Hello Dr. Haller,

This email is being sent on behalf of Drs. Broder and Schaefer, Site Principal Investigators for the Uniformed Services University of the Health Sciences to collaborate with Dr. Thomas Geisbert, Prime PI with The University of Texas Medical Branch at Galveston (UTMB). Below is a listing of the attached documents. If you require additional information, please do not hesitate to contact me. Upon receipt of the attachments, please send a confirmation. Thank you for doing business with HJF.

1. Key Person Biosketches – 5 pages, NIH format– please address your role and expertise for this U19 in personal statement
2. Key Person Information (including person to be contacted on matters for this application for your institution)
3. Site Information
4. Abstract/Project Summary (30 lines)
5. Facilities & Resources (Word doc)
6. Equipment (Word doc)
7. Resource Sharing Plan (Word doc)
8. Vertebrate Animals (Word doc as applicable)
9. Select Agent Research Plan (as applicable)
10. Authentication of Key Biological/Chemical Resources
11. Budget (SF424) & Justification (Word doc) – please include justification for Core A effort as well Project Leads at least 1.2 person months effort
12. Signed Letter of Intent/Consortium Agreement- for projects that include only effort but no salary or other costs, we will provide a collaborative agreement for signature instead.
13. Specific Aims- 1 page

14. Research Strategy: 12 pages for Research Project
15. Letters of Support

Yours in good health,

Jacquelyne M. Ford
Sr. Proposal Specialist, Domestic Portfolio
Investigator Initiatives – Business Development

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches **which can be adapted across members of each viral family in a "plug-and-play" manner**. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses. (2) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. Specifically, we will:

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

1.1 Subunit immunogens and MNP vaccination: Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus.

1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments: Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.

RESEARCH STRATEGY:

1. SIGNIFICANCE:

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens (REF) where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness (REF). Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Research Project 1(RP1) proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- **Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).
- **New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- **Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective

protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.
- First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.
- In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.

Pre-exposure prophylaxis (PREP) and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-~~-~~risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will ~~also~~ perform pilot studies to examine the feasibility of PREP ~~utilizing~~ with a serum half-life extended mAb against JUNV~~s~~. Clinically validated Fc mutations can result in an improvement in serum half-life from 3-4 weeks to 2-4 months ~~which can increase the instant barrier immunity from 30-45 days to 60+ days~~ ([44, 45][46] [47]~~refs~~).

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[11] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[11]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[12-17]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[18]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine(REFS). Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Commented [CRW1]: Need to confirm

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens

CCHFV is a divergent virus with up to seven genetic lineages (REFS). This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on (REF). Conversely, NP is highly conserved but not exposed on the virus surface cellular surface (REFs). Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [19]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses

For situations where a vaccine does not exist or is not appropriate (*e.g.* immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [44, 45] and LA [46] [47] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

Commented [CRW2]: Larry, feel free to refine and/or elaborate.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:

3. APPROACH

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

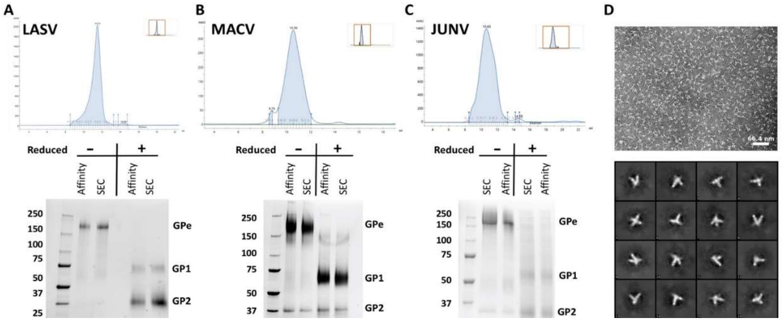

Figure XX. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide-linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[20]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[20] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure xx)**. Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 3)**. Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure xx)**. Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[21]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches have largely focused on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[12-17] suggests that the cellular response, mediated by T cells, can play a highly important and complementary role in the long-term protection against pathogens. Based on literature reports that T cell responses highly correlate with LASV recovery, and that LASV NP plays a significant role in inducing those responses[12, 22], we also generated LASV NP antigens. We chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle (**Figure xx**) and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

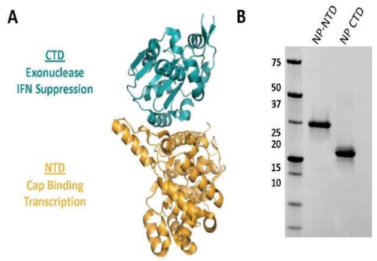

Figure xx. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B)

Figure 6. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 μg of GP, or 2x50 μg doses of GP + 2x25μg of NP-NTD + 2x25 μg of NP-CTD, or either 2x25 μg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

We evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 6)** to assess whether immune responses to GP only, or GP+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking (**Figure 6**), and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP but no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of

NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

*Engineering glycoproteins antigens for the CCHFV*The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to test serum reactivity in CCHF survivors (Figure XX). We will use established protocols [23] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Rescue of recombinant viruses. An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.

Commented [CRW3]: VERBIAGE FROM CORE C, NEED TO ADAPT AND ELABORATE HERE.

APPROACH

Overall Hypothesis:FILL THIS IN

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

Rationale: The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- *Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).
- *New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).
- *Nairoviridae*. We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].

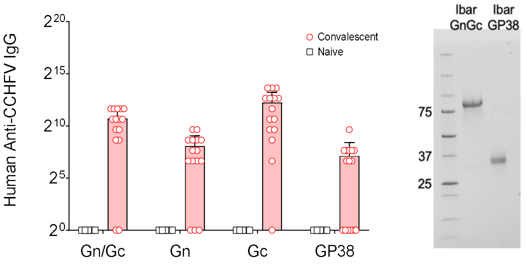

Figure XX: Engineered CCHFV proteins are reactive with serum from CCHFV survivors. SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification

Paragraph about subunit vaccines and PREP study.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in table XX using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in Table XX. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core C** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group (REFS). After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table XX** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV **(REFs).**

1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs. Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core C** as outlined in Table XX. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Similarly, after down selecting the optimal adjuvant and vaccination route, we will assess the potential for our MACV subunit vaccines to confer heterologous protection against thre lineages of MACV endemic to genetically distinct from the prototype strain (Chicava-Lineage 2). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core C** as outlined in Table XX. We will also utilize JUNV (Romero strain)(**REF**) challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP: 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals (Table XX). Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

1.1.1.F: Determination of cellular and humoral immune correlates associated with protection

1.1.1.F.a: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups.

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard whole blood flow cytometric staining protocols will be used for surface and intracellular staining markers, briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye for 20 minutes at room temperature. Cells are then washed again, surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS.

Stained, fixed cells will then either be acquired directly. Cell populations are then quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments:. PBMC stimulations will be set up according to modifications of well established, previously published protocols. [24, 25] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37ºC for 1 hour. A protein transport inhibitor such as brefeldinA will then be added at a concentration of 10mg/mL and incubated at 37ºC for until flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37ºC. Stimulations to assess secreted analytes by multiplex-bead based assays will be set up in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye for 20 minutes at room temperature, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are incubated in BD Cytofix/Cytoperm solution for 20 minutes followed by a wash with BD Perm/Wash Buffer. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a 4-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated for 3 hours at room temperature, protected from light. 1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes. Wash buffer will be removed and discarded. Beads will be resuspended in 300uL wash buffer and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37ºC. Wells will be washed manually 3-times, followed by the addition of detection antibody and incubated either overnight at 4ºC or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes at room temperature, protected from light. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37ºC), and spot forming units (SPU) will be read on an **need model** ELISPOT Fluorescence Microplate Reader.

Data Analysis: We will look at the differences in immune responses across groups between each timepoint and baseline. Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

1.1.1.F.b: Systems serology ***Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups.***

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform developed by Dr. Gunn in Core D[26-28] to define the Fc-mediated humoral antiviral functions associated with vaccination. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV,LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens utilized for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages. We will use a multiplexed analysis to determine the levels of antibodies against the viral antigens using on MagPix xMAP instrument as described.[27, 29] Specifically, each viral antigen will be coupled to coded magnetic beads (Luminex), mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will make a standard using pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry at KGH.

ADCC: Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates for 5 hours at 37C 5% CO_2, and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses were performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction was used to determine statistical significance between groups. A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted $P < .05$) were used to generate networks in Cytoscape (version 3.4.0).

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and additional clinical information (ie: PES symptoms). These will be included in the network analysis.

1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine. In conjunction with ~~RP1~~ Cores D and ~~Core~~ E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb ~~with~~ whose potent therapeutic efficacy [39, 43] ~~(guinea pig and NHP references)~~ we have previously described ~~by Abelson, Geisbert and Zeitlin~~ will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb~~(Table 4)~~. The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (~~Bioqual, Inc.; Rockville, MD~~see Core D) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. ~~For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference).~~ We will select t~~T~~he variant with the most favorable pharmacokinetics ~~PK will be selected~~ for testing with ~~by~~ ~~**RP1/**~~**Core E**. Briefly, groups of 4 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV (~~Espindola or~~ Romero~~?~~) delivered IV. For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory ~~Committee~~ Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Commented [CRW4]: From Larry, adapt from this.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, and CCHFV ……. If this is not the case any of these three viruses by year 2 we will refocus effects on the remaining virus families adjusting the requested budgets accordingly after consulation with NIAID and SAC

Please note: Discussion of expected results, other alternative approaches and criteria for "go" or "no go" decisions for MILESTONES 1-4 are discussed as required in RFA-AI-20-023 in the **Project Milestones and Timelines** *section.*

JUNV GP/NP as alternative strategy, mRNA as an alternative strategy,

AIM 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches **which can be adapted across members of each viral family in a "plug-and-play" manner**. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses. (2) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. Specifically, we will:

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

1.1 Subunit immunogens and MNP vaccination: Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus.

1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments: Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.

RESEARCH STRATEGY:

1. SIGNIFICANCE:

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens (REF) where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness (REF). Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Research Project 1(RP1) proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- **Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).
- **New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- **Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective

protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.
- First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.
- In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.

Pre-exposure prophylaxis (PREP) and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high risk individuals for infections such as rabies or COVID-19 (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will also perform pilot studies to examine the feasibility PREP utilizing half-life extended mAbs which can increase the instant barrier immunity from 30-45 days to 60+ days (refs).

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[11] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[11]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[12-17]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[18]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine(REFS). Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Commented [CRW1]: Need to confirm

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens

CCHFV is a divergent virus with up to seven genetic lineages (REFS). This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on (REF). Conversely, NP is highly conserved but not exposed on the virus surface cellular surface (REFs). Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [19]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses

For this proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE and LA Fc point mutations to determine the potential for delivering instantaneous barrier immunity using monoclonal antibodies.

Commented [CRW2]: Larry, feel free to refine and/or elaborate.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:

3. APPROACH

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

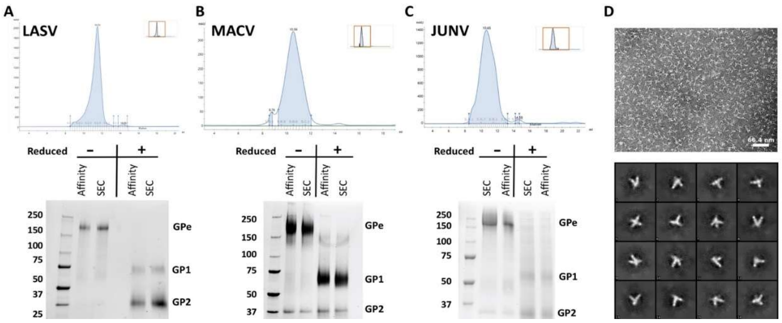

Figure XX. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide-linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[20]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[20] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure xx)**. Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 3)**. Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure xx)**. Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[21]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.

LASV subunit vaccine protects guinea pigs against lethal challenge

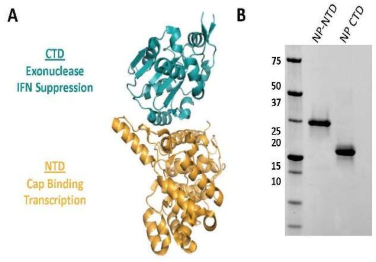

Figure xx. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

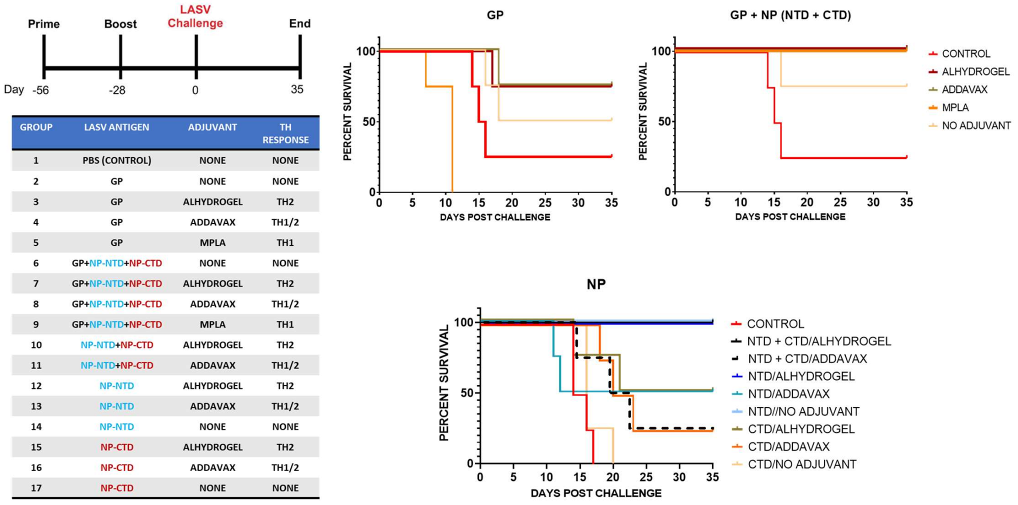
While classical vaccine approaches have largely focused on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[12-17] suggests that the cellular response, mediated by T cells, can play a highly important and complementary role in the long-term protection against pathogens. Based on literature reports that T cell responses highly correlate with LASV recovery, and that LASV NP plays a significant role in inducing those responses[12, 22], we also generated LASV NP antigens. We chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle (**Figure xx**) and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

We evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 6)** to assess whether immune responses to GP only, or GP+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE
1	PBS (CONTROL)	NONE	NONE

Figure 6. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking (**Figure 6**), and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP but no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

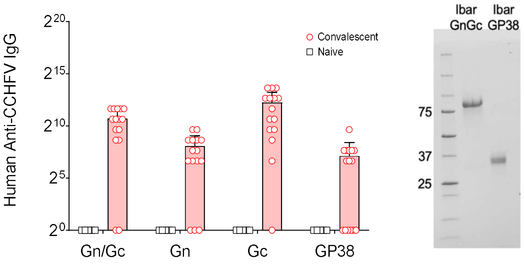

Figure XX: Engineered CCHFV proteins are reactive with serum from CCHFV survivors. SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification

*Engineering glycoproteins antigens for the CCHFV*The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to test serum reactivity in CCHF survivors (Figure XX). We will use established protocols [23] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Rescue of recombinant viruses. An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.

Commented [CRW3]: VERBIAGE FROM CORE C, NEED TO ADAPT AND ELABORATE HERE.

APPROACH

Overall Hypothesis:FILL THIS IN

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

Rationale: The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- *Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).
- *New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).
- *Nairoviridae.* We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].

Paragraph about subunit vaccines and PREP study.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in table XX using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in Table XX. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core C** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group (REFS). After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

VACCINE	IM VACCINATION		PATCH VACCINATION

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table XX** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV **(REFs).**

1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs. Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core C** as outlined in Table XX. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table: XX outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

Similarly, after down selecting the optimal adjuvant and vaccination route, we will assess the potential for our MACV subunit vaccines to confer heterologous protection against thre lineages of MACV endemic to genetically distinct from the prototype strain (Chicava-Lineage 2). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core C** as outlined in Table XX. We will also utilize JUNV (Romero strain)(**REF**) challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP: 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals (Table XX). Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table XX** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will confirm protection in NHPs if demonstrated in guinea pigs **(REFs).**

1.1.1.F: Determination of cellular and humoral immune correlates associated with protection

1.1.1.F.a: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups.

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard whole blood flow cytometric staining protocols will be used for surface and intracellular staining markers, briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye for 20 minutes at room temperature. Cells are then washed again, surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then either be acquired directly. Cell populations are then quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments:. PBMC stimulations will be set up according to modifications of well established, previously published protocols. [24, 25] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldinA will then be added at a concentration of 10mg/mL and incubated at 37°C for until flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays will be set up in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye for 20 minutes at room temperature, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are incubated in BD Cytofix/Cytoperm solution for 20 minutes followed by a wash with BD Perm/Wash Buffer. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a 4-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated for 3 hours at room temperature, protected from light. 1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes. Wash buffer will be removed and discarded. Beads will be resuspended in 300uL wash buffer and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37ºC. Wells will be washed manually 3-times, followed by the addition of detection antibody and incubated either overnight at 4ºC or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes at room temperature, protected from light. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37ºC), and spot forming units (SPU) will be read on an **need model** ELISPOT Fluorescence Microplate Reader.

Data Analysis: We will look at the differences in immune responses across groups between each timepoint and baseline. Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

1.1.1.F.b: Systems serology *Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups.*

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform developed by Dr. Gunn in Core D[26-28] to define the Fc-mediated humoral antiviral functions associated with vaccination. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV,LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens utilized for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages. We will use a multiplexed analysis to determine the levels of antibodies against the viral antigens using on MagPix xMAP instrument as described.[27, 29] Specifically, each viral antigen will be coupled to coded magnetic beads (Luminex), mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will make a standard using pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry at KGH.

ADCC: Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates for 5 hours at 37C 5% CO_2, and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses were performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction was used to determine statistical significance between groups. A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted $P < .05$) were used to generate networks in Cytoscape (version 3.4.0).

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and additional clinical information (ie: PES symptoms). These will be included in the network analysis.

1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine. In conjunction with RP1 and Core E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by Abelson, Geisbert and Zeitlin will be produced with YTE and LA Fc point mutations (Table 4). The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (Bioqual, Inc.; Rockville, MD) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference). The variant with the most favorable PK will be selected for testing by **RP1/Core E**. Briefly, groups of 4 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV (Espindola or Romero?) delivered

IV. For further details of the NHP testing, please see **Core E**. These data will be used by the Advisory Committee to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes.

Commented [CRW4]: From Larry, adapt from this.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, and CCHFV ……. If this is not the case any of these three viruses by year 2 we will refocus effects on the remaining virus families adjusting the requested budgets accordingly after consulation with NIAID and SAC

Please note: Discussion of expected results, other alternative approaches and criteria for "go" or "no go" decisions for MILESTONES 1-4 are discussed as required in RFA-AI-20-023 in the **Project Milestones and Timelines** *section.*

JUNV GP/NP as alternative strategy, mRNA as an alternative strategy,

Subject: RE: ReVAMPP Bunyavirales Project

Hi Chris,

Some thoughts…

On the PREP, this is just the one study being proposed as proof of concept. Will let Larry elaborate, but we will need to wordsmith to suggest that if successful this may be an avenue to look at with other viruses with the support of SAC and program.

On the cellular and humoral part. Space is a big issue here and I'm not sure we will need to describe in detail in every RP or core, but it needs to be outlined somewhere clearly and that will eat up some space. I put it in my RP since there was no room in the animal core and Larry's core didn't detail it too much either (so far). My version will likely need to be whittled down as well to make everything fit, so but not so much that the gist is lost. I wonder if we could find a small amount of space to describe the immunology work up I described will be carried out in the scientific cores (and in collaboration with RP1) as outlined in RP1? That said, we can maybe refer to methods used in RP1 for the core as well since that write-up is already having issues with space? Also note that I'm not doing any immunology on rodents since the patch core mentioned they would do rudimentary serology and ELISPOTs, all this advanced immunology work will be done with primates only due to lack of reagents.

Bob

Subject: Re: ReVAMPP Bunyavirales Project

hi all
RP2 is not looking anything like this post-vaccination subject analysis on the CD4/CD8 and cellular responses or the serological studies.

We were allowing the Upitt core to explore the mice with cellular responses as the pilot.
The plan for the MNP vaccines is to test efficacy in ferrets then proceed to AGMs.

Not sure what to do or how to proceed here! Are there analysis text sections from what the animal core can or should propose here or outline here, as Bob laid out? I dont have anything like this in hand,

also, i saw the comment on PREP
We dont have any plans for PREP for NiV/HeV included here either, our best candidates are already in Mapp's pipeline, or in the CETR

chris

Subject: RE: ReVAMPP Bunyavirales Project

A ways to go on the text, but studies mapped out fairly well at this point, working on filling in text for areas highlighted in blue. Sending now to give the group an idea on direction for aims and subaims

Will work on fleshing out significance/innovation sections/and approach text tomorrow. Tables will be shrunk to fit, but followed Larry's color scheme to be consistent for now.

- Bonnie I adapted the immunology support sections from our pilot grant to start with. Will very likely need to majorly consolidate, but better to have too much and refine to essentials once all the content is there.

- Larry, I just included the pilot study for the PREP study assuming you and Tom already budgeted for it. You mentioned go-no-go, but I did not budget for any "go" studies, so maybe you mean PREP for henipaviruses?

- Dafna and Larry, open to thoughts on the CCHF proteins for prelimary data or innovation. I had some serology which we did using your proteins on human survivors to demonstrate reactivity which I think is helpful. Open to other thoughts.

- Tom, I added another group for each of the NHP studies to allow for 2 groups to be evaluated either with different doses or different vax formulations. Was thinking this might be ideal for grantsmanship to have at least another option. Thinking was that we would not use all 5 controls for all studies and may be able to make these up?

Subject: Re: ReVAMPP Bunyavirales Project

Bob,

This is what is in Core D so far:

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine. In conjunction with RP1 and Core E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by Abelson, Geisbert and Zeitlin will be produced with YTE and LA Fc point mutations (Table 4). The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (Bioqual, Inc.; Rockville, MD) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference). The variant with the most favorable PK will be selected for testing by **RP1/Core E**. Briefly, groups of 4 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV (Espindola or Romero?) delivered IV. For further details of the NHP testing, please see **Core E**. These data will be used by the Advisory Committee to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes.

Feel free to tweak so it fits with what you are thinking about. I can also give you some innovation language if you'd like on this topic.

Best

Subject: Re: ReVAMPP Bunyavirales Project

Tom,

I like the idea of it as a sub-aim. Core D will refer to it (manufacturing the mAb as well as performing PK to select the best Fc mutant). Depending on how much you are mentioning about the protocols in the Animal Core, you could also mention it there (e.g. "For studies looking at long-acting mAbs as an alternative to a vaccine, NHPs will receive a single dose 1 month prior to challenge…).

I can also if preferred, describe the study in Core D rather than RP1. I'm certainly setting up the idea of it with the PK work…

Larry, Dafna

How do you want to handle the Junin NHP prophylaxis study? At the very least I think RP1 has to mention it somewhere. Does it go into RP1 as a subaim? I don't think we can say it is alternate strategy as that route is usually taken when something proposed fails. Does it get pitched as a subaim to derisk the project? Not quite sure here.

Many thanks!

Tom

Great, thanks!

Yeah it was challenging to add a lot into the SA page. But we can refine to make it more inclusive of all points addressed. Definitely will stretch out in the Research strategy.

We can maybe add some reverse genetics, especially for missing MACV lineages…maybe CCHF for the same reason using the cassette approach. Need to think about it a little today, but this may work.

Do we need to add the JUNV prophy study into RP1? Or is that in the core?

Subject: Re: ReVAMPP Bunyavirales Project

Thanks Bob! One thing that we need to think about as Chris outlined for the rescue of Langya in the RP2 Aims is are we going to tackle reverse genetics at all for arenaviruses and CCHF? If so will need to tie that into the Animal Core in terms of rescue. Other thing is tie into Mapp Core for the Junin NHP prophylaxis study in Year 1 as an alternative approach to vaccination. And then need to think about if we need an approach to tie into RP4 and RP5. All of this of course does not need to be on the Aims page and can be addressed in the 12 page Research Strategy. If you tackle reverse genetics it could be its own Aim along the lines of what Chris has in RP2.

Agree, this SA page from Crystal is super helpful. Was going to start putting pen to paper to get a rough draft started for the Bunya RP. Unless you guys have already started?

Is there a format we need to follow for writing the proposal? I think we had 12 pages correct?

Assuming the standard NIH format?

- Significance
- Innovation
- Preliminary data
- Approach/SpecificAim 1-?
- Alternative strategies
- Milestones-Timelines
- Summary statement impact

Subject: Re: ReVAMPP Bunyavirales Project

Just a few thoughts:

1. It looks like we can have multiple prototypes per family if justified. I think lassa and junin would be great prototypes for old and new world arenas…seems easy to justify as we don't know if a single product could cover both and pursuing both could help to answer the question.
2. Might be good to confirm with program, but as I initially read it, it looks like if we start with CCHF we'd be expected in Y4-Y5 to expand to other nairos. Hantas may be a little easier – Jim has some mAbs and Mapp does as well, but those are encumbered a bit with Kartik's CETR so we'd have to have some conversations to make sure that would be kosher.
3. The RFA has a bit of mixed message on vaccines and mAbs. I do think they go well together and mAbs can be an alternative option to a vaccine.
4. Do the microneedle people have some experience transitioning to the clinic? I'm looking at this language: "Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways." Mapp can fill that role for mAb vaccines, but not so well for traditional vaccines. It looks like we don't have to have them lined up yet, but might be nice to have a letter of support if needed. DVC is an option as is IBT.

Subject: Re: ReVAMPP Bunyavirales Project

Hi Tom

We do have the Junin PBMCs you sent and I like the idea of including Junin in the proposal because we already have cell lines in house to express Machupo, Junin and Lassa GPs. I think we could hit the ground running on arenavirus antibody discovery.

I don't have strong feelings on Hanta vs CCHF. Larry?

Subject: ReVAMPP Bunyavirales Project

All,

We need to think about the ReVAMPP Bunyavirales Project and what viruses and how to integrate with all of the other projects. I know it is tough to schedule a Zoom call so maybe we can kick this around on email a little. I think we all agree that the Mapp Lassa vaccine data is great. So maybe Lassa is the prototype even though we know CEPI is funding Lassa vaccines and it has a lot more attention than other things. But prototype with a plan to transition to other arenaviruses. So move the Lassa vaccine to the microneedle patch which ties in nicely with that Core. I guess we need to think about whether to have pan arenavirus vaccines or individual. I think Junin is a good choice as well. To that end I think we had sent PBMC from Junin Candid 1 vaccinees to Mapp right before COVID-19 hit. Do you still have those? If we go with Lassa do we have a plan for Lassa MAbs to support? Then for another family I think CCHF for Nairoviridae makes the most sense as we have already been working on it for MAbs as has Jim Crowe. We would need to sort out the vaccine angle that ties into the microneedle patch. So I guess then for arenaviruses we would have Lassa and maybe Junin as prototypes and for nairoviruses CCHFV. Where I get confused and am struggling is the transition in Years 4 and 5 that NIAID/NIH has to approve where I think the expectation is that you move from prototypes to more broad coverage. So do we say for example for Lassa since there are so many lineages that the prototype is lineage IV Josiah but in the out years we show that it protects against all lineages? Same thing for CCHF. Or is the expectation that you go beyond the prototype virus so for example from Lassa and Junin to also cover say Machupo, Guanarito, Chapare, etc.? Or is it better instead of CCHF say to start with Andes as the prototype and then move in the out years to Hantaan or vice versa? Thoughts?

Tom

Project Summary

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the World Health Organizations (WHO) Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phleboviruses Rift Valley fever virus (RVFV) and severe fever with thrombocytopenia syndrome virus (SFTSV). LASV and RVFV are also included among the WHO List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The Machine Learning-(ML)-Enabled Design of Prototype Pathogen Vaccines and Antibodies Center is a well-integrated consortium conducting a set of discovery and translational research programs composed of an Administrative Core, a Data Management Core, X Scientific Cores, and X Research Projects (RPs). The synergistic activities of the Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV) and JUNV to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BSL-3 and BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-3 and BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

Relevance

The Animal Models and Vaccine Evaluation Scientific Core (Core D) provides BSL-3 and BSL-4 resources and expertise for RP1 and RP2. The goal of Core D is to work closely with Research Project and Scientific Core Leaders and staff, the Scientific Advisory Board, and NIAID to advance the development of countermeasures against Paramyxoviridae and Bunyavlrales.

ANIMAL MODELS AND VACCINE EVALUATION SCIENTIFIC CORE (CORE D)

1. SPECIFIC AIMS

The main objective of the Animal Models and Vaccine Evaluation Scientific Core is to test and characterize the host response and efficacy of the vaccines and monoclonal antibody (mAb) based treatments identified in RP1 and RP2 against paramyxoviruses, arenaviruses, and phleboviruses under BSL-3/ABSL-3 and BSL-4/ABSL-4 containment. The Core will also develop select reporter viruses and conduct cell-based assays to characterize vaccine-induced neutralizing antibody responses and mAbs.

The Specific Aims of the Animal Models and Vaccine Evaluation Scientific Core are to:

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

Aim 4: Develop and/or optimize animal models for Sosuga virus and Junin virus.

The Aims will be achieved by the following specific functions to be carried out by the Animal Models and Vaccine Evaluation Scientific Core Leader, Co-Core Leaders, and personnel:

1. Maintain records of well characterized BSL-3 and BSL-4 Hendra virus (HeV), Sosuga virus (SOSV), Lassa virus (LASV), Junin virus (JUNV), Rift valley fever virus (RVFV), and severe fever with thrombocytopenia syndrome virus (SFTSV) seed stocks including background history, passage history, genomic information, periodic monitoring of titer, mycoplasma testing, endotoxin testing, and sterility testing.
2. Perform *in vitro* antiviral activity assays. Including high-throughput BSL-2 based neutralization testing of henipavirus vaccine responses and mAbs.
3. Assist Center Investigators in designing animal studies, prepare animal protocols, and obtain IACUC approval of BSL-3 and BSL-4 animal studies.
4. Perform animal challenges using well characterized HeV, SOSV, LASV, JUNV, RVFV, and SFTSV seed stocks for RP1 and RP2.
5. Perform vaccination and treatment of animals with vaccines and treatments provided by RP1 and RP2.
6. Provide samples from animals collected during the vaccination portion of studies to RP1 for immunological analysis.
7. Perform all duties associated with animal challenge studies including monitoring of animals, collection of samples, and necropsies.
8. Perform clinical pathology assays including hematology and clinical chemistry assays.
9. Perform virology assays on blood and/or tissue samples collected from infected animals including viral load by plaque assay and RT-PCR.
10. Perform gross pathology analysis on all animals at necropsy.
11. Perform histopathologic analysis on tissues from animals collected at necropsy.
12. Develop and/or optimize animal models for SOSV and JUNV to fill gaps; make these models available to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers
13. Provide all data generated in Core D to Data Management Core B.

RESEARCH STRATEGY

A. SIGNIFICANCE

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the World Health Organizations (WHO) Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phleboviruses Rift Valley fever virus (RVFV) and severe fever with thrombocytopenia syndrome virus (SFTSV). LASV and RVFV are also included among the WHO List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The Machine Learning-(ML)-Enabled Design of Prototype Pathogen Vaccines and Antibodies Center is a well-integrated consortium conducting a set of discovery and translational research programs composed of an Administrative Core, a Data Management Core, X Scientific Cores, and X Research Projects (RPs). The synergistic activities of the Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV) and JUNV to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BSL-3 and BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-3 and BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

All X of the RPs within the Center focus on developing vaccines or monoclonal antibody (mAb) based therapies against paramyxoviruses, arenaviruses, and phleboviruses. RP1 and RP2 require that countermeasures be evaluated in animals against infectious paramyxoviruses, arenaviruses, and phleboviruses. As HeV, LASV, JUNV, and RVFV are CDC and/or USDA select agents Federal regulations require that these viruses be handled in Biosafety Level (BSL)-3 or BSL-4 containment. Core D provides approved BSL-3/ABSL-3 and BSL-4/BSL-4 facilities and a trained and experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2.

B. INNOVATION

Scientific Core D will be co-located within the Galveston National Laboratory (GNL) and Robert Shope Laboratory at the University of Texas Medical Branch (UTMB) at Galveston. The GNL is a high and maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda and stands ready to assist local, state and national public health efforts in the event of a public health emergency. The facility is unique in that it is one of two operational BSL-4 facilities in the United States that is located on an academic campus. This unique location benefits the Center in several ways. Regarding physical resources the GNL is a state-of-the-art facility with many specialized assets including BSL-4 imaging, telemetry, and aerobiology equipment. In addition, being located on an academic campus Drs. Geisbert (Core D, Project Leader (PL), Cross, Freiberg, and Ikegami are faculty members in the Departments of Microbiology and Immunology and Pathology. This academic environment is a major strength, that fosters creativity and collaboration with other UTMB investigators which will be beneficial to the overall success of Core D. Dr. Broder, is faculty member of the Department of Microbiology and Immunology at Uniformed Services University (USU). Drs. Broder and Geisbert have a long-standing emerging virus research collaboration which has included the development and characterization the first nonhuman primate (NHP) models for HeV and Nipah virus (NiV) that will be employed by the Center's RPs. Another strength within the Core is Drs. Geisbert, Broder, Cross, and Veesler (Center Co-PI) currently collaborate and lead active henipavirus projects that are focused on translational countermeasure development which includes more traditional vaccine and mAb therapeutics approaches, and the shared knowledge base and experience in these areas will greatly facilitate the Core's abilities in supporting the Center's research goals in applying advanced machine learning-enabled designs of effective prototype pathogen vaccines and antibodies. Along with animal model development and animal modeling expertise, many of the unique virological tools including recombinantly generated RNA viruses, reporter gene-encoding viruses, and other pseudotype virus technologies, that will be employed by the Core, have been developed from UTMB-USU collaboration.

C. APPROACH

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Paramyxovirus, arenavirus, and phlebovirus seed stocks. UTMB will provide fully equipped BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities that are required to work with HeV, SOSV, LASV, JUNV, RVFV, and SFTSV. UTMB will also provide and maintain all required approvals to work these viruses. The BSL-3 and BSL-4 paramyxovirus, arenavirus, and phlebovirus seed stocks employed for RP1 and RP2 have been or will be titered by conventional standard plaque assay and qRT-PCR as detailed in Aim 2 below. The virus strain identity of each seed stock has been or will be confirmed by sequence analysis. In addition, RNA has been or will be deep sequenced to verify the complete viral genome of each virus seed stock used for animal challenge studies. We have or will test each seed stock for mycoplasma contamination. Endotoxin testing has been or will be performed on paramyxovirus, arenavirus, and phlebovirus stocks using the Endosafe PTS system (Charles River Laboratories) following the manufacturer’s instructions. The Endosafe PTS system is a cartridge-based testing system utilizing FDA-licensed cartridges (0.1 EU/ml, 0.05 EU/ml, 0.01 EU/ml, 0.05 EU/ml) for ultrasensitive testing. Seed stocks will also be evaluated for morphological identity by transmission electron microscopy (TEM). Virus particle counts will be determined using a Virus Counter and confirmed by conventional TEM methods if needed. The bacteriological and mycological sterility of the product will be determined by selection of aliquots of the dispensed stock, inoculation of a sterile 500 ml bottle of Dulbecco's high glucose MEM with 10% FBS and then after 3 days subcultured to FTM and TBS media. paramyxovirus, arenavirus, and phlebovirus seed stocks will be inventoried in the UTMB BSL-4 and BSL-4 virus stock databases and secured in dedicated controlled access alarmed minus 80°C freezers in the GNL or Robert Shope Laboratory. Paramyxovirus, arenavirus, and phlebovirus seed stocks are monitored periodically for any changes in virus titer.

Plan for staffing, managing, and prioritizing Core use. The Core Leader and Co-Leaders have a cadre of staff that are trained and highly experienced in all BSL-3 and BSL-4 procedures and assays needed to conduct the proposed work. In addition to the Core Leader and Co-Leaders this staff includes an ACVP board certified veterinary pathologist, two BSL-4 contributing scientists, a BSL-4 Technical Director, a BSL-4 trained postdoctoral fellow, six BSL-4 experienced technical staff, a BSL-4 trained histotechnologist, and a BSL-4 trained graduate student. We do not anticipate any BSL-3 or BSL-4 scheduling problems regarding studies proposed in RP1 or RP2. However, we have developed a mitigation strategy if unforeseen events cause any prioritization of resources. A committee consisting of the Core D Leader, the PI of the Center, and the members of the external Scientific Advisory Committee (SAC) will review the status of RP1 and RP2 and any circumstances causing a prioritization of work. The Committee will also hold a meeting or teleconference (Zoom, Teams) with the Project Leaders and key staff of RP1 and RP2 to gather additional information. After careful review of all available information the Committee will then make a recommendation on prioritization to the Center PI. The Center PI will then consult with NIAID/NIH program staff and make the final determination on prioritization.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

In vitro antiviral activity assays: Core D will perform conventional virus neutralization assays for RP1 and RP2 to determine the ability of sera/plasma from immunized animals from RP1 and antibodies from RP2 to inhibit the replication of paramyxoviruses, arenaviruses, and phleboviruses *in vitro* using infectious viruses in the UTMB BSL-3 and BSL-4 laboratories. In brief, cultures of Vero, Vero E6, SW13, or other cell types will be infected with a range of m.o.i. of paramyxoviruses, arenaviruses, and bunyaviruses and treated with various concentrations of the provided sera/plasma or antibodies. Cells and/or culture fluids will be harvested at various time points after infection and infectious virus enumerated by conventional plaque assay as detailed below.

Develop chimeric reporter-gene encoding viruses and virus neutralization assays for BSL-2 use. We have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP)[1,2] , as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses[3,4]. In addition, we have generated a reverse genetics platform for generating recombinant Cedar virus (rCedV) and rCedV chimeras whereby the fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-B) or HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without reporter genes[4-8]. The rCedV chimeras are a replication competent authentic henipavirus platform that is a high-throughput surrogate neutralization assay that is rapid, cost-effective and can be utilized outside high containment. Similar approaches will be applied here to generate new reporter viruses for Ghana bat virus (GhV). We will design, construct and rescue both VSV and rCedV chimeras that encode the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of GhV. Two reporter-gene encoding versions will be attempted for VSV-GhV: one encoding GFP (VSV-GhV-GFP) and the other encoding the *Photinus pyralis* (firefly) luciferase gene (VSV-GhV-Luc). We will also construct and rescue GFP and Luc reporter gene encoding versions of rCedV chimeras encoding the GhV F and G genes (rCedV-GhV-GFP and rCedV-GhV-Luc) (**Fig. 1**). The rescued viruses will be characterized using cell-based infection tropism and growth kinetics assays.

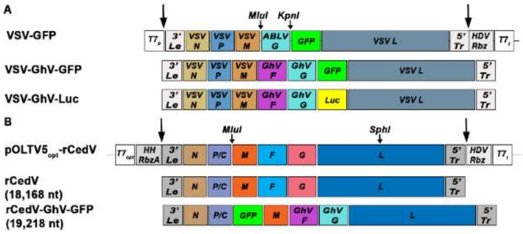

Figure 1. Schematic of chimeric reporter viruses. (**A**)The VSV-ABLV G-GFP plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and KpnI to construct VSV-GhV-GFP and VSV-GhV-Luc. (**B**) pOLTV5$_{opt}$-rCedV plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and SphI used to construct rCedV-GhV-GFP.

The rCedV (NiV-B and HeV) chimeric virus platform serves as a robust surrogate neutralization assay system for quantifying antibody neutralization potency of anti-NiV and anti-HeV antisera and mAbs[8]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP are highly correlated with those obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization test (PRNT). Pearson correlation of rCedV chimeras BSL-2 PRNT to the NiV-B or HeV BSL-4 PRNT is shown in **Fig. 2a**. A high-throughput quantitative assay based on reduction of GFP foci (fluorescent reduction neutralization test (FRNT)) was also developed. Correlation analysis with mAb neutralization values by PRNT vs FRNT (**Fig. 2b)**, Pearson's r ≥ 0.9 and p-value < 0.001).

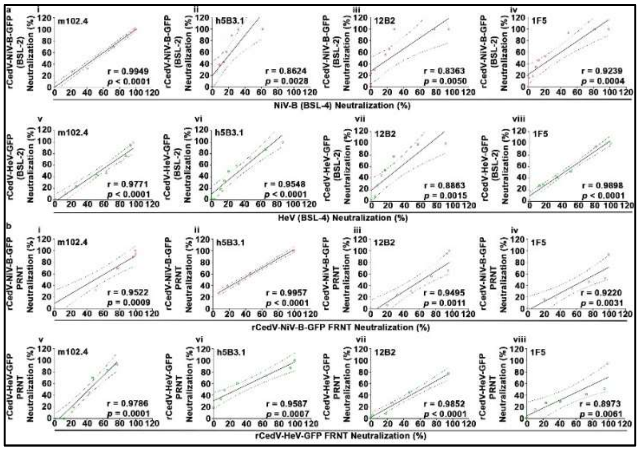

Figure 2. Panel a: Pearson correlation for BSL-2 PRNT vs BSL-4 PRNT (rCedV-NiV-B-GFP versus NiV-B (**i-iv**) and rCedV-HeV-GFP versus HeV (**v-viii**)). Panel b: Pearson correlation for PRNT vs FRNT ((rCedV-NiV-B-GFP (**i-iv**) and rCedV-HeV-GFP (**v-viii**)).

Rescue and characterize reporter viruses encoding GhV envelope glycoproteins.

Generation of a VSV encoding GhV envelope glycoproteins. We will construct reporter gene encoding versions of a replication competent VSV encoding the GhV F and G glycoproteins (GFP and Luc) (**Fig. 1A)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the GhV F and G coding sequences will be synthesized. The GhV F and G coding sequences will be based on the GhV isolate Eid_hel/GH-M74a/GHA/2009 (GenBank: NC_025256.1). The GenBank accession number for GhV F is YP_009091837.1 and that for the GhV G protein is YP_009091838.1. Unique restriction enzyme sites, MluI and KpnI will facilitate the insertion of the GhV F and G gene cassette into the VSV backbone plasmid. The VSV-GhV-Luc will be similarly made. Cloning procedures are performed in *E. coli* Stbl2 and all plasmids verified by sequencing. Rescue will be performed in BSR-T7/5 cells, transfected helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-GhV-GFP or VSV-GhV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells by inoculation with the supernatant from step 1. When GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks are tittered by serial dilution on HEK293T cells by plaque assay[9].

Generation of rCedV encoding GhV envelope glycoproteins. rCedV-GhV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the GhV F and G coding sequences. The CedV non-coding intergenic regions are retained as is adherence to the genomic "rule of six". Unique restriction sites, MluI and SphI will facilitate the insertion of the GhV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) generating rCedV-GhV-GFP (**Fig. XB**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-GhV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. At maximal syncytia and GFP (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[7,10,11].

Characterization of the recombinant reporter viruses in cell-based infection assays: The replication kinetics of the VSV-based and rCedV-based GhV F/G encoding viruses will be assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and tittered. VSV-GhV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G[1]. Similarly, rCedV-GhV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Unlike NiV and HeV, GhV G engages only the ephrin-B2 ligand to trigger membrane fusion[12]. The GhV F/G bearing reporter viruses will be verified for this specific ephrin ligand tropism in cell infection and/or syncytia formation experiments and comparisons made to wildtype VSV or VSV-ABLV G and also alternatively to rCedV, and rCedV NiV/HeV chimeras. We have generated murine mAbs to GhV F and G (10C4-LY and 10D5-LY to GhV G; and 5B7-LY and 7C11-LY to GhV F) and these will be used in neutralization tests. The VSV-GhV-GFP assays will be conducted by FRNTs and VSV-GhV-Luc in luciferase assays.

Evaluating neutralization potential of vaccine platforms from other research projects. Our rCeV chimeras (rCedV-NiV-B-GFP and rCedV-HeV-GFP) will allow this Core to conduct large numbers of neutralization tests by FRNT, to the many ML-derived prototype henipavirus vaccine antigen constructs, mAbs, and nanobinders, that will be generated by the Center's RPs. In Center years 1-3 the focus will be on HeV and NiV prototypes, and in years 4-5 the Core is expected to shift to GhV test case. The FRNT assay is rapid (36hrs), high throughput, and performed in 96-well plates to establish typical 7-point dose response virus neutralization data and performed at BSL-2. Typically, immune sera, mAbs, or other entry inhibitors are analyzed by serially dilution and mixed with virus (rCedV-NiV-B-GFP or rCedV-HeV-GFP) for 2hrs then samples used in triplicate to infect confluent Vero 76 cells in black-walled clear bottom 96-well plates and incubated 24hrs, and then plates are fixed and imaged and fluorescent foci quantitated with CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) is determined by 50% reduction in fluorescent foci versus untreated controls.

Anticipated Results, Potential Pitfalls and Alternative Strategies. We anticipate the reporter viruses will replicate to titers fit for purpose. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. If we encounter unexpected limitations in rescuing VSV-based or rCedV-based GhV F/G bearing reporter viruses; we will 1) test different ratios of helper plasmids and antigenome plasmids; 2) perform rescue using different cell lines; 3) construct alternate versions of the GhV F and G genes within the antigenome plasmids, such as truncating the GhV G protein which has been shown to enhance GhV mediated F/G membrane fusion[13]. Alternatively, fusion of the GhV F and G ectodomains with the transmembrane and cytoplasmic tail domains of the corresponding CedV F and G elements may facilitate virus particle formation and membrane fusion activity.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

The Core D Leader and Co-Leaders will work closely with the Project Leaders and key staff of RP1 and RP2 to develop vaccination, treatment and sampling regimens, study protocols, and animal protocols that utilize countermeasures identified in RP1 and RP2. The Core Leader and Co-Leaders will write and obtain UTMB IACUC approval for all animal protocols performed in Core D. The animal models and clinical pathology, immunology, virology, and histopathology assays employed for Aim 3 are detailed below. All raw data as well as graphed or tabulated data generated by Core D will be handled and analyzed in coordination with the Core B.

Animal models: Core D will employ established animal models for HeV, LASV, JUNV, RVFV, and SFTSV. While animal models exist for SOSV and JUNV we will optimize these models to fill gaps and provide new tools as detailed in Aim 4 below. Mice, guinea pigs, hamsters, ferrets, and cats have been used as small animal models of HeV infection[14]. This project will employ Syrian golden hamsters as the small animal model of HeV disease because they are more suitable than other small animals for screening large numbers of vaccines and mAbs. Using hamsters will allow us to select optimal vaccine and mAb formulations and regimens prior to efficacy testing in NHPs. In 2010 Drs. Geisbert and Broder developed the first highly lethal NHP model for henipavirus infection (Nipah virus) using African green monkeys (AGM)[15]. They subsequently developed a lethal AGM model for HeV infection[16]. Henipavirus NHP models mirror human disease with animals showing severe respiratory pathology, neurological disease, and generalized vasculitis. For LASV and JUNV, Core D will use established lethal outbred guinea pig models that cover several lineages of LASV[17-21] and several genetically distinct strains of JUNV[22-25] as guinea pigs are the only immunocompetent small animal model for LASV and JUNV disease. Core D will also use established cynomolgus monkey models that cover several genetically distinct lineages of LASV[26-29] and strains of JUNV[30].

Animal vaccinations: All animals will be obtained from commercial vendors and allowed to acclimate prior to vaccination (~ 3-7 days for mice, hamsters, and guinea pigs and ~ 14 days for ferrets and NHPs). Mice, hamsters, and guinea pigs will be vaccinated by intramuscular (i.m.) or intraperitoneal (i.p.) injection of the vaccines provided by RP1. Ferrets and NHPs will be vaccinated by i.m. injection of the vaccines provided by RP1. All animals will be vaccinated in ABSL-2. Animals will be monitored daily for any reaction or adverse events caused by the vaccination. Blood will be collected for plasma, serum, and PBMC isolations before vaccination and at times after vaccination for assessment of the host immune response.

Animal challenges: Hamsters, ferrets, and NHPs will be challenged with infectious HeV or SOSV as previously described[31-33]. After appropriate acclimation, hamsters and ferrets will be exposed to HeV or SOSV by intranasal (i.n.) or i.p. administration of virus. NHPs will be challenged with HeV by the intratracheal (i.t.) and/or i.n. routes. Mice, guinea pigs, and ferrets will be exposed to arenaviruses and phleboviruses by i.p. injection[19,24,25,34,35]. NHPs will be exposed to LASV or JUNV by i.m. injection[28-30] while marmosets will be exposed to RVFV as previously described[36]. For all animals, blood will be collected with or without anticoagulants for plasma and serum isolations, respectively, at times before paramyxovirus, arenavirus, or phlebovirus challenge, on the day of challenge, and at various times after challenge as detailed in RP1 and RP2. Animals will be monitored for clinical signs daily. We will apply a scoring sheet approved by the UTMB IACUC depicted in the Vertebrate Animals section to assist in determining the time of euthanasia depending on clinical signs (e.g., respiratory distress, anorexia, activity, appearance, neurologic signs, etc.). Animals will be euthanized according to the 2013 AVMA Guidelines on Euthanasia. Any surviving animals will be euthanized on day 35-42 days after paramyxovirus, arenavirus, or phlebovirus challenge.

Clinical pathology assays: *Hematology on EDTA whole blood*: For NHP studies, we will measure the following parameters at time points before and after HeV, LASV, or JUNV challenge: total white blood cell counts (WBC), percent lymphocytes (LY), percent monocytes (MO), percent neutrophils (NEU), percent eosinophils (EOS), percent basophils (BAS), total lymphocyte counts (LY#), total monocyte counts (MO#), total neutrophil counts (NEU#), total eosinophil counts (EOS #), total basophil counts (BAS #), red blood cell counts (RBC), total hemoglobin (Hgb), hematocrit values (HCT), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), platelets (PLT), and mean platelet volume (MPV), and Plateletcrit (PCT). Values will be obtained from the Abaxis VetScan HM5 following manufacturer's directions.

Clinical chemistry on serum: For NHP studies, the following parameters will be measured at time points before and after HeV, LASV, and JUNV challenge: Albumin (ALB), amylase (AMY), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyltransferase (GGT), glucose (GLU), total protein (TP), blood urea nitrogen (BUN), and creatinine (CRE), C-reactive protein (CRP), Calcium (Ca2+), and uric acid (UA). Values will be obtained from the Abaxis Piccolo chemistry analyzer following manufacturer's directions.

Viral load assays: *PCR Assay:* To assess viral loads in whole blood and tissues, RNA will be extracted using a virus RNA isolation kit (Qiagen, Valencia, CA) followed by TaqMan PCR for the viral genome being studied. Qiagen buffers have been safety tested for inactivation of paramyxoviruses, arenaviruses, and phleboviruses. PCR assays employed for HeV, SOSV, LASV, JUNV, RVFV, and SFTSV have been previously described[28-30,33,37-39].

Plaque Assay: The plaque assays employed for paramyxoviruses, arenaviruses, and phleboviruses have previously been described[28-30,33,40]. Briefly, 10-fold dilutions (10-1 to 10-6) of serum, plasma, or whole blood samples are prepared in cell maintenance medium (DMEM/10%FBS/gentamicin) and adsorbed to 70-90% confluent monolayers of Vero E6 cells in 6-well plates, adding 0.2 mL/well. The plates are incubated at 37°C, 5% CO2 for 45 min, with periodical rocking every 10-15 min. The incubation period is followed by addition of 2 mL 1% agarose-containing medium (2X EBME/Hepes/10% FBS/gentamicin) to each well. After the agarose has solidified, the plates are returned to the C02 incubator and maintained for 2-14 days until plaques are visualized. At this time, 2 mL PBS containing 5% neutral red and 5% FBS is added to each well, the plates returned to the CO2 incubator and held overnight. The following day, the liquid stain overlay is removed from each well and plaques are counted.

Bead-based multiplex assays: Plasma inflammatory mediators, thrombosis markers, and fibrinolysis analytes were measured by flow cytometry using Biolegend LegendPlex assays and a FACS Canto-II cytometer (Becton Dickson). Samples will be processed in duplicate for each Nonhuman Primate Inflammation 13-plex (1:4 dilution), Human Thrombosis (1:100), and Human Fibrinolysis (1:40,000) panel as previously described[41-43].

Gross pathology and histopathology: A necropsy will be performed on all NHPs. We will examine the external surfaces of the body, all orifices, and the thoracic and peritoneal cavities and their contents. Core D will prepare a written report of the gross pathology findings of each NHP. The following NHP tissues will be collected at necropsy, fixed in 10% neutral-buffered formalin, embedded in paraffin, and stained by H&E: liver, spleen, lung, kidney, adrenal gland, pancreas, axillary lymph node, inguinal lymph node, mesenteric lymph node, duodenum, ileum, colon, brain (frontal cortex, cerebellum, brain stem), cervical spinal cord, urinary bladder, ovary or testis, prostate or uterus, and eye. A microscopic evaluation will be performed on H&E slides of all tissues collected from all NHPs by an ACVP board certified veterinary pathologist. Reports of the histologic findings of each tissue from each animal will be provided to RP1 Leaders. In consultation with the RP1 Leaders, Core D may also perform immunohistochemical and/or special stains such as PTAH for fibrin as previously described[28-30,33].

Quality systems management of all records and data collected from animal studies: Although the animal studies conducted by Core D will not be required to be performed under GLP compliance, UTMB will provide Quality Assurance that will achieve data quality and integrity when conducting animal experiments. Quality refers to whether the study was conducted in accordance with the protocol, standard operating procedures, and applicable standards of research. Integrity refers to assurance that the raw data and documentation are consistent with reported results. All animal study personnel will be trained by the UTMB Office of Regulated Nonclinical Studies (ORNcS). on Good Documentation Practices (GDP). All animal study data generated by Core D will be provided to Core B as detailed in the Core B Research Strategy.

Aim 4: Develop and/or optimize animal models for Sosuga virus and Junin virus.

For HeV and LASV Core D will employ animal models that have already been developed and are well established. However, for SOSV, JUNV, RVFV, SFTSV while animal models exist there are gaps that need to be addressed. Recently, it was shown that i.n. or i.p. infection of hamsters with SOSV resulted in viremia and mild clinical disease[34] but there is no lethal model for SOSV. Core B will further explore the hamster model for SOSV by 1) using higher challenge doses of SOSV which is often required to produce lethal disease in other paramyxovirus hamster models[32,44] or 2) serially passage of tissues in hamsters. Core D will also assess the pathogenic potential of ferrets for SOSV as they are often used as animal models for paramyxoviruses. For arenaviruses such as JUNV, serial adaptation is often required to produce lethal disease in outbred guinea pigs. While adapted viruses have utility in assessing the protecting efficacy of medical countermeasures in animal models non adapted wild type viruses are preferred to better assess vaccines and treatments. We and others recently showed that for Ebolaviruses while serial adaptation is required to produce lethality in mice, hamsters, and guinea pigs, infection of ferrets with *Zaire ebolavirus*, *Sudan ebolavirus*, *Bundibugyo ebolavirus*, or *Reston ebolavirus* resulted in uniform lethality with wild type viruses and did not require adaptation[45-48]. Therefore, Core D will assess the pathogenic potential of JUNV in ferrets.

Here you go. We need you to add a little that is highlighted as we were not sure of the final Center structure. Alex, Tetsuro, I did not think they you were proposing new reporter viruses or animal models for RVFV or SFTSV. If that is not correct we still have some room left in the Research Strategy for additions.

Hi Bob et al,

Hope all is well.

I am checking in to confirm that you will be able to please send us a near final draft of the science write-up for your Core in the next few hours?

Thanks in advance
David

RESEARCH STRATEGY

A. SIGNIFICANCE

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the WHO Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phlebovirus Rift Valley fever virus (RVFV). All of these viruses are also included among the World Health Organization's (WHO) List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The Machine Learning-(ML)-Enabled Design of Prototype Pathogen Vaccines and Antibodies Center is a well-integrated consortium conducting a set of discovery and translational research programs composed of an Administrative Core, a Data Management Core, X Scientific Cores, and X Research Projects (RPs). The synergistic activities of the X Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the X Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV), JUNV, RVFV, and severe fever with thrombocytopenia syndrome virus (SFTSV) to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

All X of the research projects within the X Center focus on developing vaccines or monoclonal antibody (mAb) based therapies against paramyxoviruses, arenaviruses, and phleboviruses. All X of these research projects require that countermeasures be evaluated in animals against infectious paramyxoviruses, arenaviruses, and phleboviruses. As HeV, LASV, JUNV, and RVFV are CDC and/or USDA select agents Federal regulations require that these viruses be handled in Biosafety Level (BSL)-3 or BSL-4 containment. Core D provides approved BSL-3/ABSL-3 and BSL-4/BSL-4 facilities and a trained and experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2.

B. INNOVATION

Scientific Core D will be co-located within the Galveston National Laboratory (GNL) and Robert Shope Laboratory at the University of Texas Medical Branch (UTMB) at Galveston. The GNL is a high and maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda and stands ready to assist local, state and national public health efforts in the event of a public health emergency. The facility is unique in that it is one of two operational BSL-4 facilities in the United States that is located on an academic campus. This unique location benefits the X Center in several ways. Regarding physical resources the GNL is a state-of-the-art facility with many specialized assets including BSL-4 imaging, telemetry, and aerobiology equipment. In addition, being located on an academic campus Drs. Geisbert (Core D, Project Leader (PL), Cross, Freiberg, and Ikegami are faculty members in the Departments of Microbiology and Immunology and Pathology. This academic environment is a major strength, that fosters creativity and collaboration with other UTMB investigators which will be beneficial to the overall success of Core D. Dr. Broder, is faculty member of the Department of Microbiology and Immunology at Uniformed Services University (USU). Drs. Broder and Geisbert (PL) have a long-standing emerging virus research collaboration which has included the development and characterization the first nonhuman primate (NHP) models for HeV and Nipah virus (NiV) that will be employed by the Center's RPs. Another strength within the Core is Drs. Geisbert, Broder, Cross, and Veesler (Center Co-PI) currently collaborate and lead active henipavirus projects that are focused on translational countermeasure development which includes more traditional vaccine and mAb therapeutics approaches, and the shared knowledge base and experience in these areas will greatly facilitate the Core's abilities in supporting the Center's research goals in applying advanced machine learning-enabled

designs of effective prototype pathogen vaccines and antibodies. Along with animal model development and animal modeling expertise, many of the unique virological tools including recombinantly generated RNA viruses, reporter gene-encoding viruses, and other pseudotype virus technologies, that will be employed by the Core, have been developed from UTMB-USU collaboration.

C. APPROACH

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Paramyxovirus, arenavirus, and phlebovirus seed stocks. UTMB will provide fully equipped BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities that are required to work with HeV, SOSV, LASV, JUNV, RVFV, and SFTSV. UTMB will also provide and maintain all required approvals to work these viruses. The BSL-3 and BSL-4 paramyxovirus, arenavirus, and phlebovirus seed stocks employed for RP1 and RP2 have been or will be titered by conventional standard plaque assay and qRT-PCR as detailed in Aim 2 below. The virus strain identity of each seed stock has been or will be confirmed by sequence analysis. In addition, RNA has been or will be deep sequenced to verify the complete viral genome of each virus seed stock used for animal challenge studies. We have or will test each seed stock for mycoplasma contamination. Endotoxin testing has been or will be performed on paramyxovirus, arenavirus, and phlebovirus stocks using the Endosafe PTS system (Charles River Laboratories) following the manufacturer’s instructions. The Endosafe PTS system is a cartridge-based testing system utilizing FDA-licensed cartridges (0.1 EU/ml, 0.05 EU/ml, 0.01 EU/ml, 0.05 EU/ml) for ultrasensitive testing. Seed stocks will also be evaluated for morphological identity by transmission electron microscopy (TEM). Virus particle counts will be determined using a Virus Counter and confirmed by conventional TEM methods if needed. The bacteriological and mycological sterility of the product will be determined by selection of aliquots of the dispensed stock, inoculation of a sterile 500 ml bottle of Dulbecco's high glucose MEM with 10% FBS and then after 3 days subcultured to FTM and TBS media. paramyxovirus, arenavirus, and phlebovirus seed stocks will be inventoried in the UTMB BSL-4 and BSL-4 virus stock databases and secured in dedicated controlled access alarmed minus 80°C freezers in the GNL or Robert Shope Laboratory. Paramyxovirus, arenavirus, and phlebovirus seed stocks are monitored periodically for any changes in virus titer.

Plan for staffing, managing, and prioritizing Core use. The Core Leader and Co-Leaders have a cadre of staff that are trained and highly experienced in all BSL-3 and BSL-4 procedures and assays needed to conduct the proposed work. In addition to the Core Leader and Co-Leaders this staff includes an ACVP board certified veterinary pathologist, two BSL-4 contributing scientists, a BSL-4 Technical Director, a BSL-4 trained postdoctoral fellow, six BSL-4 experienced technical staff, a BSL-4 trained histotechnologist, and a BSL-4 trained graduate student. We do not anticipate any BSL-3 or BSL-4 scheduling problems regarding studies proposed in RP1 or RP2. However, we have developed a mitigation strategy if unforeseen events cause any prioritization of resources. A committee consisting of the Core D Leader, the PI of the Center, and the members of the external Scientific Advisory Committee (SAC) will review the status of RP1 and RP2 and any circumstances causing a prioritization of work. The Committee will also hold a meeting or teleconference (Zoom, Teams) with the Project Leaders and key staff of RP1 and RP2 to gather additional information. After careful review of all available information the Committee will then make a recommendation on prioritization to the Center PI. The X Center PI will then consult with NIAID/NIH program staff and make the final determination on prioritization.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

In vitro antiviral activity assays: Core D will perform conventional virus neutralization assays for RP1 and RP2 to determine the ability of sera/plasma from immunized animals from RP1 and antibodies from RP2 to inhibit the replication of paramyxoviruses, arenaviruses, and phleboviruses *in vitro* using infectious viruses in the UTMB BSL-3 and BSL-4 laboratories. In brief, cultures of Vero, Vero E6, SW13, or other cell types will be infected with a range of m.o.i. of paramyxoviruses, arenaviruses, and bunyaviruses and treated with various concentrations of the provided sera/plasma or antibodies. Cells and/or culture fluids will be harvested at various time points after infection and infectious virus enumerated by conventional plaque assay as detailed below.

Develop chimeric reporter-gene encoding viruses and virus neutralization assays for BSL-2 use.
We have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP) (PMID: 23849788 and PMID: 24576301), as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses (PMID: 32407866 and PMID: 30875748). In addition, we have generated a reverse genetics platform for generating recombinant Cedar virus (rCedV) and rCedV chimeras whereby the

fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-B) or HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without reporter genes (PMID: 35617431, PMID: 31548390, PMID: 29587789, PMID: 37243163). The rCedV chimeras are a replication competent authentic henipavirus platform that is a high-throughput surrogate neutralization assay that is rapid, cost-effective and can be utilized outside high containment. Similar approaches will be applied here to generate new reporter viruses for Ghana bat virus (GhV). We will design, construct and rescue both VSV and rCedV chimeras that encode the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of GhV. Two reporter-gene encoding versions will be attempted for VSV-GhV: one encoding GFP (VSV-GhV-GFP) and the other encoding the *Photinus pyralis* (firefly) luciferase gene (VSV-GhV-Luc). We will also construct and rescue GFP and Luc reporter gene encoding versions? of rCedV chimeras encoding the GhV F and G genes (rCedV-GhV-GFP and rCedV-GhV-Luc) (**Fig. 1**). The rescued viruses will be characterized using cell-based infection tropism and growth kinetics assays.

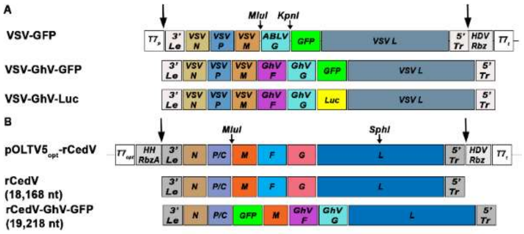

Figure 1. Schematic of chimeric reporter viruses. (**A**)The VSV-ABLV G-GFP plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and KpnI to construct VSV-GhV-GFP and VSV-GhV-Luc. (**B**) pOLTV5$_{opt}$-rCedV plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and SphI used to construct rCedV-GhV-GFP.

The rCedV (NiV-B and HeV) chimeric virus platform serves as a robust surrogate neutralization assay system for quantifying antibody neutralization potency of anti-NiV and anti-HeV antisera and mAbs [Amaya et al, Viruses 2023 see comment box]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP are highly correlated with those obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization test (PRNT). Pearson correlation of rCedV chimeras BSL-2 PRNT to the NiV-B or HeV BSL-4 PRNT is shown in **Fig. 2a**. A high-throughput quantitative assay based on reduction of GFP foci (fluorescent reduction neutralization test (FRNT)) was also developed. Correlation analysis with mAb neutralization values by PRNT vs FRNT (**Fig. 2b**), Pearson's r ≥ 0.9 and p-value < 0.001).

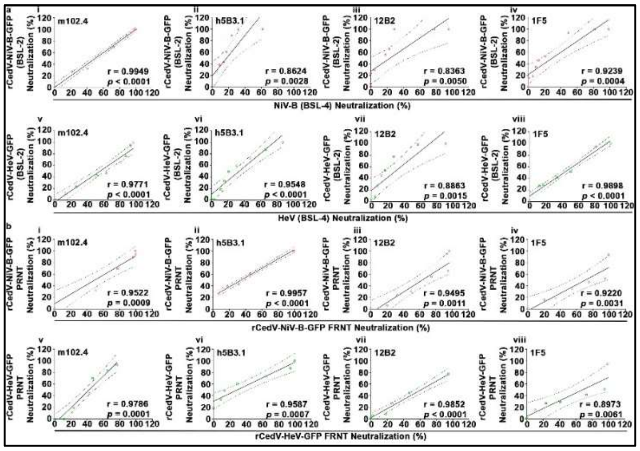

Figure 2. Panel a: Pearson correlation for BSL-2 PRNT vs BSL-4 PRNT (rCedV-NiV-B-GFP versus NiV-B (**i-iv**) and rCedV-HeV-GFP versus HeV (**v-viii**)). Panel b: Pearson correlation for PRNT vs FRNT ((rCedV-NiV-B-GFP (**i-iv**) and rCedV-HeV-GFP (**v-viii**)).

Rescue and characterize reporter viruses encoding GhV envelope glycoproteins.

Generation of a VSV encoding GhV envelope glycoproteins. We will construct reporter gene encoding versions of a replication competent VSV encoding the GhV F and G glycoproteins (GFP and Luc) (**Fig. 1A)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the GhV F and G coding sequences will be synthesized. The GhV F and G coding sequences will be based on the GhV isolate Eid_hel/GH-M74a/GHA/2009 (GenBank: NC_025256.1). The GenBank accession number for GhV F is YP_009091837.1 and that for the GhV G protein is YP_009091838.1. Unique restriction enzyme sites, MluI and KpnI will facilitate the insertion of the GhV F and G gene cassette into the VSV backbone plasmid. The VSV-GhV-Luc will be similarly made. Cloning procedures are performed in *E. coli* Stbl2 and all plasmids verified by sequencing. Rescue will be performed in BSR-T7/5 cells, transfected helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-GhV-GFP or VSV-GhV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells by inoculation with the supernatant from step 1. When GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks are tittered by serial dilution on HEK293T cells by plaque assay (PMID: 32833351).

Generation of rCedV encoding GhV envelope glycoproteins. rCedV-GhV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the GhV F and G coding sequences. The CedV non-coding intergenic regions are retained as is adherence to the genomic "rule of six".

Unique restriction sites, MluI and SphI will facilitate the insertion of the GhV F and G gene cassette into the genome clone ($pOLTV5_{opt}$-rCedV) generating rCedV-GhV-GFP (**Fig. XB**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and $pOLTV5_{opt}$-rCedV-GhV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. At maximal syncytia and GFP (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C (PMCID: PMC8631057, PMCID: PMC5869790, PMCID: PMC1563797).

Characterization of the recombinant reporter viruses in cell-based infection assays: The replication kinetics of the VSV-based and rCedV-based GhV F/G encoding viruses will be assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and tittered. VSV-GhV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G (PMID: 23849788). Similarly, rCedV-GhV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Unlike NiV and HeV, GhV G engages only the ephrin-B2 ligand to trigger membrane fusion (PMID: 24296468). The GhV F/G bearing reporter viruses will be verified for this specific ephrin ligand tropism in cell infection and/or syncytia formation experiments and comparisons made to wildtype VSV or VSV-ABLV G and also alternatively to rCedV, and rCedV NiV/HeV chimeras. We have generated murine mAbs to GhV F and G (10C4-LY and 10D5-LY to GhV G; and 5B7-LY and 7C11-LY to GhV F) and these will be used in neutralization tests. The VSV-GhV-GFP assays will be conducted by FRNTs and VSV-GhV-Luc in luciferase assays.

Evaluating neutralization potential of vaccine platforms from other research projects. Our rCeV chimeras (rCedV-NiV-B-GFP and rCedV-HeV-GFP) will allow this Core to conduct large numbers of neutralization tests by FRNT, to the many ML-derived prototype henipavirus vaccine antigen constructs, mAbs, and nanobinders, that will be generated by the Center's RPs. In Center years 1-3 the focus will be on HeV and NiV prototypes, and in years 4-5 the Core is expected to shift to GhV test case. The FRNT assay is rapid (36hrs), high throughput, and performed in 96-well plates to establish typical 7-point dose response virus neutralization data and performed at BSL-2. Typically, immune sera, mAbs, or other entry inhibitors are analyzed by serially dilution and mixed with virus (rCedV-NiV-B-GFP or rCedV-HeV-GFP) for 2hrs then samples used in triplicate to infect confluent Vero 76 cells in black-walled clear bottom 96-well plates and incubated 24hrs, and then plates are fixed and imaged and fluorescent foci quantitated with CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) is determined by 50% reduction in fluorescent foci versus untreated controls.

Anticipated Results, Potential Pitfalls and Alternative Strategies. We anticipate the reporter viruses will replicate to titers fit for purpose. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. If we encounter unexpected limitations in rescuing VSV-based or rCedV-based GhV F/G bearing reporter viruses; we will 1) test different ratios of helper plasmids and antigenome plasmids; 2) perform rescue using different cell lines; 3) construct alternate versions of the GhV F and G genes within the antigenome plasmids, such as truncating the GhV G protein which has been shown to enhance GhV mediated F/G membrane fusion (PMID: 31470664). Alternatively, fusion of the GhV F and G ectodomains with the transmembrane and cytoplasmic tail domains of the corresponding CedV F and G elements may facilitate virus particle formation and membrane fusion activity.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

The Core D Leader and Co-Leaders will work closely with the Project Leaders and key staff of RP1 and RP2 to develop vaccination, treatment and sampling regimens, study protocols, and animal protocols that utilize countermeasures identified in RP1 and RP2. The Core Leader and Co-Leaders will write and obtain UTMB IACUC approval for all animal protocols performed in Core D. The animal models and clinical pathology, immunology, virology, and histopathology assays employed for Aim 3 are detailed below. All raw data as well as graphed or tabulated data generated by Core D will be handled and analyzed in coordination with the Core B.

Animal models: Core D will employ established animal models for HeV, LASV, RVFV, and SFTSV. While animal models also exist for SOSV and JUNV we will optimize these models to fill gaps and provide new tools as detailed in Aim 4 below. Mice, guinea pigs, hamsters, ferrets, and cats have been used as small animal models of HeV infection (PMID: 22476556). This project will employ Syrian golden hamsters as the small animal model of HeV disease because they are more suitable than other small animals for screening large numbers of vaccines and mAbs. Using hamsters will allow us to select optimal vaccine and mAb formulations and regimens prior to efficacy testing in NHPs. In 2010 Drs. Geisbert and Broder developed the first highly lethal NHP model for henipavirus infection (Nipah virus) using African green monkeys (AGM) (PMCID: PMC2872660.). They subsequently developed a lethal AGM model for HeV infection (PMCID: PMC2937751.). Henipavirus NHP models mirror human disease with animals showing severe respiratory pathology, neurological disease, and generalized vasculitis. For LASV, Core D will use established lethal outbred guinea pig models that cover several lineages of LASV (PMCID: PMC1892204; PMCID: PMC4401668; PMCID: PMC5032844.; PMCID: PMC6763766; PMCID: PMC10052409) as guinea pigs are the only immunocompetent small animal model for Lassa fever. Core D will also use established cynomolgus monkey models that cover several genetically distinct lineages of LASV (PMCID: PMC2681932. ; PMCID: PMC3104370. ; PMCID: PMC6934204.)

Animal vaccinations: All animals will be obtained from commercial vendors and allowed to acclimate prior to vaccination (~ 3-7 days for mice, hamsters, and guinea pigs and ~ 14 days for ferrets and NHPs). Mice, hamsters, and guinea pigs will be vaccinated by intramuscular (i.m.) or intraperitoneal (i.p.) injection of the vaccines provided by RP1. Ferrets and NHPs will be vaccinated by i.m. injection of the vaccines provided by RP1. All animals will be vaccinated in ABSL-2. Animals will be monitored daily for any reaction or adverse events caused by the vaccination. Blood will be collected for plasma, serum, and PBMC isolations before vaccination and at times after vaccination for assessment of the host immune response.

Animal challenges: Hamsters, ferrets, and NHPs will be challenged with infectious HeV or SOSV as previously described (PMCID: PMC4971471. ; PMCID: PMC8527959.; PMCID: PMC7199785). After appropriate acclimation, hamsters and ferrets will be exposed to HeV or SOSV by intranasal (i.n.) or i.p. administration of up to 1x10^6 PFU of virus. NHPs will be challenged with HeV by the intratracheal (i.t.) and/or i.n. routes using up to 1 x 10^6 PFU of virus. Mice, guinea pigs, and ferrets will be exposed with up to 5,000 PFU of arenaviruses and phleboviruses by i.p. injection (PMCID: PMC7593599. ; PMCID: PMCID: PMC5032844. PMCID: PMC4843420.; PMCID: PMC8781158). NHPs will be exposed with up to 5.000 PFU of LASV by i.m. injection (PMCID: PMC5719877; PMCID: PMC6934204), Junin virus by intravenous (i.v.) injection (PMCID: PMC7980402) while marmosets will be exposed to up to 1x10^7 PFU of RVFV as previously described (PMCID: PMC3302397). For all animals, blood will be collected with or without anticoagulants for plasma and serum isolations, respectively, at times before paramyxovirus, arenavirus, or phlebovirus challenge, on the day of challenge, and at various times after challenge as detailed in RP1 and RP2. Animals will be monitored for clinical signs daily. We will apply a scoring sheet approved by the UTMB IACUC depicted in the Vertebrate Animals section to assist in determining the time of euthanasia depending on clinical signs (e.g., respiratory distress, anorexia, activity, appearance, neurologic signs, etc.). Animals will be euthanized according to the 2013 AVMA Guidelines on Euthanasia. Any surviving animals will be euthanized on day 35-42 days after paramyxovirus, arenavirus, or phlebovirus challenge.

Clinical pathology assays: *Hematology on EDTA whole blood*: For NHP studies, we will measure the following parameters at time points before and after HeV, LASV, or JUNV challenge: total white blood cell counts (WBC), percent lymphocytes (LY), percent monocytes (MO), percent neutrophils (NEU), percent eosinophils (EOS), percent basophils (BAS), total lymphocyte counts (LY#), total monocyte counts (MO#), total neutrophil counts (NEU#), total eosinophil counts (EOS #), total basophil counts (BAS #), red blood cell counts (RBC), total hemoglobin (Hgb), hematocrit values (HCT), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), platelets (PLT), and mean platelet volume (MPV), and Plateletcrit (PCT). Values will be obtained from the Abaxis VetScan HM5 following manufacturer's directions.

Clinical chemistry on serum: For NHP studies, the following parameters will be measured at time points before and after HeV, LASV, and JUNV challenge: Albumin (ALB), amylase (AMY), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyltransferase (GGT), glucose (GLU), total protein (TP), blood urea nitrogen (BUN), and creatinine (CRE), Creactive protein (CRP), Calcium (Ca2+), and uric acid (UA). Values will be obtained from the Abaxis Piccolo chemistry analyzer following manufacturer's directions.

Viral load assays: *PCR Assay:* To assess viral loads in whole blood and tissues, RNA will be extracted using a virus RNA isolation kit (Qiagen, Valencia, CA) followed by TaqMan PCR for the viral genome being studied. Qiagen buffers have been safety tested for inactivation of paramyxoviruses, arenaviruses, and phleboviruses. PCR assays employed for HeV, SOSV, LASV, JUNV, RVFV, and SFTSV have been previously described

(PMCID: PMC7870971; PMCID: PMC7980402. ; PMID: 36521633; PMCID: PMC5719877; PMCID: PMC5627234).

Plaque Assay: The plaque assays employed for paramyxoviruses, arenaviruses, and phleboviruses have previously been described (PMCID: PMC7870971; PMCID: PMC7980402. ; PMCID: PMC5719877; PMCID: PMC1395455). Briefly, 10-fold dilutions (10-1 to 10-6) of serum, plasma, or whole blood samples are prepared in cell maintenance medium (DMEM/10%FBS/gentamicin) and adsorbed to 70-90% confluent monolayers of Vero E6 cells in 6-well plates, adding 0.2 mL/well. The plates are incubated at 37°C, 5% CO2 for 45 min, with periodical rocking every 10-15 min. The incubation period is followed by addition of 2 mL 1% agarose-containing medium (2X EBME/Hepes/10% FBS/gentamicin) to each well. After the agarose has solidified, the plates are returned to the C02 incubator and maintained for 2-14 days until plaques are visualized. At this time, 2 mL PBS containing 5% neutral red and 5% FBS is added to each well, the plates returned to the CO2 incubator and held overnight. The following day, the liquid stain overlay is removed from each well and plaques are counted.

Bead-based multiplex assays: Plasma inflammatory mediators, thrombosis markers, and fibrinolysis analytes were measured by flow cytometry using Biolegend LegendPlex assays and a FACS Canto-II cytometer (Becton Dickson). Samples will be processed in duplicate for each Nonhuman Primate Inflammation 13-plex (1:4 dilution), Human Thrombosis (1:100), and Human Fibrinolysis (1:40,000) panel as previously described (PMCID: PMC7790436; PMCID: PMC8406165; PMCID: PMC9225728).

Gross pathology and histopathology: A necropsy will be performed on all NHPs. We will examine the external surfaces of the body, all orifices, and the thoracic and peritoneal cavities and their contents. Core D will prepare a written report of the gross pathology findings of each NHP. The following NHP tissues will be collected at necropsy, fixed in 10% neutral-buffered formalin, embedded in paraffin, and stained by H&E: liver, spleen, lung, kidney, adrenal gland, pancreas, axillary lymph node, inguinal lymph node, mesenteric lymph node, duodenum, ileum, colon, brain (frontal cortex, cerebellum, brain stem), cervical spinal cord, urinary bladder, ovary or testis, prostate or uterus, and eye. A microscopic evaluation will be performed on H&E slides of all tissues collected from all NHPs by an ACVP board certified veterinary pathologist. Reports of the histologic findings of each tissue from each animal will be provided to RP1 Leaders. In consultation with the RP1 Leaders, Core D may also perform immunohistochemical and/or special stains such as PTAH for fibrin as previously described (PMCID: PMC5719877; PMCID: PMC5719877; PMCID: PMC7980402.).

Quality systems management of all records and data collected from animal studies: Although the animal studies conducted by Core D will not be required to be performed under GLP compliance, UTMB will provide Quality Assurance that will achieve data quality and integrity when conducting animal experiments. Quality refers to whether the study was conducted in accordance with the protocol, standard operating procedures, and applicable standards of research. Integrity refers to assurance that the raw data and documentation are consistent with reported results. All animal study personnel will be trained by the UTMB Office of Regulated Nonclinical Studies (ORNcS). on Good Documentation Practices (GDP). All animal study data generated by Core D will be provided to Core B as detailed in the Core B Research Strategy.

Aim 4: Develop and/or optimize animal models for Sosuga virus and Junin virus.

For HeV and LASV Core D will employ animal models that have already been developed and are well established. However, for SOSV, JUNV, RVFV, SFTSV while animal models exist there are gaps that need to be addressed. Recently, it was shown that i.n. or i.p. infection of hamsters with SOSV resulted in viremia and mild clinical disease (PMID: 36521633) but there is no lethal model for SOSV. Core B will further explore the hamster model for SOSV by 1) using higher challenge doses of SOSV which is often required to produce lethal disease in other paramyxovirus hamster models (PMCID: PMC8527959; PMCID: PMC3147900) or 2) serially passage of tissues in hamsters. Core D will also assess the pathogenic potential of ferrets for SOSV as they are often used as animal models for paramyxoviruses. For JUNV, serial adaptation is often required to produce lethal disease in outbred guinea pigs. We recently showed that for Ebolaviruses while serial adaptation is required to produce lethality in mice, hamsters, and guinea pigs, infection of ferrets with *Zaire ebolavirus*, *Sudan ebolavirus*, or *Bundibugyo ebolavirus* resulted in uniform lethality with wild type viruses and did not require adaptation (PMCID: PMC4957446.). Therefore, Core D will assess the pathogenic potential of JUNV in ferrets.

BIBLIOGRAPHY AND REFERENCES CITED

ANIMAL MODELS AND VACCINE EVALUATION SCIENTIFIC CORE (CORE D)

1. SPECIFIC AIMS

The main objective of the Animal Models and Vaccine Evaluation Scientific Core is to test and characterize the host response and efficacy of the vaccines and monoclonal antibody (mAb) based treatments identified in RP1 and RP2 against paramyxoviruses, arenaviruses, and phleboviruses under BSL-3/ABSL-3 and BSL-4/ABSL-4 containment. The Core will also develop select reporter viruses and conduct cell-based assays to characterize vaccine-induced neutralizing antibody responses and mAbs.

The Specific Aims of the Animal Models and Vaccine Evaluation Scientific Core are to:

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

Aim 4: Develop and/or optimize animal models for Sosuga virus and Junin virus.

The Aims will be achieved by the following specific functions to be carried out by the Animal Models and Vaccine Evaluation Scientific Core Leader, Co-Core Leaders, and personnel:

1. Maintain records of well characterized BSL-3 and BSL-4 Hendra virus (HeV), Sosuga virus (SOSV), Lassa virus (LASV), Junin virus (JUNV), Rift valley fever virus (RVFV), and severe fever with thrombocytopenia syndrome virus (SFTSV) seed stocks including background history, passage history, genomic information, periodic monitoring of titer, mycoplasma testing, endotoxin testing, and sterility testing.
2. Perform *in vitro* antiviral activity assays. Including high-throughput BSL-2 based neutralization testing of henipavirus vaccine responses and mAbs.
3. Assist Center Investigators in designing animal studies, prepare animal protocols, and obtain IACUC approval of BSL-3 and BSL-4 animal studies.
4. Perform animal challenges using well characterized HeV, SOSV, LASV, JUNV, RVFV, and SFTSV seed stocks for RP1 and RP2.
5. Perform vaccination and treatment of animals with vaccines and treatments provided by RP1 and RP2.
6. Provide samples from animals collected during the vaccination portion of studies to RP1 for immunological analysis.
7. Perform all duties associated with animal challenge studies including monitoring of animals, collection of samples, and necropsies.
8. Perform clinical pathology assays including hematology and clinical chemistry assays.
9. Perform virology assays on blood and/or tissue samples collected from infected animals including viral load by plaque assay and RT-PCR.
10. Perform gross pathology analysis on all animals at necropsy.
11. Perform histopathologic analysis on tissues from animals collected at necropsy.
12. Develop and/or optimize animal models for SOSV and JUNV to fill gaps; make these models available to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers
13. Provide all data generated in Core D to Data Management Core B.

RESEARCH STRATEGY

A. SIGNIFICANCE

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the WHO Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phlebovirus Rift Valley fever virus (RVFV). All of these viruses are also included among the World Health Organization's (WHO) List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The Machine Learning-(ML)-Enabled Design of Prototype Pathogen Vaccines and Antibodies Center is a well-integrated consortium conducting a set of discovery and translational research programs composed of an Administrative Core, a Data Management Core, X Scientific Cores, and X Research Projects (RPs). The synergistic activities of the X Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the X Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV), JUNV, RVFV, and severe fever with thrombocytopenia syndrome virus (SFTSV) to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

All X of the research projects within the X Center focus on developing vaccines or monoclonal antibody (mAb) based therapies against paramyxoviruses, arenaviruses, and phleboviruses. All X of these research projects require that countermeasures be evaluated in animals against infectious paramyxoviruses, arenaviruses, and phleboviruses. As HeV, LASV, JUNV, and RVFV are CDC and/or USDA select agents Federal regulations require that these viruses be handled in Biosafety Level (BSL)-3 or BSL-4 containment. Core D provides approved BSL-3/ABSL-3 and BSL-4/BSL-4 facilities and a trained and experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2.

B. INNOVATION

Scientific Core D will be co-located within the Galveston National Laboratory (GNL) and Robert Shope Laboratory at the University of Texas Medical Branch (UTMB) at Galveston. The GNL is a high and maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda and stands ready to assist local, state and national public health efforts in the event of a public health emergency. The facility is unique in that it is one of two operational BSL-4 facilities in the United States that is located on an academic campus. This unique location benefits the X Center in several ways. Regarding physical resources the GNL is a state-of-the-art facility with many specialized assets including BSL-4 imaging, telemetry, and aerobiology equipment. In addition, being located on an academic campus Drs. Geisbert (Core D, Project Leader (PL), Cross, Freiberg, and Ikegami are faculty members in the Departments of Microbiology and Immunology and Pathology. This academic environment is a major strength, that fosters creativity and collaboration with other UTMB investigators which will be beneficial to the overall success of Core D. Dr. Broder, is faculty member of the Department of Microbiology and Immunology at Uniformed Services University (USU). Drs. Broder and Geisbert (PL) have a long-standing emerging virus research collaboration which has included the development and characterization the first nonhuman primate (NHP) models for HeV and Nipah virus (NiV) that will be employed by the Center's RPs. Another strength within the Core is Drs. Geisbert, Broder, Cross, and Veesler (Center Co-PI) currently collaborate and lead active henipavirus projects that are focused on translational countermeasure development which includes more traditional vaccine and mAb therapeutics approaches, and the shared knowledge base and experience in these areas will greatly facilitate the Core's abilities in supporting the Center's research goals in applying advanced machine learning-enabled

designs of effective prototype pathogen vaccines and antibodies. Along with animal model development and animal modeling expertise, many of the unique virological tools including recombinantly generated RNA viruses, reporter gene-encoding viruses, and other pseudotype virus technologies, that will be employed by the Core, have been developed from UTMB-USU collaboration.

C. APPROACH

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Paramyxovirus, arenavirus, and phlebovirus seed stocks. UTMB will provide fully equipped BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities that are required to work with HeV, SOSV, LASV, JUNV, RVFV, and SFTSV. UTMB will also provide and maintain all required approvals to work these viruses. The BSL-3 and BSL-4 paramyxovirus, arenavirus, and phlebovirus seed stocks employed for RP1 and RP2 have been or will be titered by conventional standard plaque assay and qRT-PCR as detailed in Aim 2 below. The virus strain identity of each seed stock has been or will be confirmed by sequence analysis. In addition, RNA has been or will be deep sequenced to verify the complete viral genome of each virus seed stock used for animal challenge studies. We have or will test each seed stock for mycoplasma contamination. Endotoxin testing has been or will be performed on paramyxovirus, arenavirus, and phlebovirus stocks using the Endosafe PTS system (Charles River Laboratories) following the manufacturer's instructions. The Endosafe PTS system is a cartridge-based testing system utilizing FDA-licensed cartridges (0.1 EU/ml, 0.05 EU/ml, 0.01 EU/ml, 0.05 EU/ml) for ultrasensitive testing. Seed stocks will also be evaluated for morphological identity by transmission electron microscopy (TEM). Virus particle counts will be determined using a Virus Counter and confirmed by conventional TEM methods if needed. The bacteriological and mycological sterility of the product will be determined by selection of aliquots of the dispensed stock, inoculation of a sterile 500 ml bottle of Dulbecco's high glucose MEM with 10% FBS and then after 3 days subcultured to FTM and TBS media. paramyxovirus, arenavirus, and phlebovirus seed stocks will be inventoried in the UTMB BSL-4 and BSL-4 virus stock databases and secured in dedicated controlled access alarmed minus 80°C freezers in the GNL or Robert Shope Laboratory. Paramyxovirus, arenavirus, and phlebovirus seed stocks are monitored periodically for any changes in virus titer.

Plan for staffing, managing, and prioritizing Core use. The Core Leader and Co-Leaders have a cadre of staff that are trained and highly experienced in all BSL-3 and BSL-4 procedures and assays needed to conduct the proposed work. In addition to the Core Leader and Co-Leaders this staff includes an ACVP board certified veterinary pathologist, two BSL-4 contributing scientists, a BSL-4 Technical Director, a BSL-4 trained postdoctoral fellow, six BSL-4 experienced technical staff, a BSL-4 trained histotechnologist, and a BSL-4 trained graduate student. We do not anticipate any BSL-3 or BSL-4 scheduling problems regarding studies proposed in RP1 or RP2. However, we have developed a mitigation strategy if unforeseen events cause any prioritization of resources. A committee consisting of the Core D Leader, the PI of the Center, and the members of the external Scientific Advisory Committee (SAC) will review the status of RP1 and RP2 and any circumstances causing a prioritization of work. The Committee will also hold a meeting or teleconference (Zoom, Teams) with the Project Leaders and key staff of RP1 and RP2 to gather additional information. After careful review of all available information the Committee will then make a recommendation on prioritization to the Center PI. The X Center PI will then consult with NIAID/NIH program staff and make the final determination on prioritization.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

In vitro antiviral activity assays: Core D will perform conventional virus neutralization assays for RP1 and RP2 to determine the ability of sera/plasma from immunized animals from RP1 and antibodies from RP2 to inhibit the replication of paramyxoviruses, arenaviruses, and phleboviruses *in vitro* using infectious viruses in the UTMB BSL-3 and BSL-4 laboratories. In brief, cultures of Vero, Vero E6, SW13, or other cell types will be infected with a range of m.o.i. of paramyxoviruses, arenaviruses, and bunyaviruses and treated with various concentrations of the provided sera/plasma or antibodies. Cells and/or culture fluids will be harvested at various time points after infection and infectious virus enumerated by conventional plaque assay as detailed below.

Develop chimeric reporter-gene encoding viruses and virus neutralization assays for BSL-2 use.
We have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP) (PMID: 23849788 and PMID: 24576301), as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses (PMID: 32407866 and PMID: 30875748). In addition, we have generated a reverse genetics platform for generating recombinant Cedar virus (rCedV) and rCedV chimeras whereby the

fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-B) or HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without reporter genes (PMID: 35617431, PMID: 31548390, PMID: 29587789, PMID: 37243163). The rCedV chimeras are a replication competent authentic henipavirus platform that is a high-throughput surrogate neutralization assay that is rapid, cost-effective and can be utilized outside high containment. Similar approaches will be applied here to generate new reporter viruses for Ghana bat virus (GhV). We will design, construct and rescue both VSV and rCedV chimeras that encode the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of GhV. Two reporter-gene encoding versions will be attempted for VSV-GhV: one encoding GFP (VSV-GhV-GFP) and the other encoding the *Photinus pyralis* (firefly) luciferase gene (VSV-GhV-Luc). We will also construct and rescue GFP and Luc reporter gene encoding versions? of rCedV chimeras encoding the GhV F and G genes (rCedV-GhV-GFP and rCedV-GhV-Luc) (**Fig. 1**). The rescued viruses will be characterized using cell-based infection tropism and growth kinetics assays.

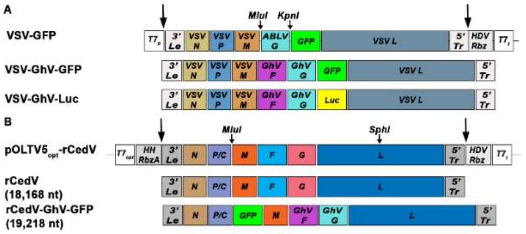

Figure 1. Schematic of chimeric reporter viruses. (**A**)The VSV-ABLV G-GFP plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and KpnI to construct VSV-GhV-GFP and VSV-GhV-Luc. (**B**) pOLTV5$_{opt}$-rCedV plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and SphI used to construct rCedV-GhV-GFP.

The rCedV (NiV-B and HeV) chimeric virus platform serves as a robust surrogate neutralization assay system for quantifying antibody neutralization potency of anti-NiV and anti-HeV antisera and mAbs [Amaya et al, Viruses 2023 see comment box]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP are highly correlated with those obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization test (PRNT). Pearson correlation of rCedV chimeras BSL-2 PRNT to the NiV-B or HeV BSL-4 PRNT is shown in **Fig. 2a**. A high-throughput quantitative assay based on reduction of GFP foci (fluorescent reduction neutralization test (FRNT)) was also developed. Correlation analysis with mAb neutralization values by PRNT vs FRNT (**Fig. 2b)**, Pearson's r ≥ 0.9 and p-value < 0.001).

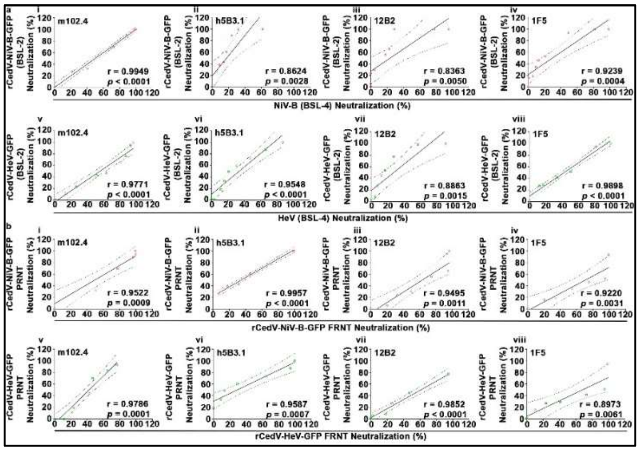

Figure 2. Panel a: Pearson correlation for BSL-2 PRNT vs BSL-4 PRNT (rCedV-NiV-B-GFP versus NiV-B (**i-iv**) and rCedV-HeV-GFP versus HeV (**v-viii**)). Panel b: Pearson correlation for PRNT vs FRNT ((rCedV-NiV-B-GFP (**i-iv**) and rCedV-HeV-GFP (**v-viii**)).

Rescue and characterize reporter viruses encoding GhV envelope glycoproteins.

Generation of a VSV encoding GhV envelope glycoproteins.

We will construct reporter gene encoding versions of a replication competent VSV encoding the GhV F and G glycoproteins (GFP and Luc) (**Fig. 1A)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the GhV F and G coding sequences will be synthesized. The GhV F and G coding sequences will be based on the GhV isolate Eid_hel/GH-M74a/GHA/2009 (GenBank: NC_025256.1). The GenBank accession number for GhV F is YP_009091837.1 and that for the GhV G protein is YP_009091838.1. Unique restriction enzyme sites, MluI and KpnI will facilitate the insertion of the GhV F and G gene cassette into the VSV backbone plasmid. The VSV-GhV-Luc will be similarly made. Cloning procedures are performed in *E. coli* Stbl2 and all plasmids verified by sequencing. Rescue will be performed in BSR-T7/5 cells, transfected helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-GhV-GFP or VSV-GhV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells by inoculation with the supernatant from step 1. When GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks are tittered by serial dilution on HEK293T cells by plaque assay (PMID: 32833351).

Generation of rCedV encoding GhV envelope glycoproteins. rCedV-GhV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the GhV F and G coding sequences. The CedV non-coding intergenic regions are retained as is adherence to the genomic "rule of six".

Unique restriction sites, MluI and SphI will facilitate the insertion of the GhV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) generating rCedV-GhV-GFP (**Fig. XB**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-GhV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. At maximal syncytia and GFP (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C (PMCID: PMC8631057, PMCID: PMC5869790, PMCID: PMC1563797).

Characterization of the recombinant reporter viruses in cell-based infection assays: The replication kinetics of the VSV-based and rCedV-based GhV F/G encoding viruses will be assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and tittered. VSV-GhV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G (PMID: 23849788). Similarly, rCedV-GhV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Unlike NiV and HeV, GhV G engages only the ephrin-B2 ligand to trigger membrane fusion (PMID: 24296468). The GhV F/G bearing reporter viruses will be verified for this specific ephrin ligand tropism in cell infection and/or syncytia formation experiments and comparisons made to wildtype VSV or VSV-ABLV G and also alternatively to rCedV, and rCedV NiV/HeV chimeras. We have generated murine mAbs to GhV F and G (10C4-LY and 10D5-LY to GhV G; and 5B7-LY and 7C11-LY to GhV F) and these will be used in neutralization tests. The VSV-GhV-GFP assays will be conducted by FRNTs and VSV-GhV-Luc in luciferase assays.

Evaluating neutralization potential of vaccine platforms from other research projects. Our rCeV chimeras (rCedV-NiV-B-GFP and rCedV-HeV-GFP) will allow this Core to conduct large numbers of neutralization tests by FRNT, to the many ML-derived prototype henipavirus vaccine antigen constructs, mAbs, and nanobinders, that will be generated by the Center's RPs. In Center years 1-3 the focus will be on HeV and NiV prototypes, and in years 4-5 the Core is expected to shift to GhV test case. The FRNT assay is rapid (36hrs), high throughput, and performed in 96-well plates to establish typical 7-point dose response virus neutralization data and performed at BSL-2. Typically, immune sera, mAbs, or other entry inhibitors are analyzed by serially dilution and mixed with virus (rCedV-NiV-B-GFP or rCedV-HeV-GFP) for 2hrs then samples used in triplicate to infect confluent Vero 76 cells in black-walled clear bottom 96-well plates and incubated 24hrs, and then plates are fixed and imaged and fluorescent foci quantitated with CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) is determined by 50% reduction in fluorescent foci versus untreated controls.

Anticipated Results, Potential Pitfalls and Alternative Strategies. We anticipate the reporter viruses will replicate to titers fit for purpose. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. If we encounter unexpected limitations in rescuing VSV-based or rCedV-based GhV F/G bearing reporter viruses; we will 1) test different ratios of helper plasmids and antigenome plasmids; 2) perform rescue using different cell lines; 3) construct alternate versions of the GhV F and G genes within the antigenome plasmids, such as truncating the GhV G protein which has been shown to enhance GhV mediated F/G membrane fusion (PMID: 31470664). Alternatively, fusion of the GhV F and G ectodomains with the transmembrane and cytoplasmic tail domains of the corresponding CedV F and G elements may facilitate virus particle formation and membrane fusion activity.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

The Core D Leader and Co-Leaders will work closely with the Project Leaders and key staff of RP1 and RP2 to develop vaccination, treatment and sampling regimens, study protocols, and animal protocols that utilize countermeasures identified in RP1 and RP2. The Core Leader and Co-Leaders will write and obtain UTMB IACUC approval for all animal protocols performed in Core D. The animal models and clinical pathology, immunology, virology, and histopathology assays employed for Aim 3 are detailed below. All raw data as well as graphed or tabulated data generated by Core D will be handled and analyzed in coordination with the Core B.

Animal models: Core D will employ established animal models for HeV, LASV, RVFV, and SFTSV. While animal models also exist for SOSV and JUNV we will optimize these models to fill gaps and provide new tools as detailed in Aim 4 below. Mice, guinea pigs, hamsters, ferrets, and cats have been used as small animal models of HeV infection (PMID: 22476556). This project will employ Syrian golden hamsters as the small animal model of HeV disease because they are more suitable than other small animals for screening large numbers of vaccines and mAbs. Using hamsters will allow us to select optimal vaccine and mAb formulations and regimens prior to efficacy testing in NHPs. In 2010 Drs. Geisbert and Broder developed the first highly lethal NHP model for henipavirus infection (Nipah virus) using African green monkeys (AGM) (PMCID: PMC2872660.). They subsequently developed a lethal AGM model for HeV infection (PMCID: PMC2937751.). Henipavirus NHP models mirror human disease with animals showing severe respiratory pathology, neurological disease, and generalized vasculitis. For LASV, Core D will use established lethal outbred guinea pig models that cover several lineages of LASV (PMCID: PMC1892204; PMCID: PMC4401668; PMCID: PMC5032844.; PMCID: PMC6763766; PMCID: PMC10052409) as guinea pigs are the only immunocompetent small animal model for Lassa fever. Core D will also use established cynomolgus monkey models that cover several genetically distinct lineages of LASV (PMCID: PMC2681932. ; PMCID: PMC3104370. ; PMCID: PMC6934204.)

Animal vaccinations: All animals will be obtained from commercial vendors and allowed to acclimate prior to vaccination (~ 3-7 days for mice, hamsters, and guinea pigs and ~ 14 days for ferrets and NHPs). Mice, hamsters, and guinea pigs will be vaccinated by intramuscular (i.m.) or intraperitoneal (i.p.) injection of the vaccines provided by RP1. Ferrets and NHPs will be vaccinated by i.m. injection of the vaccines provided by RP1. All animals will be vaccinated in ABSL-2. Animals will be monitored daily for any reaction or adverse events caused by the vaccination. Blood will be collected for plasma, serum, and PBMC isolations before vaccination and at times after vaccination for assessment of the host immune response.

Animal challenges: Hamsters, ferrets, and NHPs will be challenged with infectious HeV or SOSV as previously described (PMCID: PMC4971471. ; PMCID: PMC8527959.; PMCID: PMC7199785). After appropriate acclimation, hamsters and ferrets will be exposed to HeV or SOSV by intranasal (i.n.) or i.p. administration of up to 1x10^6 PFU of virus. NHPs will be challenged with HeV by the intratracheal (i.t.) and/or i.n. routes using up to 1 x 10^6 PFU of virus. Mice, guinea pigs, and ferrets will be exposed with up to 5,000 PFU of arenaviruses and phleboviruses by i.p. injection (PMCID: PMC7593599. ; PMCID: PMCID: PMC5032844. PMCID: PMC4843420.; PMCID: PMC8781158). NHPs will be exposed with up to 5.000 PFU of LASV by i.m. injection (PMCID: PMC5719877; PMCID: PMC6934204), Junin virus by intravenous (i.v.) injection (PMCID: PMC7980402) while marmosets will be exposed to up to 1x10^7 PFU of RVFV as previously described (PMCID: PMC3302397). For all animals, blood will be collected with or without anticoagulants for plasma and serum isolations, respectively, at times before paramyxovirus, arenavirus, or phlebovirus challenge, on the day of challenge, and at various times after challenge as detailed in RP1 and RP2. Animals will be monitored for clinical signs daily. We will apply a scoring sheet approved by the UTMB IACUC depicted in the Vertebrate Animals section to assist in determining the time of euthanasia depending on clinical signs (e.g., respiratory distress, anorexia, activity, appearance, neurologic signs, etc.). Animals will be euthanized according to the 2013 AVMA Guidelines on Euthanasia. Any surviving animals will be euthanized on day 35-42 days after paramyxovirus, arenavirus, or phlebovirus challenge.

Clinical pathology assays: *Hematology on EDTA whole blood*: For NHP studies, we will measure the following parameters at time points before and after HeV, LASV, or JUNV challenge: total white blood cell counts (WBC), percent lymphocytes (LY), percent monocytes (MO), percent neutrophils (NEU), percent eosinophils (EOS), percent basophils (BAS), total lymphocyte counts (LY#), total monocyte counts (MO#), total neutrophil counts (NEU#), total eosinophil counts (EOS #), total basophil counts (BAS #), red blood cell counts (RBC), total hemoglobin (Hgb), hematocrit values (HCT), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), platelets (PLT), and mean platelet volume (MPV), and Plateletcrit (PCT). Values will be obtained from the Abaxis VetScan HM5 following manufacturer's directions.

Clinical chemistry on serum: For NHP studies, the following parameters will be measured at time points before and after HeV, LASV, and JUNV challenge: Albumin (ALB), amylase (AMY), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyltransferase (GGT), glucose (GLU), total protein (TP), blood urea nitrogen (BUN), and creatinine (CRE), Creactive protein (CRP), Calcium (Ca2+), and uric acid (UA). Values will be obtained from the Abaxis Piccolo chemistry analyzer following manufacturer's directions.

Viral load assays: *PCR Assay:* To assess viral loads in whole blood and tissues, RNA will be extracted using a virus RNA isolation kit (Qiagen, Valencia, CA) followed by TaqMan PCR for the viral genome being studied. Qiagen buffers have been safety tested for inactivation of paramyxoviruses, arenaviruses, and phleboviruses. ~~The~~ PCR assays employed for HeV, SOSV, LASV, JUNV, RVFV, and SFTSV have been previously described

(PMCID: PMC7870971; PMCID: PMC7980402. ; PMID: 36521633; PMCID: PMC5719877; PMCID: PMC5627234).

Plaque Assay: The plaque assays employed for paramyxoviruses, arenaviruses, and phleboviruses have previously been described (PMCID: PMC7870971; PMCID: PMC7980402. ; PMCID: PMC5719877; PMCID: PMC1395455). Briefly, 10-fold dilutions (10-1 to 10-6) of serum, plasma, or whole blood samples are prepared in cell maintenance medium (DMEM/10%FBS/gentamicin) and adsorbed to 70-90% confluent monolayers of Vero E6 cells in 6-well plates, adding 0.2 mL/well. The plates are incubated at 37°C, 5% CO2 for 45 min, with periodical rocking every 10-15 min. The incubation period is followed by addition of 2 mL 1% agarose-containing medium (2X EBME/Hepes/10% FBS/gentamicin) to each well. After the agarose has solidified, the plates are returned to the C02 incubator and maintained for 2-14 days until plaques are visualized. At this time, 2 mL PBS containing 5% neutral red and 5% FBS is added to each well, the plates returned to the CO2 incubator and held overnight. The following day, the liquid stain overlay is removed from each well and plaques are counted.

Bead-based multiplex assays: Plasma inflammatory mediators, thrombosis markers, and fibrinolysis analytes were measured by flow cytometry using Biolegend LegendPlex assays and a FACS Canto-II cytometer (Becton Dickson). Samples will be processed in duplicate for each Nonhuman Primate Inflammation 13-plex (1:4 dilution), Human Thrombosis (1:100), and Human Fibrinolysis (1:40,000) panel as previously described (PMCID: PMC7790436; PMCID: PMC8406165; PMCID: PMC9225728).

Gross pathology and histopathology: A necropsy will be performed on all NHPs. We will examine the external surfaces of the body, all orifices, and the thoracic and peritoneal cavities and their contents. Core D will prepare a written report of the gross pathology findings of each NHP. The following NHP tissues will be collected at necropsy, fixed in 10% neutral-buffered formalin, embedded in paraffin, and stained by H&E: liver, spleen, lung, kidney, adrenal gland, pancreas, axillary lymph node, inguinal lymph node, mesenteric lymph node, duodenum, ileum, colon, brain (frontal cortex, cerebellum, brain stem), cervical spinal cord, urinary bladder, ovary or testis, prostate or uterus, and eye. A microscopic evaluation will be performed on H&E slides of all tissues collected from all NHPs by an ACVP board certified veterinary pathologist. ~~A written r~~Reports of the histologic findings of each tissue from each animal will be provided to ~~the Project Leader of~~ RP1 Leaders. In consultation with the ~~Project Leader of~~ RP1 Leaders, Core D may also perform immunohistochemical and/or special stains such as PTAH for fibrin as previously described (PMCID: PMC5719877; PMCID: PMC5719877; PMCID: PMC7980402.).

Quality systems management of all records and data collected from animal studies: Although the animal studies conducted by Core D will not be required to be performed under GLP compliance, UTMB will provide Quality Assurance that will achieve data quality and integrity when conducting animal experiments. Quality refers to whether the study was conducted in accordance with the protocol, standard operating procedures, and applicable standards of research. Integrity refers to assurance that the raw data and documentation are consistent with reported results. All animal study personnel will be trained by the UTMB Office of Regulated Nonclinical Studies (ORNcS). on Good Documentation Practices (GDP). All animal study data generated by Core D will be provided to Core B as detailed in the Core B Research Strategy.

Aim 4: Develop and/or optimize animal models for Sosuga virus and Junin virus.

For HeV and LASV Core D will employ animal models that have already been developed and are well established. However, for SOSV, JUNV, RVFV, SFTSV while animal models exist there are gaps that need to be addressed. Recently, it was shown that i.n. or i.p. infection of hamsters with SOSV resulted in viremia and mild clinical disease (PMID: 36521633) but there is no lethal model for SOSV. Core B will further explore the hamster model for SOSV by 1) using higher challenge doses of SOSV which is often required to produce lethal disease in other paramyxovirus hamster models (PMCID: PMC8527959; PMCID: PMC3147900) or 2) serially passage of tissues in hamsters. Core D will also assess the pathogenic potential of ferrets for SOSV as they are often used as animal models for paramyxoviruses. For JUNV, serial adaptation is often required to produce lethal disease in outbred guinea pigs. We recently showed that for Ebolaviruses while serial adaptation is required to produce lethality in mice, hamsters, and guinea pigs, infection of ferrets with *Zaire ebolavirus*, *Sudan ebolavirus*, or *Bundibugyo ebolavirus* resulted in uniform lethality with wild type viruses and did not require adaptation (PMCID: PMC4957446.). Therefore, Core D will assess the pathogenic potential of JUNV in ferrets.

ANIMAL MODELS AND VACCINE EVALUATION SCIENTIFIC CORE (CORE D)

1. SPECIFIC AIMS

The main objective of the Animal Models and Vaccine Evaluation Scientific Core is to test and characterize the host response and efficacy of the vaccines and monoclonal antibody (mAb) based treatments identified in RP1 and RP2 against paramyxoviruses, arenaviruses, and phleboviruses under BSL-3/ABSL-3 and BSL-4/ABSL-4 containment. The Core will also develop select reporter viruses and conduct cell-based assays to characterize vaccine-induced neutralizing antibody responses and mAbs.

The Specific Aims of the Animal Models and Vaccine Evaluation Scientific Core are to:

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Aim 2: Provide technical expertise and conduct *in vitro* assays in BSL-3 and BSL-4 containment.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, virology assays, and necropsies in BSL-3 and BSL-4 containment.

Aim 4: Develop and/or optimize animal models for Sosuga virus, Junin virus Rift valley fever virus, and severe fever with thrombocytopenia syndrome virus.

The Aims will be achieved by the following specific functions to be carried out by the Animal Models and Vaccine Evaluation Scientific Core Leader, Co-Core Leaders, and personnel:

1. Maintain records of well characterized BSL-3 and BSL-4 Hendra virus (HeV), Sosuga virus (SOSV), Lassa virus (LASV), Junin virus (JUNV), Rift valley fever virus (RVFV), and severe fever with thrombocytopenia syndrome virus (SFTSV) seed stocks including background history, passage history, genomic information, periodic monitoring of titer, mycoplasma testing, endotoxin testing, and sterility testing.
2. Perform *in vitro* antiviral activity assays. Including high-throughput BSL-2 based neutralization testing of henipavirus vaccine responses and mAbs.
3. Assist Center Investigators in designing animal studies, prepare animal protocols, and obtain IACUC approval of BSL-3 and BSL-4 animal studies.
4. Perform animal challenges using well characterized HeV, SOSV, LASV, JUNV, RVFV, and SFTSV seed stocks for RP1 and RP2.
5. Perform vaccination and treatment of animals with vaccines and treatments provided by RP1 and RP2.
6. Perform all duties associated with animal challenge studies including monitoring of animals, collection of samples, and necropsies.
7. Perform clinical pathology assays including hematology and clinical chemistry assays.
8. Perform virology assays on blood and/or tissue samples collected from infected animals including viral load by plaque assay and RT-PCR.
9. Perform gross pathology analysis on all animals at necropsy.
10. Perform histopathologic analysis on tissues from animals collected at necropsy.
11. Develop and/or optimize animal models for SOSV, JUNV, RFVF, and SFTSV to fill gaps where no models exist; make these models available to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers
12. Provide all data generated in Core D to Data Management Core B.

RESEARCH STRATEGY

A. SIGNIFICANCE

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the WHO Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phlebovirus Rift Valley fever virus (RVFV). All of these viruses are also included among the World Health Organization's (WHO) List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The Machine Learning-(ML)-Enabled Design of Prototype Pathogen Vaccines and Antibodies Center is a well-integrated consortium conducting a set of discovery and translational research programs composed of an Administrative Core, a Data Management Core, X Scientific Cores, and X Research Projects (RPs). The synergistic activities of the X Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the X Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV), JUNV, RVFV, and severe fever with thrombocytopenia syndrome virus (SFTSV) to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

All X of the research projects within the X Center focus on developing vaccines or monoclonal antibody (mAb) based therapies against paramyxoviruses, arenaviruses, and phleboviruses. All X of these research projects require that countermeasures be evaluated in animals against infectious paramyxoviruses, arenaviruses, and phleboviruses. As HeV, LASV, JUNV, and RVFV are CDC and/or USDA select agents Federal regulations require that these viruses be handled in Biosafety Level (BSL)-3 or BSL-4 containment. Core D provides approved BSL-3/ABSL-3 and BSL-4/BSL-4 facilities and a trained and experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support RP1 and RP2.

B. INNOVATION

Scientific Core D will be co-located within the Galveston National Laboratory (GNL) and Robert Shope Laboratory at the University of Texas Medical Branch (UTMB) at Galveston. The GNL is a high and maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda and stands ready to assist local, state and national public health efforts in the event of a public health emergency. The facility is unique in that it is one of two operational BSL-4 facilities in the United States that is located on an academic campus. This unique location benefits the X Center in several ways. Regarding physical resources the GNL is a state-of-the-art facility with many specialized assets including BSL-4 imaging, telemetry, and aerobiology equipment. In addition, being located on an academic campus Drs. Geisbert (Core D, Project Leader (PL), Cross, Freiberg, and Ikegami are faculty members in the Departments of Microbiology and Immunology and Pathology. This academic environment is a major strength, that fosters creativity and collaboration with other UTMB investigators which will be beneficial to the overall success of Core D. Dr. Broder, is faculty member of the Department of Microbiology and Immunology at Uniformed Services University (USU). Drs. Broder and Geisbert (PL) have a long-standing emerging virus research collaboration which has included the development and characterization the first nonhuman primate (NHP) models for HeV and Nipah virus (NiV) that will be employed by the Center's RPs. Another strength within the Core is Drs. Geisbert, Broder, Cross, and Veesler (Center Co-PI) currently collaborate and lead active henipavirus projects that are focused on translational countermeasure development which includes more traditional vaccine and mAb therapeutics approaches, and the shared knowledge base and experience in these areas will greatly facilitate the Core's abilities in supporting the Center's research goals in applying advanced machine learning-enabled

designs of effective prototype pathogen vaccines and antibodies. Along with animal model development and animal modeling expertise, many of the unique virological tools including recombinantly generated RNA viruses, reporter gene-encoding viruses, and other pseudotype virus technologies, that will be employed by the Core, have been developed from UTMB-USU collaboration.

C. APPROACH

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses.

Paramyxovirus, arenavirus, and phlebovirus seed stocks. UTMB will provide fully equipped BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities that are required to work with HeV, SOSV, LASV, JUNV, RVFV, and SFTSV. UTMB will also provide and maintain all required approvals to work these viruses. The BSL-3 and BSL-4 paramyxovirus, arenavirus, and phlebovirus seed stocks employed for RP1 and RP2 have been or will be titered by conventional standard plaque assay and qRT-PCR as detailed in Aim 2 below. The virus strain identity of each seed stock has been or will be confirmed by sequence analysis. In addition, RNA has been or will be deep sequenced to verify the complete viral genome of each virus seed stock used for animal challenge studies. We have or will test each seed stock for mycoplasma contamination. Endotoxin testing has been or will be performed on paramyxovirus, arenavirus, and phlebovirus stocks using the Endosafe PTS system (Charles River Laboratories) following the manufacturer's instructions. The Endosafe PTS system is a cartridge-based testing system utilizing FDA-licensed cartridges (0.1 EU/ml, 0.05 EU/ml, 0.01 EU/ml, 0.05 EU/ml) for ultrasensitive testing. Seed stocks will also be evaluated for morphological identity by transmission electron microscopy. The bacteriological and mycological sterility of the product will be determined by selection of aliquots of the dispensed stock, inoculation of a sterile 500 ml bottle of Dulbecco's high glucose MEM with 10% FBS and then after 3 days subcultured to FTM and TBS media. paramyxovirus, arenavirus, and phlebovirus seed stocks will be inventoried in the UTMB BSL-4 and BSL-4 virus stock databases and secured in dedicated controlled access alarmed minus 80°C freezers in the GNL or Robert Shope Laboratory. Paramyxovirus, arenavirus, and phlebovirus seed stocks are monitored periodically for any changes in virus titer.

Plan for staffing, managing, and prioritizing Core use. The Core Leader and Co-Leaders have a cadre of staff that are trained and highly experienced in all BSL-3 and BSL-4 procedures and assays needed to conduct the proposed work. In addition to the Core Leader and Co-Leaders this staff includes an ACVP board certified veterinary pathologist, two BSL-4 contributing scientists, a BSL-4 Technical Director, a BSL-4 trained postdoctoral fellow, six BSL-4 experienced technical staff, a BSL-4 trained histotechnologist, and a BSL-4 trained graduate student. We do not anticipate any BSL-3 or BSL-4 scheduling problems regarding studies proposed in RP1 or RP2. However, we have developed a mitigation strategy if unforeseen events cause any prioritization of resources. A committee consisting of the Core D Leader, the PI of the Center, and the members of the external Scientific Advisory Committee (SAC) will review the status of RP1 and RP2 and any circumstances causing a prioritization of work. The Committee will also hold a meeting or teleconference (Zoom, Teams) with the Project Leaders and key staff of RP1 and RP2 to gather additional information. After careful review of all available information the Committee will then make a recommendation on prioritization to the Center PI. The X Center PI will then consult with NIAID/NIH program staff and make the final determination on prioritization.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

In vitro antiviral activity assays: Core D will perform conventional virus neutralization assays for RP1 and RP2 to determine the ability of sera/plasma from immunized animals from RP1 and antibodies from RP2 to inhibit the replication of paramyxoviruses, arenaviruses, and phleboviruses *in vitro* using infectious viruses in the UTMB BSL-3 and BSL-4 laboratories. In brief, cultures of Vero, Vero E6, SW13, or other cell types will be infected with a range of m.o.i. of paramyxoviruses, arenaviruses, and bunyaviruses and treated with various concentrations of the provided sera/plasma or antibodies. Cells and/or culture fluids will be harvested at various time points after infection and infectious virus enumerated by conventional plaque assay as detailed below.

Develop chimeric reporter-gene encoding viruses and virus neutralization assays for BSL-2 use.
We have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP) (PMID: 23849788 and PMID: 24576301), as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses (PMID: 32407866 and PMID: 30875748). In addition, we have generated a reverse genetics platform for generating recombinant Cedar virus (rCedV) and rCedV chimeras whereby the fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-

B) or HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without reporter genes (PMID: 35617431, PMID: 31548390, PMID: 29587789, PMID: 37243163). The rCedV chimeras are a replication competent authentic henipavirus platform that is a high-throughput surrogate neutralization assay that is rapid, cost-effective and can be utilized outside high containment. Similar approaches will be applied here to generate new reporter viruses for Ghana bat virus (GhV). We will design, construct and rescue both VSV and rCedV chimeras that encode the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of GhV. Two reporter-gene encoding versions will be attempted for VSV-GhV: one encoding GFP (VSV-GhV-GFP) and the other encoding the *Photinus pyralis* (firefly) luciferase gene (VSV-GhV-Luc). We will also construct and rescue GFP and Luc reporter gene encoding versions? of rCedV chimeras encoding the GhV F and G genes (rCedV-GhV-GFP and rCedV-GhV-Luc) (**Fig. 1**). The rescued viruses will be characterized using cell-based infection tropism and growth kinetics assays.

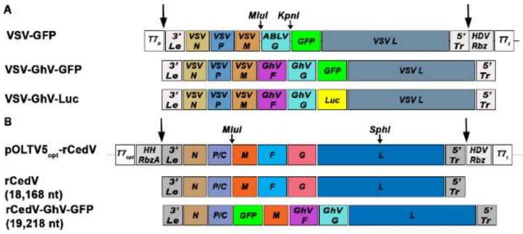

Figure 1. Schematic of chimeric reporter viruses. (**A**)The VSV-ABLV G-GFP plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and KpnI to construct VSV-GhV-GFP and VSV-GhV-Luc. (**B**) pOLTV5$_{opt}$-rCedV plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and SphI used to construct rCedV-GhV-GFP.

The rCedV (NiV-B and HeV) chimeric virus platform serves as a robust surrogate neutralization assay system for quantifying antibody neutralization potency of anti-NiV and anti-HeV antisera and mAbs [Amaya et al, Viruses 2023 see comment box]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP are highly correlated with those obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization test (PRNT). Pearson correlation of rCedV chimeras BSL-2 PRNT to the NiV-B or HeV BSL-4 PRNT is shown in **Fig. 2a**. A high-throughput quantitative assay based on reduction of GFP foci (fluorescent reduction neutralization test (FRNT)) was also developed. Correlation analysis with mAb neutralization values by PRNT vs FRNT (**Fig. 2b)**, Pearson's r ≥ 0.9 and p-value < 0.001).

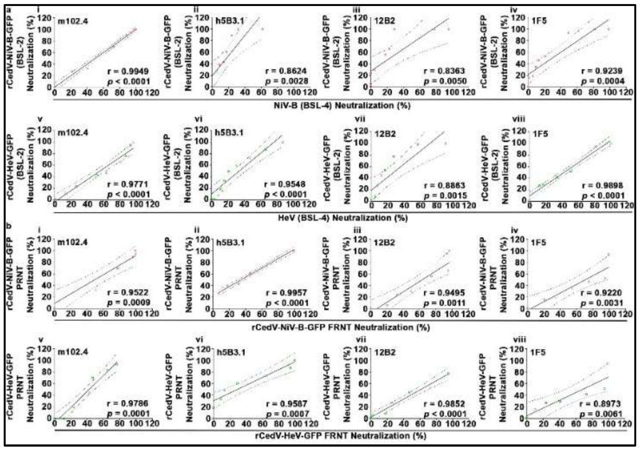

Figure 2. Panel a: Pearson correlation for BSL-2 PRNT vs BSL-4 PRNT (rCedV-NiV-B-GFP versus NiV-B (**i-iv**) and rCedV-HeV-GFP versus HeV (**v-viii**)). Panel b: Pearson correlation for PRNT vs FRNT ((rCedV-NiV-B-GFP (**i-iv**) and rCedV-HeV-GFP (**v-viii**)).

Rescue and characterize reporter viruses encoding GhV envelope glycoproteins.

<u>Generation of a VSV encoding GhV envelope glycoproteins.</u> We will construct reporter gene encoding versions of a replication competent VSV encoding the GhV F and G glycoproteins (GFP and Luc) (**Fig. 1A)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the GhV F and G coding sequences will be synthesized. The GhV F and G coding sequences will be based on the GhV isolate Eid_hel/GH-M74a/GHA/2009 (GenBank: NC_025256.1). The GenBank accession number for GhV F is YP_009091837.1 and that for the GhV G protein is YP_009091838.1. Unique restriction enzyme sites, MluI and KpnI will facilitate the insertion of the GhV F and G gene cassette into the VSV backbone plasmid. The VSV-GhV-Luc will be similarly made. Cloning procedures are performed in *E. coli* Stbl2 and all plasmids verified by sequencing. Rescue will be performed in BSR-T7/5 cells, transfected helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-GhV-GFP or VSV-GhV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells by inoculation with the supernatant from step 1. When GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks are tittered by serial dilution on HEK293T cells by plaque assay (PMID: 32833351).

<u>Generation of rCedV encoding GhV envelope glycoproteins.</u> rCedV-GhV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the GhV F and G coding sequences. The CedV non-coding intergenic regions are retained as is adherence to the genomic "rule of six". Unique restriction sites, MluI and SphI will facilitate the insertion of the GhV F and G gene cassette into the

genome clone (pOLTV5$_{opt}$-rCedV) generating rCedV-GhV-GFP (**Fig. XB**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-GhV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. At maximal syncytia and GFP (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C (PMCID: PMC8631057, PMCID: PMC5869790, PMCID: PMC1563797).

Characterization of the recombinant reporter viruses in cell-based infection assays: The replication kinetics of the VSV-based and rCedV-based GhV F/G encoding viruses will be assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and tittered. VSV-GhV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G (PMID: 23849788). Similarly, rCedV-GhV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Unlike NiV and HeV, GhV G engages only the ephrin-B2 ligand to trigger membrane fusion (PMID: 24296468). The GhV F/G bearing reporter viruses will be verified for this specific ephrin ligand tropism in cell infection and/or syncytia formation experiments and comparisons made to wildtype VSV or VSV-ABLV G and also alternatively to rCedV, and rCedV NiV/HeV chimeras. We have generated murine mAbs to GhV F and G (10C4-LY and 10D5-LY to GhV G; and 5B7-LY and 7C11-LY to GhV F) and these will be used in neutralization tests. The VSV-GhV-GFP assays will be conducted by FRNTs and VSV-GhV-Luc in luciferase assays.

Evaluating neutralization potential of vaccine platforms from other research projects. Our rCeV chimeras (rCedV-NiV-B-GFP and rCedV-HeV-GFP) will allow this Core to conduct large numbers of neutralization tests by FRNT, to the many ML-derived prototype henipavirus vaccine antigen constructs, mAbs, and nanobinders, that will be generated by the Center's RPs. In Center years 1-3 the focus will be on HeV and NiV prototypes, and in years 4-5 the Core is expected to shift to GhV test case. The FRNT assay is rapid (36hrs), high throughput, and performed in 96-well plates to establish typical 7-point dose response virus neutralization data and performed at BSL-2. Typically, immune sera, mAbs, or other entry inhibitors are analyzed by serially dilution and mixed with virus (rCedV-NiV-B-GFP or rCedV-HeV-GFP) for 2hrs then samples used in triplicate to infect confluent Vero 76 cells in black-walled clear bottom 96-well plates and incubated 24hrs, and then plates are fixed and imaged and fluorescent foci quantitated with CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) is determined by 50% reduction in fluorescent foci versus untreated controls.

Anticipated Results, Potential Pitfalls and Alternative Strategies. We anticipate the reporter viruses will replicate to titers fit for purpose. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. If we encounter unexpected limitations in rescuing VSV-based or rCedV-based GhV F/G bearing reporter viruses; we will 1) test different ratios of helper plasmids and antigenome plasmids; 2) perform rescue using different cell lines; 3) construct alternate versions of the GhV F and G genes within the antigenome plasmids, such as truncating the GhV G protein which has been shown to enhance GhV mediated F/G membrane fusion (PMID: 31470664). Alternatively, fusion of the GhV F and G ectodomains with the transmembrane and cytoplasmic tail domains of the corresponding CedV F and G elements may facilitate virus particle formation and membrane fusion activity.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, virology assays, and necropsies in BSL-3 and BSL-4 containment.

The Core D Leader and Co-Leaders will work closely with the Project Leaders and key staff of RP1 and RP2 to develop vaccination, treatment and sampling regimens, study protocols, and animal protocols that utilize countermeasures identified in RP1 and RP2. The Core Leader and Co-Leaders will write and obtain UTMB IACUC approval for all animal protocols performed in Core D. The animal models and clinical pathology, immunology, virology, and histopathology assays employed for Aim 3 are detailed below. All raw data as well as graphed or tabulated data generated by Core D will be handled and analyzed in coordination with the Core B.

Animal models: Core D will employ established animal models for HeV and LASV. While animal models also exist for SOSV, JUNV, RVFV, and SFTSV we will optimize these models to fill gaps and provide new tools as detailed in Aim 4 below. Mice, guinea pigs, hamsters, ferrets, and cats have been used as small animal models of HeV infection (refs). This project will employ Syrian golden hamsters as the small animal model of HeV disease because they are more suitable than other small animals for screening large numbers of vaccines and mAbs. Using hamsters will allow us to select optimal vaccine and mAb formulations and regimens prior to efficacy testing in NHPs. In 2010 Drs. Geisbert and Broder developed the first highly lethal NHP model for henipavirus infection (Nipah virus) using African green monkeys (AGM) (ref). They subsequently developed a lethal AGM model for HeV infection (ref). Henipavirus NHP models mirror human disease with animals showing severe respiratory pathology, neurological disease, and generalized vasculitis. For LASV, Core D will use established lethal outbred guinea pig models that cover several lineages of LASV (refs) as guinea pigs are the only immunocompetent small animal model for Lassa fever. Core D will also use established cynomolgus monkey models that cover several genetically distinct lineages of LASV (refs).

Animal vaccinations: All animals will be obtained from commercial vendors and allowed to acclimate prior to vaccination (~ 3-7 days for mice, hamsters, and guinea pigs and ~ 14 days for ferrets and NHPs). Mice, hamsters, and guinea pigs will be vaccinated by intramuscular (i.m.) or intraperitoneal (i.p.) injection of the vaccines provided by RP1. Ferrets and NHPs will be vaccinated by i.m. injection of the vaccines provided by RP1. All animals will be vaccinated in ABSL-2. Animals will be monitored daily for any reaction or adverse events caused by the vaccination. Blood will be collected for plasma, serum, and PBMC isolations before vaccination and at times after vaccination for assessment of the host immune response.

Animal challenges: Hamsters, ferrets, and NHPs will be challenged with infectious HeV or SOSV as previously described (refs). After appropriate acclimation, hamsters and ferrets will be exposed to HeV or SOSV by intranasal (i.n.) or i.p. administration of up to 1x10^6 PFU of virus. NHPs will be challenged with HeV by the intratracheal (i.t.) and/or i.n. routes using up to 1 x 10^6 PFU of virus. Mice, guinea pigs, and ferrets will be exposed to arenaviruses and phleboviruses by i.p. injection. NHPs will be exposed to LASV by i.m. injection and Junin virus by intravenous (i.v.) injection as previously described (refs). For all animals, blood will be collected with or without anticoagulants for plasma and serum isolations, respectively, at times before paramyxovirus, arenavirus, or phlebovirus challenge, on the day of challenge, and at various times after challenge as detailed in RP1 and RP2. Animals will be monitored for clinical signs daily. We will apply a scoring sheet approved by the UTMB IACUC depicted in the Vertebrate Animals section to assist in determining the time of euthanasia depending on clinical signs (e.g., respiratory distress, anorexia, activity, appearance, neurologic signs, etc.). Animals will be euthanized according to the 2013 AVMA Guidelines on Euthanasia. Any surviving animals will be euthanized on day 35-42 days after paramyxovirus, arenavirus, or phlebovirus challenge.

Clinical pathology assays: *Hematology on EDTA whole blood*: For NHP studies, we will measure the following parameters at time points before and after HeV, LASV, or JUNV challenge: total white blood cell counts (WBC), percent lymphocytes (LY), percent monocytes (MO), percent neutrophils (NEU), percent eosinophils (EOS), percent basophils (BAS), total lymphocyte counts (LY#), total monocyte counts (MO#), total neutrophil counts (NEU#), total eosinophil counts (EOS #), total basophil counts (BAS #), red blood cell counts (RBC), total hemoglobin (Hgb), hematocrit values (HCT), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), platelets (PLT), and mean platelet volume (MPV), and Plateletcrit (PCT). Values will be obtained from the Abaxis VetScan HM5 following manufacturer's directions.

Clinical chemistry on serum: For NHP studies, the following parameters will be measured at time points before and after HeV, LASV, and JUNV challenge: Albumin (ALB), amylase (AMY), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyltransferase (GGT), glucose (GLU), total protein (TP), blood urea nitrogen (BUN), and creatinine (CRE), Creactive protein (CRP), Calcium (Ca2+), and uric acid (UA). Values will be obtained from the Abaxis Piccolo chemistry analyzer following manufacturer's directions.

Viral load assays: *PCR Assay:* To assess viral loads in whole blood and tissues, RNA will be extracted using a virus RNA isolation kit (Qiagen, Valencia, CA) followed by TaqMan PCR for the viral genome being studied. Qiagen buffers have been safety tested for inactivation of paramyxoviruses, arenaviruses, and phleboviruses. ~~The~~ PCR assays employed for HeV, SOSV, LASV, JUNV, RVFV, and SFTSV have been previously described (refs).

Plaque Assay: The plaque assays employed for paramyxoviruses, arenaviruses, and phleboviruses have previously been described (refs). Briefly, 10-fold dilutions (10-1 to 10-6) of serum, plasma, or whole blood samples are prepared in cell maintenance medium (DMEM/10%FBS/gentamicin) and adsorbed to 70-90% confluent monolayers of Vero E6 cells in 6-well plates, adding 0.2 mL/well. The plates are incubated at 37°C, 5% CO2 for 45 min, with periodical rocking every 10-15 min. The incubation period is followed by addition of 2 mL 1% agarose-containing medium (2X EBME/Hepes/10% FBS/gentamicin) to each well. After the agarose has solidified, the plates are returned to the C02 incubator and maintained for 2-14 days until plaques are visualized. At this time, 2 mL PBS containing 5% neutral red and 5% FBS is added to each well, the plates returned to the CO2 incubator and held overnight. The following day, the liquid stain overlay is removed from each well and plaques are counted.

Gross pathology and histopathology: A necropsy will be performed on all NHPs. We will examine the external surfaces of the body, all orifices, and the thoracic and peritoneal cavities and their contents. Core D will prepare a written report of the gross pathology findings of each NHP. The following NHP tissues will be collected at necropsy, fixed in 10% neutral-buffered formalin, embedded in paraffin, and stained by H&E: liver, spleen, lung, kidney, adrenal gland, pancreas, axillary lymph node, inguinal lymph node, mesenteric lymph node, duodenum, ileum, colon, brain (frontal cortex, cerebellum, brain stem), cervical spinal cord, urinary bladder, ovary or testis, prostate or uterus, and eye. A microscopic evaluation will be performed on H&E slides of all tissues collected from all NHPs by an ACVP board certified veterinary pathologist. ~~A written r~~Reports of the histologic findings of each tissue from each animal will be provided to ~~the Project Leader of~~ RP1 Leaders. In consultation with the ~~Project Leader of~~ RP1 Leaders, Core D may also perform immunohistochemical and/or special stains such as PTAH for fibrin as previously described (refs).

Quality systems management of all records and data collected from animal studies: Although the animal studies conducted by Core D will not be required to be performed under GLP compliance, UTMB will provide Quality Assurance that will achieve data quality and integrity when conducting animal experiments. Quality refers to whether the study was conducted in accordance with the protocol, standard operating procedures, and applicable standards of research. Integrity refers to assurance that the raw data and documentation are consistent with reported results. All animal study personnel will be trained by the UTMB Office of Regulated Nonclinical Studies (ORNcS). on Good Documentation Practices (GDP). All animal study data generated by Core D will be provided to Core B as detailed in the Core B Research Strategy.

Aim 4: Develop and/or optimize animal models for Sosuga virus, Junin virus Rift valley fever virus, and severe fever with thrombocytopenia syndrome virus.

For HeV and LASV Core D will employ animal models that have already been developed and are well established. However, for SOSV, JUNV, RVFV, SFTSV while animal models exist there are gaps that need to be addressed. Recently, it was shown that i.n. or i.p. infection of hamsters with SOSV resulted in viremia and mild clinical disease (ref) but there is no lethal model for SOSV. Core B will further explore the hamster model for SOSV by 1) using higher challenge doses of SOSV which is often required to produce lethal disease in other paramyxovirus hamster models (refs) or 2) serially passage of tissues in hamsters. Core D will also assess the pathogenic potential of ferrets for SOSV as they are often used as animal models for paramyxoviruses. For JUNV, serial adaptation is often required to produce lethal disease in outbred guinea pigs. We recently showed that for Ebolaviruses while serial adaptation is required to produce lethality in mice, hamsters, and guinea pigs, infection of ferrets with *Zaire ebolavirus*, *Sudan ebolavirus*, or *Bundibugyo ebolavirus* resulted in uniform lethality with wild type viruses and did not require adaptation (ref). Therefore, Core D will assess the pathogenic potential of JUNV in ferrets.

RVFV and SFTSV text needed here.

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats~~,~~ through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Commented [CB1]:
I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

The *Bunyavirales*.

Fill out

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

vaccine ‘plug-and-play’ approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

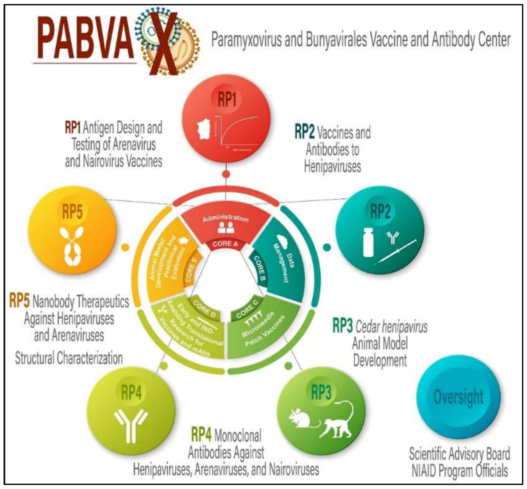

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center-(PABVAX). **(connecting arrows are needed between elements and the SAB)**

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development of human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from

the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach (PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based prophylactics and therapies.
~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~
HELP

Commented [CB2]: Larry/Dafna you are needed for this.

Commented [LZ3R2]: Here is something though we probably need a few sentences on nanobodies…

Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah [1], Hendra [2], Ebola [3, 4], Marburg [5] and Lassa [6]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D**. In addition to therapeutic applications, mAbs with Fc mutations to dramatically extend serum half-life [18][19, 20] offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.
Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the A~~A~~nimal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation S~~s~~cientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including ~~……~~ animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective ~~therapeutic~~ efficacy of antivirals and vaccines as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera

Formatted: Not Highlight

Formatted: Not Highlight

or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. ~~Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy.~~ The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV,

are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

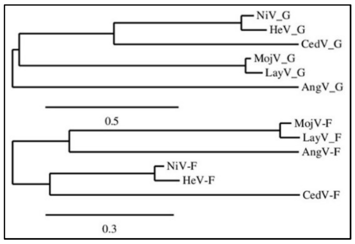

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Arenaviridae* and *Nairoviridae:

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (aarenavirus and nairovirus~~renaviridae and nairoviridae~~ projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

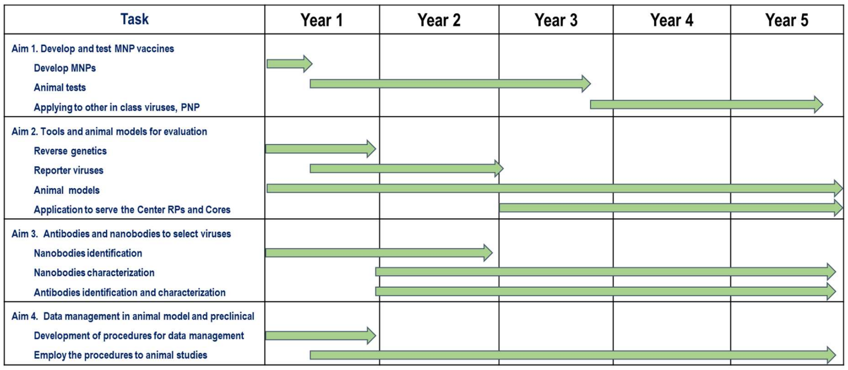
An additional and outstanding advantage of the PABVAX Center is the **Animal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

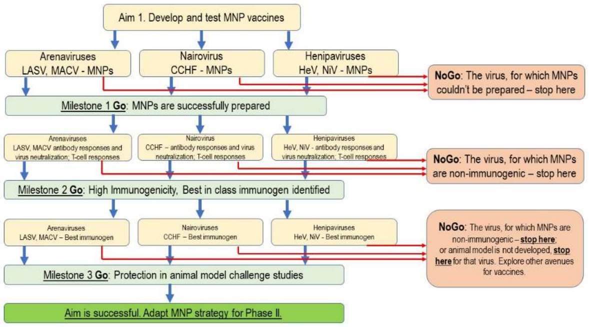


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

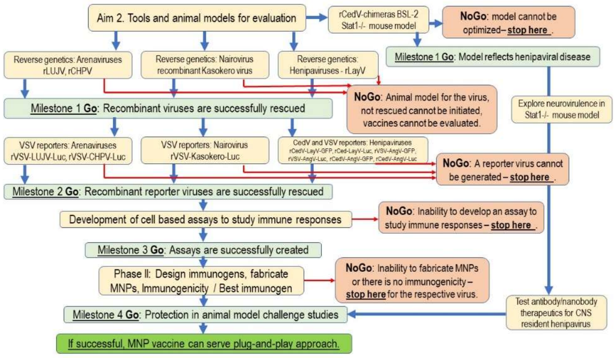

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

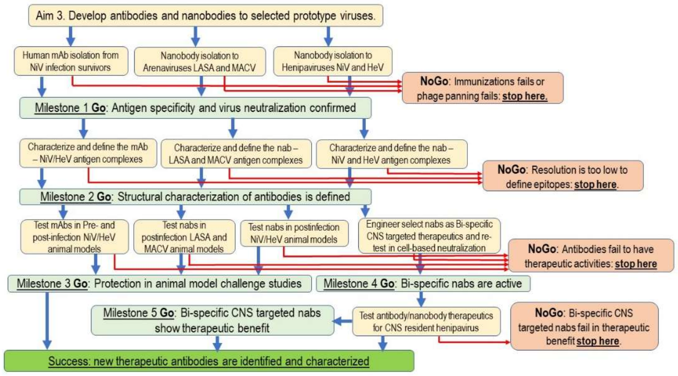

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

Commented [LZ9]: I can expand on this if needed.

Formatted: Font: Not Italic

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370~~187~~ separate NHP studies employing a total of 2,772~~1,318~~ animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses ~~Ebola and Marburg viruses and also Nipah and Hendra~~ have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has

Formatted: Not Highlight

a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP~~nonhuman primate~~ facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and in conjunction with **Core A** also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, ~~to meet regulatory requirements by assuring regulatory compliance,~~ quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a “well documented” quality system program. ~~Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS.~~ Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over 250~~XXX~~ peer-reviewed articles in these areas. Dr. Geisbert’s research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Formatted: Font: Bold

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical has deep experience with antigens and monoclonal antibodies (mAbs) against these antigens. ~~’s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp™ which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and production of antigens, antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies {Mulangu, 2019 #818} {Group, 2016 #649}; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1 {Politch, 2021 #897}. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio’s expertise and experience will be a very important and valuable asset to the Center.~~

Formatted: Font: Italic

Bonnie Genovac

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe’s (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of

Formatted: Font: Bold

human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in xxx,000 of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Formatted: Font: 11 pt

Commented [LZ10]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats~~,~~ through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

The *Bunyavirales*.

Fill out

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

vaccine ‘plug-and-play’ approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

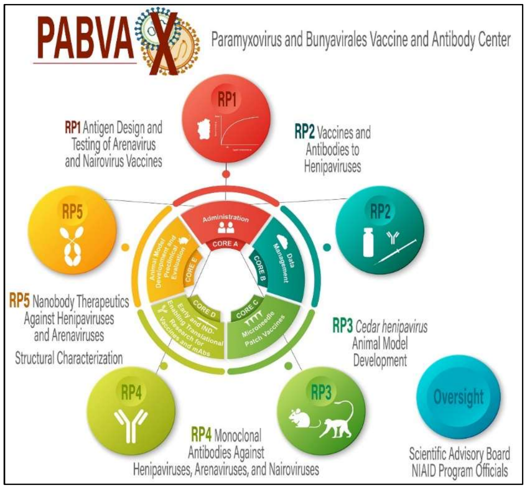

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center- (PABVAX). **(connecting arrows are needed between elements and the SAB)**

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development of human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from

the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach (PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based prophylactics and therapies.
~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~
HELP

Commented [CB2]: Larry/Dafna you are needed for this.

Commented [LZ3R2]: Here is something though we probably need a few sentences on nanobodies…

Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah [1], Hendra [2], Ebola [3, 4], Marburg [5] and Lassa [6]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D**. In addition to therapeutic applications, mAbs with Fc mutations to dramatically extend serum half-life [18][19, 20] offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.
Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal model development and preclinical evaluation scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including…….. animal model development and use of animal models for the study of viral pathogenesis and assessing the therapeutic efficacy of antivirals and vaccines. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and

alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. Data generated to support ~~of~~ possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the

human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

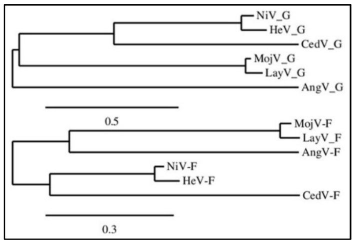

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Arenaviridae* and *Nairoviridae:

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (arenaviridae and nairoviridae projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

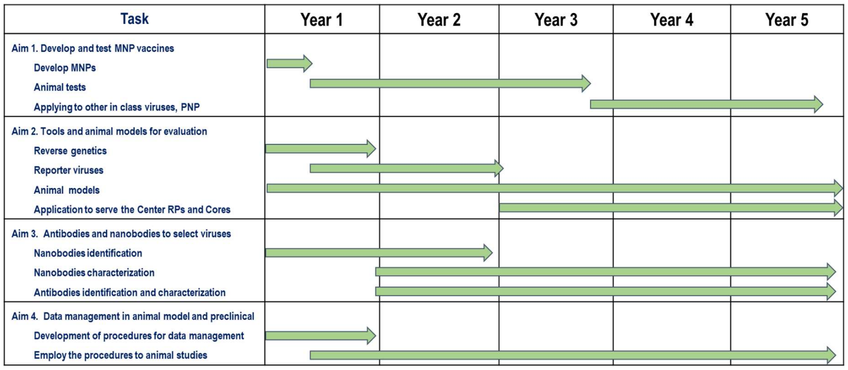
An additional and outstanding advantage of the PABVAX Center is the **Animal model development and preclinical evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

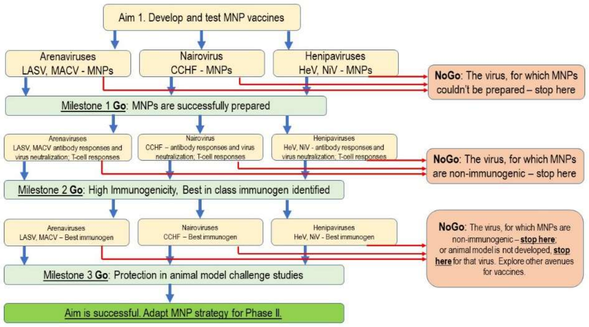


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

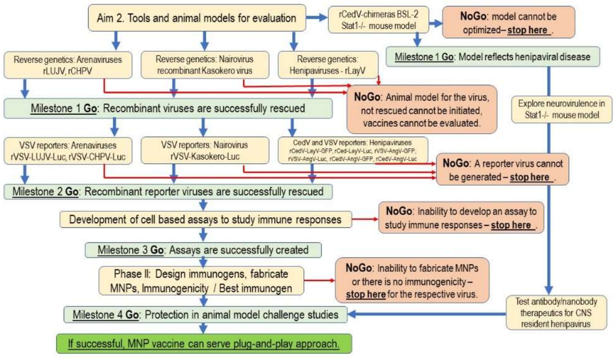

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

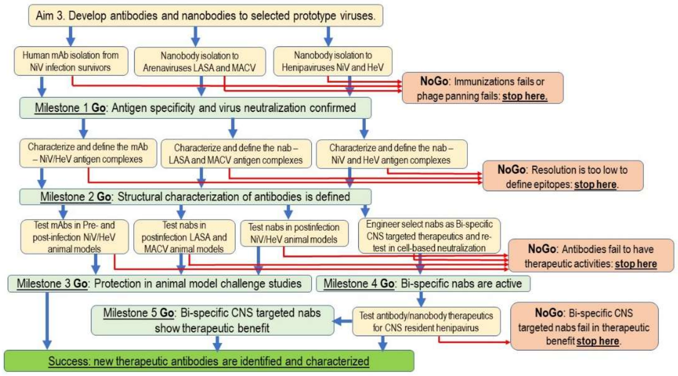

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

Commented [LZ9]: I can expand on this if needed.

Formatted: Font: Not Italic

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 187 separate NHP studies employing a total of 1,318 animals and 10 different BSL-4 viruses including Ebola and Marburg viruses and also Nipah and Hendra have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited nonhuman primate facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies to meet regulatory requirements by assuring regulatory compliance, quality assurance and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a “well documented” quality system program. Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over XXX peer-reviewed articles in these areas. Dr. Geisbert’s research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical has deep experience with antigens and monoclonal antibodies (mAbs) against these antigens. ~~’s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp™ which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and production of antigens, antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies {Mulangu, 2019 #818} {Group, 2016 #649}; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1 {Politch, 2021 #897}. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio’s expertise and experience will be a very important and valuable asset to the Center.~~

Formatted: Font: Italic

Bonnie Genovac

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe’s **(RP4)** research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of

Formatted: Font: Bold

human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in xxx,000 of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Formatted: Font: 11 pt

Commented [LZ10]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Emerging and periodically reemerging pathogenic enveloped RNA viruses are a continuous infectious disease and potentially pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats, through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

The *Bunyavirales*.

Fill out

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

vaccine ‘plug-and-play’ approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade.

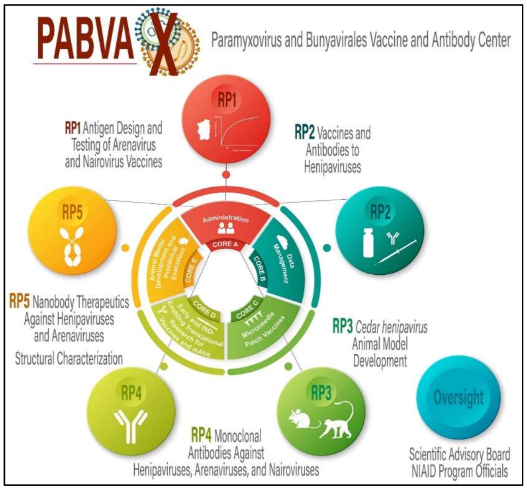

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center-(PABVAX). **(connecting arrows are needed between elements and the SAB)**

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

<u>With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:</u>

1) Establish an effective and adaptable vaccination technology.

2) Discover effective antibody-based therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

<u>An adaptable plug-and-play vaccine platform.</u>
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach

(PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based therapies.
PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.
HELP

Commented [CB2]: Larry/Dafna you are needed for this.

Develop new tools and animal models to facilitate the translation of effective countermeasures.
Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal model development and preclinical evaluation scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including…….. animal model development and use of animal models for the study of viral pathogenesis and assessing the therapeutic efficacy of antivirals and vaccines. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

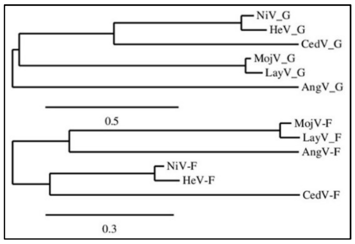

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and

disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Arenaviridae* and *Nairoviridae:

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (arenaviridae and nairoviridae projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

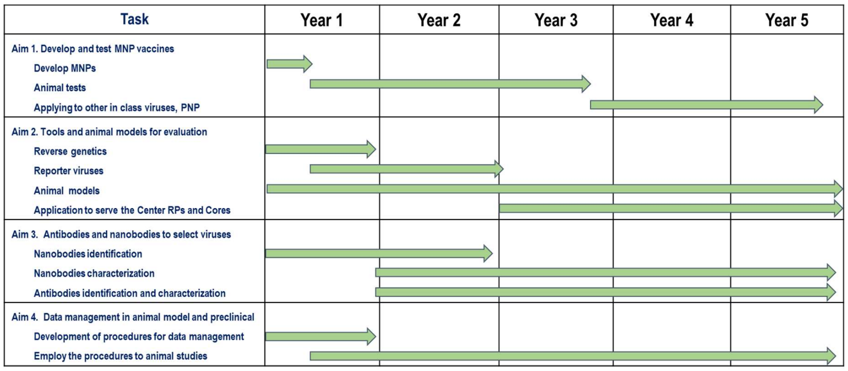
An additional and outstanding advantage of the PABVAX Center is the **Animal model development and preclinical evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

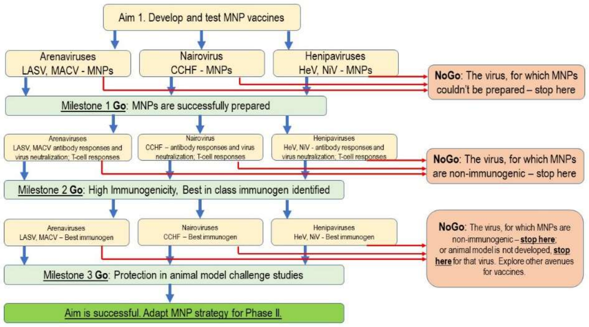


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

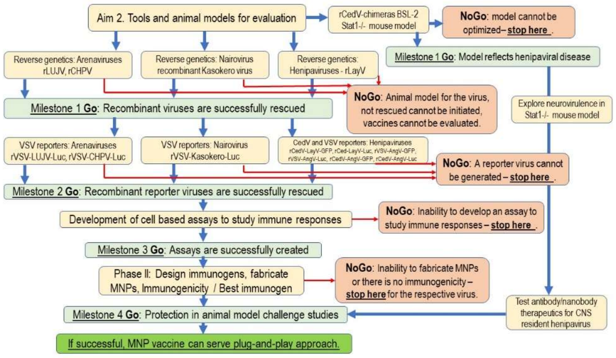

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

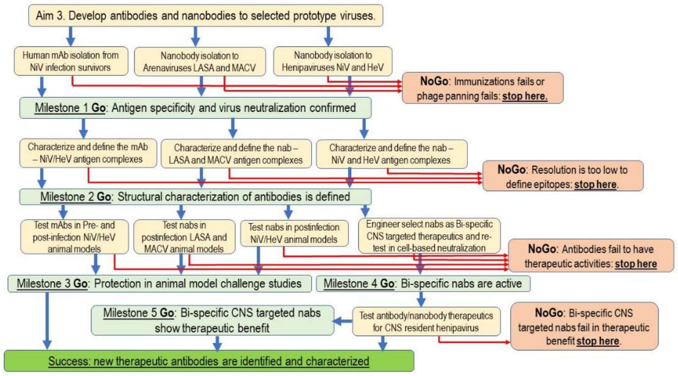

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 187 separate NHP studies employing a total of 1,318 animals and 10 different BSL-4 viruses including Ebola and Marburg viruses and also Nipah and Hendra have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited nonhuman primate facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies to meet regulatory requirements by assuring regulatory compliance, quality assurance and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over XXX peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical's product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp^{TM} which is being advanced to licensure as part of Project Bioshield. OTHER MAbs The early development and research group has expertise in immunology, infectious diseases, and production of antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio's expertise and experience will be a very important and valuable asset to the Center.

Bonnie Genovac

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.

BIBLIOGRAPHY AND REFERENCES CITED

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

SPECIFIC AIMS

Emerging and reemerging pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans worldwide with associated high morbidity and mortality. A host of arenaviruses viruses, including Lassa, Machupo, Lujo, and Chapare (LASV, MACV, LUJV, CHPV) and the Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also included among the World Health Organization's (WHO) List of Priority Pathogens. Several of these viruses are specifically identified as NIAID Category A pathogens. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the **Paramyxoviridae**. These HNVs have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease, and are significant biothreats to humans and livestock in South and South East Asia and Australia. These threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures to address the threat of natural outbreaks, epidemics, or deliberate release*.

The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates against a selection of these viruses. In the out years of the effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its Research Projects (RPs) and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAbs and nanobodies to the virus prototypes to foster pandemic preparedness. The Center's translational objectives will be accomplished by the completion of the following Aims:

AIM 1: Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae. Subunit viral antigen(s) MNP vaccines will be explored. **RP1** will test vaccines for both Old world (LASV) and New world (MACV) prototype viruses. **RP2** will test vaccines against the prototype viruses NiV and HeV. Each RP will implement this 'plug-and-play' vaccine approach with test case virus antigens in Phase 2. All three Scientific Cores (MNP-**Core C**), (Antigens and Antibodies-**Core D**) and (Animal models and testing-**Core E**) will support the RPs.

AIM 2: Develop new tools and animal models for the conduct of cell-based and *in vivo* therapeutics evaluation. Reverse genetics and recombinant pseudoviruses will be developed for both prototype and test case viruses by **RP1** and **RP2**. New high-containment (**RP1, RP2,** and **Core E**) and novel low-containment (**RP3**) animal models will be developed to explore pathogenesis and facilitate therapeutics testing.

AIM 3: Develop antibodies and nanobodies to selected prototype viruses. New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed in collaboration with **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses.

AIM 4: Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures. The Center will conduct a well-integrated, discovery and translational research program, and the goal of this Aim is to ensure the quality and integrity of collected data. Each RP and Core will employ procedures ensuring quality system data management in collaboration with Data Management-**Core B**. Further, quality system and regulatory science processes for animal studies (**Core E**) will be used under the guidance of a quality system team.

ok,
based on the RFA i made sections to address the requirements
some bits are from the CETR

The biggest thing this RFA wanted was the Milestones and go and no go
and timelines and diagrams.

needed items are green. need your magic guys especially industry and mabs and bunyas

there are never to many refs needed, yellow, so best to
have Sherry and Sonya do this (add them from your library) like the admin ect,,

pending space, the other bits are yellow and optional depending on what you think

Core C - Microneedle Patch Vaccines (Falo, Andrianov, Korkmaz): ABSTRACT/PROJECT SUMMARY

The threat of emerging and re-emerging infectious diseases highlights the need for continued improvement of vaccination strategies to enable more effective, sustainable, and equitable global immunization campaigns. As a complementary strategy to the proposed work in the Research Projects (RPs) of this Center, the ***goal*** of Core C is to develop, characterize, and validate highly innovative, *plug-and-play* polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP) platforms with RP-specific viral antigens to support the proposed research in the RPs of the Center. Development of efficacious, patient-friendly, broadly deployable, and rapidly adaptable PPZ MNP vaccination platforms and validation of their product attributes and immunological properties with the RP-specific antigens against prototype viruses will be of great significance to maximize pandemic preparedness against existing and novel human pathogenic viruses. The Core C of the Center will work seamlessly with Core D and RPs of the Center to bring together the transformative project components, ***1)*** *cutaneous immunization*, ***2)*** Polyphosphazene (*PPZ) adjuvant*, and ***3)*** *dissolvable MNPs*, with the rationally designed antigens that will be developed in RPs against high-priority pathogens to enable the achievement of the overall goals of the Center, as well as to support the translational development of a next-generation immunization strategy. The RP-specific *recombinant viral glycoprotein antigens* will drive the generation of virus-specific protective immune responses. *The PPZ macromolecules* will serve as an immunoadjuvant nanoassembly that will provide many immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. *Dissolvable MNPs* will enable targeting vaccine components to the highly immunoresponsive skin layers in a reproducible and self-administered manner for efficacious immunization, as well as facilitate the improved vaccine storage, distribution, and coverage due to their thermostability and cost-effectiveness. Together, PPZ MNP vaccines will effectively and safely harness the highly immunoresponsive cutaneous microenvironments to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The Core C will develop and batch release PPZ MNP vaccine platforms with RP-specific antigens based on well-defined quantitative release criteria of their validated physicochemical and immunological properties to enable the development of clinically feasible, highly protective vaccines against several prototype pathogens from multiple viral families in the RPs. Ultimately, these clinically translatable PPZ MNP vaccine platforms are readily adaptable to develop efficacious and broadly deployable vaccines against emerging and re-emerging viruses, including those with RP-specific viral antigens.

Core D will leverage the relationship between vaccines and antibodies to optimize the translational activities performed by the PABVAX Center. Vaccines and antibodies are inextricably linked:

1. mAbs can help define protective epitopes for a vaccine
2. mAbs can help establish correlates of protection for vaccines
3. Vaccine antigens can be used to discover mAbs
4. mAbs can provide an alternative to a vaccine in immunocompromised populations and in emergency situations where immediate protection is required (*i.e.* there isn't sufficient time to allow natural host immunity to develop from vaccination)

Developing mAb countermeasures and vaccines simultaneously will allow us to take advantage of natural synergies between the two types of interventions and more efficiently advance superior prototypes.

To meet the goals of the PABVAX Center, Core D has the following Specific Aims:

Aim 1*: Manufacture vaccine antigens and mAbs in support of the RPs and Cores*

Manufacturing will be performed by Mapp Biopharmaceutical and Genovac to support the efforts of the other Scientific Cores and the Research Projects. The largest scale manufacturing runs will be sufficient to support stability testing and NHP dosing. This will also include production of a mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine to be evaluated in Core E (Animal Models).

Aim 2*: Stability, manufacturability testing, and early process development of subunit vaccines.*

Small scale manufacturing, stability testing and early-stage process development will be performed. As vaccines are regulated by CBER, all activities will be performed consistent with regulatory expectations for this branch of the FDA. Input from the Core's vaccine industrial partners (**Emergent Biosolutions** and **Moderna**) will be integrated into the translational development efforts.

Aim 3*: Identification of correlates of protection, lead optimization, stability and manufacturability testing of mAbs*.

Together with Dr. Gunn, engineered mAbs (altered N-glycans, Fc mutations for effector functions and extended half-life, multimeric formats and nanobodies from RP5) will be evaluated to correlate mechanisms of action with maximal efficacy. This work, in conjunction with stability and manufacturability assessment, will identify a lead prototype format to transition to early process development. The goal will be to identify a single prototype for long-term intramuscular prophylaxis as well as for intravenous post-exposure prophylaxis and therapy. As mAbs are regulated by CDER, performance of all activities will be as per regulatory expectations.

Project Summary

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, the Arenaviridae and Nairoviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa, Machupo, Lujo, and Chapare, and the nairovirus Crimean-Congo hemorrhagic fever virus. All of these viruses are also included among the World Health Organization's (WHO) List of Priority Pathogens. Within the Paramyxovirdae the zoonotic henipaviruses Hendra virus and Nipah virus (NiV) are also on the WHO Priority Pathogens list. Notably, these henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75% for NiV. Significantly, there is evidence of multiple rounds of person-to-person transmission of NiV. All of these RNA viruses pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for countermeasures to address the threat of natural outbreaks, epidemics, or deliberate release. The Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX) is a well-integrated consortium conducting a set of discovery and translational research programs composed of a Data Management Core, three Scientific Cores, and five Research Projects (RPs). The synergistic activities of PABVAX partners will be focused on developing novel vaccines, treatments, and tools to foster pandemic preparedness. Federal law requires that the arenaviruses, nairoviruses, and henipaviruses used in the PABVAX Center be handled in an approved Biosafety Level (BSL)-4 containment laboratory. Core E provides an approved BSL-4 facility and a trained and highly experienced team of BSL-4 investigators and staff to perform studies that support RP1, RP2, RP4, RP5, Core C, and Core D. Core E will perform "well-documented" animal efficacy studies based on a quality system approach that will be supported by Core A with all data generated managed by Core B. The services provided by Core E will include 1) a secure repository of well characterized seed stocks of BSL-4 arenaviruses, nairoviruses, and henipaviruses 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for strains or variants of henipaviruses, arenaviruses, and nairoviruses to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies.

Relevance

The Animal Model Development and Preclinical Evaluation (Core E) provides BSL-4 resources and expertise for RP1, RP2, RP4, RP5, Core C, and Core D. The goal of Core E is to work closely with Research Project and Scientific Core Leaders and staff, the Scientific Advisory Committee, and NIAID/NIH to advance the development of countermeasures against Paramyxoviridae and Bunyavlrales.

TITLE: Vaccines and antibodies to henipavirus
Funding announcement: RFA-AI-23-020
Funding Title: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picronaviridae
PRINCIPAL INVESTIGATOR: Christopher Broder, Ph.D., Site Principal Investigator

Prime PI: Thomas Geisbert, Ph.D., UTMB
Period of Performance: March 1, 2024 - February 28, 2029

Project Summary/Abstract

Pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among these are the two emerged zoonotic paramyxoviruses: the ‘prototype’ henipaviruses (HNVs); Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. The prototype HNVs have a uniquely broad tropism capable of infecting 18 species across 6 orders of mammals using the conserved ephrin-B2 and -B3 ligands as entry receptors. NiV and HeV infection often results in a systemic and fatal respiratory and/or neurological disease in multiple mammalian species including humans. NiV and henipaviral disease are also included in the WHO List of Priority Pathogens, and they are significant biothreats to humans and livestock in South and South East Asia and Australia. HNVs have two membrane glycoproteins: the attachment glycoprotein (G) and the fusion glycoprotein (F) that are the major targets of neutralizing antibodies and the focus of all vaccine and antiviral monoclonal antibody (mAb) strategies. The most extensively studied HNV vaccine is a soluble recombinant form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including nonhuman primates (NHPs). With no licensed vaccines or treatments available for human use, this project will use the prototype HNVs as a model to develop, test, and translate a novel vaccination platform (a thermostable, needle-free, adaptable, and widely deployable polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP)). Preliminary data demonstrates potent immunogenicity of a PPZ-MNP-HeV-sG vaccine in mice, inducing robust antigen-specific HNV cross-neutralizing antibody and cellular immune responses. The MNP vaccines will be used to evaluate HeV-sG and compare stabilized soluble forms of HNV G and F (sG_{tet} and sF_{stb}) and combinations in challenge studies. A reverse genetics system has been developed to generate recombinant, nonpathogenic Cedar virus (rCedV) and rCedV chimeric virus tools by swapping the G and F glycoproteins with those of NiV/HeV as a rapid, surrogate, BSL-2 high-throughput neutralization platform to be used to rapidly evaluate HNV vaccine responses. Also, divergent and pathogenic zoonotic HNVs have been discovered including the related rodent borne Mòjiāng virus and Langya virus (LayV)), and the divergent bat-borne Angavokely virus (AngV). This project will develop and test the rapid, adaptable and readily deployable MNP vaccine platform together with new virological tools to facilitate the translational nature of this pandemic preparedness approach. Specifically, we will: 1) Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV vaccines; 2) Construct new reