Bags are placed into mixing systems within the Media Prep (MP) or Buffer Prep (BP) areas. Small components are staged on a rack for cleaning. A pass-through parts washer is provided. It is supplied with USP purified water for initial rinse and cleaning, and USP Water-for-Injection for final rinse. Parts are removed from the washer on the clean side and staged. Those parts that require autoclaving are loaded into a pass-through autoclave. The autoclave has an integral pure steam generator. The generator is fed with purified water. A steam quality sampling point is included in the design.

Standby Power Supply: The purpose of the Standby Diesel Generator system is to provide partial facility AC power to mitigate short outages, and provide power to bring systems and processes to a safe shutdown condition. The standby diesel generator output is connected to an automatic transfer switch that signals the generator to start, and transfers the standby loads to the generator after the generator has started.

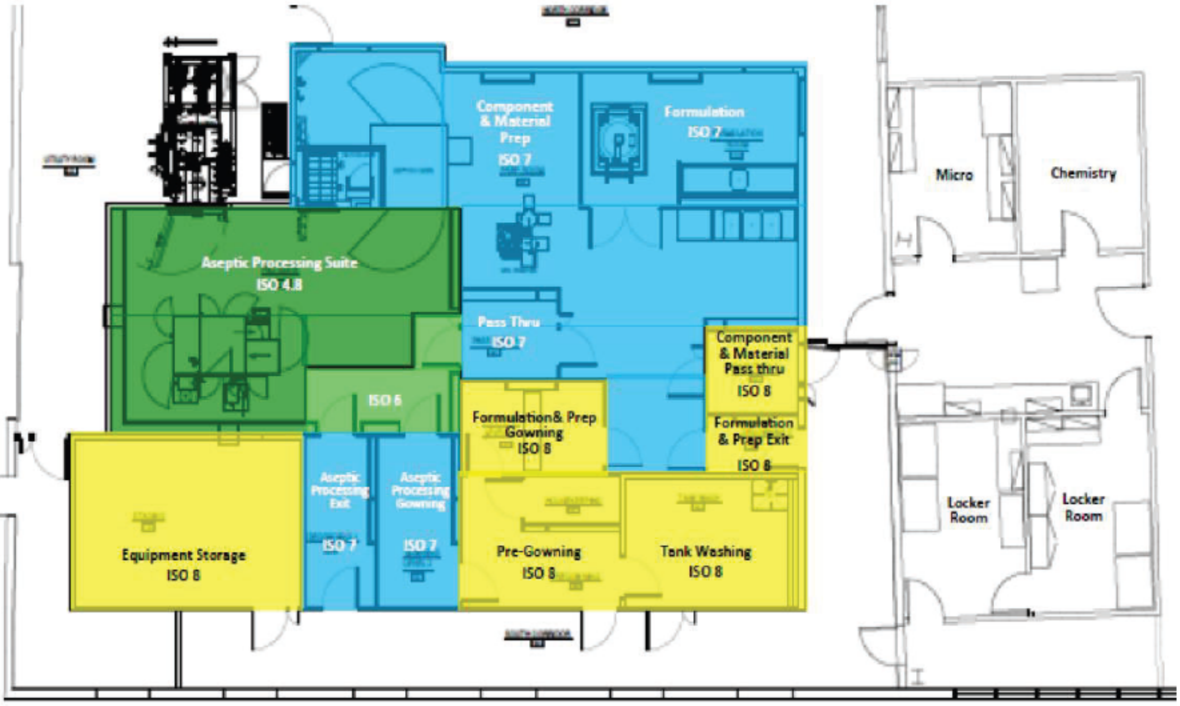
UPS Power Supply: The UPS system provides immediate / no break AC power for short periods of time. It is used to supply power to critical control systems. The UPS is used for equipment inside the data center, Catalent process control equipment, and existing building services equipment. In addition, stand- alone UPS's are installed on critical production and analytical equipment as appropriate

Heating, Ventilation, and Air Conditioning Systems: The HVAC systems associated with the facility is designed in accordance with the International Building Code, NFPA requirements, and ASHRAE standards. Room design conditions i.e. air change rates, temperatures, etc. are those typically found within cGMP facilities with similar operations and in accordance with ISO guidelines where specified in the Design Criteria for the Catalent Madison Project. Air Handlers and HVAC equipment is monitored and controlled via the Building Automation System (BAS) system. Each air handler is fitted with a dedicated controller for its respective unit. The AHU controller is networked on a BAS control area LAN and accessed via the BAS web portal. Field instruments and control devices are hardwired utilizing discrete signals directly to the HVAC controllers. Environmental monitoring of cGMP areas is accomplished through the Process Control System and Environmental Monitoring System (PCS) specifically designed to monitor temperature, humidity and differential pressure (DP) parameters within the production areas. Differential Pressure sensors have their impulse tubing routed to static pressure probes located in the ceilings of the rooms that are monitored for DP. A common area is used as the reference for each static measurement. The HVAC system also includes chilled water plant steam, hot water for reheat and heat reclaim system.

Building Automation System (BAS): Building Automation System (BAS) services the cGMP and R&D areas. This system monitors and controls utility, mechanical, electrical, HVAC and facility-related support systems not directly involved with production systems. The primary function of the BAS is to control cGMP & R&D noncritical equipment and systems. In addition, monitoring of R&D equipment and systems is performed by the BAS.

GRAM Facilities. GRAM is a new CMO for Profectus since the previous facility at Catalent to manufacture PBS's protein vaccine with Aluminium Phosphate has been shut down. GRAM has qualified the unique aseptic compounding which is a critical process in making protein vaccine with aluminium. Profectus QA and Outsourcing has reviewed the Media Fill Qualification Summary Report and verified that the established processes at GRAM will be applicable in manufacturing HeV-sG vaccines. GRAM is qualified to fill up to 144,000 vials at 3,000 vial/hour for 48 hours.

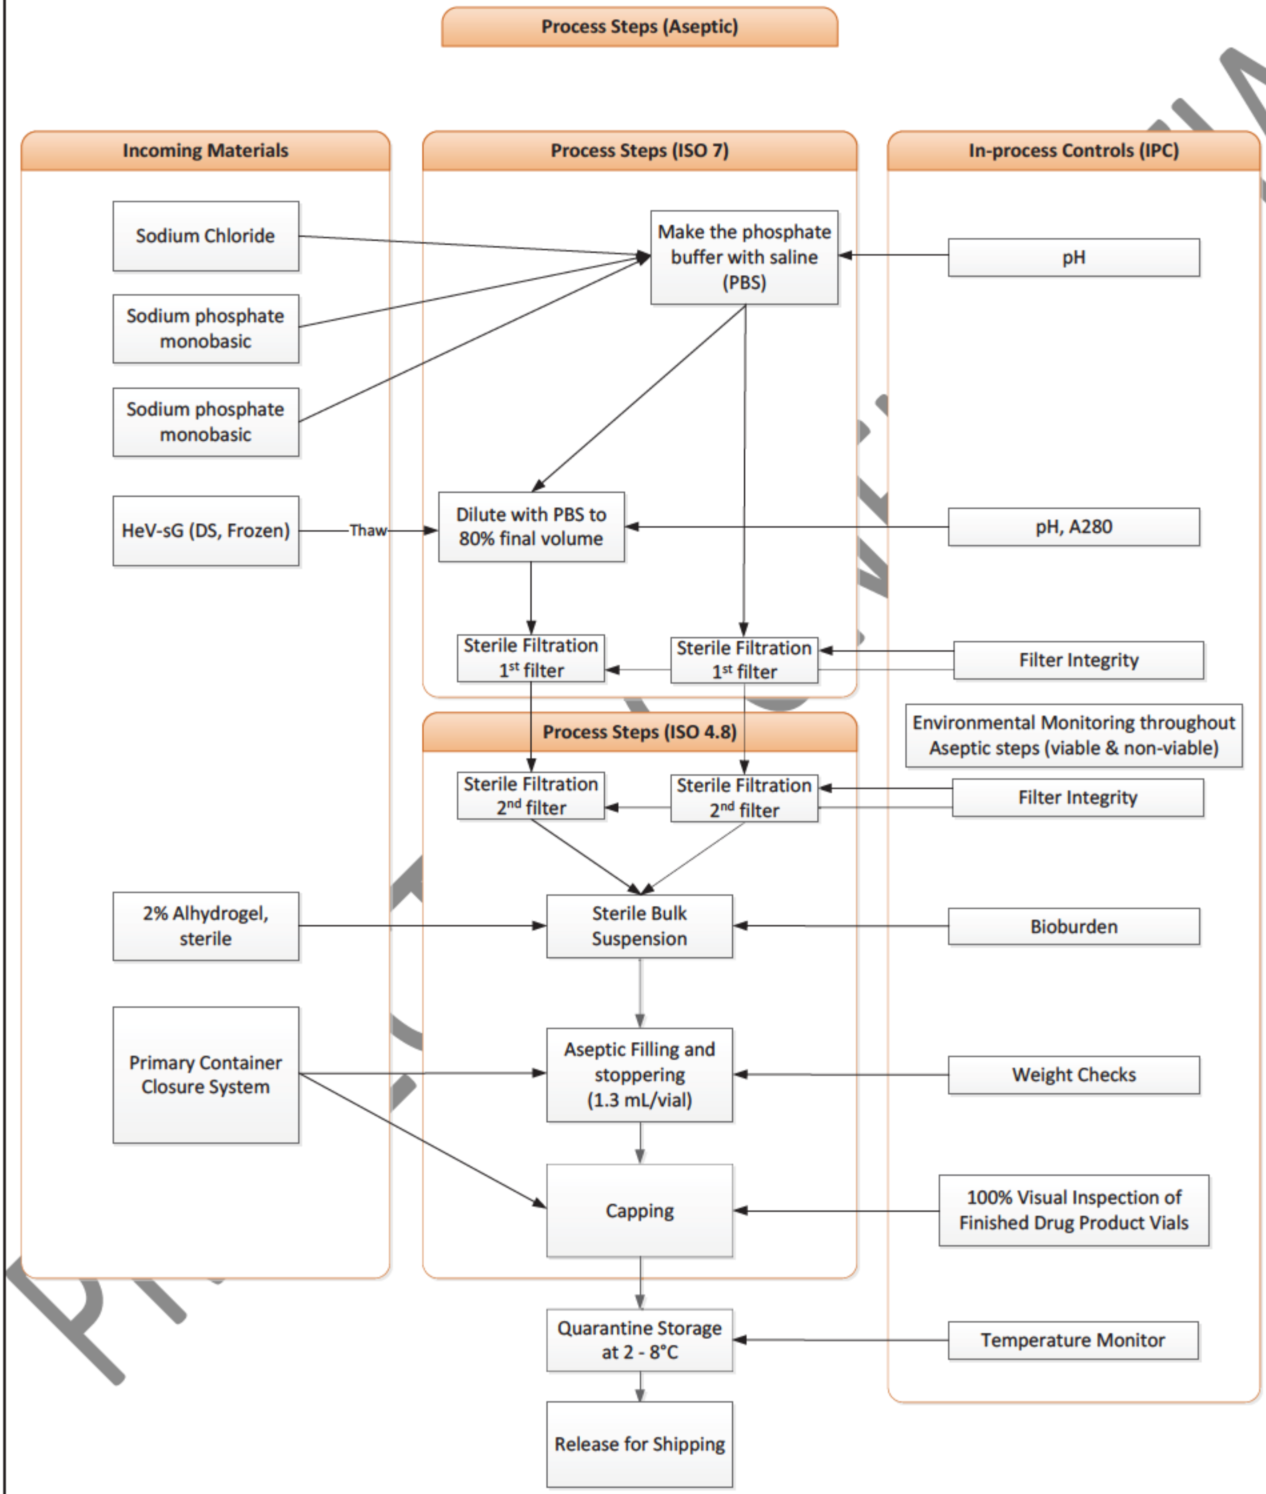
Grand River Aseptic Manufacturing (GRAM) is a full-service parenteral contract manufacturing organization supporting new product development and cGMP manufacturing. GRAM is approved by FDA to manufacture 4 commercial drug products since 2013. Current portfolio is 57% biologics and 43% small molecules with 80% being sterilized by aseptic filtration and 20% by terminal sterilization. GRAM is approved by the FDA for aseptic manufacturing with and without terminal sterilization. GRAM manufactures drug products in vials and syringes to support clinical trial from Phase 1 to Phase 3.



Manufacturing areas

GRAM is located in downtown Grand Rapids, Michigan. The manufacturing space is 11,400 ft^2 within a facility of 28,000 ft^2. In addition to the manufacturing area, other areas provides supporting functions such as analytical and microbiological testing, formulation development, process development/validation, labelling/packaging, warehouse, and storage

Operation of the manufacture Process: GRAM is equipped with a USP compliant Water for Injection system, a fully automatic filling machine inside an isolator, a vial washer, and a de-pyrogenation oven. The manufacturing areas have designated areas that are compliant to ISO standards; ISO 4.8 (Grade A under EU GMP Annex 1) for the aseptic filling suite, ISO 7 for the preparation areas, and ISO 8 for the general areas as schematic presented in various colors above. Drug products are manufactured on a campaign basis according to applicable cGMP guidelines. The manufacturing area is dedicated to production of only one product at any one time, with complete cleaning and changeover between products. Warehouse personnel identify and label all incoming raw materials and packaging materials according to established standard procedures. Samples for QC testing are selected by the QC Department. Materials are stored in a logical quarantine area until all required acceptance activities have been completed. Data related to the status, lot numbers, material description, and location and the lot of the materials to be used are handled according to established standard procedures. The concept of the facility includes high level containment control and aseptic manufacturing by the use of isolation systems and automated manufacturing equipment. Flows for materials and personnel are restrictedly designed to prevent cross-contamination between suites and to prevent the introduction of any adventitious agents into the processes. The HVAC (Heating, Ventilation and Air Conditioning) system servicing the facility are designed to provide proper control and segregation of the environments. All the environmental classified rooms related to the sterile manufacturing areas are at a decreasing nominal pressure differential starting from the highest classified rooms down to the lower grades. In sterile area parameters such as overpressure, temperature, humidity, non-viable particulate levels are continuously monitored and recorded. Alert and action limits are described in a master program that ensures maintenance of proper temperature, humidity and ventilation. All process equipment is qualified and validated accordingly and routine maintenance is scheduled according to established standard procedures. Written procedures are designed to prevent microbiological and particle contamination of products. A routine environmental control of viable and not viable particles is performed in the sterile area and the relevant trend is periodically examined. The sterilization processes are validated and documented via media fill every 6 months in a rotational basis. All manufacturing operations are performed in accordance with Standard Operating Procedures and process or solution batch records. The manufacture process of HeV-sG-V Drug product with in-process control is presented below.



<u>Duke-NUS Facilities.</u> SingHealth Investigational Medicine Unit, Singapore General Hospital, Block 7 Level 7, Outram Road, Singapore 169608. & Duke-NUS Medical School, 8 College Road, Singapore 169857.

Manufacturing and scale-up for industrial suppl

Profectus Manufacturing and Scale-Up Experience: Profectus performs GMP, GLP, and GCP activities through outsourcing, and has developed and implemented the key quality system policies and procedures needed to support the manufacture, testing, and conduct of human clinical trials utilizing GMP, GLP and GCP contract service providers. These standard operating procedures (SOPs) include systems for quality policy and quality roles and responsibilities, document control, quality agreements, batch record review and product disposition, deviations/investigations, employee GMP, GLP and GCP training, stability programs, contractor audits and qualification programs, outsourcing, and managing/investigating clinical trial product complaints.

Prospective contract service providers are evaluated using established Standard Operating Procedures (SOPs) for qualifying vendors. Profectus utilizes qualifying audits as a mechanism for initially qualifying cGMP, GLP, and clinical (GCP) contract service providers for use in drug and vaccine development programs, and performs routine, directed or other audits to measure and monitor on-going GMP, GLP, and GCP compliance. In addition, it is the policy of Profectus to execute Quality Agreements with all GMP, GLP, and GCP contract service providers prior to the release of clinical trial materials (CTMs), the performance of non-clinical GLP studies at contractor sites, or the conduct of clinical trials by Clinical Research Organizations (CROs). Profectus reviews and approves all master and executed batch records, including quality control testing and stability documentation in support of the manufacture of CTMs. All investigations are thoroughly reviewed and approved by Profectus QA. Service contracts are managed through an interdisciplinary Contract Management Team led by the Executive Director of Outsourcing, or designee. The Contract Management Team is comprised of the appropriate individuals from both Profectus and the contract service provider. The Contract Management Team holds regularly scheduled meetings with agendas, minutes and time constrained action items. This approach has supported the successful GMP manufacture of 5 pDNA vaccines (pDNA-HIVgag/pol, pDNA-HIVenv/nef-tat-vif, 2 Lots of pDNA-huIL-12, and pDNA-huIL-15), and 4 rVSV vaccines [rVSV-HIVgag, rVSV-HIVenv, rVSV-EBOV(Zaire), and rVSV-MARV(Angola)].

Profectus has audited, qualified and contracted with Fisher BioServices (FBS) for GMP storage and cold chain management for distribution of clinical supplies. A Quality Agreement is also in place. FBS has more than 22 years providing worldwide collection, storage and distribution of biological materials with 26 facilities in the US, 2 in Europe, 1 in Asia, and over 240 employees. Profectus currently has contracts with FBS for GMP storage at +4°C, -20°C, and -80°C. E. coli cell banks and various CTM produced under multiple US government contracts are presently in storage at FBS, and CDC and USDA permits are in place to allow storage of VSV vectors at the appropriate FBS facilities.

Profectus has audited and contracted with three Charles River Laboratory (CRL) facilities for GMP and GLP testing. The CRL group is a widely recognized and respected GLP and GMP contract testing organization with facilities worldwide. Profectus has audited and qualified the facilities we propose to use for this contract effort and have a Quality Agreement in place to cover all CRL facilities.

- CRL-Montreal, Canada provides IND enabling GLP toxicology testing. This group has already performed two successful toxicology studies for Profectus using pDNA and VSV vectors. Rabbits, which is the animal species proposed for toxicology testing under this contract, were used for both previous IND-enabling toxicology studies. CRL also has the capability to perform GLP toxicology studies in other species, including mice, rats, and various monkeys, should it be required. CRL-Montreal has been granted the Health Canada and Canada Food Inspection Agency permits that are required to conduct toxicology studies in their facility with VSV, a BL-2 class organism.
- CRL-Wilmington, MA provides GLP safety testing for both research and product release. This site provides murine neuro-virulence testing by intra-thalamic inoculation of VSV vectors; in vivo adventitious agent testing in embryonated eggs, suckling mice and guinea pigs for MVS and CTM drug substance (DS); and General Safety Testing in guinea pigs which is required for release of each lot of CTM. Protocols and final reports for each of these tests are reviewed and approved by Profectus QA. CDC and USDA permits are in place to allow CRL-Wilmington to handle VSV vectors.
- CRL-Malvern, PA performs in vitro adventitious agent testing (direct and indirect Mycoplasma and Tissue Culture Safety Test) for MVS and CTM DS as well as nucleic acid sequencing of MVS and CTM DS. These tests are required for release of MVS and CTM. Protocols and final reports for each of these tests are reviewed and approved by Profectus QA. CDC and USDA permits are in place to allow CRL-Malvern to handle VSV vectors.

The two individuals within Profectus BioSciences with primary responsibility for outsourcing are Tracy Chen, Ph.D., Senior Director of Operations and Outsourcing, and Marc Tremblay, Director, Quality Assurance. Each has over two decades of experience in their respective roles and expertise in their areas covering all phases of pharmaceutical and vaccine Development.

PATH partners with emerging-market manufacturers around the world to develop, introduce, and scale-up vaccine products that will be accessible and affordable for use in low-income countries. Our initiatives currently support producers in India, Brazil, China, Indonesia, Serbia, Brazil and Vietnam, on vaccines targeting a range of infections, including influenza, Japanese encephalitis, rotavirus, pneumococcus, yellow fever, measles, rubella, human papillomavirus, polio, and Group B Streptococcus (GBS).

We provide technical expertise, project management, financial support, and assistance in complying with national and global regulatory bodies for vaccine development and introduction. This includes assisting manufacturers in achieving WHO prequalification, a critical step in expanding vaccine access. Our support helps manufacturers improve safety and quality system compliance, conduct clinical trials according to international standards, and achieve efficiencies that lower costs, improve yields, and enable scale-up to meet national, regional, and global needs.

Examples of PATH's work to strengthen manufacturing capacity and scale up the supply of life-saving vaccines include:

- Helping a manufacturer in Vietnam (Institute of Vaccines and Medical Biologicals; IVAC) ready its influenza vaccine production facility and advance pandemic and seasonal vaccine candidates in clinical studies.
- Supporting the production of cell-culture-based influenza vaccines at a state-owned vaccine and biological production company in Vietnam (VABIOTECH) by helping to obtain licenses, conducting technical training, and purchasing equipment and supplies.
- Providing technical and financial assistance to help a Chinese manufacturer (Chengdu Institute of Biological Products Co., Ltd.) build and validate a new facility to meet the international manufacturing standards required for WHO prequalification of its Japanese encephalitis vaccine, which was the first Chinese vaccine ever to achieve WHO prequalification.
- Supporting technology transfer, process development and validation, and manufacturing scale-up of a meningitis A vaccine developed by an Indian manufacturer (Serum Institute of India, Ltd.) specifically for use in sub-Saharan Africa.
- Partnering with the only vaccine manufacturer in South Africa (The Biovac Institute) to develop a low-cost polyvalent GBS conjugate vaccine that will significantly reduce neonatal mortality caused by GBS in Africa and other low-income regions of the world.

The training and technical support that we provide to emerging-market vaccine manufacturers is helping to speed and strengthen their ability to sustainably supply critical vaccines for the future.

Duke-NUS list of relevant publications. Attached as **Table 4** (above)

2.3. Stakeholder engagement strategy

Development of the vaccine will take place under the regulatory oversight of US FDA, and the consortium will seek scientific advice from US FDA and other relevant regulators to ensure that the development plan is tailored to meet the requirements for stockpiling, emergency use, and eventual licensure as appropriate. More information on this is included in section 4.6.

The consortium will work with multiple partners in countries where we conduct clinical trials, including researchers, regulators, and other decision-makers. We will collaborate with in-country researchers in developing the vaccines and building capacity through investments in clinical trial and laboratory facilities and training. As the studies progress, we will convene local trial groups and other experts in countries where the clinical development is taking place to confidentially share progress and preliminary findings, build evidence for regulatory and policy discussions, and plan for upcoming activities. We also will partner with the local trial groups in the dissemination of results once the in-country trials have concluded, including publication and presentation for scientific audiences, as well as local dissemination activities in the communities where the trials are conducted.

We also will work with key decision-makers in the countries where we are conducting clinical trials, including regulators and ethics committees, to ensure that they have access to the information necessary to make evidence-based decisions around the testing and potential use of vaccines.

We recognize that engagement of regulators and decision-makers at the global level (e.g., WHO) and in countries at high risk of Lassa feverwill be important to ensure that they have the information needed to make decisions about deployment of the vaccine in the event of an outbreak. It is our understanding that CEPI intends to facilitate discussions to build consensus around emergency use protocols and other key issues in advance of an outbreak to facilitate rapid deployment of stockpiled vaccines when an outbreak is identified. Our consortium is eager to engage in and support these discussions as appropriate.

The consortium also will engage with WHO's R&D Blueprint for Action to Prevent Epidemics and other global coordinating mechanisms that are working to establish norms and standards and ensure streamlined approaches to development of vaccines for use during outbreaks and epidemics. The focus of this engagement will be to ensure that our efforts are consistent with global approaches (i.e., target product profiles, roadmaps, clinical endpoints, etc.) and policies. We also anticipate bringing the results of our clinical trials to the attention of the WHO Product Development for Vaccines Advisory Committee (PDVAC) and Strategic Advisory Group of Experts (SAGE) and other advisory bodies to inform policy around Lassa fever vaccines.

3. Project background

3.1. The proposed vaccine candidate

Vaccine Candidate: A recombinant subunit vaccine derived from the ectodomain of HeV attachment G glycoprotein (HeV-sG) in formulation with Alhydrogel™ for intra-muscular injection.

3.2. Scientific rationale

Scientific Rationale: As noted above, the HeV-sG subunit vaccine is based on the currently licensed HeV-sG vaccine for veterinary use (Equivac® HeV, Zoetis), which has been administered to more than 300,000 horses in Australia (see https://www.health4horses.com.au/Documents/H4H_Factsheet_V5_WEB2.pdf. In addition, accidental administration of the veterinary vaccine suggests robust immunogenicity in humans.

3.3. Pre-clinical evidence to date

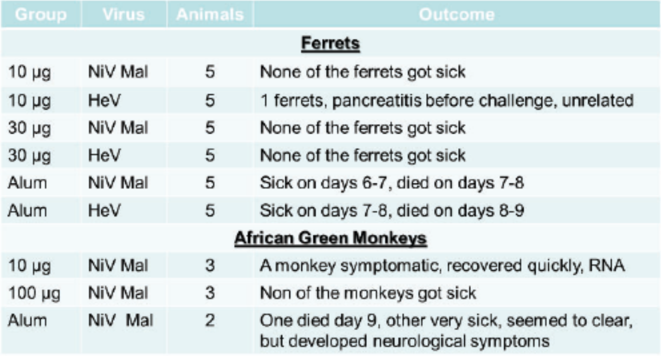
Preliminary Data

HeV-sG in animal vaccine studies. Several animal models have been used to study NiV and HeV disease, including: cats (12, 13), hamsters (16-18), ferrets (14, 19), horses, and AGMs (10, 20). To date, HeV-sG subunit vaccine in co-formulation with the adjuvants Alhydrogel™ and CpG ODM 2007 has been tested in four animal species: cats, ferrets, AGMs, and horses. Following 2 doses of vaccine separated by 21 days, all immunized animals were protected from lethal challenge with either HeV or NiV (**Table 8**). Immunization not only protected against mortality, but also prevented all clinical symptoms and resulted in no virus genetic material being detectable in any tissues harvested from the immunized cats, ferrets, and AGMs.

Table 8: Summary of HeV-sG vaccine challenge protection studies

model / virus	**HeV-sG dose / adjuvant**	**# animals challenged**	**# animals protected**
Cat / NiV **(12)**	100 µg / Montanide - Quil A – DEAE dextran	2	2
	Adjuvant only (Control)	2	0
Cat / NiV **(13)**	50 µg / CpG ODN 2007 - Alum	2	2
	25 µg / CpG ODN 2007 - Alum	2	2
	5 µg / CpG ODN 2007 - Alum	2	2
	Adjuvant only (Control)	2	0
Ferret /HeV (14)	100 µg / CpG ODN 2007 - Alum	2	2
	20 µg / CpG ODN 2007 - Alum	2	2
	4 µg / CpG ODN 2007 - Alum	2	2
	Adjuvant only (Control)	2	0
AGM / NiV (15)	100 µg / CpG ODN 2006 - Alum	3	3
	50 µg / CpG ODN 2006 - Alum	3	3
	10 µg / CpG ODN 2006 - Alum	3	3
	Adjuvant only (Control)	1	0
Horse / HeV	All immunized animals survived.		

Alhydrogel (Alum) as single adjuvant. The preliminary data presented in **Table 5** were generated using HeV-sG in co-formulation with both Alhydrogel and CpG ODN 2006 adjuvants. To simplify vaccine development, subsequent studies were performed using Alhydrogel™ only. Two studies in ferrets and one in AGM confirmed that HeV-sG formulated with Alhydrogel™ alone provides a fully protective vaccine. Each study had a low dose group (10 µg HeV-sG per dose), a high dose group (30 µg for ferrets and 100 µg for AGMs per dose), and a control group dosed with Alhydrogel™ only. The ratio of HeV-sG /Alum was kept at 1/25 as in the preliminary studies. The results from these studies are summarized in **Table 9**. In brief, all vaccinated animals were protected from lethal challenge with either NiV or HeV. Thus, Alhydrogel™ alone is an effective adjuvant for HeV-sG.



Group	Virus	Animals	Outcome
			Ferrets
10 µg	NiV Mal	5	None of the ferrets got sick
10 µg	HeV	5	1 ferrets, pancreatitis before challenge, unrelated
30 µg	NiV Mal	5	None of the ferrets got sick
30 µg	HeV	5	None of the ferrets got sick
Alum	NiV Mal	5	Sick on days 6-7, died on days 7-8
Alum	HeV	5	Sick on days 7-8, died on days 8-9
			African Green Monkeys
10 µg	NiV Mal	3	A monkey symptomatic, recovered quickly, RNA
100 µg	NiV Mal	3	Non of the monkeys got sick
Alum	NiV Mal	2	One died day 9, other very sick, seemed to clear, but developed neurological symptoms

Table 9. Results from the HeV-sG/Alum vaccine formulation efficacy test against NiV challenge in ferrets and AGMs and against HeV challenge in ferrets. All vaccinated animals survived challenge, but one monkey in the low dose group became symptomatic and was positive of viral RNA. The same monkey had the lowest serum IgG anti-NiV titer, suggesting a correlation betweenthe serum IgG titer and protection.

HeV-sG/Alum formulation. To this point in development, all the animal studies utilized a HeV-sG/Alum ratio 1/25. Thus, if a 100µg dose HeV-sG of this formulation were to be tested in the clinic, it would contain 2.5 mg of Al^{3+}, which is twice the maximum dose recommended by the FDA for single site administration. To determine if a lower amount of alum could be used, absorption/desorption studies were performed at various HeV-sG/Alum ratios. These studies demonstrated that HeV-sG is fully absorbed to Alhydrogel™ at a ratio as low as 1/7. Therefore, a ratio of 1/10 HeV-sG/Alhydrogel™ provides 70% absorption saturation and a 100µg dose of HeV-sG will contain 1 mg Al^{3+}, which is 80% of the maximum allowed Al^{3+} dose per shot. Therefore, a rabbit immunogenicity study was performed that directly compared the immunogenicity of a 30µg dose of HeV-sG when formulated with Alhydrogel™ at ratios of 1/10 vs 1/25. As shown in **Figure 1**, changing the HeV-sG/Alum ratio from 1/25 to 1/10 did not alter HeV-sG immunogenicity, and both formulations provided exceptionally good responses. Thus, a 1/10 HeV-sG/Alhydrogel™ formulation was selected for development and clinical evaluation.

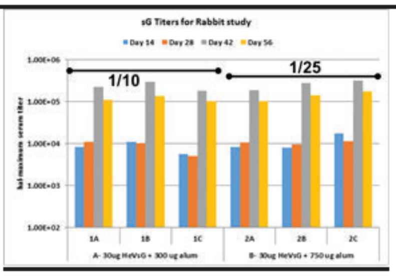


Figure 1. Immunogenicity study to test HeV-sG/Alum ratio effect. Two groups of three rabbits were immunized with formulation at 1/10 (Vac 1) and at 1/25 (Vac 2). Sera were tittered for anti-HeV-sG antibodies. Vac 1 and Vac 2 showed indistinguishable immune responses, measured in serum titers.

Preliminary stability data for the HeV-sG/Alum formulation. To support development, a 32-week stability study of the HeV-sG/Alhydrogel™ formulation used in the above studies was conducted. As seen in **Figure 2**, unformulated HeV-sG is stable at 4⁰C for 32 weeks, but undergoes degradation if stored at 21⁰C or 37⁰C for this period. In contrast, Alhydrogel™ formulated HeV-sG remains 100% bound and intact at either 4⁰C or 21⁰C for 32 weeks. Thus, HeV-sG/Alhydrogel™ provides a product with projected multi-year stability at refrigerator temperature, that can withstand extended handling at room temperature, and that will likely withstand multi-day handling at 37⁰C.

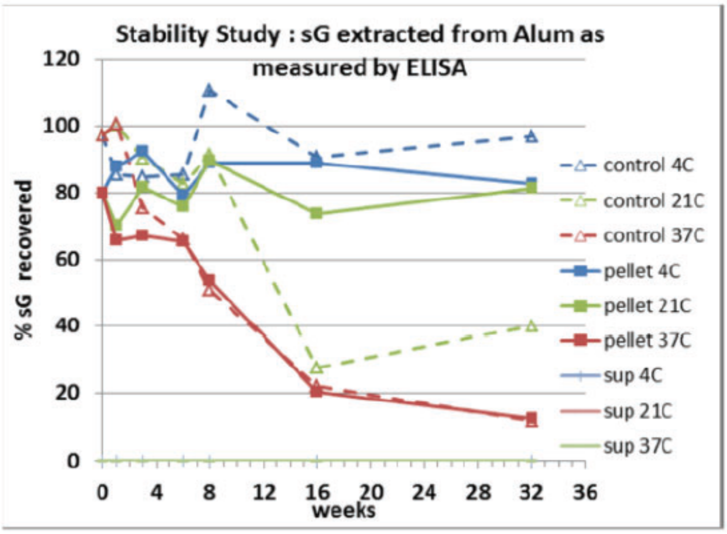

Figure 2. HeV-sG/Alhydrogel™ vaccine is stable for 32 weeks when stored at 4⁰C and 21⁰C. Formulated and non-formulated HeV-sG was stored at 4ᵒC, 21ᵒC, and 37ᵒC for 32 weeks. Samples were examined at weeks 1, 3, 6, 8, 16, and 32 to determine HeV-sG integrity, quantity, and percent bound to the Alhydrogel™ by quantitative ELISA that discriminates between intact and degraded HeV-sG. Control = non-formulated HeV-sG, Sup = supernatant of centrifuged HeV-sG/Alhydrogel™, Pellet = HeV-sG extracted from the pellet of centrifuged HeV-sG/Alhydrogel™.

Cell line creation and MCB manufacture. A HEK-293 Research Cell Bank (RCB) expressing HeV-sG protein (HeV-sG-HEK-293) was prepared by Profectus, using multiple transductions of parent HEK-293F cells with a recombinant MoMuLV carrying the HeV-sG gene, followed by two consecutive rounds of limited dilution cloning. The productivity of the RCB was greater than 1 gm/L HeV-sG when grown in shake flasks using a preliminary optimized feeding schedule. The RCB was used as a seed to manufacture a HeV-sG-HEK-293 master cell bank (MCB) at CRL – lot #5407580MCB2, December 31, 2013, 325 vials, 1.16×10^7 viable cells/vial. The MCB has passed all testing and has been released by Profectus QA.

Expression and purification of HeV-sG. Under Profectus oversight, our CMO, Catalent, has developed a scalable upstream process (USP) suitable for cGMP protein production, in which the concentration of HeV-sG in the supernatant exceeds 0.6 g/L, which was judged adequate for further development. A scalable downstream purification process (DSP) suitable for cGMP manufacture of HeV-sG has also been developed at Catalent. The process consists of: 1) Media clarification by depth filtration (3M Zeta Plus 60SP02A); 2) Triton-X 100 added to 0.1% v/v and incubated for one hour (for viral inactivation) followed by pH reduction to 5.0; 3) Capto MMC mixed-mode hydrophobic cation exchange chromatography with elution over a 20 column volume gradient starting with 100% 25mM MES, pH 6.0 and moving to 25mM MES, pH 6.0, 0.5M NaCl followed by increase in pH to 8.0; 4) intermediate purification using CaptoAdhere mixed-mode hydrophobic anion exchange chromatography with elution over a 20 column volume gradient starting with 100% 50mM Tris, pH 8.0 and moving to 50mM Tris, pH 8.0, 1M NaCl, followed by adding an equal volume 2M ammonium sulfate, pH 7.5; 5) polishing purification using Phenyl HP hydrophobic interaction chromatography with elution over a 32 column volume gradient starting with 80% 50mM Tris, 1M ammonium sulfate, pH 7.5 and moving to 50mM Tris, pH 7.5; 6) an additional polishing chromatography by diafiltration with 7 volumes 50mM Tris, pH 7.5 followed by Sartobind Q membrane in flow-through mode with 50mM Tris, pH 7.5; 7), and viral filtration by using a Virosart 150 CPV capsule filter. Finally, the HeV-sG solution was dialyzed against PBS (10 mM sodium phosphate, 150mM NaCl, pH 7.0), concentrated to 9.84 mg/mL using tangential flow filtration with a 50 kD MWCO PES membrane, and sterile filtered through a 0.2-µm PES filter. This cGMP-like purification process was used to purify HeV-sG from the supernatant of a 10-L bioreactor run to obtain 2.5 grams HeV-sG, 2x125 mL in PETG bottles at 9.84 mg/mL in PBS. This non-GMP DS was used to formulate the toxicology lot of HeV-sG/Alhydrogel™ vaccine.

Vaccine formulation, toxicology lot manufacture. The toxicology lot of HeV-sG/Alhydrogel™, labelled as "0.1 mg/mL HeV-sG, 1.0 mg/mL Al^{3+} in Aluminum Hydroxide Suspension for Injection, (Toxicology Supplies), Lot PUP05401A" from 19 July 2016 was prepared at Catalent Pharma. 624 of the 649 filled vials were made available for stability testing, the GLP toxicology study, and animal efficacy testing studies. A 36-page batch record details each step in the preparation process that basically consists of mixing 10.2 mL HeV-sG DS with 100 mL Alhydrogel™ in 890 mL PBS with continuous stirring.

GLP Tox Study. A 4-cycle (1 dose every 3 weeks) toxicity study in rabbits administered HeV-sG/Alum by intramuscular injection initiated October 2016 at CRL (**Table 10**). Three groups of 20 New Zealand White Rabbits, aged from 3 to 5 months and from 2.0 to 4.0 kg each are being used in the study. The control group was dosed with saline, the low dose group was injected with the maximum intended human dose, and the high dose group was injected with 3X the maximum intended human dose. The un-audited toxicology report contains no significant observations, and the final audited report will be available on or about 01-Aug-2017.

Table 10. A 4-cycle Study in Rabbits Administered HeV-sG/Alhydrogel™ by Intramuscular Injection

Group No.	Test Item[a]	Dose Level (mg/day)	Dose Concentration (mg/mL)	Dose Volume (mL)	No. of Animals			
					Main Study[b]		Recovery Study[c]	
					Males	Females	Males	Females
1	Saline Control	0	0	3.0	5	5	5	5
2	HeV-sG-V	0.1	0.1	1.0	5	5	5	5
3	HeV-sG-V	0.3	0.1	3.0	5	5	5	5

[a] Dosing will be performed once every three weeks (= 1 cycle) for 4 cycles

[b] Main study animals will undergo necropsy 3 days following the last dose administration.

[c] Recovery study animals will undergo necropsy 28 days following the last dose administration.

CRL is an accredited CMO for carrying out GLP toxicity studies and we do not expect procedural complications with the study. Antibody titers from blood samples will be determined under well documented practices at Profectus.

Animal efficacy confirmation studies. Two AGM challenge studies has been conducted to confirm the HeV-sG/Alhydrogel™ vaccine produced under GMP-like conditions will protect against lethal challenge with NiV and HeV. Twelve AGMs were used in each study. In the first study, groups of AGMs were vaccinated on experimental days 0 and 28 with 100 µg (group 1, N=6) or 300 µg (Group 2, N=3) of the same preparation of HeV-sG/Alhydrogel™ used in the GLP toxicology study, and a control group of 3 AGMs received Alhydrogel™ suspension only. On experimental day 56, all AGMs in study 1 were challenged with a lethal dose of NiV (1998-99 Malaysian outbreak strain). Within 13 days of challenge, all control AGMs had succumbed to lethal NiV disease, while all vaccinated animals remained completely healthy. Study 2 was carried out identically to the first, except that the challenge consisted of HeV (1994 Australian outbreak strain). As in the first study, all vaccinated AGMs remained healthy, while 2 of the 3 control animals died of haemorrhagic disease.

3.4. Clinical evidence to date

The HeV-sG/Alhydrogel™ vaccine candidate has not yet entered clinical evaluation. However, the human immune response to accidental inoculation (N=2) with the veterinary vaccine has been shown to be potent and to cross-neutralize both NiV and HeV (I. Smith and C. Broder, unpublished).

3.5. Assays, animal models and supporting relevant data developed

The assays to be employed to support clinical evaluation are described under **Task 2** in **Section 4.2 Objectives** (below). Characterization of the HeV-sG/Alhydrogel™ vaccine candidate and the animal models providing the data that support advancement of the vaccine into clinical evaluation are described in **Section 3.3 Pre-clinical evidence to date** (above).

3.6. Evidence from other pathogens

The HeV-sG/Alhydrogel™ vaccine candidate is a subunit vaccine specific to NiV and HeV. However, subunit vaccines have been successfully developed for a number of viral pathogens, including HBV, HPV, influenza.

3.7. Intellectual property

Profectus BioSciences, Inc. has executed a term sheet and is finalizing the license necessary to manufacture, use, sell and sublicense its subunit Nipah/Hendra soluble G vaccine. Profectus's Nipah/Hendra soluble G vaccine does not come within the scope of any valid third party issued patent claims. Therefore, Profectus has freedom to operate.

4. Research and Technical Objectives – Statement of work

4.1. Project governance/management and applicant's and partner's roles and responsibilities in the project

Table 12 provides a listing of the 12 Primary and 5 Optional Tasks that make up the work proposed under this application, and the Cooperating Partner(s) or contracted organization(s) responsible for completion of the Task. Each of these Tasks is described in detail in section 4.2 Objectives, including Task-specific Deliverables and Go/No Go criteria. Each **Task** will be managed through the establishment of an interdisciplinary Task Management Team comprised of the appropriate individuals from both Profectus and the collaborating partner or contract service provider. The Task Management Teams will hold regularly scheduled meetings with agendas, minutes and time constrained action items. The overall timing of the **Tasks** and their relationship for decision making is illustrated in the **Detailed Milestone Plan**.

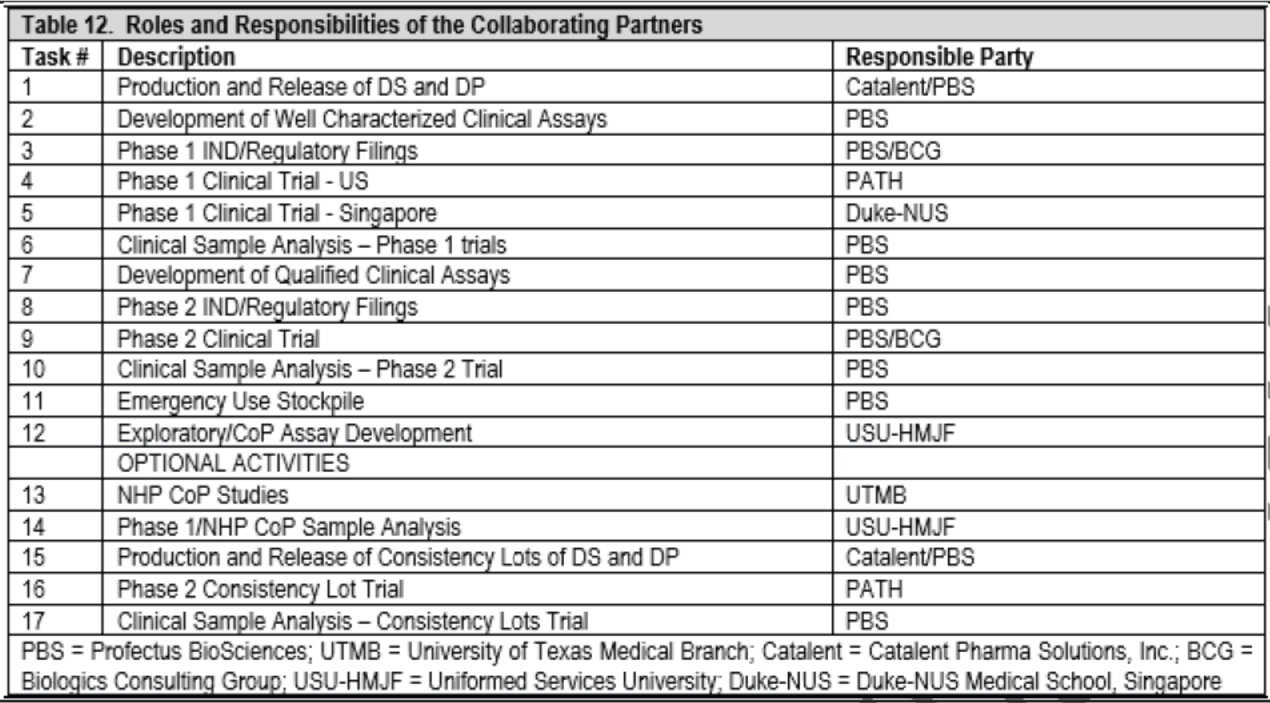

Table 12. Roles and Responsibilities of the Collaborating Partners

Task #	Description	Responsible Party
1	Production and Release of DS and DP	Catalent/PBS
2	Development of Well Characterized Clinical Assays	PBS
3	Phase 1 IND/Regulatory Filings	PBS/BCG
4	Phase 1 Clinical Trial - US	PATH
5	Phase 1 Clinical Trial - Singapore	Duke-NUS
6	Clinical Sample Analysis – Phase 1 trials	PBS
7	Development of Qualified Clinical Assays	PBS
8	Phase 2 IND/Regulatory Filings	PBS

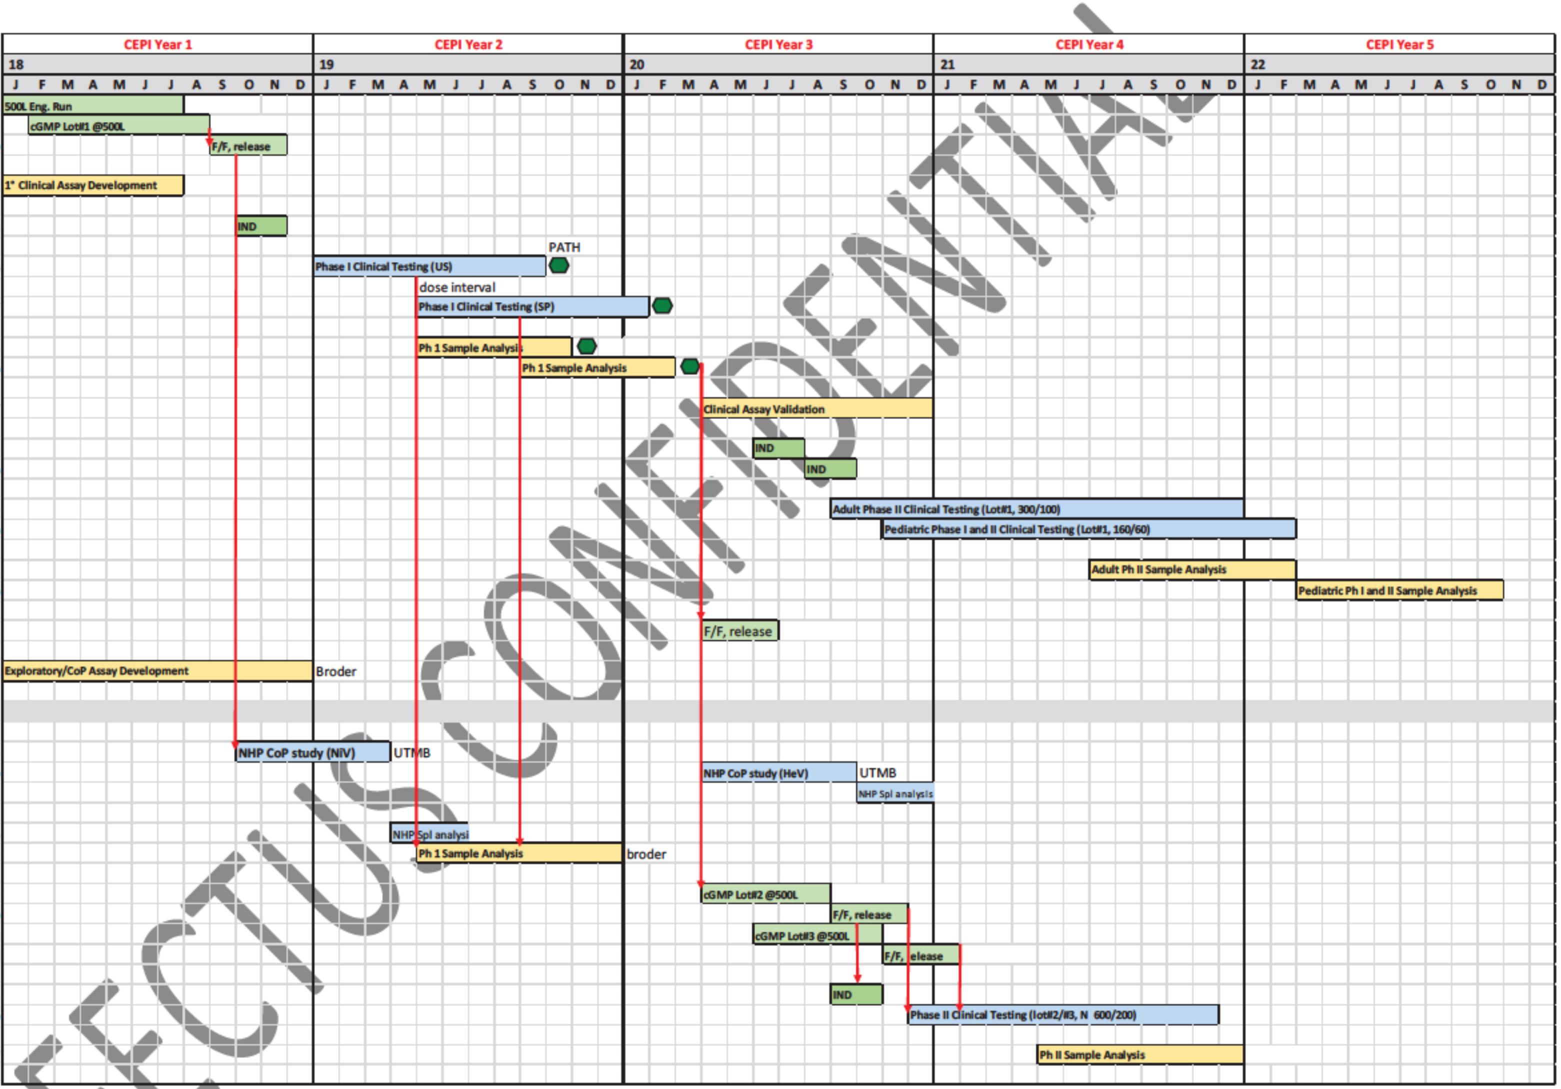
	Ph II Clininical Trial Lot#2/#3 Singapore (12 mon, PATH)	16b
17	Ph II Clinical Sample testing USA (PBS)	17



4.2. Objectives

This application proposes to advance the HeV-sG/Alhydrogel™ vaccine through Phase 2 clinical development and to produce and stockpile sufficient vaccine stocks to support emergency use and for potential licensure studies. To achieve these goals, the specific tasks outlined in **Table 5** will be undertaken. The proposed timeline for these activities is outlined in the attached **Detailed Milestone Plan**.

What follows is a brief description of each proposed task:

Task 1: **Production and Release of HeV-sG/Alhydrogel DS and DP**: GMP production of HeV-sG Bulk Drug Substance (BDS) will be performed at Catalent Pharma Solutions, Madison, WI. Now that the engineering run is complete, the MPR and associated GMP manufacturing methods have been finalized. Manufacturing runs will be produced under cGMP conditions at 1,000L working volume. Profectus will provide Catalent with a set of product specifications, or acceptance criteria, in writing, before GMP manufacturing commences. Based on the yields obtained in pilot-scale runs, it is projected the 1,000L GMP run will provide approximately 120 gm of DS. Since Catalent does not have an automated fill/finish facility (the toxicology lot was filled by hand in their cGMP suite), fill/finish of the Bulk Drug Product (BDP) will be performed at Grand River Aseptic Manufacturing, Inc, Grand Rapids, MI per fill requirements in terms of vial size and volume provided by Profectus. Two fill/finish runs are anticipated. The first run will supply 1,000 vials at 100µg/dose to support a phase 1 dose escalation study (10.0µg, 33.0µg, and 100.0µg) to establish safety and the optimally immunogenic dose. The second filling run will provide approximately 50,000 vials at the optimal clinical dose to support phase 2 testing and the stockpile of vaccine for emergency use. The finished vials will be stored at Fisher BioServices. Final release testing for the GMP material will be consistent with the General Biological Products Standards (21CFR610.11). Master Batch Records and all testing documentation will be provided to Profectus for QA review and final release. A complete listing of the testing and release criteria is provided in **Section 4.7 Chemistry, Manufacturing & Control (CMC) Development.**

> **Deliverables and Go/No Go Criteria:** The deliverables for this work segment will be fully characterized Lots of HeV-sG/Alhydrogel™ vaccine produced under full GMP compliance. Failure of any one of the components to pass release testing would result in an inability to proceed to clinical evaluation.

Task 2: **Development of Well Characterized Clinical Assays**: To support phase I clinical evaluation of the HeV-sG/Alhydrogel™ vaccine, Profectus will develop four well characterized assays to measure HeV and NiV GP immune responses in vaccine recipients. The assays will measure serum HeV and NiV GP-specific IgG antibody by direct ELISA, and serum HeV and NiV neutralizing antibody by plaque reduction neutralization of a green fluorescent protein (GFP)-expressing rVSV pseudo-typed with HeV or NiV GP. Each will be based on assays which PBS has developed and characterized for use in clinical trials of the mono-valent and tri-valent rVSVN4CT1-vectored filovirus vaccines. The general process for the transition of research assays to well characterized assays for use in support of phase 1 clinical testing is outlined below:

1. Research assay SOPs will be converted to DRAFT Profectus Test Methods. These Test Method documents will be the change control documents which outline all aspects of the assays, including:
    i. Scope
    ii. Roles and responsibilities
    iii. Safety
    iv. Abbreviations and definitions
    v. Reagents, materials and equipment
    vi. Procedures
    vii. References
2. In addition, for each DRAFT Profectus Test Method, the conduct or preparation of all supporting assay activities and reagents will be documented in DRAFT Profectus "Lab Method" documents. As an example:
    i. Preparation of clinical reagent lots
    ii. Procedures for assigning biological units to antibody reference standards
    iii. Preparation of Dulbecco's Phosphate Buffer Saline with 0.1% Tween-20
3. With DRAFT Test and Lab Method documents in place, the assays will be conducted over numerous days by several operators to confirm assay precision and reproducibility and the results of this testing compiled into "Characterization Reports".
    i. To demonstrate reproducibility, the assay will be conducted twice on three separate occasions using the same source material. Reproducibility will be based on a measure of the coefficient of variance (CV) for the assay read-out. CVs of <20% will be sufficient for demonstration of reproducibility.
    ii. For precision evaluations, positive control samples (reference standard and R&D antiserum for example) will be used as "samples". For each sample, a combination of different plates, test days and different operators will be set up to evaluate precision. The assays will be performed three times by one operator, and a second operator performed the same assay three times.

Profectus QA will review and approve the assay Characterization Reports. With the completion of the assay Characterization Report, the DRAFT Test and Lab Methods will also be reviewed and approved as FINAL Test and Lab Methods by PBS QA.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be FINAL Test and Lab Methods. Failure to qualify any of the assays would necessitate redevelopment and possibly delay the phase 1 clinical program.

Task 3: Phase 1 IND/Regulatory Filings: Over the past 4 years Profectus has prepared 8 IND license applications (BB-IND-14557, BB-IND-14665, BB-IND-14770, BB-IND-14976, BB-IND-15459, BB-IND-15462, BB-IND-16670, and BB-IND-16783) which have all been successful. The writing and assembly of the application for the US trial, the planning and execution of the communications and meetings with the FDA will be led by Dr. Susan Sciotto-Brown, Senior Director of Regulatory Affairs at Profectus. Electronic submission of the IND will be performed under subcontract through the electronic portal maintained by Biologics Consulting Group, Rockville, MD. The exact design of the trial will be determined by the guidance supplied by the FDA in response to a pre-IND briefing package. However, it is anticipated this will be a randomized, double-blind, placebo-controlled, truncated dose escalation trial evaluating vaccine doses 10.0µg, 33.0µg, and 100.0µg administered by IM injection in 3 groups of 26 healthy adult subjects (20 active/6 placebo). Subjects will be administered two doses of vaccine separated by 56 days.

A second phase 1 trial is proposed at the clinical trials center of the Duke-NUS Medical School in Sigapore, an area where NiV is endemic. The Profectus Regulatory Affairs group will interface with the Duke-NUS collaborators in the preparation of the necessary local regulatory filings. Although the exact design of this trial will be determined in discussions with the local regulatory agency, it is anticipated this trial will be a randomized, double-blind, placebo-controlled trial using the 33.0µg dose to evaluate vaccine dose interval (28, 56, and 120 days) in 3 groups of 26 healthy adult subjects (20 active/6 placebo).

Deliverable and Go/No Go Criteria: The deliverables for this work segment will be the safe to proceed letters from the US FDA and the relevant Singapore regulatory agency. The risk in preparation of these applications is mitigated by the experience and demonstrated success of the Profectus team in preparing IND license applications.

Task 4: Phase 1 Clinical Trial - US: Two partners have been identified to conduct phase 1 clinical evaluation of the HeV-sG/Alhydrogel™ vaccine. The first is PATH, Seattle WA and Washington, DC, who will use their clinical trials infrastructure to conduct a Phase I trial to test the safety and immunogenicity of the HeV-sG/Alhydrogel™ vaccine in normal healthy adults in the US. Although final design will be established in consultation with US FDA, it is anticipated this will be a randomized, double-blind, placebo-controlled, truncated dose escalation trial evaluating vaccine doses of 20 µg, 50 µg, and 100µg HeV-sG protein in a 1/10 wt/wt formulation with Alhydrogel™ adjuvant administered by IM injection in 3 groups of 25 healthy adult subjects (20 vaccine5 placebo). Subjects in this 3 groups will be administered two doses of vaccine separated by 56 days. A fourth group of subjects (20 vaccine/5 placebo) will receive a single dose of HeV-sG at the highest tolerated level. The primary objective of the study is to assess vaccine safety and tolerability by close clinical and laboratory follow-up of subjects after each vaccination; the secondary objective will be evaluation of the vaccine immunogenicity.

Deliverables and Go/No Go Criteria: The deliverables will be interim and final clinical trials reports demonstrating that the HeV-sG/Alhydrogel™vaccine is safe, well tolerated and immunogenic. This will support the initiation of **Task 5** (Phase I clinical testing in Singapore), and **Task 8** (Phase 2 clinical testing). Any results which suggest the vaccine is not safe, well tolerated or immunogenic will trigger a review to determine if it is judged prudent to discontinue development of the vaccine.

Task 5: Phase 1 Clinical Trial - Singapore: The second clinical trial partner is Dr. Linfa (Lin-Fa) Wang, Ph.D. FTSE, Professor & Director, Programme in Emerging Infectious Disease, Duke-NUS Medical School who has independent co-funding to conduct a phase 1 trial in Singapore where NiV is endemic. Drs. Broder and Dimitrov have had a longstanding collaboration with Dr. Wang to study Henipaviruses and develop an effective vaccine. The design of the Phase 1 clinical trial will be determined in collaboration with clinical site investigators, the funders of the trial, the Profectus development team, and the local regulatory authorities. Trial initiation is planned to follow demonstration in the PATH trial of vaccine safety at the dose level selected from the phase 1 study in the US This dose level when administered twice by IM injection to normal healthy adults at 91, 181, and 366 day intervals The primary endpoint will be safety with secondary endpoints consisting of immunogenicity defined by ELISA and neutralizing anti-NiV and anti-HeV antibody responses.

Deliverables and Go/No Go Criteria: The deliverables will be interim and final clinical trials reports demonstrating that the HeV-sG/Alhydrogel™vaccine is safe, well tolerated and immunogenic. This will support the initiation of **Task 8** (Phase 2 clinical testing). Any results which suggest the vaccine is not safe, well tolerated or immunogenic will trigger a review to determine if it is judged prudent to discontinue development of the vaccine.

Task 6: Clinical Sample Analysis – Phase 1 trials: In support of the phase 1 clinical evaluation of the HeV-sG/Alhydrogel™ in the US and Singapore, Profectus will perform the well characterized assays to measure immune responses to NiV and HeV in vaccine recipients. The assays will measure serum IgG antibody by direct ELISA, and serum neutralizing antibody by plaque reduction neutralization of GFP-expressing rVSV pseudo-typed with the relevant GPs.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be interim and final clinical trial assay reports. The failure of these assays to remain in control would necessitate redevelopment and trigger a review to determine if further vaccine development is justified.

Task 7: **Development of Qualified Clinical Assays**: A key task will be to establish qualified assays, standard operating procedures (SOPs) and acceptance criteria that will establish the identity, structural integrity, purity of HeV-sG consistent with the General Biological Products Standards (21CFR610.11). Currently, we have SDS-PAGE analysis and binding to anti-G MAb, m102.4, ELISA developed under the preclinical development as product specific release assays. Other product specific assays may be added as deemed necessary by the Product Development Team. Microbial sterility, bioburden, endotoxin and other standard release assays that are used to characterize protein based products to meet 21CFR610.11 will also be used. Profectus will import an authentic henipavirus infection, replication and reporter system based on the non-pathogenic CedPV that is being developed by Dr. Broder's laboratory to determine serum neutralization titers (Task 12 below). Profectus will optimize and qualify the assays to be suitable for GLP practices. We will also evaluate whether immunogenicity in rabbits will provide a suitable potency assay as specified in the General Biological Products Standards. Induction of cross-reactive NiV serum neutralizing titers >160 after immunization will confirm the suitability of rabbits to evaluate the potency of the product.

Task 8: **Phase 2 IND/Regulatory Filings**: Phase 2 testing of the HeV-sG/Alhydrogel™ vaccine for expanded safety and immunogenicity will be conducted by PATH in multiple clinical sites, likely located in multiple countries. Therefore, the regulatory filings to support Phase 2 testing will be prepared by a working team with members from both the PATH and Profectus Regulatory Affairs groups.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be the safe to proceed letters from the US FDA and the relevant foreign regulatory agencies. The risk in preparation of these applications is mitigated by the experience and demonstrated success of the Profectus and PATH Regulatory Affairs groups in preparing the relevant applications.

Task 9: **Phase 2 Adult and Phase 1/2 Child Clinical Trials**:

Adults - It is planned that phase 2 testing of the HeV-sG/Alhydrogel™ vaccine for expanded safety and immunogenicity will be conducted by PATH, and that it will examine the dose level and dosing interval identified as best supporting rapid and sustained protective immunity. Although it is difficult to accurately predict the required phase 2 trial size until the phase 1 trial safety and immunogenicity profiles are known, some assumptions can be made for planning purposes. It is anticipated that a phase 2 trial of approximately 400 (320 active/80 placebo) will be adequate to establish human safety and immunogenicity data bases, which when viewed in the context of the completed and ongoing AGM protection studies, will be adequate to support clinical efficacy (phase 3) evaluation in an outbreak, and potential emergency use with appropriate authorization. This trial will be conducted at established trial sites with strong infrastructure for the collection of adverse events, to best support emergency use authorization in the event of an outbreak.

Deliverables and Go/No Go Criteria: The deliverables will be interim and final clinical trials reports demonstrating that the HeV-sG/Alhydrogel™vaccine is safe, well tolerated and immunogenic in Phase 2 testing. This will support the use of this vaccine with emergency use authorization and trigger **Task 10** (Emergency use stockpile). Any results which suggest the vaccine is not safe, well tolerated or immunogenic will trigger a review to determine if it is judged prudent to stockpile or discontinue development of this vaccine.

Children - PATH will conduct a Phase 1/2 clinical trial to test the safety and immunogenicity of the HeV-sG vaccine in healthy 3-17 year old children in Bangladesh, a country where several outbreaks of Nipah infection have occurred. This will be a randomized, double-blind, placebo-controlled, descending age study to evaluate the optimal vaccine dose/schedule determined from the Phase 2 trial in adults. The trial will first enrol thirty 8-17 year old subjects who will receive vaccine (20), or placebo (10). Once the safety data is analysed by the safety team (including independent experts), a second group of thirty 3-7 year old children will receive the vaccine (n=20) or placebo (n=10). Absence of safety concerns in these two group will lead to starting a third cohort of 160 subjects (120 vaccine, 40 placebo recipients) who will receive the same vaccine regimen. The primary objective of the study is to assess vaccine safety and tolerability by close clinical and laboratory follow-up of subjects after each vaccination; the secondary objective will be evaluation of the vaccine immunogenicity in this age group.

Deliverables and Go/No Go Criteria: The deliverables will be interim and final clinical trials reports demonstrating that the HeV-sG/Alhydrogel™vaccine is safe, well tolerated and immunogenic in 3-17 year old children. This will support the use of this vaccine with emergency use authorization in this age group (Emergency use stockpile). Any results which suggest the vaccine is not safe, well tolerated or immunogenic will trigger a review to determine if it is judged prudent to use the vaccine in this age group.

Task 10: **Clinical Sample Analysis – Phase 2 trial**: In support of the phase 2 clinical evaluation of the HeV-sG/Alhydrogel™, Profectus will perform qualified assays to measure immune responses to NiV and HeV in vaccine recipients. The assays will measure serum IgG antibody by direct ELISA, and serum neutralizing antibody by plaque reduction neutralization of GFP-expressing rVSV pseudo-typed with the relevant GPs.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be interim and final clinical trial assay reports. The failure of these assays to remain in control would necessitate redevelopment and trigger a review to determine if further vaccine development is justified.

Task 11: **Emergency Use Stockpile**: As outlined above, a single 1,000L run of HeV-sG is projected to yield more than sufficient vaccine to allow the stockpiling of 50,000 doses for investigational use during an outbreak, and potentially emergency use with appropriate authorization. In addition, preliminary data indicate that multi-year stability of the Alhydrogel™ formulated vaccine can be anticipated. Thus, it is proposed a portion of the BDS be formulated and used to fill 50,000 doses of vaccine at the dose level determined to be optimal in the phase 1 dose-finding trial conducted by PATH. Further, it is proposed this be carried out as soon as practical after the phase 1 results are known.

This vaccine would be eligible for two of FDA's expedited development and review programs, Fast Track and Priority Review. Fast Track is a process designed to facilitate the development of products that address serious conditions and fill unmet medical need by providing enhanced Agency support during product development. Priority Review designation allows for accelerated BLA review and is based on a product's potential to provide a significant improvement in the prevention of a disease relative to standard of care.

<u>**Deliverables and Go/No Go Criteria:**</u> The deliverables for this work segment will be 50,000 doses of HeV-sG/Alhydrogel™ vaccine produced under full GMP compliance and released for clinical use. Failure of the vaccine to pass release testing would result in an inability to proceed to stockpile.

<u>Task 12</u>: Exploratory/CoP Assay Development: Although assays are available to support clinical evaluation, it is believed that a more appropriate assay to establish a CoP should be investigated. The assay will be enabled by the recent identification of a third henipavirus, Cedar virus (CedPV), that was isolated from pooled bat urine collected in Queensland, Australia[1]. CedPV is closely related to HeV and NiV, genetically and antigenically. A notable distinction between CedPV and HeV/NiV lies in the phosphoprotein gene (P), which contains the open reading frames for the V and W proteins in HeV/NiV. The CedPV P gene does not encode the V and W proteins[2], which contribute to HeV and NiV pathogenicity[3-5], and is an important factor underlying its failure to cause disease in experimental infections of mice, ferrets or guinea pigs[1]. Despite the pathogenic differences and low level of protein sequence homologies of CedPV G to HeV and NiV G (29% and 30%, respectively), CedPV infection, like both HeV and NiV, is supported by the cell surface protein ephrin-B2 as an entry receptor[1]. The Broder lab has been studying the functional characteristics and cellular receptor use profile of CedPV and its interactions with host cells of varied species. A reverse genetics system has recently been established for CedPV and this platform represents a new system which can be exploited in the present application that can be used safely under BSL-2 containment.

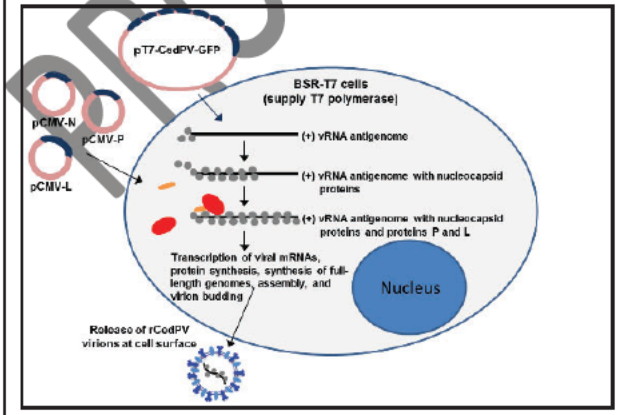
<u>*Innovation:*</u> The difficulties faced in the quantitation and assessment of vaccine-induced neutralizing antibody responses to NiV/HeV are significant owing to the requirements of BSL-4 containment for use of infectious virus. The innovation here are two-fold: **First**, we propose here a cell-based SNT that will make use of an <u>authentic</u> henipavirus infection and replication reporter system (a replication competent, reporter gene-encoding CedPV) which has never been done before. Second, the recombinant CedPV based platform requires only BSL-2 containment, relieving the cost and technical challenges of the high-containment environment when 100's to 1000's of samples will need to be tested.

<u>*Approach: Develop, characterize and adapt a rCedPV luciferase reporter virus for use in SNT*</u>.

Here, we will develop the very first cell-based, authentic henipavirus infection, replication and reporter system based on the non-pathogenic CedPV. We will rescue a second CedPV reporter virus encoding the *Photinus pyralis* luciferase gene[6] (rCedPV-Luc) and characterize and compare it to wild-type and rCedPV-GFP viruses using cell-based infection tropism and growth kinetics assays. The novelty of our approach is that the virus reporter system is an authentic henipavirus and one that may be used in the BSL-2 setting.

<u>*Experimental Methods and Design:*</u>

<u>Generation of plasmids and rescue of recombinant viruses:</u> We have already constructed a recombinant CedPV antigenome clone by synthesis of several large segments of the genome into pOLTV5[7] between a T7 RNA promoter and hepatitis delta virus (HDV) ribozyme. The pOLTV5 vector was similarly used for cloning and expression of recombinant HeV[8] and methods similar to those used in the rescue of recombinant NiV[9]. The first reporter virus chosen was using Turbo-GFP, and the GFP gene was modified to be flanked by the CedPV intragenic P stop and M start sequences conforming to the "rule of six". As with recombinant HeV[8] the GFP gene was inserted between the P and M genes to maintain the levels of N and P transcripts. Helper plasmids for the N, P, and L genes from CedPV were also prepared (pCMV). To generate recombinant CedPV, pCMV CedPV N, pCMV CedPV P, pCMV CedPV L, and pOLTV5 full-length rCedPV-GFP anti-genome plasmid were mixed with Lipofectamine LTX (Invitrogen) in OptiMEM, and used to transfect 5x10^5 BSR-T7 cells (**Figure 1**).



<u>**Figure 1**. Plasmid transfection and rescue of recombinant CedPV.</u> Full length genome clone together with the N, P, and L helper plasmids are transfected into T7-polymerase expressing BSR-T7 cells. Rescued virus is recovered from cell culture by the collection of both supernatant and freeze-thawed cells and amplified on Vero cell cultures.

At day 4, GFP was observed in BSR-T7 cells transfected with the rCedPV-GFP antigenome and N, P, and L helper plasmids. Non-adherent BSR-T7 cells and culture supernatant were collected and freeze-thawed 3-times. Vero cells at a density of 1x10^6 cells/well in 6-well plates were inoculated with the freeze-thaw supernatant. Maximal GFP signal and syncytia were observed after 6 days, supernatant was clarified by centrifugation and 300µL of supernatant was passaged to fresh 1x10^6 Vero cells in 6-well plates. Within 24h, GFP signal and syncytia were observed. At 3 days, maximal GFP signal was observed and supernatant was passaged on fresh Vero cells (75cm2 flasks) for amplification of rCedPV-GFP. **Figure 2** shows rescue results with the pOLTV5 full-length rCedPV-GFP anti-genome plasmid. We also plan to increase the efficiency of CedPV rescue, and the pOLTV5-CedPV vector has been modified to express a 5' HDV ribozyme site anterior to the CedPV 3' leader sequence, which has been demonstrated to increase the rescue efficiency of paramyxoviruses by reverse genetics[10]. With this modified anti-genome two additional recombinant viruses will be made; a CedPV void of any reporter gene but retaining the introduced restriction site (rCedPV+6) which will be our wild-type CedPV, and luciferase encoding virus (rCedPV-Luc). **Figure 3** shows the planned viral genomes and the current GFP-encoding genome of rCedPV. The rCedPV-GFP virus has been amplified on Vero cells, and typically 8 T-75cm2 flasks, after 4 days in culture, the final viral stock, after purification and resuspension, had a titer of $1x10^8$ pfu/mL in ~3ml; and is stored aliquoted at-80ºC.

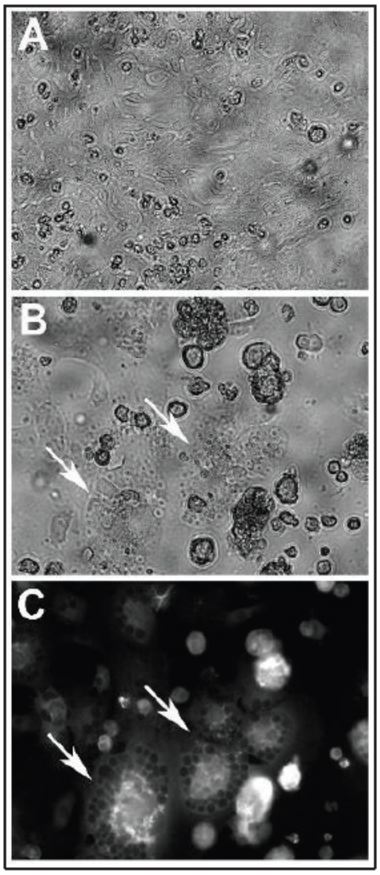


Figure 2. Rescued rCedPV-GFP from the plasmid transfected BSR-T7 cells at day 10. A: an unsuccessful well with no rescue, bright field. B: the successful rescue well showing syncytia, bright field. C: the same field as in B using fluorescence. White arrows are highlighting syncytia, the darker circles within the syncytia are nuclei.

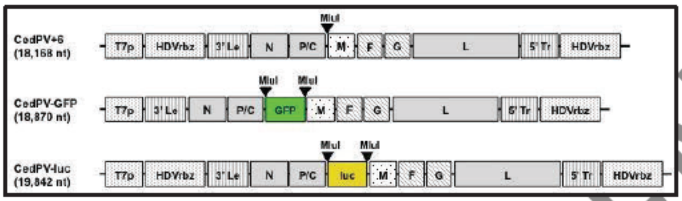

Figure 3. Anti-genome clones in-hand. All genomes adhere to the rule of 6. T7p: promtor; HDVrbz: hepatitis D virus ribozyme; Le: leader; Tr: trailer.

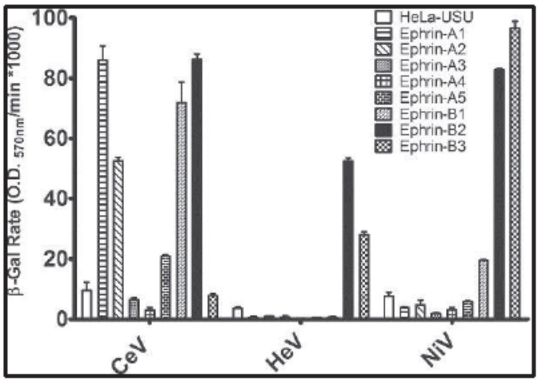
We have determined that CedPV exhibits a remarkably broader ephrin receptor usage profile, and cells bearing CedPV G and F can also mediate fusion with cells expressing ephrin-B1 and the glycosylphosphatidylinositol (GPI) anchored ephrin-A proteins; ephrin-A1, A2 and A5. Shown in **Figure 4** is the CedPV F and G cell fusion obtained with all B and A class ephrins. CedPV cell fusion also correlates with CedPV G glycoprotein binding to ephrins and this data has been confirmed by surface plasmon resonance experiments with soluble ephrins and CedPV soluble G. (C. Navaratnarajah, R. Cattaneo, and C. Broder, data not shown).

Figure 4. CedPV (CeV) glycoprotein-mediated fusion with a panel of A-type and B-type ephrin-expressing cells. Target cells were prepared by transfecting a panel of ephrin expression plasmids into HeLa USU cells infected with vCB21R(Laz-reporter vaccinia virus) and allowed to fuse with CedPV F+G expressing HeLa USU effector cells infected with vTF7.3 (T7-polymerase reporter vaccine virus. Fusion is quantitated as the rate of β-galactosidase activity[11]. CedPV mediated fusion with cells expressing ephrins-A1, -A2, -A5, -B1, and -B2.



Generation of rCedPV Chimeras: The Broder lab was the first to show the unique functional similarities between NiV and HeV G and F glycoproteins by demonstrating that they are the only paramyxoviruses that can bi-directionally functionally complement heterotypically[12] perhaps owing to their aa identity (~83% and 89% for G and F). Our new data with CedPV has provided a breakthrough in finally distinguishing between a functional vs. non-functional F-G interaction. The CedPV-F is only 42% and 43% identical with HeV-F and NiV-F respectively; and CedPV-G is 29% and 30% identical with HeV-G and NiV-G. Performing F and G coexpression and fusion assays using combinations of CedPV, HeV and NiV (**Figure 5**) has provided some very important observations. Ephrin-B2 and -B3 negative HeLa-USU cells are negative for CedPV fusion, as are ephrin-B3 bearing Hela-B3 cells. Fusion does occur with 293T and ephrin-B2 bearing HeLa-B2 cells. Thus, CedPV-F has heterotypic function with both HeV-G and NiV-G, but CedPV-G has heterotypic function with only HeV-F and not NiV-F and correlates with ephrin use. Of significance, these data support the hypothesis that we will be able to construct and generate novel rCedPV isolates using our reverse genetics system, whereby the F and G genes within the rCedPV genome maybe removed and replaced by with NiV F and G or HeV F and G. These new reporter gene encoding **authentic henipaviruses** that may be used under BSL-2 containment and they will be the ideal tools in establishing a robust SNT assay to assess virus neutralizing antibody responses in HeV-sG vaccinated subjects. Experiments on the generation and manipulation of the non-pathogenic rCedPVs, including the proposed development of novel chimeric viruses using the NiV and HeV F and G glycoproteins, have been approved by the Institutional Biosafety Committee (IBC). The chimeric viruses will in fact be loss-of-function recombinant viruses because of the reduced ephrin receptor use profiles between CedPV and either NiV or HeV.

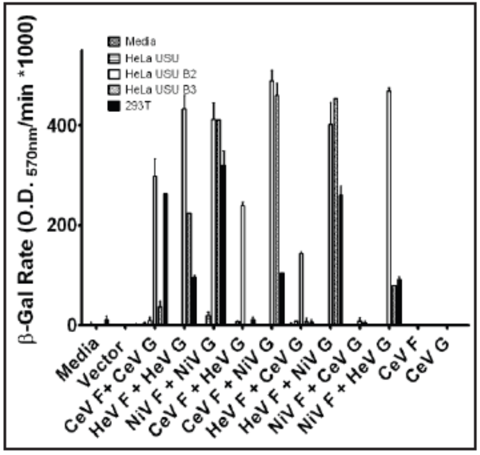


Figure 5. CedPV mediated cell fusion and heterotypic mixing with HeV and NiV. Various target cell populations are shown in the legend.

Characterization of the recombinant CedPV viruses: We expect the reporter gene encoding virus will not be hindered in any way based on the amplification results and titer of rCedPV-GFP, but we will analyze the replication kinetics of rCedPV-Luc and also compare those results to wild-type rCedPV (no reporter gene). Each virus will be used in experiments to determine receptor tropism and compared to the CedPV cell fusion assays using CedPV F and G expression as done with HeV and NiV[11-14].

Expected Results and Data Analysis: We are preparing the CedPV+6 and CedPV-Luc anti-genome plasmids and will proceed with the rescue of each of these new viruses. The rescue and amplification of the rCedPV+6 and the rCedPV-Luc viruses will be carried out as detailed above and recombinant virus stocks prepared. We expect that all recombinant viruses will have an infection profile identical to the cell-cell fusion assays using recombinant expressed F and G from CedPV, NiV and HeV. Because we have rescued the GFP-encoding CedPV, we do not anticipate any unexpected limitations in recusing the rCedPV chimeras encoding NiV or HeV F and G. Based on the replication results with rCedPV-GFP, we expect that large amounts of reporter virus stocks can be prepared, providing a consistent source of material for conducting the number of SNT assays expected to be carried out.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be FINAL Test and Lab Methods. Failure to characterize this assay would remove it from consideration as the best measure of immunity.

Optional Work Proposed Under the Product Development Strategy

It is the understanding of Profectus that the development gap CEPI envisions filling extends only to the point of establishing an investigational vaccine emergency use stockpile, and that studies directed toward licensure are viewed as out of scope. However, the collaborating partners propose that studies beyond those minimally needed to enable emergency use will enhance the likelihood that a pharmaceutical partner will step forward to license the vaccine and ensure stable supply. Therefore, we propose optional work to support licensure, as follows.

Task 13: Animal Rule Studies to Establish a Correlate of Protection Against Lethal NiV and HeV Challenge: These studies will seek to establish an immune response in the AGM, the most relevant model of human NiV and HeV disease. The exact design of these studies will be decided in consultation with the US FDA, however, the following design has been used to successfully determine a preliminary correlate of immunity for Marburg virus. In brief, Groups of 10 AGMs will be administered a single IM dose of various dose levels of HeV-sG/Alhydrogel™, ranging from a high of 100.0 µg to a low of 1.0 µg **(Table 13)**. A control group of 10 AGMs will receive saline control. On day 28 all AGMs will be bled to obtain samples of sera, and on day 36 following immunization they will be administered a lethal challenge of NiV. This study is designed to induce serologic responses that span the range from non-protective through protective. By determining the ELISA, neutralization, and fine-specificity responses outlined above, it will be possible to determine which immune response(s) and the level(s) that correlate with protection from challenge. An identical study using HeV lethal challenge will be conducted to establish the immunologic correlate(s) of protection against this virus. Once the most useful correlate of protection is established it will be possible to design assays that bridge/normalize the AGM protective response to the same response in human recipients of the HeV-sG vaccine.

Table 13. HeV-sG/Alhydrogel™ Dose-down Study in AGMs

Group	N	Vaccine Dose	Vaccination	Bleed	Challenge
1	10	100.0 µg HeV-sG/Alhydrogel™	Day 0	Day 28	Day 36
2	10	33.3 µg HeV-sG/Alhydrogel™			
3	10	10.0 µg HeV-sG/Alhydrogel™			
4	10	3.3 µg HeV-sG/Alhydrogel™			
5	10	1.0 µg HeV-sG/Alhydrogel™			
6	10	Control (saline)			
Total	60				
Notes: All immunizations delivered IM in the deltoid as a single 1.0mL injection.					

Task 14: Phase 1/NHP CoP Sample Analysis: It is anticipated that the CedPV-based neutralization assay developed under **Task 12** will provide the most appropriate measure of the protective immune response against NiV and HeV. To establish this, it is proposed the Broder laboratory uses this assay to quantify the neutralizing antibody responses in subjects vaccinated in the phase 1 dose escalation study conducted under **Task 4**, and the NHP responses in the dose-down CoP study conducted under **Task 13**. In this way it will be possible to bridge the human neutralizing antibody response to the protective response in NHP, and establish a human CoP.

Deliverables and Go/No Go Criteria: The deliverable for this work segment will be a final Study Report documenting the the human CoP against NiV and HeV morbidity and mortality.

Task 15: Production and Release of Consistency Lots of DS and DP: Vaccine licensure, whether using the standard or animal rule route to licensure, requires the demonstration that the vaccine product can be consistently manufactured to the established release specifications, and that various Lots of vaccine induce an equivalent immune response in the target population. Generally, three consecutive Lots of DP produced using the final process, at or near final scale, with at least two Lots produced in the final production facility, are judged necessary. Thus, it is proposed that successful completion and CEPI review of the phase 1 clinical trials trigger the manufacture and release of two additional consecutive consistency Lots of HeV-sG/Alhydrogel™ DP.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be two additional Lots of HeV-sG/Alhydrogel™ vaccine produced under full GMP compliance and released for clinical use. Failure of the vaccine to pass release testing would result in an inability to proceed to the consistency Lots trial under **Task 16**.

Task 16: Phase 2 Consistency Lot Trial: The demonstration of Lot-to-Lot immunogenic consistency generally requires testing of three consecutive Lots, produced as described above, each be tested in approximately 400 subjects (300 active/ 100 placebo). Therefore, a Lot consistency trial in 800 subjects (600 active/ 200 placebo) with equal distribution of the two-additional consistency Lots would be performed by PATH. Ideally, these studies would be conducted in areas of NiV and HeV endemicity, to evaluate immunogenicity in the population(s) most likely to require an outbreak response.

Deliverables and Go/No Go Criteria: The deliverables will be interim and final clinical trials reports demonstrating that the HeV-sG/Alhydrogel™vaccine is safe, well tolerated, and provides Lot-to-Lot immunogenic consistency. This will support the use of this vaccine with emergency use authorization and support licensure under the "animal rule". Any results which suggest the vaccine is not safe, well tolerated or consistently immunogenic will trigger a review to determine if it is judged prudent to continue development of this vaccine.

Task 17: Clinical Sample Analysis – Consistency Lots Trial: In support of the consistency Lots trial of the HeV-sG/Alhydrogel™ vaccine, Profectus will perform validated assays to measure immune responses to NiV and HeV in vaccine recipients. The assays will measure serum IgG antibody by direct ELISA, and serum neutralizing antibody by plaque reduction neutralization of GFP-expressing rVSV pseudo-typed with the relevant GPs. It is anticipated that the CedPV-based neutralization assay developed under **Task 12** will be available for use, successfully validated, and used in support of this trial.

Deliverables and Go/No Go Criteria: The deliverables for this work segment will be interim and final clinical trial assay reports.

4.3. Endpoints

The endpoints for the proposed work are provided as the deliverables for each of the **17 Tasks** detailed in **Section 4.2 Objectives** (above).

4.4. Non/pre-clinical product development approach

Key immunogenicity/efficacy data in any eventual animal model used

Establish an Immunologic CoP in a Relevant Animal Model and Bridging the Correlate to the Human Response. Optional Work Proposed Under the Product Development Strategy in **Section 4.2** (above) outlines the tasks required to establish a human CoP for licensure under the "animal rule"

Dose-ranging/rationale for doses for clinical testing .

The vaccine doses and adjuvant formulation selected for phase 1 clinical testing are based upon the pre-clinical animal studies outlined in **Section 3.3 Pre-clinical evidence to date** (above).

4.4.1. Assay development

The development and characterization of the ELISA and Neutralization assays proposed under this application are described under **Tasks 2, 7, and 12** in **Section 4.2 Objectives** (above).

4.4.2. Toxicology

GLP Tox Study. A 4-cycle (1 dose every 3 weeks) toxicity study in rabbits administered HeV-sG/Alum by intramuscular injection initiated October 2016 at CRL. Three groups of 20 New Zealand White Rabbits, aged from 3 to 5 months and from 2.0 to 4.0 kg each are being used in the study. The control group was dosed with saline, the low dose group was injected with the maximum intended human dose, and the high dose group was injected with 3X the maximum intended human dose. The study design is presented in **Table 14** below:

Table 14. A 4-cycle Study in Rabbits Administered HeV-sG/Alhydrogel™ by Intramuscular Injection

Group No.	Test Item[a]	Dose Level (mg/day)	Dose Concentration (mg/mL)	Dose Volume (mL)	No. of Animals			
					Main Study[b]		Recovery Study[c]	
					Males	Females	Males	Females
1	Saline Control	0	0	3.0	5	5	5	5
2	HeV-sG-V	0.1	0.1	1.0	5	5	5	5
3	HeV-sG-V	0.3	0.1	3.0	5	5	5	5

[a] Dosing will be performed once every three weeks (= 1 cycle) for 4 cycles

[b] Main study animals will undergo necropsy 3 days following the last dose administration.

[c] Recovery study animals will undergo necropsy 28 days following the last dose administration.

CRL is an accredited CMO for carrying out GLP toxicity studies and we do not expect procedural complications with the study. Antibody titers from blood samples will be determined under well documented practices at Profectus.

4.5. Clinical Development Plan CDP

The Clinical Development Plan (CDP) for this vaccine includes a “first-in-human” safety trials in adults (18-50 years old), a phase 2 dose ranging study in adults, and a phase 1/2 study in children (3-17 years old). In the event of an outbreak after the completion of the phase 2 studies, additional pharmacovigilance and an effectiveness trial would be proposed. Additional studies to examine production lot consistency, duration of protection, and safety in older persons may be necessary. The regulatory strategy for the vaccine will be based on successful application of the “Animal Rule” requirements, namely the identification of a clear immune correlate measure of protection in appropriate animal models and identifying a dose of vaccine in humans that induces a “protective” level of immunity. Successful identification of an appropriate dose and regimen would support the stockpiling of the vaccine and potential emergency use. Additional safety and effectiveness studies may need to be conducted with the stockpile material depending on the observations of the phase 1/2 studies.

Clinical objectives

Describe the clinical objectives of the project by including quantifiable criteria (e.g., “go/no-go” decision criteria), goals and time-lines for the program. Please link/match these aspects with the milestone plan

The baseline approach we are proposing to CEPI includes four clinical trials, described briefly below. The objectives, endpoints, rationale, design, and other aspects of these trials is described in more detail in the abbreviated protocol synopses included at the bottom of this section.

A Phase 1 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy US adults. The first study of the vaccine will evaluate the vaccine’s safety in a limited number of 18-50 years old subjects under a typical double-blinded randomized, placebo-control dose-escalation design. The study will be conducted at an experienced clinical research unit in the US, under an IND to be sponsored by Profectus and will focus on closely investigating post-vaccination safety parameters, including solicited local (pain, tenderness, erythema, induration) and systemic (fever, malaise/fatigue, myalgia, arthralgia, headache, nausea, vomiting) and systemic reactogenicity, vaccine-related adverse experiences (AEs) and serious AEs (SAEs). The trial will be conducted in a dose escalation design in which the subjects will receive two doses of 20ug (group 1), 50ug (group 2), or 100 ug (group 3) of vaccine 28 days apart. Immunogenicity will be tested at baseline, 3 weeks after each vaccination and at a late time point (90 days post final vaccination). An additional cohort of 25 subjects (20 vaccinees, 5 placebos) will receive a single dose of 100 ug of vaccine (group 4). This first phase 1 study will support the conduct of a phase 2 study to expand the safety database and refine the selection of dose/schedule, providing that the vaccine is safe and tolerable and that at least one of the groups under test shows an immune response rate of 50% on the assay identified as potential “Correlate of Protection” in the preclinical studies.

A Phase 2 randomized, placebo-controlled, double blind, dose ranging study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Bangladeshi adults. If the immunogenicity bar set up for the phase 1 trial is met, the two highest tolerated doses observed in that study (noted as “low” and “high” hereon) will be tested at two different time intervals between the first and second vaccination, 7 days and 28 days. The optimal dose/schedule will be selected from this study. Five groups of healthy 18-50 year old adults will receive: Group 1: 2 injections of “low dose” vaccine on days 1 and 8, and placebo on day 28; Group 2: 2 injections of “low dose” vaccine on days 1 and 28 and placebo on day 8; Group 3: 2 injections of “high dose” vaccine on days 1 and 8 and placebo on day 28; Group 4: 2 injections of “high dose” vaccine on days 1 and 22 and placebo on day 28; Group 5: placebo on days 1, 8 and 28. The study will be conducted in 2-3 clinical sites in, Bangladesh. Statistical analysis to select the optimal dose/schedule will be conducted by a “Selection Design” approach.

A Phase 1 randomized, placebo-controlled, double-blind dose interval study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Singaporean adults. The safety and immunogenicity of the vaccine will also be assessed in a limited number of 18-45 year old subjects in Singapore in a study leading to identify the optimal interval between the priming dose of vaccine and a second, “booster” dose. The highest tolerated vaccine dose identified in the phase 1 will be used. The study will be conducted as a double-blinded randomized, placebo-control design. The general schema of the study is shown below. In summary, the trial will randomize subjects in three groups to receive: group (1) vaccine on days 1 and 91; group (2) vaccine on days 1 and 181; group (3) vaccine on days 1 and 366. Immunological testing will be conducted 28 after the day 1 vaccination, on the day of the second vaccination and 5 and 28 days later.

A Phase 1-2 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy 3-17 year old children in Bangladesh. Once safety data are available from the phase 1 and phase 2 studies in adults and the vaccine is shown to be safe and immunogenic, a phase 1-2 clinical trial will be conducted in younger populations (ages 3-17, inclusive) to support delivery of the vaccine to individuals of that age range in the event of an outbreak. The study will start out as a descending age trial in which initially children 8-17 years old will receive two doses of vaccine at the dose level and schedule selected from the studies in adults, or placebo (group 1), followed for a cohort (group 2) of 3-7 year old children to begin enrolling when and if the safety in the group 1 cohort is demonstrated. Following demonstration of safety in group 2, 60 additional children 3-17 years old will be vaccinated along with 30 placebo recipients randomized at the same time. The study will be conducted at an experienced clinical research unit in a country where Nipah outbreaks have occurred (e.g., Bangladesh) and will focus on closely investigating post-vaccination safety parameters, including solicited reactogenicity (typical local and systemic reactions to parenteral vaccines), vaccine-related adverse experiences (AEs) and serious AEs (SAEs).

The figure below demonstrates the overall timelines for the proposed clinical trials.

Clinical trial planning

Phase 1 (adults): The phase 1 study will be conducted in the US, under FDA IND. It will include 100 healthy US adults (18-50 years old, inclusive, at time of first vaccination).

Phase 2 (adults): The phase 2 study is planned to be conducted in an area where outbreaks of Nipah virus have occurred (e.g., Bangladesh). The study will include 400 healthy adults (18-50 years old, inclusive, at time of first vaccination). The study will be conducted under FDA IND, and will have the approval of the local regulatory authority. We will utilize 2-3 sites to ensure sufficient availability of study subjects.

Phase 1/2 (children): The Phase 1/2 study in children is planned to be conducted in Bangladesh. The study will be conducted under FDA IND, and will have the approval of the local regulatory authority.

Clinical trial execution

Please describe the intended strategy and rationale for clinical trial sites, and possible establishment of clinical trial sites; planning for clinical trial execution.

Phase 1 (adults): Given that HeV-sG has never been tested in humans it will be important to select centers with high level of experience and associated with top medical expertise, diagnostic, and treatment facilities. The phase 1 study will be conducted in the US, under FDA IND, at one of the academic sites sponsored by the NIH (DMID Vaccine Evaluation Units) and with which PATH has long-standing collaboration (e.g., U. Maryland Center for Vaccine Development, Children's Hospital Medical Center, Cincinnati) or at Johns Hopkins University Center for Immunization Research. PATH has successfully conducted two to four phase 1 or phase 2 clinical trials at those sites, including in patient studies (for live vaccine and challenge studies). In most cases PATH sponsored the regulatory submissions.

The Phase 1 study in Singapore will be conducted at the Duke-NUS Medical School, a center with proven experience in the conduct of clinical trials, under the direction of Prof. Linfa Wang.

Phase 2 (adults): The phase 2 study is planned to be conducted in areas in which Nipah virus outbreaks have occurred, most likely in Bangladesh or in India. PATH has conducted several phase 1-2 trials in Bangladesh for childhood diarrhea (live shigella, killed ETEC, live rotavirus) and JEV vaccines, and recently a phase 3 rotavirus vaccine trial in collaboration of the BMGF's PROVIDE consortium. Alternatively, the studies could be conducted in India, where PATH has conducted multi-site efficacy trials of rotavirus vaccines leading to the licensure of two products. Although the regulatory sponsorship for the trials in India and Bangladesh was the responsibility of the local partners (Serum Institute of India and Bharat manufacturers in India and the icddrb (International Center for Diarrheal Diseases Research in Bangladesh) PATH was directly involved in implementation and monitoring of the studies, as well as in the preparation of the regulatory submission (IND-equivalent, CSRs, BLAs and manuscripts).

The phase 2 will require the engagement of a minimum of two sites in Bangladesh, or three sites If the study were to be implemented in India. SOPs and site/CRO selection tools are available at PATH for final evaluation and selection of the appropriate clinical trial sites for the phase 2 study. Preselected clinical sites will be audited unless they are currently participating in PATH studies, in which case documentation is available about site performance and quality.

PATH will prepare all trial-specific documents and will use its SOPs for the implementation of the study. Selected sites and CROs (for data management, randomization, monitoring and statistical support, immunological laboratories) will be directly contracted by PATH, who will prepare the sites for the trial and monitor day to day activities, including auditing of facilities, data and procedures.

Phase 1/2 (children): The Phase 1 study in children will be conducted at an experienced clinical research unit in Bangladesh. Most of the vaccine trials that PATH has conducted in India and Bangladesh (with minor exceptions) have included children (6 weeks to 10 years old), including testing of a live shigella vaccine, inactivated oral ETEC, several live rotaviruses and a JEV live virus vaccine candidate. The conduct of these studies has been impeccable (from the standpoint of GCP and protocol adherence) and has led to important steps on the qualification of those vaccines (e.g., the JEV Chengdu vaccine trial in Bangladesh was essential for WHO prequalification). Working closely with the leadership of icddrb, PATH has been able to facilitate the efficient review of the studies within the center as well as with the Bangladesh MOH.

Site selection and trial implementation will follow the PATH SOPs referenced above. If possible, PATH will seek to use one of the sites selected to conduct the Phase 2 study.

Target study populations

An outbreak of Nipah virus infection will be a major public health emergency that would likely affect individuals of all ages, primarily active adults and school age older toddlers and children, reason why we propose to conduct the initial phase 1 and phase 2 testing of the HeV-sG in those populations. The participants will be selected among healthy individuals, to provide for an optimal evaluation of its potential, and diminish the chance of observing SAEs or severe AEs due to underlying disease.

For the Phase 1 and 2 components of the CDP that will be supported by CEPI, we will limit the studies to healthy adults and children 3-17 years of age. These studies will provide a safety database potentially sufficient to deploy vaccine under the "Animal Rule," providing that the immunogenicity results support that the vaccine is capable of inducing an immune response qualitatively and quantitatively similar to that observed to prevent infection from challenge in the animal models. Additional clinical studies that we are considering, beyond the completion of this grant, include a "lot consistency" study to test the equivalence of the immunogenicity of three different lots of the vaccine.

If and when HeV-sG is submitted and approved under the "Animal Rule," and if an outbreak of Nipah virus occurs, we will conduct a pharmacoivigilance / effectiveness studies to more directly evaluate the vaccine. The use of the vaccines in the elderly, pregnant women, and individuals with underlying disease will be fostered by post-licensure studies (post-deployment, in case of emergency use).

Candidate vaccine control strategy

The Clinical Development Plan (CDP) for this vaccine includes a "first-in-human" safety trials in adults (18-50 years old), a phase 2 dose ranging study in adults, and a phase 1/2 study in children (3-17 years old). In the event of an outbreak after the completion of the phase 2 studies, additional pharmacovigilance and an effectiveness trial would be proposed. Additional studies to examine production lot consistency, duration of protection, and safety in older persons may be necessary. The regulatory strategy for the vaccine will be based on successful application of the "Animal Rule" requirements, namely the identification of a clear immune correlate measure of protection in appropriate animal models and identifying a dose of vaccine in humans that induces a "protective" level of immunity. Successful identification of an appropriate dose and regimen would support the stockpiling of the vaccine and potential emergency use. Additional safety and effectiveness studies may need to be conducted with the stockpile material depending on the observations of the phase 1/2 studies.

Clinical objectives

The baseline approach we are proposing to CEPI includes four clinical trials, described briefly below. The objectives, endpoints, rationale, design, and other aspects of these trials is described in more detail in the abbreviated protocol synopses included at the bottom of this section.

A Phase 1 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy US adults. The first study of the vaccine will evaluate the vaccine's safety in a limited number of 18-50 years old subjects under a typical double-blinded randomized, placebo-control dose-escalation design. The study will be conducted at an experienced clinical research unit in the US, under an IND to be sponsored by Profectus and will focus on closely investigating post-vaccination safety parameters, including solicited local (pain, tenderness, erythema, induration) and systemic (fever, malaise/fatigue, myalgia, arthralgia, headache, nausea, vomiting) and systemic reactogenicity, vaccine-related adverse experiences (AEs) and serious AEs (SAEs). The trial will be conducted in a dose escalation design in which the subjects will receive two doses of 20ug (group 1), 50ug (group 2), or 100 ug (group 3) of vaccine 28 days apart. Immunogenicity will be tested at baseline, 3 weeks after each vaccination and at a late time point (90 days post final vaccination). An additional cohort of 25 subjects (20 vaccinees, 5 placebos) will receive a single dose of 100 ug of vaccine (group 4). This first phase 1 study will support the conduct of a phase 2 study to expand the safety database and refine the selection of dose/schedule, providing that the vaccine is safe and tolerable and that at least one of the groups under test shows an immune response rate of 50% on the assay identified as potential "Correlate of Protection" in the preclinical studies.

A Phase 2 randomized, placebo-controlled, double blind, dose ranging study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Bangladeshi adults. If the immunogenicity bar set up for the phase 1 trial is met, the two highest tolerated doses observed in that study (noted as "low" and "high" hereon) will be tested at two different time intervals between the first and second vaccination, 7 days and 28 days. The optimal dose/schedule will be selected from this study. Five groups of healthy 18-50 year old adults will receive: Group 1: 2 injections of "low dose" vaccine on days 1 and 8, and placebo on day 28; Group 2: 2 injections of "low dose" vaccine on days 1 and 28 and placebo on day 8; Group 3: 2 injections of "high dose" vaccine on days 1 and 8 and placebo on day 28; Group 4: 2 injections of "high dose" vaccine on days 1 and 22 and placebo on day 28; Group 5: placebo on days 1, 8 and 28. The study will be conducted in 2-3 clinical sites in, Bangladesh. Statistical analysis to select the optimal dose/schedule will be conducted by a "Selection Design" approach.

A Phase 1 randomized, placebo-controlled, double-blind dose interval study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Singaporean adults. The safety and immunogenicity of the vaccine will also be assessed in a limited number of 18-45 year old subjects in Singapore in a study leading to identify the optimal interval between the priming dose of vaccine and a second, "booster" dose. The highest tolerated vaccine dose identified in the phase 1 will be used. The study will be conducted as a double-blinded randomized, placebo-control design. The general schema of the study is shown below. In summary, the trial will randomize subjects in three groups to receive: group (1) vaccine on days 1 and 91; group (2) vaccine on days 1 and 181; group (3) vaccine on days 1 and 366. Immunological testing will be conducted 28 after the day 1 vaccination, on the day of the second vaccination and 5 and 28 days later.

A Phase 1-2 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy 3-17 year old children in Bangladesh. Once safety data are available from the phase 1 and phase 2 studies in adults and the vaccine is shown to be safe and immunogenic, a phase 1-2 clinical trial will be conducted in younger populations (ages 3-17, inclusive) to support delivery of the vaccine to individuals of that age range in the event of an outbreak. The study will start out as a descending age trial in which initially children 8-17 years old will receive two doses of vaccine at the dose level and schedule selected from the studies in adults, or placebo (group 1), followed for a cohort (group 2) of 3-7 year old children to begin enrolling when and if the safety in the group 1 cohort is demonstrated. Following demonstration of safety in group 2, 60 additional children 3-17 years old will be vaccinated along with 30 placebo recipients randomized at the same time. The study will be conducted at an experienced clinical research unit in a country where Nipah outbreaks have occurred (e.g., Bangladesh) and will focus on closely investigating post-vaccination safety parameters, including solicited reactogenicity (typical local and systemic reactions to parenteral vaccines), vaccine-related adverse experiences (AEs) and serious AEs (SAEs). The figure below demonstrates the overall timelines for the proposed clinical trials.

Clinical trial planning

Describe the clinical trials planned for safety, immunogenicity and eventually efficacy, including assumptions related to intended location of studies, regulatory approval, target populations, and availability of study subjects.

Phase 1 (adults): The phase 1 study will be conducted in the US, under FDA IND. It will include 100 healthy US adults (18-50 years old, inclusive, at time of first vaccination).

Phase 2 (adults): The phase 2 study is planned to be conducted in an area where outbreaks of Nipah virus have occurred (e.g., Bangladesh). The study will include 400 healthy adults (18-50 years old, inclusive, at time of first vaccination). The study will be conducted under FDA IND, and will have the approval of the local regulatory authority. We will utilize 2-3 sites to ensure sufficient availability of study subjects.

Phase 1/2 (children): The Phase 1/2 study in children is planned to be conducted in Bangladesh. The study will be conducted under FDA IND, and will have the approval of the local regulatory authority.

Clinical trial execution

Please describe the intended strategy and rationale for clinical trial sites, and possible establishment of clinical trial sites; planning for clinical trial execution.

Phase 1 (adults): Given that HeV-sG has never been tested in humans it will be important to select centers with high level of experience and associated with top medical expertise, diagnostic, and treatment facilities. The phase 1 study will be conducted in the US, under FDA IND, at one of the academic sites sponsored by the NIH (DMID Vaccine Evaluation Units) and with which PATH has long-standing collaboration (e.g., U. Maryland Center for Vaccine Development, Children's Hospital Medical Center, Cincinnati) or at Johns Hopkins University Center for Immunization Research. PATH has successfully conducted two to four phase 1 or phase 2 clinical trials at those sites, including in patient studies (for live vaccine and challenge studies). In most cases PATH sponsored the regulatory submissions.

The Phase 1 study in Singapore will be conducted at the Duke-NUS Medical School, a center with proven experience in the conduct of clinical trials, under the direction of Prof. Linfa Wang.

Phase 2 (adults): The phase 2 study is planned to be conducted in areas in which Nipah virus outbreaks have occurred, most likely in Bangladesh or in India. PATH has conducted several phase 1-2 trials in Bangladesh for childhood diarrhea (live shigella, killed ETEC, live rotavirus) and JEV vaccines, and recently a phase 3 rotavirus vaccine trial in collaboration of the BMGF's PROVIDE consortium. Alternatively, the studies could be conducted in India, where PATH has conducted multi-site efficacy trials of rotavirus vaccines leading to the licensure of two products. Although the regulatory sponsorship for the trials in India and Bangladesh was the responsibility of the local partners (Serum Institute of India and Bharat manufacturers in India and the icddrb (International Center for Diarrheal Diseases Research in Bangladesh) PATH was directly involved in implementation and monitoring of the studies, as well as in the preparation of the regulatory submission (IND-equivalent, CSRs, BLAs and manuscripts).

The phase 2 will require the engagement of a minimum of two sites in Bangladesh, or three sites If the study were to be implemented in India. SOPs and site/CRO selection tools are available at PATH for final evaluation and selection of the appropriate clinical trial sites for the phase 2 study. Preselected clinical sites will be audited unless they are currently participating in PATH studies, in which case documentation is available about site performance and quality.

PATH will prepare all trial-specific documents and will use its SOPs for the implementation of the study. Selected sites and CROs (for data management, randomization, monitoring and statistical support, immunological laboratories) will be directly contracted by PATH, who will prepare the sites for the trial and monitor day to day activities, including auditing of facilities, data and procedures.

Phase 1/2 (children): The Phase 1 study in children will be conducted at an experienced clinical research unit in Bangladesh. Most of the vaccine trials that PATH has conducted in India and Bangladesh (with minor exceptions) have included children (6 weeks to 10 years old), including testing of a live shigella vaccine, inactivated oral ETEC, several live rotaviruses and a JEV live virus vaccine candidate. The conduct of these studies has been impeccable (from the standpoint of GCP and protocol adherence) and has led to important steps on the qualification of those vaccines (e.g., the JEV Chengdu vaccine trial in Bangladesh was essential for WHO prequalification). Working closely with the leadership of icddrb, PATH has been able to facilitate the efficient review of the studies within the center as well as with the Bangladesh MOH.

Site selection and trial implementation will follow the PATH SOPs referenced above. If possible, PATH will seek to use one of the sites selected to conduct the Phase 2 study.

Target study populations

Provide a high level summary of the targeted study population and include if and when you expect to have data on

- *Paediatric and elderly populations*
- *Pregnant/lactating women*
- *Populations with underlying diseases*

An outbreak of Nipah virus infection will be a major public health emergency that would likely affect individuals of all ages, primarily active adults and school age older toddlers and children, reason why we propose to conduct the initial phase 1 and phase 2 testing of the HeV-sG in those populations. The participants will be selected among healthy individuals, to provide for an optimal evaluation of its potential, and diminish the chance of observing SAEs or severe AEs due to underlying disease.

For the Phase 1 and 2 components of the CDP that will be supported by CEPI, we will limit the studies to healthy adults and children 3-17 years of age. These studies will provide a safety database potentially sufficient to deploy vaccine under the "Animal Rule," providing that the immunogenicity results support that the vaccine is capable of inducing an immune response qualitatively and quantitatively similar to that observed to prevent infection from challenge in the animal models. Additional clinical studies that we are considering, beyond the completion of this grant, include a "lot consistency" study to test the equivalence of the immunogenicity of three different lots of the vaccine.

If and when HeV-sG is submitted and approved under the "Animal Rule," and if an outbreak of Nipah virus occurs, we will conduct a pharmacoivigilance / effectiveness studies to more directly evaluate the vaccine. The use of the vaccines in the elderly, pregnant women, and individuals with underlying disease will be fostered by post-licensure studies (post-deployment, in case of emergency use).

Abbreviated protocol synopses

The proposal to CEPI includes four clinical trials, described in the protocol synopses below:

- A Phase 1 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy US adults.

STUDY HYPOTHESES **Safety**: The HeV-sG vaccine will be well-tolerated and with an acceptable safety profile **Immunogenicity**: The HeV-sG vaccine is immunogenic and will induce neutralizing immune responses in 50% or more of participants in at least one of the study groups.
STUDY OBJECTIVES **Primary Objectives** **Safety**: to evaluate the safety and tolerability of the HeV-sG vaccine at three escalating dose levels in healthy adults

Immunogenicity: to evaluate the immunogenicity of two doses of the He-VsG vaccine at three different dose levels in healthy adults

Secondary Objectives

Safety: to evaluate the longer term safety (through 6 months after the last vaccination) of the HeV-sG vaccine at escalating dose levels.

Immunogenicity: to evaluate the immunogenicity of two doses of the HeV-sG vaccine six months after receipt of the last vaccination.

Exploratory Objectives

Immunogenicity: to develop additional immune assays to evaluate responses to the HeV-sG vaccine

STUDY ENDPOINTS

Primary Endpoints

Safety: 1) number of SAEs through 21 days after the last study injection; 2) number of AEs through 21 days after the last study injection; 3) number of Vaccine-induced local and systemic reactions (solicited reactions) during the 7 days after administration of each dose

Immunogenicity: 1) proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 1-week and baseline and 3-weeks post-first study injection); 2) proportion of subjects with neutralizing antibody responses (4-fold increase in antibody titers between baseline and 1-week and baseline and 3-weeks post-second study injection)

Secondary Endpoints

Safety: 1) number of SAEs at any time during the study; 2) number of AEs at any time during the study

Immunogenicity: **1) g**eometric mean titers (GMT) (baseline and 1 week and baseline and 3 weeks post second study injection) in ELISA assays; 2) geometric mean titers (GMT) (baseline and 1 week and baseline and 3 weeks post second study injection) in Neutralization assays

STUDY RATIONALE

The subunit HeV-sG vaccine developed by Profectus be studied in a series of trials starting with this proposed phase 1, first in humans study. The trial focuses on vaccine safety, but will be able to provide early evidence of immunogenicity, in particular the ability of the vaccine to induce neutralization antibody, which has been identified as a potential correlate of protection in animal studies.

Subsequent to this study a phase 2 study in adults will be conducted to determine the appropriate dose and schedule. Given the unexpectedness of HeV, and NiV outbreaks, it will be virtually impossible to conduct a prospective double blind randomized efficacy trial. On the other hand, if the vaccine is demonstrated to induce the qualitative and quantitative responses associated with protection in non-human primates, it may be eligible for two FDAs expedited development and review programs, Fast Track and Priority Review. Application of the animal rule will be potentially feasible to accelerate introduction.

STUDY DESIGN

The trial will be a double-blind, randomized, placebo-controlled, dose-escalation study testing three different vaccine dose levels in separate cohorts, in which the second and third cohort will be enrolled based on assessment of safety and tolerability in the previous cohort. Each cohort will consist of 25 participants (20 vaccine recipients and 5 placebo recipients) per dose level, who will receive two intramuscular injections three weeks apart. The three dose levels of vaccine to be tested will be 20 ug, 50 ug and 100 ug. Progression from low- to high-dose will be dependent on a positive assessment of safety and tolerability during the week after the first injection in the adult low-dose cohort. A fourth cohort will be enrolled once safety data from the high dose cohort is available. Subjects in this group will receive a single dose of the vaccine high dose. Should all three doses be tolerated in this phase 1 study, a separate phase 2 will be conducted to further expand both safety and immunogenicity of the two higher dose levels in a Phase 2 study.

HeV-sG vaccine	n subjects		Vaccine dose	Vaccination schedule	
Phase 1 USA	Vaccine	Placebo		dose 1 (day)	dose 2 (day)
Group 1	20	5	20 ug	1	29
Group 2	20	5	50 ug	1	29
Group 3	20	5	100 ug	1	29
Group 4	20	5	100 ug	1	-

Progression from group 1 to groups 2 and 3 will require review of clinical and safety lab data through 7 days after the first dose at the lower dose level. Safety laboratory blood specimens will be drawn at baseline for all participants (screening) and 7 days after first study injection in Groups A, B and C. Blood samples for immunogenicity analysis will be obtained at baseline for and on Days 29, 36, 57 and 209.

IMMUNOLOGICAL ASSESSMENTS

- Anti-HeV-sG IgG antibodies by ELISA
- Neutralization activity against Nipah and Hendra virus using attenuated VSV-recombinants carrying the corresponding glycoproteins.

STATISTICAL CONSIDERATIONS

Safety: With 20 vaccine recipients per dose group, this study will provide a greater than 90% chance of observing an AE that has an 11% rate of occurrence.

Conversely, if no SAEs are observed among the 20 vaccine recipients per group, the study will be able to rule out SAEs occurring at a rate of approximately 14% based on the upper bound of the one-sided 95% confidence interval.

Immunogenicity: Based on the results in non-human primates receiving the HeV-sG vaccine, specific seroresponse rates are expected to be ≥80% for the optimal dose group. For comparisons between the optimal dose group and the combined placebo groups, this study will provide ≥90% power to detect ≥62 percentage point difference or 80% power to detect a ≥56 percentage point difference.

For the Geometric Mean Titer (GMT) endpoint, the $\log_{10}$ standard deviations will be descriptively estimated for each group. No comparison hypotheses will be applied.

- A Phase 2 randomized, placebo-controlled, double blind, dose ranging study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Bangladeshi adults.

STUDY HYPOTHESES

Immunogenicity: The HeV-sG vaccine will be immunogenic in healthy Bangladeshi adults and will induce neutralizing antibody responses, the presumed correlate of protection, in >=50% (lower bound CI 20%) in at least one of the study groups.

Safety: The HeV-sG vaccine will be well-tolerated and with an acceptable safety profile

STUDY OBJECTIVES

Immunogenicity: to identify a vaccine dose / schedule that induces maximal immunogenicity of rapid onset. Towards that objective two vaccine injections will be administered on two different schedules and the responses after each vaccination evaluated at various timepoints.

Safety: to evaluate safety and tolerability of two HeV-sG vaccine injections at two different doses and two different schedules

Secondary Objectives

Immunogenicity: to evaluate the immunogenicity of two doses of HeV-sG vaccine 3 and 6 months after the last vaccination.

Safety: to evaluate vaccine safety through 6 months after the last vaccination

STUDY ENDPOINTS

Primary Endpoints

Immunogenicity: 1) Proportion of subjects exhibiting anti-HeV-sG neutralizing antibody responses (4-fold increase in antibody titers between baseline and 3-weeks post-second study injection); 2) Proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 3-weeks post-second study injection)

Safety: 1) Number of vaccine related SAEs through the 6 months of the study; 2) Number of vaccine related vaccine related grade 3 AEs through the 6 months of the study; 3) Number of vaccine-induced local and systemic reactions (solicited reactions) during the 7 days after administration of each dose

Secondary Endpoints

Immunogenicity: 1) Proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 3-weeks post-first study injection); 2) Proportion of subjects with neutralizing antibody responses (4-fold increase in antibody titers between baseline and 3-weeks post-first study injection); 3) Geometric mean titers (GMT) (baseline, 3 weeks post first and 3 weeks post second study injection) in ELISA assays; 4) Geometric mean titers (GMT) (baseline, 3 weeks post first and 3 weeks post second study injection) in neutralization assays

STUDY RATIONALE

The phase two trial will focus on the selection of an optimal safe regimen capable to induce neutralization responses in at least 50% of the subjects in one of the study groups (see study design below). The study will be conducted under a "selection design that would allow the identification of the optimal dose/schedule combination. It will be conducted in 2-3 sites in a country where outbreaks of Nipah virus occur with frequency (e.g., Bangladesh, India).

STUDY DESIGN

The trial will be a double-blind, randomized, placebo-controlled, dose/schedule selection study testing two different vaccine dose levels under two different schedules in separate cohorts which will be enrolled simultaneously. Each cohort will consist of 80 participants who will receive: Group 1: two intramuscular injections of the low dose of vaccine one week apart; Group 2: two intramuscular injections of the low dose of vaccine four weeks apart; Group 3: two intramuscular injections of the high dose of vaccine one week apart; Group 4: two intramuscular injections of the high dose of vaccine four weeks apart; Group 5: three intramuscular injections of placebo on days 1, 8 and 28. To maintain the blind, placebo injections will be given to subjects in groups 1-4 at either day 8 or day 28 (see schema below).

Phase 2	n subjects	Vaccine dose	Vaccination schedule		
			Day 1	Day 8	Day 28
Group 1	80	Low	Vac	Vac	Plac
Group 2	80	Low	Vac	Plac	Vac
Group 3	80	High	Vac	Vac	Plac
Group 4	80	High	Vac	Plac	Vac
Group 5	80	None	Plac	Plac	Plac

Vaccine dose will be selected from the safety data from the phase 1 trial. Blood samples for immunogenicity analysis will be obtained at baseline for all participants, and on Days 8, 22 and 43.

IMMUNOLOGICAL ASSESSMENTS

- Anti-HeV-sG IgG ELISA
- Neutralization activity against Nipah and Hendra virus using attenuated VSV-recombinants carrying the corresponding glycoproteins.

STATISTICAL CONSIDERATIONS

Immunogenicity: We will employ a selection design as a more efficient design for screening multiple regimens compared to traditional superiority or non-inferiority trials although the distinctions between these should be made clear. With 72 evaluable subjects per group, the selection design will provide >90% probability of choosing the optimal regimen if there is at least a 15 percentage point difference between the highest seroresponse rate and the 2nd highest seroresponse rate. For a two-sample comparison between the optimal group and the other combined vaccine groups, this study will provide ≥90% power to detect ≥ 21 percentage point difference (assuming 0.90* 80=72 evaluable subjects per group and 80% seroresponse in optimal group). A traditional design is powered to compare pairs of vaccine arms and hence requires a large total sample size to detect even moderate sized differences when there are many vaccines. In contrast, the selection design requires a smaller sample size since the trial is powered to rank vaccine arms against the placebo group and then select the top ranked vaccine. The selection design can be used appropriately to select among various doses of a vaccine product, various product combinations or various schedules. The procedure ranks the response rates of N treatment groups and selects the treatment with the largest observed response rate regardless of the magnitude of the difference between it and the other groups. Sample size calculations are driven by the smallest difference of interest between the best and next best treatment, and the minimum acceptable probability of correct selection. Simulations are used to calculate the sample size to ensure that if the true response rate of the best vaccine exceeds all others by the smallest possible difference, the probability of selecting that vaccine is sufficiently high.
For the Geometric Mean Titer (GMT) endpoint, $\log_{10}$ standard deviations will be descriptively estimated for each group. No comparison hypotheses will be applied.

Safety: The large sample size of this study (n=400 subjects / 800 vaccine exposures) allows a tighter bound on the rate of vaccine-related SAEs; e.g., if no SAEs are observed, the upper bound of an exact one-sided 95% confidence interval is 4% for each arm of 80, 2% for combined (low or high dose) arms of 160, and 1% for 320 vaccine recipients overall. Eighty vaccine recipients per group, or 160 recipients for combined groups will provide a greater than 90% chance of observing an AE that has a 3% and 1.5% chance of occurrence, respectively.

- A Phase 1/2 randomized, placebo-controlled, double blind study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in healthy 3-17 year old children in Bangladesh.

STUDY HYPOTHESES

Safety: The HeV-sG vaccine is safe and well tolerated in healthy 3-17 year old children in Bangladesh.
Immunogenicity: The HeV-sG vaccine is immunogenic in healthy 3-17 year old children in Bangladesh and will induce neutralizing immune responses in 50% or more of the participants.

STUDY OBJECTIVES

Primary Objectives:
Safety: To evaluate the safety and tolerability of two doses of HeV-sG vaccine in healthy Bangladeshi children
Immunogenicity: To evaluate the immunogenicity of two doses of the He-VsG three weeks after the second vaccination in healthy Bangladeshi children.
Secondary Objectives:
Safety: To evaluate the longer term safety (through 6 months after the last vaccination) of the HeV-sG vaccine
Immunogenicity: To evaluate the immunogenicity of the HeV-sG one week (or four weeks, depending on the schedule chosen) after receipt of the first vaccination.

STUDY ENDPOINTS

Primary Endpoints:

Safety: 1) Number of SAEs through 21 days after the last study injection; 2) Number of AEs through 21 days after the last study injection; 3) Number of vaccine-induced local and systemic reactions (solicited reactions) during the 7 days after administration of each dose

Immunogenicity: 1) Proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 3-weeks post-second study injection); 2) Proportion of subjects with neutralizing antibody responses (four-fold increase in antibody titers between baseline and 3-weeks post-second study injection)

Secondary Endpoints:

Safety: **1)** Number of SAEs at any time during the study; 2) Number of AEs at any time during the study

Immunogenicity: 1) Proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 3-weeks post-first study injection); 2) Proportion of subjects with neutralizing antibody responses (four-fold increase in antibody titers between baseline and 3-weeks post-first study injection); 3) Geometric mean titers (GMT) in ELISA assays at baseline and 3 weeks after second study injection; 4) Geometric mean titers (GMT) in neutralization assays at baseline and 3 weeks after second study injection

STUDY RATIONALE

It is imperative that the the Nipah-Hendra vaccine be tested in children, given that in the event of an outbreak they are likely to be the most vulnerable group. But such studies in children should only take place if the vaccine is safe and shows promise in the preceding adult studies. The Phase 1 study in children will be initiated as soon as the safety profile of the vaccine is supportive (over 300 adults would have been tested by then). The dose and schedule will be selected from the Phase 2 study results. The trial in children focuses on vaccine safety, but will also provide additional evidence of immunogenicity, in particular the ability of the vaccine to induce neutralization antibody. In order to proceed cautiously, the study will first enroll older (8-17 years old) children, and move down in age to 3-7 years old children only when the safety in the first group is confirmed.

STUDY DESIGN

The trial will be a double-blind, randomized, placebo-controlled, descending age study testing the dose and schedule of vaccine selected from the adult trials. The study will first enroll a cohort of 8-17 years old children and will move to a second cohort of 3-7 years old once the safety of the vaccine in the earlier age group is proven, including laboratory data on key parameters. If the safety profile of the vaccine is supportive a third cohort of children 3-17 years old will be included to complete a total of about 72 immunized children. Placebo recipients will be included in each cohort at a ratio of 1:2 (one placebo for two vaccine recipients) for a total of 36.

Each of the first two cohorts will include 30 children (20 vaccine and 10 placebo recipients). Once the safety of the first vaccine dose is confirmed in the first two cohorts, a third cohort of 180 3-17 years old children (120 vaccine and 60 placebo recipients) will be enrolled.

Phase 1 (children)	n subjects		subjects age range	Vaccine dose	Vaccination schedule	
	Vaccine	Placebo			dose 1 (day)	dose 2 (day)
Group 1	20	10	8-17 y/o	Selected from Phase 1	1	To be selected from adult studies
Group 2	20	10	3-8 y/o		1	
Group 3	120	60	3-17 y/o		1	

Blood samples for safety analysis will be obtained before (at screening) and 7 days after the vaccination in groups 1 and 2. Serum samples for immunogenicity analysis will be obtained at baseline, and 21 days after each vaccination for participants in groups 1 and 2. Progression to each new cohort will require review of clinical and safety laboratory data through 7 days after study injection in the previous cohort(s). These determinations will be made by the Safety Review Committee (SRC).

IMMUNOLOGY ASSESSMENTS

- Anti-HeV-sG IgG ELISA
- Neutralization activity against Nipah and Hendra virus using attenuated VSV-recombinants carrying the corresponding glycoproteins.

STATISTICAL CONSIDERATIONS

Safety: With a total of 160 vaccine recipients, this study will provide a greater than 90% chance of observing an AE that has a 1.5% or higher rate of occurrence.

Conversely, if no SAEs are observed among the 160 vaccine recipients, the study will be able to rule out SAEs occurring at a rate of approximately 2% based on the upper bound of the one-sided 95% confidence interval.

Immunogenicity: Based on the results in non-human primates receiving the HeV-sG vaccine, specific seroresponse rates are expected to be ≥80% for the optimal dose group. For comparisons between the vaccine and the placebo arms in groups 1 and 2, this study will provide ≥90% power to detect ≥ 48 percentage point difference. This takes into account a potential dropout rate of 10%.

For the Geometric Mean Titer (GMT) endpoint, the $\log_{10}$ standard deviations will be descriptively estimated for each group. No comparison hypotheses will be applied.

- A Phase 1 randomized, placebo-controlled, double-blind dose interval study to test the safety and immunogenicity of HeV-sG, a vaccine that targets Nipah and Hendra infections, in Singaporean adults.

STUDY HYPOTHESES

Safety: The HeV-sG vaccine will be well-tolerated and with an acceptable safety profile.

Immunogenicity: The HeV-sG vaccine is immunogenic and will induce neutralizing immune responses in 50% or more of participants in at least one of the study groups.

STUDY OBJECTIVES

Primary Objectives

Safety: to evaluate the safety and tolerability of the HeV-sG vaccine in healthy adults In Singapore.

Immunogenicity: to evaluate the immunogenicity of He-VsG vaccine, assess the effect of a second dose of vaccine and identify the optimal inter-dose interval.

Secondary Objectives

Safety: to evaluate the longer term vaccine safety (through 12 months from vaccination).

Immunogenicity: to evaluate the ability of HeV-sG vaccine to prime for immunological memory by assessing the ability of a second dose to boost the response at various time intervals.

STUDY ENDPOINTS

Primary Endpoints

Safety: 1) number of SAEs through 21 days after the last study injection; 2) number of AEs through 21 days after the last study injection; 3) number of Vaccine-induced local and systemic reactions (solicited reactions) during the 7 days after administration of each dose

Immunogenicity: 1) proportion of subjects with anti-HeV-sG seroresponses by ELISA (four-fold increase in antibody titers between baseline and 5 days, and baseline and 4-weeks post study injection); 2) proportion of subjects with neutralizing antibody responses (4-fold increase in antibody titers between baseline and 5 days, and baseline and 4-weeks post-second study injection)

Secondary Endpoints

Safety: 1) number of SAEs at any time during the study; 2) number of AEs at any time during the study

Immunogenicity: 1) geometric mean titers (GMT) at baseline, 5 days, and 4 weeks post first and 4 weeks post second study injection in ELISA assays; 2) geometric mean titers (GMT) at baseline, 5 days, and 4 weeks post first and 4 weeks post second study injection in Neutralization assays; 3) proportion of subjects exhibiting an anamnestic response by ELISA at 5 days post-second injection in comparison with baseline (just before second injection); 4) proportion of subjects exhibiting an anamnestic response 5 days post-second injection in comparison with baseline (just before second injection.

STUDY RATIONALE

This trial to be conducted in Singapore focuses on demonstrating the ability of the vaccine to effectively prime for an anamnestic response to a booster dose administered 90, 180, or 365 days after the initial vaccination. The study will be initiated once the optimal vaccine schedule and dose are determined from the phase 2 trial in adults in Bangladesh. The trial will also provide data on antibody persistence (3, 6 and 12 months after the initial vaccination), including ELISA and neutralization titers.

STUDY DESIGN

The trial will be a double-blind, randomized, placebo-controlled, dose-escalation study testing the vaccine dose level selected in the phase 2 study in Bangladesh in three separate cohorts. All enrolled subjects will receive an initial dose (100 ug, if tolerated in the phase 2) on day 1, and will be boosted at either day 91, day 181 or day 365 with the same dose of vaccine. Each cohort will consist of 25 participants (20 vaccine recipients and 5 placebo recipients).

HeV-sG vaccine	n subjects		Vaccine dose	Vaccination schedule	
Phase 1 Singapore	Vaccine	Placebo		dose 1 (day)	dose 2 (day)
Group 1	20	5	100 ug	1	91
Group 2	20	5	100 ug	1	181
Group 3	20	5	100 ug	1	366

Blood samples for immunogenicity analysis will be obtained at baseline for and on Days 6, 29, 91, 96 and 119 (group 1); days 1, 6, 29, 181, 186, and 214 (group 2), and on days 1, 6, 29, 365, 370 and 393 (group 3)

IMMUNOLOGICAL ASSESSMENTS

- Anti-HeV-sG IgG antibodies by ELISA
- Neutralization activity against Nipah and Hendra virus using attenuated VSV-recombinants carrying the corresponding glycoproteins.

STATISTICAL CONSIDERATIONS

Safety: With 20 vaccine recipients per dose group, this study will provide a greater than 90% chance of observing an AE that has an 11% rate of occurrence. Conversely, if no SAEs are observed among the 20 vaccine recipients per group, the study will be able to rule out SAEs occurring at a rate of approximately 14% based on the upper bound of the one-sided 95% confidence interval.

Immunogenicity: Based on the results in non-human primates receiving the HeV-sG vaccine, specific seroresponse rates are expected to be ≥80% for the optimal dose group. For comparisons between the optimal dose group and the combined placebo groups, this study will provide ≥90% power to detect ≥62 percentage point difference or 80% power to detect a ≥56 percentage point difference.

For the Geometric Mean Titer (GMT) endpoint, the $\log_{10}$ standard deviations will be descriptively estimated for each group. No comparison hypotheses will be applied.

4.6. Strategy for regulatory approval of trials and product

Describe the proposed strategy you will take to be under review within WHO emergency use assessment and listing procedure (EUAL), when applicable[1]: Profectus BioSciences has developed a vaccine that protects against disease caused by both Nipah and Hendra viruses. This vaccine has been designed to meet or exceed WHO's proposed Target Product Profile (TPP) for Nipah. Prior to Phase 1, Profectus and PATH will meet with WHO to share our TPP and to confirm that it adequately aligns with WHO Prequalification requirements. We will also share our clinical and regulatory plans for Licensure.

While Nipah is listed on WHO's R&D Blueprint to Action to Prevent Epidemics, it is not currently on WHO's list of diseases which are of "Public Health Emergency of International Concern". Application will be made for listing under the EUAL (Emergency Use Assessment and Listing Procedure) in case it becomes appropriate to use the vaccine before it has been licensed by FDA, or another functional regulatory authority. The availability of early safety data and correlate of protection studies will help determine suitability of use and appropriate dose level prior to completion of Phase 2/3 safety and immunogenicity studies. To meet WHO's requirements for an EUAL in the event of an outbreak, information submitted to the IND can be shared with WHO for review. This would include summary information on available preclinical and clinical data; and manufacturing, testing and stability data. The manufacturing facility would also be available for inspection. Early in clinical development, we would like to meet with WHO to establish acceptable wording for labeling, and put a plan in place for conducting pharmacovigilance and effectiveness studies under outbreak conditions if needed.

Provide the plans for regulatory approval to conduct clinical trials before and during the outbreak: Nipah is not a prevalent disease or endemic to any region, but outbreaks incur high mortality. Since efficacy studies are not feasible and challenge studies are not ethical, registration will be sought with the US FDA by the Animal Rule. Phase 1 First-in-Human safety studies assessing dose level and dosing interval will be conducted in adults in the US. Subsequent studies will be conducted in countries that have experienced outbreaks in the past (e.g. Bangladesh and Singapore) and where the vaccine is most likely to be used. CTA submissions or Ethics Committee contact for ex-US countries as required will be made for these studies, however, all studies will be filed to the US IND. Initial clinical strategy will be reviewed with FDA in a preIND meeting, and prior to the start of Phase 2/3 safety and immunogenicity studies once the previous study's clinical data and subsequent study design is available. We will also seek alignment on how an ongoing clinical study might be adapted in the event of an outbreak to minimize delays in an emergency.

If an outbreak occurs during Phase 1 and available clinical results indicate vaccine safety, we would aim to rapidly initiate a Phase 2/3 study to obtain safety and efficacy data in the field setting, which would potentially support "emergency use" of the investigational vaccine. If the outbreak occurs during Phase 2 or 3, and adequate safety, immunogenicity, and correlate of protection data are available, the investigational vaccine could be considered for emergency use. In that event, a pharmacovigilance and effectiveness study would be conducted. Once dose level and dose interval have been established in adults, we propose to conduct dose escalation studies in the pediatric population to enable vaccination of children during an outbreak scenario. These data would be supported by the results of the nonclinical Correlate of Protection study that will be conducted upon completion of Phase 1 studies. Additionally, after the vaccine has been demonstrated to be safe and an effective dose has been identified in adults and reproductive toxicology data is available, a Phase 1 study may be considered in pregnant women to support vaccination of this population during an outbreak.

Define the proposed strategy for regulatory approval for licensure. Include any major assumptions, including which National Regulatory Authority will be the target of regulatory approval applications: The Nipah/Hendra vaccine consists of a recombinant surface glycoprotein in suspension with an aluminum hydroxide adjuvant. While there have been no discussions with regulatory bodies

---

[1] http://www.who.int/medicines/news/public_consult_med_prods/en/

to date on this specific vaccine, Profectus has had discussions with FDA on a similar protein vaccine for HIV (FLSC-IHV01). The technology platform is not novel, however, we will seek confirmation with FDA on all proposed testing in a preIND meeting.

For the Nipah/Hendra vaccine, licensure will be sought under the Animal Rule. After completion of Phase 2/3 clinical studies that demonstrate safety and immunogenicity and identify an effective dose based on the correlate of protection studies; plus lot consistency and nonclinical efficacy, registration will be sought with the US FDA. After FDA approval, an official request will be made for WHO Prequalification. Registration can also be pursued with relevant country regulatory body such as Singapore's Health Sciences Authority (HAS) or other countries that require a CPP (Certificate of Pharmaceutical Product) once FDA approval has been obtained.

Our regulatory strategy targets registration of the Nipah/Hendra vaccine in the US, with global access for outbreaks through WHO Prequalification. Nipah is on WHO's 2017 Blueprint Priority List as needing urgent R&D attention. This priority list seeks to promote epidemic preparedness by focusing accelerated R&D on emerging pathogens likely to cause severe outbreaks in the near future, for which few or no medical countermeasures exist [http://www.who.int/blueprint/priority-diseases/en/]. The vaccine may also be licensed for use directly in countries where the disease is endemic or outbreaks are likely to occur.

The design of initial preclinical and clinical studies for the Nipah/Hendra will based on regulatory advice previously received for other vaccines which consist of glycoproteins adsorbed to aluminum, however, a preIND meeting would be requested with FDA to confirm our strategy. As clinical development progresses, additional meetings will be sought to prepare for later stage studies and to achieve concurrence on a registration pathway. We will also meet with WHO to align on prequalification requirements.

The clinical studies would be conducted under a US IND, with the First-in-Human study in the US. Phase 2 confirmation of dose and dosing interval, and Phase 2/3 safety and immunogenicity studies will be conducted in Bangladesh, where recurrent outbreaks of Nipah disease have occurred. Countries that have experienced earlier disease outbreaks (e.g. Singapore, Malaysia, and India) may also be considered as clinical study sites, or for future registration.

A Phase 1 dose ranging pediatric study should be conducted after initial safety, dose, and dose interval data are available from adult studies (during Adult Phase 2). Reproductive toxicology studies will be conducted prior to the start of Phase 3, or sooner if funds are available and a dose and dosing interval have been identified. Preclinical correlate of protection studies will be conducted to help predict the protective antibody range in humans (using high titer serum harvested in Phase 1) and as a basis for registration by the Animal Rule. This information could also be helpful in the event of an outbreak (emergency use) that occurred prior to Phase 2/3 completion and vaccine registration, and will be supportive of later stage clinical design.

Studies in pregnant or lactating women would not be conducted until after studies in healthy adults are completed. A pregnancy registry will be established to monitor the outcome of pregnancies that may occur during the clinical studies. Studies in other populations (e.g. elderly, immunocompromised, etc.) can be conducted after registration, or earlier if supported.

In the US, a pediatric plan must be in place prior to Biologics License Application (BLA) submission. However, it is imperative that pediatric studies are conducted upon demonstration of safety and identification of an appropriate dose in adults to prepare for emergency use in children in the event of an outbreak.

4.7. Chemistry, Manufacturing & Control (CMC) Development

Although a MCB has been manufactured, tested, characterized, and release for future cGMP production, a stability study was not funded. The following table lists the proposed specifications of the WCB stability program for which funding is requested in the present application.

Specification of WCB

Test	Purpose	Target Specification	Testing Site
Appearance	Visual	Report Result	Catalent
Cell Viability	MCB integrity	> 70%	Catalent
Growth Rate	MCB integrity	Report Results	Catalent

Our current reference standard was manufactured at Profectus in 2014. A new reference standard is required and will prepared using the drug substance produced in an Engineering Run, i.e., finalized upstream and downstream process and characterized using qualified test methods as specified below.

Specification of Reference Standard

Test	Purpose	Target Specification	Testing Site
Appearance	Visual	Report Result	Catalent
Protein Concentration by A_{280}	Potency	0.9 - .1.1 mg/mL	Catalent
pH	MCB integrity	Doubling time	Catalent
Bioassay, ED_{50}	Potency	TBD	Catalent
SDS-PAGE (Reduced, Non-Reduced)	Purity	TBD	Catalent
SEC-HPLC (% Tetramer, Dimer, and Monomer)	Purity	TBD	Catalent

SEC-HPLC, retention times	Identity	TBD	Catalent
Charge distribution by HPLC or cIEF	Characterization	TBD	Catalent
Glycosylation profile	Characterization	TBD	Catalent
Peptide mapping	Characterization	TBD	Catalent

The testing strategy for in-process, release, and stability testing of **DRUG SUBSTANCE** is outlined in the following table. The tests will be conducted at the Drug Substance Manufacturer, Catalent, or at Charles River Labs (Malvern or Wilmington).

Proposed Analytical Testing of HeV-sG In-Process and Drug Substance

Test	Purpose	Target Specification	Testing Site
In process Control during Cell Culture			
Viable Cell Density	Monitor growth	Report results	Catalent
Cell Viability	Monitor growth	Report results	Catalent
Metabolites	Monitor growth	Report results	Catalent
Productivity	Monitor growth	Report results	Catalent
Post-Production Cells or Unprocessed Harvest			
Sterility	Safety	Absence of Growth	CRL
Isoenzyme analysis	Identity	Human Origin	CRL
DNA Finger printing	Identity	Human Origin	CRL
Mycoplasma (EP, USP, PTC,JP) (with Mycoplasmastatsis)	Safety	No evidence of mycoplasma	CRL
In vivo Adventitious Agents	Safety	No evidence of virus	CRL
In vitro Adventitious Agents	Safety	No evidence of virus	CRL
Transmission Electron Microscopy	Safety	No viruses, mycoplasmas, fungi, yeasts, bacteria	CRL
Assays for human viruses	Safety	No evidence of virus	CRL
Assays for Retrovirus	Safety	No evidence of virus	CRL
Bovine Virus assay	Safety	No evidence of virus	CRL
Porcine Virus assay	Safety	No evidence of virus	CRL
Porcine Circovirus assay	Safety	No evidence of virus	CRL
In process Control during Purification			
Protein Concentration by A_{280}	Potency	Per batch record specifications	Catalent
pH	General Quality	Per batch record specifications	Catalent
SDS-PAGE (Reduced, Non-Reduced)	Purity	TBD	Catalent
Host Cell Protein (HEK-293)	Safety	Report results	Catalent
Drug Substance			
Appearance*	Visual	Clear, colorless solution with no foreign particles	Catalent
Protein Concentration by A_{280}*	Potency	0.9 - .1.1 mg/mL	Catalent
pH*	General Quality	6.7 - 7.5	Catalent
Bioassay, ED_{50}*	Potency	TBD	Catalent
SDS-PAGE (Reduced, Non-Reduced)*	Purity	TBD	Catalent

Protein Concentration by HPLC*	Potency	0.085 - 0.115 mg/mL (85 - 115 µg/mL)	GRAM
pH*	General Quality	6.7 - 7.5	GRAM
Bioassay, ED_{50}*	Potency	TBD	CRL
SDS-PAGE (Reduced, Non-Reduced)*	Purity	TBD	CRL
SEC-HPLC (% Tetramer, Dimer, and Monomer)*	Purity	TBD	GRAM
SEC-HPLC, retention times*	Identity	TBD	GRAM
Charge distribution by HPLC or cIEF*	Characterization	TBD	CRL
Withdrawable volume	General Quality	≥ 1.0 mL/vial	CRL
Sterility*	Safety	Absence of growth	CRL
Endotoxin*	Safety	≤ 30 EU/mL	CRL

* Method used in stability testing

Drug product will be stored at 2-8°C. The stability program will include accelerated temperatures of 25° and 37°C to definite the type of HEATmarker® vaccine vial monitor to be used to ensure the product quality during shipping and field use at the clinical sites.

Drug product vials will be shipped in bulk to Fisher BioServices for long term storage. Fisher BioServices will label, package, and ship to clinical sites to conduct Phase 1 and 2 clinical trials. During labelling, the appropriate HEATmarker® vaccine vial monitor will be applied to each individual vial to ensure product quality during the entire supply chain.

Profectus has supervised by man-in-plant many production runs of recombinant proteins at various scales and stages (development or clinical) at Catalent for two protein vaccines. For HeV-sG, the removal of host cell protein (HCP) was the more challenging step, but pooling of selected fractions has been identified as an effective method to achieve low levels of residual HEK HCP. The production of HeV-sG in 2x10L bioreactor and the subsequent purification steps were successful, and the resulting DP was used in a GLP toxicological study. The scale up study in 100L bioreactor is currently in progress.

As the HeV-sG vaccine project is in the pre-clinical stage at Profectus, there is limited processing data. After completing the process development at Catalent, the potential risks can be appropriately identified and a detailed risk mitigation plan can be developed prior to the manufacture of CTM. As the manufacturing processes are not defined yet and the demands (patient population and frequency of outbreaks) are unpredictable, it is difficult to calculate the COGS. For HeV-sG vaccine, realistic COGS can be calculated when the vial quantity for stockpiling and product shelf-life are established, most likely after during or after the Phase 2 development.

5. Timeline and decision/stage criteria

5.1. Work breakdown Structure

Task	Task Name	Start	Finish
	CEPI Nipah Virus (HeV-sG) Project Plan	Mon 1/7/13	Thu 4/13/23
		Mon 1/1/18	Mon 1/1/18
1	Production and Release of HeV-sG/Alhydrogel DS and DP	Mon 1/7/13	Tue 12/6/22

5.2. Decision/stage gate criteria

Each of the tasks comprising this proposal, as described in Section 4, contain a listing of Deliverables and Go/No Go criteria. Thus, the Go/No Go criteria provide the gate criteria for advancing the program.

5.3. Costs – *use budget narrative and template:*

These are uploaded as separate standalone documents.

6. Product Profile

Target Product Profile: NIPAH VACCINE

For reactive use in outbreak settings with rapid onset of immunity

Vaccine characteristic	**Expected**	**Rational / Argument**	**Variations from WHO preferred TPP**
Indication for use	For active immunization of at-risk persons in the area of an on-going outbreak for the prevention of NiV or HeV disease; to be used in conjunction with other control measures to curtail or end an outbreak.	Also protective against disease caused by Hendra virus.	Exceeds WHO preferred criteria.
Target population	Healthy adults and children, excluding pregnant and lactating women. A pregnancy registry will be set up to monitor outcomes of any pregnancies that occur during the clinical studies.	The addition of pregnant and lactating women will depend upon the outcome of reproductive toxicology studies and clinical studies in this population.	Meets WHO critical criteria.
Safety/Reactogenicity	Safety and reactogenicity sufficient to provide a highly favorable benefit/risk profile in the context of observed vaccine efficacy; ideally with only mild, transient adverse events related to vaccination and no serious AEs related to vaccination.		Meets WHO preferred criteria.
Measures of efficacy	At least 70% efficacy in preventing infection or disease with one dose. Onset of immunity in less than 10 days. Since demonstration of clinical efficacy is likely not feasible, nonclinical immunogenicity and efficacy in a standardized and relevant animal model together with clinical immunogenicity will be considered. If regulatory authorization is provided without clinical efficacy data, effectiveness data are to be generated during use in a future outbreak to the extent possible.		Meets WHO preferred criteria.
Dose regimen	Single dose primary series. A second optional dose may be administered to enhance longevity of immunity 1 to 3 months after the first dose.		Meets WHO preferred criteria.
Duration of protection	Confers protection of at least 3 months, or of at least 1 year with the optional second dose.	One year protection can be obtained with 2 doses. One year protectin may be feasible with a single dose, but that data is not yet available.	Meets WHO critical criteria.
Route of administration	IM delivery ≤1mL		Meets WHO preferred criteria.

Coverage	Monovalent against both Nipah and Hendra viruses with documentation of neutralization of NiV Bangladesh, NiV Malaysia and Hendra virus.	Also protective against Hendra virus.	Exceeds WHO preferred TPP	
Product stability and storage	Alhydrogel suspension with shelf life of at least 12 months at 2-8°C and 24 hours at ambient room temperature. An accelerated stability study will be conducted to assess thermostability at higher temperatures. A vaccine vial monitor will be on each vial of vaccine. Preservatives are not required for single dose vials.	Shelf life may be longer than 12 months at 2-8°C but those data are not yet availalble.	Meets WHO critical criteria.	
Presentation	Vaccine will be presented as a liquid suspension in single dose presentation to provide a dose injection volume of ≤1.0 mL.	In the first Phase 1 study, vaccine volume will likely be 1mL. However, ongoing formulation development is expected to achieve a 0.5mL injection volume	Meets WHO critical criteria.	
Registration and prequalification	Should be WHO pre-qualified according to the process outlined in Procedures for assessing the acceptability, in principle, of vaccines for purchase by United Nations agencies (WHO/BS/10.2155). Nipah is on the list of Blueprint Priority diseases.		Meets WHO preferred criteria.	

7. Risk assessment

Describe the top risks (1 minimum for each functional area) that have moderate to high impact to the development program. Consider risks in different functional areas (i.e. Clinical, CMC, Regulatory, Delivery, Global Access and Partner Management etc.) and how they inter-relate to each other). Add additional rows as needed to describe the risks

- Group responsible for preparation indicated

Functional Domain	Risk Factor	Probability	Likely Impact	Magnitude	Mitigation plan
Regulatory	Cannot establish correlate of protection in two animal species to predict efficacious dose in humans.	Low	Could not register by the animal rule	High	Align early with FDA on correlate of protection study design, choice of animal model(s), and the need for demonstration in two species.
Regulatory	Cannot induce immune response in humans correlated with protection in animal models	Low	Could not register by Animal Rule	High	Explore adequate dose range and dose intervals to maximize immune response
Research	Complete				
Clinical	Vaccine is overly reactogenic and/or safety signals are detected	Low		High	Test lower vaccine dose for which safety signals may be absent
Clinical	Neutralizing antibody does not correlate with protection in the animal model	Low		High	Explore other immune functions that may be better markers of

					protection (B cells, T cells, non-neutralizing antibody functions, et.)
Clinical	Delays due to extended timelines regulatory and ethical approval of clinical trials	High		Medium	Build extra time into study planning and start-up phase to allow for potential delays.
Clinical	Limited vaccine immunogenicity	Low		High	Could be compensated by the use of novel adjuvants (e.g., oil in water emulsions), higher doses and/or multiple dosing
CMC	Manufacturing process does not scale up	Medium	Cost of goods higher than desired	Medium	Several alternative DSP methods are available
Partner Management	Insufficient communication to ensure work achieved in a timely manner	Low	Timeline slippage	Low to High	The Contract Management Team holds regularly scheduled meetings with agendas, minutes and time constrained action items
Product Strategy	PBS				
Delivery	Vaccine proves unstable at refrigerator temperature	Low	Vaccine would require cold chain	High	Comprehensive testing of stabilizers planned and preliminary results good
IP	Third party controls enabling technology		Would require license negotiation and cost	Low to High	Comprehensive review of the IP landscape shows freedom to operate

8. Anticipated use potential

8.1. Suitability of the vaccine candidate for use in disease outbreak settings

Alhydrogel™ formulated HeV-sG remains 100% bound and intact at either 4⁰C or 21⁰C for 32 weeks. Thus, HeV-sG/Alhydrogel™ provides a product with projected multi-year stability at refrigerator temperature, that can withstand extended handling at room temperature, and that will likely withstand multi-day handling at 37⁰C. NHP studies have shown that a single dose of vaccine is able to protect against lethal NiV and HeV challenge. In addition, the human immune response to accidental inoculation (N=2) with the veterinary vaccine has been shown to be potent and to cross-neutralize both NiV and HeV (I. Smith and C. Broder, unpublished). In aggregate, these data indicate that this vaccine can be effectively used in an outbreak setting. Current USP and DSP yields predict a 1,000L fermenter run will provide 120 gm of product. Assuming the intermediate 33.0 µg dose proves to offer adequate immunogenicity, a single 1,000L run is projected to provide ~360,000 doses of vaccine. Therefore, the most practical approach to providing large-scale coverage would be to produce and store bulk drug product (BDP) that could be rapidly filled upon need. Assuming storage stability of 5 years, a run every 3 years would provide an overlapping supply.

8.2. Suitability of the vaccine candidate for use in endemic settings

The HeV-sG/Alhydrogel™ vaccine could be effectively used in an expanded program on immunization that targets those regions that suffer regular outbreaks of NiV disease. Available clinical data indicate that repeated boosting with this vaccine vector is effective, and periodic boosting can be implemented, if needed. In addition, it is anticipated that the AE profile of this vaccine will allow paediatric use.

8.3. Efficacy trials in outbreak situation

It may be possible to use a ring vaccination strategy to demonstrate the efficacy of this vaccine candidate. However, the sporadic nature and small size of the natural outbreaks to date make it more likely that licensure will need to be obtained under “animal rule” studies.

8.4. Application to other pathogens

HeV-sG/Alhydrogel™ is a subunit vaccine specific to NiV and HeV. As such it is not applicable to other pathogens. However, the subunit vaccine base technology has been successful with multiple viral pathogens, including HBV, HPV, and influenza virus.

9. Communication and results

9.1. Dissemination plan of study results

The collaborating partners agree to the timely dissemination of study results via public meetings and publication.

9.2. Data sharing

At the end of each study, final clinical results will be described in a study report and submitted to the IND/CTA and to the BLA for licensure. Anonymized clinical data may be share in publications. The sponsor (or the sponsor's representatives), monitors, auditors, regulatory agencies and ethics committees may have access to the medical records from the study to carry out their obligations or as required by law.

9.3. Comparison of results

Acceptable to the collaborating partners.

10. Other information

10.1. Any other information of relevance for the application

- *Any critical areas where you are likely to require assistance in completing the project, indicating specific roles that CEPI could play to facilitate you getting this type of assistance. Include examples from R&D, manufacturing, regulatory or product delivery domains*
- *Donations or other non-monetized contributions to the project by applicants and their partner(s)*
- *Other information that may be relevant for CEPI's consideration*

10.2. Has the applicant received funding for the proposed project from others sources to date? *(tick one box below)*

√YES	☐ NO

Profectus has received funding from the US National Institutes of Health to advance the HeV-sG/Alhydrogel™ vaccine through scale-up development, IND-enabling toxicology, and NHP protection studies. These activities enable the activities proposed in this contract application, but do not overlap with the current proposal.

10.3. Has the applicant applied for funding of the proposed project to others which is currently pending an award notification? *(tick one box below)*

YES	√NO

10.4. Animal welfare

The **UTMB Animal Resource Center** (ARC) is responsible for housing and care to all animals on campus. The ARC encompasses 89,694 square feet in nine facilities across the UTMB campus. UTMB is a registered Research Facility under the Animal Welfare Act. It has a current Letter of Assurance on file with the Office for Protection from Research Risks. The Geisbert laboratory and the ARC have a documented ability to conduct work in accordance with guidelines for *Biosafety in Microbiological and Biomedical Laboratories* (Fifth Edition, December 2009) and the *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (Revised 2015). The Department of Defense, CDC, and USDA have approved our laboratories for work with select agents and AAALAC (Association for the Assessment and Accreditation of Laboratory Animal Care International) has certified our animal facilities (Accreditation #000870). UTMB follows the:

- *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (2015 reprint)
- *Guide for the Care and Use of Laboratory Animals*, Eighth Edition (2011)
- US Government Principles for the Utilization and Care of Vertebrate Animals Used in Testing, Research, and Training
- USDA-administered Animal Welfare Act (Public Law [PL] 89-544 as amended by PL 91-579 [1970], PL 94-279 [1976], and PL 99-198 [1985]) and published in 9 CFR Parts 1-3 on Final Rules regarding Animal Welfare
- Health Research Extension Act of 1985 (PL 99-158) regarding "Animals in Research"; and
- PL 103-43 regarding the "Plan for Use of Animals in Research" (1993).

UTMB's ARC follows all standards for AAALAC and Institutional Animal Care and Use Committee compliance. Depending on space availability, animals may be housed in ARC facilities with animal care provided by the ARC staff including two full-time veterinarians. These facilities are capable of housing NHPs, rats, mice, hamsters and guinea pigs under BSL2/3 biohazard containment, and encompass 72,847 square feet. All facilities feature full-service animal care procedural and maintenance facilities, including laminar flow isolator caging systems, sterilization equipment, procedure rooms, cage-washing, and autoclaving.

√YES	☐ NO

(If no, please indicate your reasons).

Attachments: CEPI Nipah Full Proposal FINAL.pdf

Hi Chris,

Please find attached the Final Nipah vaccine Technical Proposal submitted by Profectus to CEPI. At the request of our attorney I have deleted any reference to the cost of the program and have marked the document Profectus confidential. As you correctly point out, the Specific Aims of the CEPI and NIAID contracts are completely different, with the exception of developing your Cedar virus-based assay. Let me know if this is adequate to address all overlap concerns.

We will get you BioSketches with updated other support by COB tomorrow.

Best,

John

Subject: CEPI and CETR U19

hi Tom and John (Jeff and Toni cc'd)

NIAID was satisfied with my revised SAC for the CETR U19. We are uploading today. I will send another msg to all partners today.

Kim Boxely (here) will be reaching out to our CETR partners (PIs and their POCs) for JIT other support docs of all
key personnel today/tomorrow.

Micheal sent msg below this AM. This specifically relates to only me (USU), Profectus and UTMB - as we are all parties to the CEPI-funded Nipah vaccine
so you both as key personnel need to put together your other support pages. and address any overlap more specifically.

Scientifically. as far as the Profecus CETR project (RP1) goes (and UTMB/GNL) (Core C) there is no scientific overlap with CEPI project (the goals and proposed studies are totally different.
CEPI project is just gearing up HeV-sG production as GMP material and alum vaccine formulation and assay development, and clinical trials.

There is only slight overlap with USU CETR project (RP3) regards to making just two Cedar chimeric viruses which i will address.

John, as you can see from the msg from NIAID, I need the final funded CEPI application for them., Is this possible? ASAP.

I will be email Micheal back shortly and give him a heads up.

v/r
Chris

Hi Chris,

We are aware that you and additional key personnel of your proposed CETR are engaged in a recently funded CEPI project to develop a Nipah virus vaccine. At this stage of CETR payplan processing, we need to assess potential scientific and budgetary overlap between the CEPI and CETR projects. Accordingly, please provide a copy of the funded CEPI application (uploaded as a JIT document vie eCommons) as soon as possible. Feel free to contact me if you have any questions.
Regards,
Michael

Version 1.2

Word Count: 3,695 (text only, not including References or Tables)

Introduction

Nipah virus (NiV), a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chua 1999, Chew 2000, Parashar 2000). At least 265 human cases of encephalitis were identified in Malaysia and most had close contact with pigs (Chua 2010, Parashar 2000). In addition, 11 abattoir workers in Singapore became ill following contact with pigs imported from Malaysia; eight patients presented with signs of encephalitis and three presented with atypical pneumonia (one of which later also had evidence of encephalitis) (Paton 1999). No new outbreaks have been reported in these countries since May 1999; however, NiV infection was subsequently recognized in Bangladesh in 2001 (Hsu 2004) and nearly annual outbreaks have occurred in that country since then (WHO 2018). Outbreaks also have been recognized in eastern India and, in 2018, an outbreak occurred in the southern Indian state of Kerala (Arunkumar 2018, Sharma 2018, Chattu 2018). To date, nearly 350 cases of NiV infection have been identified in Bangladesh and India (WHO 2018). Possible emergence of NiV in a third geographic area is evidenced by an outbreak of an unidentified henipavirus that occurred among horses and humans in the Philippines in 2014 (Ching 2015). Although detailed genomic information for the virus is limited, experts agree that the causative agent was either NiV or a virus closely related to NiV. The Henipavirus genus includes another pathogen, Hendra virus, which predominantly causes infection in horses in Australia and can also lead to human disease, usually following contact with infected horses (Ksiazek 2011).

The most common clinical syndrome associated with NiV infection is severe, rapidly progressive encephalitis (Goh 2000, Hossain 2008). The main presenting features include fever, headache, dizziness, vomiting, and altered mental status. NiV infection may result in late-onset

encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Tan 2002, Goh 2000). Some patients also have respiratory involvement or respiratory illness alone, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The overall case-fatality rate for the Malaysia outbreak was approximately 40%, whereas case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 65% to 100% (Hossain 2008, WHO 2018). Genomic sequencing has demonstrated that there are multiple strains of NiV, which may account for the differences noted in clinical features and outcomes between Malaysia and Bangladesh (Mire 2016).

Fruit bats of the Pteropus genus are considered the primary natural reservoir for NiV. In the Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and possibly limited human-to-human NiV transmission (Chua 2010). Additionally, several other domestic animal species in the outbreak area (including horses, cats, and dogs) were found to be infected with NiV (Chua 2000). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap (Islam 2016, Luby 2006, Rahman 2012) and subsequent person-to-person transmission. While person-to-person transmission was apparently minimal in the Malaysia outbreak, it has played a larger role in amplifying outbreaks in Bangladesh and India (Gurley 2007, Luby 2009, Chadha 2006, Arunkumar 2018). This may, in part, be related to the greater propensity toward respiratory disease in NiV strains found in South Asia and transmission via droplet spread (Spiropoulou 2018). The potential for droplet spread is supported by a recent study that demonstrated hamsters could be infected when exposed to NiV via a small-particle aerosol (Escaffre 2018). Given the potential for respiratory transmission of NiV and the recent experience with Ebola in West

Africa, some have raised concerns about the possibility of larger NiV outbreaks if the virus takes hold in a crowded or urban area (Donaldson 2018) or about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Pteropus fruit bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Other fruit bats of the Pteropodidae family also may harbor NiV, and such bats can be found across Africa and parts of the Middle East. Evidence of NiV infection (via virus isolation, serologic testing, or nucleic acid detection using real-time polymerase chain reaction [RT-PCR]) has been found in Pteropus bat species and other bat species in geographically diverse regions, including South Asia (Bangladesh and India); Southeast Asia (Cambodia, Indonesia, Malaysia, the Philippines, Thailand, and Vietnam); the Western Pacific region (Papua New Guinea); and Africa (Madagascar and Ghana) (Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2018, Yob 2001). This wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

WHO has determined that Nipah virus is a priority disease for epidemic preparedness (WHO 2018). To improve epidemic response for this infection, in the fall of 2017, WHO embarked on development of a research and development (R&D) roadmap for NiV disease; this report provides a summary of the key elements of that roadmap, including important challenges and barriers that need to be addressed to ensure that diagnostics, therapeutics, and vaccines are

developed, manufactured, and readily available when needed *[provide link to full roadmap here when available]*.

The NiV R&D roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one medical countermeasure category), diagnostics, therapeutics, and vaccines. The strategic goals and milestones identified in each section are focused on key achievements for the next 5 years; ~~the roadmap milestones will be tracked over time,~~ the roadmap milestones will be tracked over time, with periodic assessment of progress and updates to the roadmap as needed. The roadmap is specific to R&D for disease in humans; however, further research of NiV in animal species, including development of appropriate medical countermeasures targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV in humans and virus transmission can occur at the human-animal interface.

Cross-Cutting Issues

A major challenge for development of diagnostics, therapeutics, and vaccines for NiV is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Advocacy to policy makers in affected countries and to global stakeholders is needed to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures. As part of this process, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species and proximate

human populations in areas of predicted risk. Human health, animal health, and wildlife officials should be engaged in these efforts as part of a long-term collaborative One Health approach (Chattu 2018, Kulkarni 2013).

Another important issue is the need to optimize relevant animal challenge models for promoting development and evaluation of medical countermeasures for NiV infection, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval (Rockx 2014). For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for therapeutic or vaccine development; (3) determine when after challenge medical countermeasures should be administered in animal models to best mimic realistic timing of such use in humans; (4) bridge data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human doses; and (5) identify the best models for studying chronic (relapsing) infection (Bossart 2012, Debuysscher 2013, Dhondt 2013, Johnston 2015, Mathieu 2015, Satterfield 2016). Currently, the African green monkey is regarded as the most relevant animal model for evaluating candidate therapeutics and vaccines intended for use in humans (Geisbert 2010, Johnston 2015), and studies involving nonhuman primates may be required for licensure of therapeutics and vaccines via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns, however, constrain the use of this animal model. In addition to optimizing animal models, standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains are needed to move R&D of medical countermeasures for NiV infection forward (Satterfield 2016).

To inform development of optimal NiV medical countermeasures, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. This includes issues such as evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection.

To respond to these challenges, the strategic goals and milestones for cross-cutting issues in the NiV R&D roadmap focus primarily on developing a sustainable value proposition and identifying funding sources to promote R&D, availability, and accessibility of NiV medical countermeasures, optimizing animal models for research, and generating standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV medical countermeasures (Table 1).

Diagnostics

The most commonly used methods for diagnosing NiV infection include virus isolation, enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies, and real time-polymerase chain reaction (RT-PCR) nucleic acid testing. Virus isolation requires biosafety level 4 (BSL-4) capabilities and is generally only performed in reference laboratories for specific purposes, such as to confirm a new outbreak or to identify the virus in new host species (Wang 2012). During the Malaysia outbreak, the US Centers for Disease Control and Prevention (CDC) developed a capture ELISA for detection of IgM antibodies and an indirect ELISA for detection of IgG antibodies (Daniels 2001); since then, additional ELISA tests have been developed (Wang 2012) and serologic testing is often used for

case confirmation during outbreaks (Chadha 2006, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009). RT-PCR, which can be performed on throat and nasal swabs, cerebrospinal fluid, urine, and blood, is also often used for diagnostic testing (Chadha 2006, Guillaume 2004, Lo 2012). Quantitative RT-PCR tests have been developed for quantifying viral replication; such tools can be used to measure viral load reduction when screening vaccine candidates and potential therapeutics (Jensen 2018). More recently, pseudotyped-based serum neutralization assays for NiV detection that use vesicular stomatitis virus systems have been developed; these assays potentially can be used under BSL2 conditions in laboratories with limited diagnostic capabilities and appear to offer improved sensitivity and specificity (Kaku 2009, Kaku 2012, Tamin 2009). Antigen-capture ELISAs using monoclonal antibodies also have been developed, which could result in more rapid diagnosis (Chiang 2010). These newer technologies hold promise; however, more information is needed regarding their performance characteristics, particularly under field conditions .

Commented [DTM1]: Development and validation of immunohistochemical staining tests can facilitate studies on pathogenesis of Nipah infections and might also be useful for primary diagnosis in low-resource settings.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation, which can delay outbreak detection and implementation of infection control measures. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. To address these issues, rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes, once therapeutic options become available.

Commented [DTM2]: Where feasible, prospective surveillance of susceptible animal species (e.g., bats, pigs, equids) with potential for human spillover of Nipah infection may be implemented, in order to evaluate risk profiles and patterns of NiV circulation.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of such a repository requires addressing the following: (1) determining what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outlining the purposes of sample collection; (3) determining what organizations will be responsible for activities related to creating and maintaining the repositories; (4) establishing standardized protocols for sample collection and maintenance; (5) establishing an appropriate governance structure; (6) identifying who would have access to the samples; (7) prioritizing use of samples and sample distribution; and (8) ensuring that material transfer agreements are in place. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

To address these issues, the strategic goals and milestones for diagnostic testing outlined in the NiV R&D roadmap focus on creation of a virtual reference repository, development of highly sensitive and specific point-of-care or near-patient NiV diagnostic tests, and enhancement of laboratory diagnostic preparedness to promote early detection of NiV in areas of known or potential spillover risk (Table 2).

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients; findings from treated patients were compared to those of 54 historical controls who became ill before ribavirin was available or who refused treatment (Chong 2001).

Commented [DTM3]: (1) Clinicians, especially in endemic areas, should be asked to maintain high vigilance for cases of acute febrile encephalitic syndrome, in particular, with respiratory symptoms.
(2) Effective and appropriate risk communication strategies should be implemented in endemic areas. Recommendations on behavioral modifications should be communicated to susceptible populations, wherever Nipah infections have occurred after indigenous practices like consumption of raw date palm sap.

Results demonstrated a statistically significant reduction in mortality among treated patients (36%); however, the use of historical controls may have biased this finding. No additional clinical studies using ribavirin have been conducted, and limited studies in animal models have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Rockx 2010, Georges-Courbot 2006). Chloroquine also has been studied in animal models, but has not shown any therapeutic benefit, either alone or in combination with ribavirin (Freiberg 2010, Pallister 2009). Based on these findings, these approaches are not considered viable options for treatment of NiV infection.

A more promising therapeutic option is the development of monoclonal antibodies (mAbs) against viral envelop proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). Therapy with anti-NiV mAbs may be appropriate for early treatment and for post-exposure prophylaxis (PEP) to prevent illness in exposed persons, such as healthcare workers, family caregivers, and persons exposed to infected livestock. Researchers have demonstrated that the human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009), and it has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Recently, a phase 1 clinical trial of m102.4 with 40 human participants was completed in Australia, but results are not yet available (ANZCTR). M102.4 was deployed for use during the 2018 NiV outbreak in Kerala, India, but was not used because the outbreak was brought under control quickly (Spiropoulou 2018). One recent study in nonhuman primates showed that the therapeutic window for m102.4 may vary by virus strain, which is a consideration for further preclinical and clinical study of this agent (Mire 2016).

Commented [DTM4]: Given the limited availability of m102.4, it may also be worthwhile to explore development of alternate monoclonal antibodies against NiV, and to evaluate approaches like cocktails of monoclonal antibodies, purified convalescent human sera, egg yolk-derived immunoglobulins etc. for Immunoprophylaxis against it in humans and/or animals.

Other potential options for NiV treatment include favipiravir (a small-molecule antiviral that inhibits RNA-dependent RNA polymerase), fusion inhibitory peptides (peptides that inhibit virus-mediated membrane fusion), and remdesivir (also known as GS-5734, which is a monophosphoramidate prodrug of an adenosine analogue). Researchers recently demonstrated efficacy of favipiravir in hamsters challenged with a lethal dose of NiV (Dawes 2018), supporting proof-of-concept for favipiravir as a possible therapy against NiV infection. Studies in animal models also have been conducted for fusion inhibitory peptides; for example, investigators recently reported that lipopeptides delivered via the respiratory route can prevent lethal NiV infection in hamsters and nonhuman primates (Mathieu 2018). Remdesivir is a small-molecule antiviral that is currently being evaluated in clinical studies as a therapeutic option for treating Ebola virus disease. Investigators recently demonstrated in vitro inhibition by remdesivir against a number of different viruses, including paramyxoviruses (Lo 2017). While these agents are promising, further preclinical data are needed to assess their utility. In addition, efforts are needed to expand the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents that may be more aligned with optimal and desired characteristics for anti-NiV therapy.

Key additional considerations for moving NiV therapeutics forward include: (1) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising novel treatments for NiV disease; (2) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (3) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in both endemic and at-risk areas. To address these issues,

the goals and milestones for therapeutics in the NiV R&D roadmap focus on continuing to move promising agents forward into clinical trials and on enhancing preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Satterfield 2016). A Hendra virus subunit vaccine involving soluble glycoprotein (sG) has been developed and is commercially available for use in horses (Middleton 2014), which supports this option as a promising approach for developing a human NiV vaccine.

The Coalition for Epidemic Preparedness Innovations (CEPI), which is a partnership of government agencies, industry, academia, philanthropy, and intergovernmental institutions aimed at providing funding for R&D of new vaccines against pathogens with epidemic potential, has recently provided financial support to promote the development of several NiV candidate vaccines. In May 2018, CEPI awarded a US$ 25 million contract to Profectus BioSciences, Inc. and Emergent BioSolutions Inc. to develop an NiV vaccine that is based on the same technology

as that used for the Hendra virus vaccine (CEPI 2018). In September 2018, CEPI announced plans to award approximately US$ 2 million to the Jenner Institute at the University of Oxford and Janssen Vaccines & Prevention BV for preclinical development of a replication-deficient simian adenoviral-vectored vaccine, derived from an adenovirus originally isolated from chimpanzees (CEPI 2018). These efforts will support preclinical and early clinical development of NiV vaccines.

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012,

Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research in this area should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

The immediate goals and milestones in the vaccine section of the NiV R&D roadmap focus on moving vaccine candidates forward into clinical trials and promoting development of guidance on requirements for clinical trials, regulatory pathways, and other considerations relevant to licensure of a vaccine against NiV.

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures forward. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Tables

Table 1: Goals and Milestones for NiV Infection Cross-Cutting Issues

Goals and Milestones for NiV Infection Cross-Cutting Issues **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
	2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
2. Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
	2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Table 2: Goals and Milestones for NiV Diagnostics

Goals and Milestones for NiV Diagnostics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).
	2. By 2021, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.
2. Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are	1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.
	2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
	3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.	4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
3. Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.	1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to ~~diagnos~~diagnose~~is~~ NiV infection during future outbreaks.

Table 3: Goals and Milestones for NiV Therapeutics

Goals and Milestones for NiV Therapeutics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	4. By 2020, generate a reliable source of m102.4 to be used in clinical trials.
2. Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.	1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
	2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
	3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Table 4: Goals and Milestones for NiV Vaccines

Goals and Milestones for NiV Vaccines
Nipah Virus Roadmap

STRATEGIC GOALS	MILESTONES
1. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.	1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
	2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.
2. Develop and evaluate NiV vaccines for prevention of NiV disease in humans.	1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
	2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
	3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

The work for this project was completed with generous support from the Wellcome Trust.

The authors would also like to acknowledge Mr. Carlos R. Cruz; CIDRAP, University of Minnesota; Minneapolis, Minnesota, USA, for project management related to the WHO R&D Roadmaps project.

Word Count: 3,695 (text only, not including References or Tables)

Introduction

Nipah virus (NiV), a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chua 1999, Chew 2000, Parashar 2000). At least 265 human cases of encephalitis were identified in Malaysia and most had close contact with pigs (Chua 2010, Parashar 2000). In addition, 11 abattoir workers in Singapore became ill following contact with pigs imported from Malaysia; eight patients presented with signs of encephalitis and three presented with atypical pneumonia (one of which later also had evidence of encephalitis) (Paton 1999). No new outbreaks have been reported in these countries since May 1999; however, NiV infection was subsequently recognized in Bangladesh in 2001 (Hsu 2004) and nearly annual outbreaks have occurred in that country since then (WHO 2018). Outbreaks also have been recognized in eastern India and, in 2018, an outbreak occurred in the southern Indian state of Kerala (Arunkumar 2018, Sharma 2018, Chattu 2018). To date, nearly 350 cases of NiV infection have been identified in Bangladesh and India (WHO 2018). Possible emergence of NiV in a third geographic area is evidenced by an outbreak of an unidentified henipavirus that occurred among horses and humans in the Philippines in 2014 (Ching 2015). Although detailed genomic information for the virus is limited, experts agree that the causative agent was either NiV or a virus closely related to NiV. The Henipavirus genus includes another pathogen, Hendra virus, which predominantly causes infection in horses in Australia and can also lead to human disease, usually following contact with infected horses (Ksiazek 2011).

The most common clinical syndrome associated with NiV infection is severe, rapidly progressive encephalitis (Goh 2000, Hossain 2008). The main presenting features include fever, headache, dizziness, vomiting, and altered mental status. NiV infection may result in late-onset

encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Tan 2002, Goh 2000). Some patients also have respiratory involvement or respiratory illness alone, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The overall case-fatality rate for the Malaysia outbreak was approximately 40%, whereas case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 65% to 100% (Hossain 2008, WHO 2018). Genomic sequencing has demonstrated that there are multiple strains of NiV, which may account for the differences noted in clinical features and outcomes between Malaysia and Bangladesh (Mire 2016).

Fruit bats of the Pteropus genus are considered the primary natural reservoir for NiV. In the Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and possibly limited human-to-human NiV transmission (Chua 2010). Additionally, several other domestic animal species in the outbreak area (including horses, cats, and dogs) were found to be infected with NiV (Chua 2000). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap (Islam 2016, Luby 2006, Rahman 2012) and subsequent person-to-person transmission. While person-to-person transmission was apparently minimal in the Malaysia outbreak, it has played a larger role in amplifying outbreaks in Bangladesh and India (Gurley 2007, Luby 2009, Chadha 2006, Arunkumar 2018). This may, in part, be related to the greater propensity toward respiratory disease in NiV strains found in South Asia and transmission via droplet spread (Spiropoulou 2018). The potential for droplet spread is supported by a recent study that demonstrated hamsters could be infected when exposed to NiV via a small-particle aerosol (Escaffre 2018). Given the potential for respiratory transmission of NiV and the recent experience with Ebola in West

Africa, some have raised concerns about the possibility of larger NiV outbreaks if the virus takes hold in a crowded or urban area (Donaldson 2018) or about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Pteropus fruit bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Other fruit bats of the Pteropodidae family also may harbor NiV, and such bats can be found across Africa and parts of the Middle East. Evidence of NiV infection (via virus isolation, serologic testing, or nucleic acid detection using real-time polymerase chain reaction [RT-PCR]) has been found in Pteropus bat species and other bat species in geographically diverse regions, including South Asia (Bangladesh and India); Southeast Asia (Cambodia, Indonesia, Malaysia, the Philippines, Thailand, and Vietnam); the Western Pacific region (Papua New Guinea); and Africa (Madagascar and Ghana) (Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2018, Yob 2001). This wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

WHO has determined that Nipah virus is a priority disease for epidemic preparedness (WHO 2018). To improve epidemic response for this infection, in the fall of 2017, WHO embarked on development of a research and development (R&D) roadmap for NiV disease; this report provides a summary of the key elements of that roadmap, including important challenges and barriers that need to be addressed to ensure that diagnostics, therapeutics, and vaccines are

developed, manufactured, and readily available when needed *[provide link to full roadmap here when available]*.

The NiV R&D roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one medical countermeasure category), diagnostics, therapeutics, and vaccines. The strategic goals and milestones identified in each section are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, the roadmap milestones will be tracked over time, with periodic assessment of progress and updates to the roadmap as needed. The roadmap is specific to R&D for disease in humans; however, further research of NiV in animal species, including development of appropriate medical countermeasures targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV in humans and virus transmission can occur at the human-animal interface.

Cross-Cutting Issues

A major challenge for development of diagnostics, therapeutics, and vaccines for NiV is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Advocacy to policy makers in affected countries and to global stakeholders is needed to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures. As part of this process, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species and proximate

human populations in areas of predicted risk. Human health, animal health, and wildlife officials should be engaged in these efforts as part of a long-term collaborative One Health approach (Chattu 2018, Kulkarni 2013).

Another important issue is the need to optimize relevant animal challenge models for promoting development and evaluation of medical countermeasures for NiV infection, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval (Rockx 2014). For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for therapeutic or vaccine development; (3) determine when after challenge medical countermeasures should be administered in animal models to best mimic realistic timing of such use in humans; (4) bridge data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human doses; and (5) identify the best models for studying chronic (relapsing) infection (Bossart 2012, Debuysscher 2013, Dhondt 2013, Johnston 2015, Mathieu 2015, Satterfield 2016). Currently, the African green monkey is regarded as the most relevant animal model for evaluating candidate therapeutics and vaccines intended for use in humans (Geisbert 2010, Johnston 2015), and studies involving nonhuman primates may be required for licensure of therapeutics and vaccines via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns, however, constrain the use of this animal model. In addition to optimizing animal models, standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains are needed to move R&D of medical countermeasures for NiV infection forward (Satterfield 2016).

To inform development of optimal NiV medical countermeasures, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. This includes issues such as evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection.

To respond to these challenges, the strategic goals and milestones for cross-cutting issues in the NiV R&D roadmap focus primarily on developing a sustainable value proposition and identifying funding sources to promote R&D, availability, and accessibility of NiV medical countermeasures, optimizing animal models for research, and generating standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV medical countermeasures (Table 1).

Diagnostics

The most commonly used methods for diagnosing NiV infection include virus isolation, enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies, and real time-polymerase chain reaction (RT-PCR) nucleic acid testing. Virus isolation requires biosafety level 4 (BSL-4) capabilities and is generally only performed in reference laboratories for specific purposes, such as to confirm a new outbreak or to identify the virus in new host species (Wang 2012). During the Malaysia outbreak, the US Centers for Disease Control and Prevention (CDC) developed a capture ELISA for detection of IgM antibodies and an indirect ELISA for detection of IgG antibodies (Daniels 2001); since then, additional ELISA tests have been developed (Wang 2012) and serologic testing is often used for

case confirmation during outbreaks (Chadha 2006, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009). RT-PCR, which can be performed on throat and nasal swabs, cerebrospinal fluid, urine, and blood, is also often used for diagnostic testing (Chadha 2006, Guillaume 2004, Lo 2012). Quantitative RT-PCR tests have been developed for quantifying viral replication; such tools can be used to measure viral load reduction when screening vaccine candidates and potential therapeutics (Jensen 2018). More recently, pseudotyped-based serum neutralization assays for NiV detection that use vesicular stomatitis virus systems have been developed; these assays potentially can be used under BSL2 conditions in laboratories with limited diagnostic capabilities and appear to offer improved sensitivity and specificity (Kaku 2009, Kaku 2012, Tamin 2009). Antigen-capture ELISAs using monoclonal antibodies also have been developed, which could result in more rapid diagnosis (Chiang 2010). These newer technologies hold promise; however, more information is needed regarding their performance characteristics, particularly under field conditions.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation, which can delay outbreak detection and implementation of infection control measures. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. To address these issues, rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes, once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of such a repository requires addressing the following: (1) determining what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outlining the purposes of sample collection; (3) determining what organizations will be responsible for activities related to creating and maintaining the repositories; (4) establishing standardized protocols for sample collection and maintenance; (5) establishing an appropriate governance structure; (6) identifying who would have access to the samples; (7) prioritizing use of samples and sample distribution; and (8) ensuring that material transfer agreements are in place. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

To address these issues, the strategic goals and milestones for diagnostic testing outlined in the NiV R&D roadmap focus on creation of a virtual reference repository, development of highly sensitive and specific point-of-care or near-patient NiV diagnostic tests, and enhancement of laboratory diagnostic preparedness to promote early detection of NiV in areas of known or potential spillover risk (Table 2).

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients; findings from treated patients were compared to those of 54 historical controls who became ill before ribavirin was available or who refused treatment (Chong 2001).

Results demonstrated a statistically significant reduction in mortality among treated patients (36%); however, the use of historical controls may have biased this finding. No additional clinical studies using ribavirin have been conducted, and limited studies in animal models have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Rockx 2010, Georges-Courbot 2006). Chloroquine also has been studied in animal models, but has not shown any therapeutic benefit, either alone or in combination with ribavirin (Freiberg 2010, Pallister 2009). Based on these findings, these approaches are not considered viable options for treatment of NiV infection.

A more promising therapeutic option is the development of monoclonal antibodies (mAbs) against viral envelop proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). Therapy with anti-NiV mAbs may be appropriate for early treatment and for post-exposure prophylaxis (PEP) to prevent illness in exposed persons, such as healthcare workers, family caregivers, and persons exposed to infected livestock. Researchers have demonstrated that the human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009), and it has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Recently, a phase 1 clinical trial of m102.4 with 40 human participants was completed in Australia, but results are not yet available (ANZCTR). M102.4 was deployed for use during the 2018 NiV outbreak in Kerala, India, but was not used because the outbreak was brought under control quickly (Spiropoulou 2018). One recent study in nonhuman primates showed that the therapeutic window for m102.4 may vary by virus strain, which is a consideration for further preclinical and clinical study of this agent (Mire 2016).

Other potential options for NiV treatment include favipiravir (a small-molecule antiviral that inhibits RNA-dependent RNA polymerase), fusion inhibitory peptides (peptides that inhibit virus-mediated membrane fusion), and remdesivir (also known as GS-5734, which is a monophosphoramidate prodrug of an adenosine analogue). Researchers recently demonstrated efficacy of favipiravir in hamsters challenged with a lethal dose of NiV (Dawes 2018), supporting proof-of-concept for favipiravir as a possible therapy against NiV infection. Studies in animal models also have been conducted for fusion inhibitory peptides; for example, investigators recently reported that lipopeptides delivered via the respiratory route can prevent lethal NiV infection in hamsters and nonhuman primates (Mathieu 2018). Remdesivir is a small-molecule antiviral that is currently being evaluated in clinical studies as a therapeutic option for treating Ebola virus disease. Investigators recently demonstrated in vitro inhibition by remdesivir against a number of different viruses, including paramyxoviruses (Lo 2017). While these agents are promising, further preclinical data are needed to assess their utility. In addition, efforts are needed to expand the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents that may be more aligned with optimal and desired characteristics for anti-NiV therapy.

Key additional considerations for moving NiV therapeutics forward include: (1) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising novel treatments for NiV disease; (2) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (3) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in both endemic and at-risk areas. To address these issues,

the goals and milestones for therapeutics in the NiV R&D roadmap focus on continuing to move promising agents forward into clinical trials and on enhancing preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Satterfield 2016). A Hendra virus subunit vaccine involving soluble glycoprotein (sG) has been developed and is commercially available for use in horses (Middleton 2014), which supports this option as a promising approach for developing a human NiV vaccine.

The Coalition for Epidemic Preparedness Innovations (CEPI), which is a partnership of government agencies, industry, academia, philanthropy, and intergovernmental institutions aimed at providing funding for R&D of new vaccines against pathogens with epidemic potential, has recently provided financial support to promote the development of several NiV candidate vaccines. In May 2018, CEPI awarded a US$ 25 million contract to Profectus BioSciences, Inc. and Emergent BioSolutions Inc. to develop an NiV vaccine that is based on the same technology

as that used for the Hendra virus vaccine (CEPI 2018). In September 2018, CEPI announced plans to award approximately US$ 2 million to the Jenner Institute at the University of Oxford and Janssen Vaccines & Prevention BV for preclinical development of a replication-deficient simian adenoviral-vectored vaccine, derived from an adenovirus originally isolated from chimpanzees (CEPI 2018). These efforts will support preclinical and early clinical development of NiV vaccines.

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012,

Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research in this area should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

The immediate goals and milestones in the vaccine section of the NiV R&D roadmap focus on moving vaccine candidates forward into clinical trials and promoting development of guidance on requirements for clinical trials, regulatory pathways, and other considerations relevant to licensure of a vaccine against NiV.

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures forward. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Tables

Table 1: Goals and Milestones for NiV Infection Cross-Cutting Issues

Goals and Milestones for NiV Infection Cross-Cutting Issues **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
	2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
2. Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
	2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Table 2: Goals and Milestones for NiV Diagnostics

Goals and Milestones for NiV Diagnostics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).
	2. By 2021, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.
2. Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are	1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.
	2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
	3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.	4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
3. Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.	1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks.

Table 3: Goals and Milestones for NiV Therapeutics

Goals and Milestones for NiV Therapeutics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	4. By 2020, generate a reliable source of m102.4 to be used in clinical trials.
2. Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.	1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
	2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
	3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Table 4: Goals and Milestones for NiV Vaccines

Goals and Milestones for NiV Vaccines

Nipah Virus Roadmap

STRATEGIC GOALS	MILESTONES
1. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.	1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
	2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.
2. Develop and evaluate NiV vaccines for prevention of NiV disease in humans.	1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
	2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
	3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 5-year framework for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999. As part of that outbreak, 265 human cases were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiV infection was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since. NiV infection has also been identified periodically in eastern India and, in 2018, was identified for the first time in southern India. Case-fatality rates during outbreaks in Bangladesh and India have ranged from 75% to 100%. Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in the known natural reservoir (*Pteropus* species and several other bat species) in a number of other countries, including Cambodia, Thailand, Indonesia, Madagascar, Ghana, and the Philippines. In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, several other domestic animal species (including horses, cats, and dogs) were found to be infected with NiV on the farms involved in the outbreak. In the outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission.

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock, which can serve as a source of exposure to humans. NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia. To date, confirmed HeV disease has been confined to Australia. An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014. This outbreak likely involved spillover of NiV into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for NiV-infected patients. Detailed genomic information for this virus is limited.

NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae. Genomic sequencing has demonstrated that there are multiple strains of NiV. For example, the strain responsible for the outbreak in Malaysia is different from those identified in Bangladesh and India. Some differences have been noted in the clinical features of infection, with different strains in humans and experimentally infected non-human primates.

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiV infection is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) The strategic goals and milestones identified in the roadmap are focused on key achievements for the next 5 years; the roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of the R&D roadmap but need to be addressed as part of a broader public health control strategy. Further research of NiV in animal species, including development of appropriate MCMs targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV (or related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Robust MCMs to detect, prevent, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Securing funding for Nipah research represents a substantial challenge, since economic incentives to invest in Nipah research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks. The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand. In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions, which can increase the cost of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV; such bats can be found across Africa and parts of the Middle East. This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- While ferrets, Syrian hamsters, and interferon-alpha/beta receptor knockout (IFNAR-KO) mice are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans. Additionally, studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns constrain the use of AGMs.
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major

challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Key needs

- Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs.
- Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control.
- Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures.
- Obtaining additional prospective serosurveillance data of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk should be explored as a strategy to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure.
- Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection. Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
- Clear criteria for downselection and prioritization of candidate MCMs to move forward into clinical trials versus those that need additional preclinical research. Such criteria should align with desired characteristics outlined in the target product profiles (TPPs) and should address aspects of sustainable MCM production, stockpiling, and access.
- Early and recurrent communications between product developers and the appropriate national regulatory authorities (NRAs) or other regulatory agencies to obtain clarity and guidance on clinical trial requirements, regulatory pathways and requirements, and other considerations for NiV MCMs during the pre-licensure and post-licensure periods. Regulatory pathways and NRA capabilities will vary between countries; therefore, early engagement, potentially with support from WHO, is essential to identify country-specific considerations.
- Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection.

- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.

Knowledge gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas. Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species.
- Additional research is needed to optimize relevant animal challenge models (e.g., ferret, Syrian hamster, IFNAR-KO mouse, and AGM models) for promoting development and evaluation of MCMs, particularly if investigators are required to use an alternative pathway (such as the United States Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval. For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development; (3) determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans; (4) bridge NiV MCM data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human MCM doses; and (5) identify the best models for studying chronic (relapsing) infection.
- Additional information is needed on the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs. This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurologic sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection. In addition, identifying aspects of the immune response that are absent or counter-effective during human NiV infection may lead to the development of novel targeted intervention strategies.
- Ongoing phylogenetic and evolutionary analyses of NiV strains are needed to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development.

- Further research is needed to better understand viruses in the Henipavirus genus, including their reservoir hosts and pathogenicity.
- Additional studies applying whole-genome sequencing of NiV are needed to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses.
- Sociological and anthropological research is needed to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to estimate the relative risk and potential for global spread of NiV outbreaks.

Milestones:

1. By 2021, develop a plan for enhancing NiV surveillance, including securing funding, identifying surveillance catchment areas, engaging key partners in those areas, generating a standardized protocol, and conducting training for implementation.
2. By 2022, initiate enhanced NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), enhance case detection, and better define the disease burden in different geographic areas.

Strategic Goal 3: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.

2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and that may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Priority Areas/Activities

Research

- **Expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach.
- **Continue to perform** phylogenetic and evolutionary analyses of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Refine and optimize** relevant animal models to support the development and evaluation of NiV MCMs, particularly as needed for licensure, if alternative regulatory pathways are considered.
- **Generate** research tools to promote R&D of MCMs for NiV infection (e.g., standardized and validated assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains), particularly those that can be used at lower biosafety levels.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Define** criteria for downselection and prioritization of candidate MCMs that should be moved forward.
- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** a shared data platform to facilitate sharing of NiV sequence and strain data.

- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Establish** a sustainable value proposition and **secure** funding to complete development, licensure, manufacture, deployment, and use of affordable MCMs for NiV infection.
- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas.
- **Ensure** access to regulatory guidance, oversight, review, and authorization from appropriate NRAs for NiV MCMs. This should be done when clinical trials and approaches for regulatory approval are being determined.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an “affordable and fair” price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Initial signs and symptoms of NiV infection are nonspecific, and the diagnosis often is not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent disease can occur months to years after initial infection, which can complicate epidemiologic investigation.
- Laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited, and investigation into the cause of infection is not always pursued; these issues can lead to delays in diagnosis and outbreak investigation and response.
- Clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory can affect the accuracy of laboratory results.
- Various types of test methods and platforms are required to test patients at different phases of NiV infection, which can complicate diagnostic needs and capabilities.

- Owing to the biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis.
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the rapid disease progression of NiV infection.
- *Pteropus* species (and perhaps other bat species) appear to carry other henipaviruses in addition to NiV and HeV, some of which may prove to be pathogenic in humans and livestock. Antibodies to different henipaviruses are highly cross-reactive, making it difficult to discriminate using serologic assays which henipaviruses are in circulation. Capacity to identify additional pathogenic henipaviruses is an important challenge for ensuring diagnostic preparedness to respond to future outbreaks.

Key needs

- Clarification regarding the use cases for different diagnostic assays, since the corresponding performance, validation, and regulatory approval requirements may differ depending on how the tests will be used. For example, it may be desirable to have a point-of-care screening test that is highly sensitive and a confirmatory test that is highly specific.
- A TPP for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics to guide the development of promising diagnostic assays.
- A virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests. As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
- Rapid point-of-care or near-patient diagnostic tests for NiV that involve minimal requirements for laboratory infrastructure, can detect disease early in the clinical course, are robust for use under a variety of conditions (e.g., varying humidity, temperature), and have a high sensitivity and specificity for different NiV strains, as needed, depending on the use cases for each test. Rapid diagnostic capability is needed for early case detection to promote outbreak detection, ensure early implementation of infection control measures, and ultimately to improve patient outcomes, once therapeutic options are available.
- International reference standards to calibrate diagnostic assays.
- Validation of promising diagnostics in endemic and at-risk geographic regions.
- Diagnostic criteria and standardized testing for including patients in clinical trials of therapeutics.

- Improved diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise.
- Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection.
- In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
- A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for Nipah diagnostics, particularly given the costs of regulatory approval.

Knowledge gaps

- Further research is needed on the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease.
- More information is needed regarding the performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as pseudotype neutralization assays and antigen-capture enzyme-linked immunosorbent assays [ELISAs]) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries: Bangladesh and India.

2. By 2021, identify funding and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks and possibly as part of future clinical trials.

Strategic Goal 2: Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.

2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.

Milestones:

1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnose NiV infection during future outbreaks.

Priority Areas/Activities

Research

- **Create** a virtual repository of clinical reference samples for use in researching new diagnostic agents.
- **Explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** performance characteristics for promising new assays for diagnosis of NiV infection and **develop** appropriate standards for their use in different contexts.
- **Conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection.

Product development

- **Generate** a TPP for NiV diagnostics that defines the use cases and addresses the optimal and preferred performance characteristics for different use cases.
- **Develop and evaluate** point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in remote areas under a variety of circumstances.

Key capacities

- **Generate** international reference standards to calibrate diagnostic assays.
- **Develop** national laboratory strategies for NiV diagnosis and detection in the primary NiV-affected countries.
- **Support** in-country laboratories in monitoring performance of NiV diagnostics in the field.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV therapeutics.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons.
- In NiV-endemic areas, hundreds of patients are admitted to hospitals annually with a diagnosis of encephalitis but do not have NiV infection. Treating all patients with encephalitis and their contacts for NiV infection would be costly and labor intensive, with relatively little benefit; therefore, accurate and rapid diagnosis is critical.
- Studies in animals often evaluate the usefulness of therapeutics when delivered prior to disease onset or early during the disease course. Patients with NiV infection often are detected later in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in endemic countries often do not have adequate infection control– programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.

Key needs

- Protocols for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas, particularly during future outbreaks.
- Safe, easily administered, well-tolerated, and effective therapeutic agents that treat acute NiV infection to improve survival and decrease associated morbidity and long-term disability.
- Safe and effective PEP to prevent infection following exposure to NiV and guidance on PEP use. PEP could be used to prevent illness in healthcare workers, family caregivers, and persons exposed to infected livestock.
- Improved patient care in endemic areas (such as the ability to provide ventilator support for seriously ill patients).

Knowledge gaps

- The human monoclonal antibody (mAb) m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV. Recently, a phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia. Additional animal studies using different NiV strains and clinical trials in endemic areas are needed to further assess the safety, tolerability, and efficacy of m102.4 (and possibly other mAbs) for PEP and potentially early treatment of clinical disease.
- Additional research is needed regarding the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with mAb 102.4, it may be necessary to consider mAb cocktails.
- Preclinical and clinical data are needed on the safety, tolerability, and efficacy of the most promising novel treatments (such as fusion inhibitory peptides, antifusion peptides, favipiravir [an RNA-dependent RNA polymerase inhibitor], and GS-5734 [a broad-spectrum agent being used to treat Ebola virus disease survivors]), used alone or in combination with other therapies. Additionally, the therapeutic windows of each therapy should be determined for different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia.
- Further research is needed to broaden the number of novel antiviral candidates for treatment of NiV infection and strengthen the therapeutic pipeline.
- Additional data are needed to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
- Additional data are needed to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP distribution in both endemic and at-risk areas, including Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
- Additional information is needed regarding whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
- Patients may benefit from optimal supportive care independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.

2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
4. By 2020, generate a reliable source of m102.4 to be used in clinical trials.

Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.
3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for the treatment of NiV infection.

Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4 and favipiravir) for treating and preventing NiV infection, including conducting studies in animal models and clinical trials as appropriate and feasible.
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection.

- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Generate** a reliable source of m102.4 to be used in clinical trials.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Primary Challenges, Key Needs, and Knowledge Gaps

Primary challenges

- Currently, there is no candidate vaccine that is in late-stage development, and few companies are willing to invest in the generation of new NiV vaccines.
- Sociocultural issues may hinder trust in the formal human and veterinary clinical and public health systems, which could diminish the acceptance of NiV vaccine use.
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge in implementing a rapid reactive vaccination strategy for NiV outbreak control.

Key needs

- Nipah vaccines that: (1) are readily accessible with adequate supply chains, (2) can protect against different NiV strains, and (3) provide rapid onset of an immune response to adequately prevent and control outbreaks.
- Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
- Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

Knowledge gaps

- Additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV. Since neutralizing antibodies are likely the primary mediator of protection against NiV infection, research in this area should focus primarily on the humoral immune response for driving vaccine development.
- Further research is needed to clarify vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
- Further research is needed to determine the cross-protection efficacy for NiV of the HeV-sG subunit vaccine (i.e., the recombinant subunit vaccine Equivac HeV from Zoetis).

- Additional research is needed in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- The identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed to facilitate research on promising NiV vaccine candidates, and expedite possible licensing through nontraditional regulatory pathways, such as the US FDA’s Animal Rule and accelerated approval mechanisms. These specific correlates may vary by vaccine platform and antigen, and therefore multiple assays may need to be standardized.
- Pre-licensure evaluation of vaccine safety is needed to better understand the risk of adverse incidents associated with vaccine use. While phase 1 and phase 2 trials can be performed in non-affected countries, safety trials will also be needed involving target populations in endemic regions.
- Further epidemiologic research is needed to better define at-risk populations and identify additional areas of potential NiV spillover.
- Additional sociological research is needed to explore perceptions and concerns of at-risk populations regarding NiV vaccine implementation.
- If evidence at some point supports the need for a broader, population-based vaccination strategy (beyond reactive use for outbreak control in affected communities), additional research may be warranted on the development of multivalent vaccines that protect against more than one infection (such as a combined vaccine against NiV and HeV or NiV and measles virus) for use in NiV endemic areas.
- Mathematical modelling and forecasting may be useful in: (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure of a vaccine against NiV.

Milestones:

1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the need for licensure and future use of NiV vaccines. This consultation should include representatives from in-country regulators, other regulatory

agencies (such as the FDA or the European Medicines Agency), national and international public health agencies and organizations, and local and international researchers.

Strategic Goal 2: Develop and evaluate NiV vaccines for prevention of NiV disease in humans.

Milestones:

1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

Priority Areas/Activities

Research

- **Improve understanding** of the humoral immune response to infection to inform development and evaluation of NiV vaccines.
- **Identify and standardize** correlates and/or surrogates of protection, which are necessary for ongoing research into candidate vaccines and also may be important for vaccine licensure.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Complete** preclinical evaluation of promising candidate NiV vaccines for safety, immunogenicity, efficacy in animal models (such as through serum transfer studies), correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Perform** clinical trials to assess safety and immunogenicity in phase 1 and 2 trials, and undertake animal studies for immune bridging to facilitate regulatory licensing.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** possible strategies for conducting clinical vaccine efficacy trials in affected areas that are ethical, interpretable, and feasible or identify alternative approaches for assessing efficacy of new NiV vaccines and therapeutics, in coordination with the appropriate NRAs.
- **Establish** a plan for conducting phase 3 clinical trials in endemic regions in coordination with local government agencies, if clinical trials are considered to be a feasible option for efficacy assessment.

- **Evaluate** the feasibility of generating multivalent vaccines (i.e., that protect against more than one disease) and determine whether or not such vaccines would be useful in future NiV control efforts.

Product development

- **Develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Prepare** clinical trial sites and NRAs in affected countries for future clinical trials with NiV vaccines, if clinical trials are considered feasible.
- **Identify and address** issues with licensure and use of NiV vaccines in affected areas through a coordinated process involving key stakeholders, including in-country NRAs and public health authorities.
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Kristine Moore, MD, MPH

Medical Director

Dear Prof. Moore:

Sorry for responding late. I had been traveling therefore could not send my comments.

I have gone through the manuscript on the roadmap for R & D on Nipah. It is well-written and provides a comprehensive coverage of the topic. I have a few suggestions, indicated in-line in the attached manuscript.

With best regards,

D T Mourya

Version 1.2

Word Count: 3,695 (text only, not including References or Tables)

Introduction

Nipah virus (NiV), a paramyxovirus of the Henipavirus genus, was first identified after an outbreak of respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998-1999 (Chua 1999, Chew 2000, Parashar 2000). At least 265 human cases of encephalitis were identified in Malaysia and most had close contact with pigs (Chua 2010, Parashar 2000). In addition, 11 abattoir workers in Singapore became ill following contact with pigs imported from Malaysia; eight patients presented with signs of encephalitis and three presented with atypical pneumonia (one of which later also had evidence of encephalitis) (Paton 1999). No new outbreaks have been reported in these countries since May 1999; however, NiV infection was subsequently recognized in Bangladesh in 2001 (Hsu 2004) and nearly annual outbreaks have occurred in that country since then (WHO 2018). Outbreaks also have been recognized in eastern India and, in 2018, an outbreak occurred in the southern Indian state of Kerala (Arunkumar 2018, Sharma 2018, Chattu 2018). To date, nearly 350 cases of NiV infection have been identified in Bangladesh and India (WHO 2018). Possible emergence of NiV in a third geographic area is evidenced by an outbreak of an unidentified henipavirus that occurred among horses and humans in the Philippines in 2014 (Ching 2015). Although detailed genomic information for the virus is limited, experts agree that the causative agent was either NiV or a virus closely related to NiV. The Henipavirus genus includes another pathogen, Hendra virus, which predominantly causes infection in horses in Australia and can also lead to human disease, usually following contact with infected horses (Ksiazek 2011).

The most common clinical syndrome associated with NiV infection is severe, rapidly progressive encephalitis (Goh 2000, Hossain 2008). The main presenting features include fever, headache, dizziness, vomiting, and altered mental status. NiV infection may result in late-onset

encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Tan 2002, Goh 2000). Some patients also have respiratory involvement or respiratory illness alone, which can progress to acute respiratory distress syndrome (Hossain 2008, Paton 1999). The overall case-fatality rate for the Malaysia outbreak was approximately 40%, whereas case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 65% to 100% (Hossain 2008, WHO 2018). Genomic sequencing has demonstrated that there are multiple strains of NiV, which may account for the differences noted in clinical features and outcomes between Malaysia and Bangladesh (Mire 2016).

Fruit bats of the Pteropus genus are considered the primary natural reservoir for NiV. In the Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and possibly limited human-to-human NiV transmission (Chua 2010). Additionally, several other domestic animal species in the outbreak area (including horses, cats, and dogs) were found to be infected with NiV (Chua 2000). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap (Islam 2016, Luby 2006, Rahman 2012) and subsequent person-to-person transmission. While person-to-person transmission was apparently minimal in the Malaysia outbreak, it has played a larger role in amplifying outbreaks in Bangladesh and India (Gurley 2007, Luby 2009, Chadha 2006, Arunkumar 2018). This may, in part, be related to the greater propensity toward respiratory disease in NiV strains found in South Asia and transmission via droplet spread (Spiropoulou 2018). The potential for droplet spread is supported by a recent study that demonstrated hamsters could be infected when exposed to NiV via a small-particle aerosol (Escaffre 2018). Given the potential for respiratory transmission of NiV and the recent experience with Ebola in West

Africa, some have raised concerns about the possibility of larger NiV outbreaks if the virus takes hold in a crowded or urban area (Donaldson 2018) or about the pandemic potential of NiV if a more human-adapted strain emerges (Luby 2013).

Pteropus fruit bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar. Other fruit bats of the Pteropodidae family also may harbor NiV, and such bats can be found across Africa and parts of the Middle East. Evidence of NiV infection (via virus isolation, serologic testing, or nucleic acid detection using real-time polymerase chain reaction [RT-PCR]) has been found in Pteropus bat species and other bat species in geographically diverse regions, including South Asia (Bangladesh and India); Southeast Asia (Cambodia, Indonesia, Malaysia, the Philippines, Thailand, and Vietnam); the Western Pacific region (Papua New Guinea); and Africa (Madagascar and Ghana) (Breed 2010, Epstein 2008, Hasebe 2012, Hayman 2008, Homaira 2010, Iehlé 2007, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, WHO 2018, Yob 2001). This wide potential range of the NiV natural reservoir raises concerns about the eventual occurrence of outbreaks in new geographic areas (Deka 2018, Donaldson 2018), which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

WHO has determined that Nipah virus is a priority disease for epidemic preparedness (WHO 2018). To improve epidemic response for this infection, in the fall of 2017, WHO embarked on development of a research and development (R&D) roadmap for NiV disease; this report provides a summary of the key elements of that roadmap, including important challenges and barriers that need to be addressed to ensure that diagnostics, therapeutics, and vaccines are

developed, manufactured, and readily available when needed *[provide link to full roadmap here when available]*.

The NiV R&D roadmap is organized into four main sections: cross-cutting issues (for areas that apply to more than one medical countermeasure category), diagnostics, therapeutics, and vaccines. The strategic goals and milestones identified in each section are focused on key achievements for the next 5 years; ~~the roadmap milestones will be tracked over time,~~ the roadmap milestones will be tracked over time, with periodic assessment of progress and updates to the roadmap as needed. The roadmap is specific to R&D for disease in humans; however, further research of NiV in animal species, including development of appropriate medical countermeasures targeted to animal populations, also is needed, since disease in animals may amplify occurrence of NiV in humans and virus transmission can occur at the human-animal interface.

Cross-Cutting Issues

A major challenge for development of diagnostics, therapeutics, and vaccines for NiV is accessing adequate funding to support research. Economic incentives to invest in such research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with only small, sporadic outbreaks. Advocacy to policy makers in affected countries and to global stakeholders is needed to ensure they understand the potential health, societal, and economic benefits of devoting limited resources to improving NiV surveillance, detection, prevention, and control measures. As part of this process, the risk profile for NiV and related henipaviruses needs to be further defined through improving disease surveillance in areas of known risk and obtaining prospective serosurveillance data on henipavirus exposure for susceptible animal species and proximate

human populations in areas of predicted risk. Human health, animal health, and wildlife officials should be engaged in these efforts as part of a long-term collaborative One Health approach (Chattu 2018, Kulkarni 2013).

Another important issue is the need to optimize relevant animal challenge models for promoting development and evaluation of medical countermeasures for NiV infection, particularly if investigators are required to use an alternative pathway (such as the US Food and Drug Administration's [FDA's] Animal Rule) to obtain regulatory approval (Rockx 2014). For example, efforts are needed to: (1) determine the appropriate animal model(s) for screening assay development; (2) standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for therapeutic or vaccine development; (3) determine when after challenge medical countermeasures should be administered in animal models to best mimic realistic timing of such use in humans; (4) bridge data from animal models to humans, such as identifying thresholds of vaccine protection to determine appropriate human doses; and (5) identify the best models for studying chronic (relapsing) infection (Bossart 2012, Debuysscher 2013, Dhondt 2013, Johnston 2015, Mathieu 2015, Satterfield 2016). Currently, the African green monkey is regarded as the most relevant animal model for evaluating candidate therapeutics and vaccines intended for use in humans (Geisbert 2010, Johnston 2015), and studies involving nonhuman primates may be required for licensure of therapeutics and vaccines via alternative regulatory pathways. Costs, space requirements (particularly in BSL-4 containment facilities), and ethical concerns, however, constrain the use of this animal model. In addition to optimizing animal models, standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains are needed to move R&D of medical countermeasures for NiV infection forward (Satterfield 2016).

To inform development of optimal NiV medical countermeasures, additional research also is needed on the virology, immunology, and pathogenesis of NiV in humans and animals. This includes issues such as evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunological clearance and cause delayed onset or recurrent encephalitis, identifying factors influencing the development of permanent neurological sequelae, and further characterizing cell-mediated and humoral immune responses to NiV infection.

To respond to these challenges, the strategic goals and milestones for cross-cutting issues in the NiV R&D roadmap focus primarily on developing a sustainable value proposition and identifying funding sources to promote R&D, availability, and accessibility of NiV medical countermeasures, optimizing animal models for research, and generating standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV medical countermeasures (Table 1).

Diagnostics

Commented [EG1]: Might it be worthwhile noting that there are no commercially available tests?

The most commonly used methods for diagnosing NiV infection include virus isolation, enzyme-linked immunosorbent assays (ELISAs) for serologic detection of IgM or IgG antibodies, and real time-polymerase chain reaction (RT-PCR) nucleic acid testing. Virus isolation requires biosafety level 4 (BSL-4) capabilities and is generally only performed in reference laboratories for specific purposes, such as to confirm a new outbreak or to identify the virus in new host species (Wang 2012). During the Malaysia outbreak, the US Centers for Disease Control and Prevention (CDC) developed a capture ELISA for detection of IgM antibodies and an indirect ELISA for detection of IgG antibodies (Daniels 2001); since then, additional ELISA tests have been developed (Wang 2012) and serologic testing is often used for

case confirmation during outbreaks (Chadha 2006, Gurley 2007, Islam 2016, Lo 2012, Luby 2006, Luby 2009). RT-PCR, which can be performed on throat and nasal swabs, cerebrospinal fluid, urine, and blood, is also often used for diagnostic testing (Chadha 2006, Guillaume 2004, Lo 2012). Quantitative RT-PCR tests have been developed for quantifying viral replication; such tools can be used to measure viral load reduction when screening vaccine candidates and potential therapeutics (Jensen 2018). More recently, pseudotyped-based serum neutralization assays for NiV detection that use vesicular stomatitis virus systems have been developed; these assays potentially can be used under BSL2 conditions in laboratories with limited diagnostic capabilities and appear to offer improved sensitivity and specificity (Kaku 2009, Kaku 2012, Tamin 2009). Antigen-capture ELISAs using monoclonal antibodies also have been developed, which could result in more rapid diagnosis (Chiang 2010). These newer technologies hold promise; however, more information is needed regarding their performance characteristics, particularly under field conditions.

Initial signs and symptoms of NiV infection are nonspecific (CDC 2014) and the diagnosis often is not considered at the time of presentation, which can delay outbreak detection and implementation of infection control measures. Furthermore, laboratory infrastructure and diagnostic capabilities in endemic and at-risk areas are often limited (Chua 2013, Wang 2012); thus, etiologic diagnosis is not always pursued. To address these issues, rapid point-of-care or near-patient diagnostic tests that involve minimal requirements for laboratory infrastructure are needed to identify cases quickly, promote outbreak detection, ensure timely implementation of infection control measures, and ultimately improve patient outcomes, once therapeutic options become available.

Development of new diagnostics is impeded by lack of clinical samples for assay assessment and validation; therefore, a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples is needed to move NiV diagnostic testing forward. Development of such a repository requires addressing the following: (1) determining what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outlining the purposes of sample collection; (3) determining what organizations will be responsible for activities related to creating and maintaining the repositories; (4) establishing standardized protocols for sample collection and maintenance; (5) establishing an appropriate governance structure; (6) identifying who would have access to the samples; (7) prioritizing use of samples and sample distribution; and (8) ensuring that material transfer agreements are in place. A target product profile (TPP) for NiV diagnostics that identifies the key use cases and optimal and desirable characteristics also is needed to guide the development of promising new diagnostic assays.

To address these issues, the strategic goals and milestones for diagnostic testing outlined in the NiV R&D roadmap focus on creation of a virtual reference repository, development of highly sensitive and specific point-of-care or near-patient NiV diagnostic tests, and enhancement of laboratory diagnostic preparedness to promote early detection of NiV in areas of known or potential spillover risk (Table 2).

Therapeutics

Safe, well-tolerated, and effective therapeutic agents are not readily available for treatment of NiV infection. During the 1998-1999 NiV outbreak in Malaysia, ribavirin was used to treat 140 patients; findings from treated patients were compared to those of 54 historical controls who became ill before ribavirin was available or who refused treatment (Chong 2001).

Results demonstrated a statistically significant reduction in mortality among treated patients (36%); however, the use of historical controls may have biased this finding. No additional clinical studies using ribavirin have been conducted, and limited studies in animal models have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Rockx 2010, Georges-Courbot 2006). Chloroquine also has been studied in animal models, but has not shown any therapeutic benefit, either alone or in combination with ribavirin (Freiberg 2010, Pallister 2009). Based on these findings, these approaches are not considered viable options for treatment of NiV infection.

Commented [EG2]: Might be better phrased as a significantly lower mortality in the treated patients rather than reduction.

A more promising therapeutic option is the development of monoclonal antibodies (mAbs) against viral envelope proteins that can neutralize NiV via passive administration (Broder 2012, Guillaume 2004). Therapy with anti-NiV mAbs may be appropriate for early treatment and for post-exposure prophylaxis (PEP) to prevent illness in exposed persons, such as healthcare workers, family caregivers, and persons exposed to infected livestock. Researchers have demonstrated that the human mAb, m102.4, offers protection against lethal NiV challenge in animal models (Geisbert 2014, Bossart 2009), and it has been provided under compassionate use for a small number of individuals exposed to henipaviruses (Broder 2013). Recently, a phase 1 clinical trial of m102.4 with 40 human participants was completed in Australia, but results are not yet available (ANZCTR). M102.4 was deployed for use during the 2018 NiV outbreak in Kerala, India, but was not used because the outbreak was brought under control quickly (Spiropoulou 2018). One recent study in nonhuman primates showed that the therapeutic window for m102.4 may vary by virus strain, which is a consideration for further preclinical and clinical study of this agent (Mire 2016).

Other potential options for NiV treatment include favipiravir (a small-molecule antiviral that inhibits RNA-dependent RNA polymerase), fusion inhibitory peptides (peptides that inhibit virus-mediated membrane fusion), and remdesivir (also known as GS-5734, which is a monophosphoramidate prodrug of an adenosine analogue). Researchers recently demonstrated efficacy of favipiravir in hamsters challenged with a lethal dose of NiV (Dawes 2018), supporting proof-of-concept for favipiravir as a possible therapy against NiV infection. Studies in animal models also have been conducted for fusion inhibitory peptides; for example, investigators recently reported that lipopeptides delivered via the respiratory route can prevent lethal NiV infection in hamsters and nonhuman primates (Mathieu 2018). Remdesivir is a small-molecule antiviral that is currently being evaluated in clinical studies as a therapeutic option for treating Ebola virus disease. Investigators recently demonstrated in vitro inhibition by remdesivir against a number of different viruses, including paramyxoviruses (Lo 2017). While these agents are promising, further preclinical data are needed to assess their utility. In addition, efforts are needed to expand the therapeutic drug pipeline for treatment of NiV by supporting basic science research toward discovery of additional novel agents that may be more aligned with optimal and desired characteristics for anti-NiV therapy.

Key additional considerations for moving NiV therapeutics forward include: (1) obtaining additional preclinical and clinical data on the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of the most promising novel treatments for NiV disease; (2) ensuring that vetted and approved protocols for conducting clinical efficacy trials of promising therapeutics are in place in at-risk countries to be implemented during future NiV outbreaks; and (3) determining which agents may be appropriate for PEP, what types of exposures warrant PEP, and the feasibility of PEP distribution in both endemic and at-risk areas. To address these issues,

the goals and milestones for therapeutics in the NiV R&D roadmap focus on continuing to move promising agents forward into clinical trials and on enhancing preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Vaccines

In June 2017, WHO released a TPP for NiV vaccine (WHO 2017) and several candidate vaccines are in the pipeline (Satterfield 2016); however, there is no candidate vaccine that is in late-stage development and few companies are willing to invest in generating new NiV vaccines, which creates an important barrier to ensuring that safe and effective NiV vaccines are made available. To date, clinical trials involving NiV vaccines have not been conducted and vaccines are still in preclinical stages of research. The two primary approaches for NiV vaccine development include creating a subunit vaccine against one or both of the outer-membrane proteins (the glycoprotein [G] or the fusion protein [F]) and using live-virus vectored vaccine platforms, including vesicular stomatitis virus, adenovirus, rabies virus, measles virus, Venezuelan equine encephalitis virus, canarypox virus, and Newcastle disease virus (Broder 2013, Satterfield 2016). A Hendra virus subunit vaccine involving soluble glycoprotein (sG) has been developed and is commercially available for use in horses (Middleton 2014), which supports this option as a promising approach for developing a human NiV vaccine.

The Coalition for Epidemic Preparedness Innovations (CEPI), which is a partnership of government agencies, industry, academia, philanthropy, and intergovernmental institutions aimed at providing funding for R&D of new vaccines against pathogens with epidemic potential, has recently provided financial support to promote the development of several NiV candidate vaccines. In May 2018, CEPI awarded a US$ 25 million contract to Profectus BioSciences, Inc. and Emergent BioSolutions Inc. to develop an NiV vaccine that is based on the same technology

as that used for the Hendra virus vaccine (CEPI 2018). In September 2018, CEPI announced plans to award approximately US$ 2 million to the Jenner Institute at the University of Oxford and Janssen Vaccines & Prevention BV for preclinical development of a replication-deficient simian adenoviral-vectored vaccine, derived from an adenovirus originally isolated from chimpanzees (CEPI 2018). These efforts will support preclinical and early clinical development of NiV vaccines.

Although phase 1 and 2 clinical vaccine trials can be conducted in either endemic or non-endemic regions, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection has, to date, occurred as relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate vaccine efficacy with adequate statistical power. It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks. While it is critical to focus on conducting ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.

Additional research is needed in several areas to support development of NiV vaccines. First, identification of specific correlates or surrogates of protection and standardized assays for measuring immune correlates are needed, particularly to expedite possible licensing through nontraditional regulatory pathways (Satterfield 2016). Correlates of protection may vary by vaccine platform and antigen and, therefore, multiple assays may need to be standardized. Second, additional research is needed regarding the innate, cell-mediated, and humoral immune responses that constitute protective immunity against NiV (Mathieu 2015, Prescott 2012,

Satterfield 2016). Since neutralizing antibodies are likely the primary mediator of protection against NiV infection (Satterfield 2016), research in this area should focus primarily on the humoral immune response for driving vaccine development. Third, further work in animal models is needed to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date (Satterfield 2016). Finally, mathematical modelling and forecasting may be useful in creating a current estimate of the reproductive number for NiV, gauging the potential impact of NiV vaccines, and assessing needs for a vaccine stockpile (WHO 2017).

The immediate goals and milestones in the vaccine section of the NiV R&D roadmap focus on moving vaccine candidates forward into clinical trials and promoting development of guidance on requirements for clinical trials, regulatory pathways, and other considerations relevant to licensure of a vaccine against NiV.

Conclusion

The NiV R&D roadmap contains a series of concrete steps to be accomplished over the next 5 years to accelerate the development of NiV medical countermeasures forward. NiV infection is likely more prevalent than currently recognized; therefore, rapid, easy to use point-of-care or near-patient diagnostic tests and enhanced case detection and surveillance in areas of known or suspected NiV spillover will improve understanding of the true burden of NiV disease. These efforts, in turn, may provide information to further support the public health value proposition for NiV medical countermeasure development and, by increasing case detection, may enhance feasibility of conducting clinical trials of promising vaccines and therapeutics in endemic areas.

Tables

Table 1: Goals and Milestones for NiV Infection Cross-Cutting Issues

Goals and Milestones for NiV Infection Cross-Cutting Issues **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Identify sources of private- and public-sector funding, and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	1. By 2019, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.
	2. By 2019, create a funding plan for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
2. Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	1. By 2020, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
	2. By 2021, optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs and which may be necessary for licensure of MCM products (particularly vaccines) via non-traditional regulatory pathways.

Table 2: Goals and Milestones for NiV Diagnostics

Goals and Milestones for NiV Diagnostics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	1. By 2019, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).
	2. By 2021, identify funding and initiate creation of the virtual reference repository in the two primary NiV-affected countries (Bangladesh and India), with samples to be collected during future outbreaks and possibly as part of future clinical trials.
2. Develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are	1. By 2019, generate a TPP for NiV diagnostics that identifies the primary use cases and optimal and desirable characteristics to guide the development of promising NiV diagnostic assays.
	2. By 2019, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays.
	3. By 2021, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.

sufficiently robust for the conditions in which they will be used and that have minimal requirements for biosafety precautions and staff training.	4. By 2022, complete field studies for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP.
3. Enhance laboratory diagnostic preparedness in areas of known or potential spillover risk to promote early detection of NiV.	1. By 2021, develop national laboratory strategies for NiV detection in the primary affected countries that include plans for enhancing laboratory preparedness to diagnosis NiV infection during future outbreaks.

Table 3: Goals and Milestones for NiV Therapeutics

Goals and Milestones for NiV Therapeutics **Nipah Virus Roadmap**	
STRATEGIC GOALS	**MILESTONES**
1. Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	1. By 2019, complete a protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	2. By 2019, complete a protocol for conducting PEP trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	3. By 2020, complete a broader, regional protocol for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas and develop plans for operationalizing the protocol.
	4. By 2020, generate a reliable source of m102.4 to be used in clinical trials.
2. Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.	1. By 2019, create and implement a prioritization process for evaluating promising NiV therapeutic candidates.
	2. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.
	3. By 2023, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising therapeutic candidates or combination therapies for treatment of NiV infection.

Table 4: Goals and Milestones for NiV Vaccines

Goals and Milestones for NiV Vaccines
Nipah Virus Roadmap

STRATEGIC GOALS	MILESTONES
1. Engage NRAs (particularly in endemic and at-risk areas) and WHO to gain guidance on requirements for clinical trials, regulatory pathways, and other considerations that will impact licensure of a vaccine against NiV.	1. By 2019, convene an expert working group to assess the feasibility of conducting clinical efficacy trials of NiV vaccines and to determine the most appropriate regulatory pathways for licensure.
	2. By 2020, convene a regional consultation to clarify in-country issues around conducting clinical trials (if deemed feasible) and the needs for licensure and future use of NiV vaccines. This consultation should include representatives from the following: in-country regulators, other regulatory agencies (such as the FDA or the European Medicines Agency [EMA]), national and international public health agencies and organizations, and local and international researchers.
2. Develop and evaluate NiV vaccines for prevention of NiV disease in humans.	1. By 2021, complete preclinical evaluation of the preliminary safety, tolerability, and efficacy of at least two promising NiV vaccine candidates.
	2. By 2023, complete phase 1 and phase 2 clinical trials for at least one of the most promising NiV candidate vaccines.
	3. By 2023, complete the following if phase 3 trials are considered feasible: (1) develop a framework for conducting phase 3 clinical trials of NiV vaccine candidates, (2) develop a regional protocol for conducting phase 3 trials and plans for operationalizing the protocol, and (3) create a collaborative and transparent strategy for determining which candidate vaccines will go forward into phase 3 trials.

---

Dear Kris,

I agree that the manuscript reads well. I've attached a couple of minor comments and edits and my affiliation information.

I also agree with Steve's suggestion about how to address the limitations for development of therapeutics.

All the best,
Emily

Subject: Re: Nipah R&D roadmap and draft manuscript

Kris,

The manuscript reads well. Thanks for all of your effort in pulling these ideas together and communicating this so clearly.

I agree with the Wellcome reviewer that there is some risk of favoring one therapeutic by including a specific milestone to advance it.

If the R&D roadmap is successful in in catalyzing the development of multiple therapeutic agents a limiting constraint to assessing their effectiveness will be the number of patients with Nipah who can be enrolled. A broader discussion on how best to allocate such a scarce resource seems more appropriate than assuming that we should focus all resources on the first available agent.

Personally, I would favor an R&D roadmap for therapeutics that noted this issue, and proposed an approach to engage in a broad open conversation on how we allocate multiple scarce resources, donor interest, donor funding, and patients identified early enough to be candidates for therapeutic trials.

I have attached my identifying information.

Steve

> Dear Nipah R&D Roadmap Taskforce members:
>
> On behalf of CIDRAP, Wellcome, and WHO, attached please find the final version of the Nipah R&D Roadmap, a draft manuscript for publication, and a table for you to complete with personal information.
>
> - The roadmap is undergoing final review and clearance at WHO.
> - The draft manuscript is also being reviewed by WHO; their edits are not yet reflected in this version, so it may change. Before submission, once we have incorporated all comments, we will send a final version to you again for your approval and sign off.
>
> Here are some high-level thoughts regarding the manuscript:
>
> - We thought it was essential to provide some context for where things stand with the current status of diagnostics, therapeutics, and vaccines, so we added a few short paragraphs in order to provide this perspective. This was done for the MERS-CoV roadmap and we all agreed that this was the right approach.
> - We also decided to highlight some of the key challenges and barriers, as we did in each of the roadmaps—so we used our best judgement to focus on what we thought were the most critical issues. We also did quite a bit of reworking to put the material into a more readable format.
> - With regard to the roadmap itself, we decided to include tables of the goals and milestones, since it wasn't possible to cover everything and these seem to be the most critical. We should be able to provide a link to the full roadmap once it's posted, assuming each is posted before publication.
> - We decided that the manuscripts should be no more than about 3,500 words, so we aimed for that length.
>
> We would very much appreciate your help by doing the following:
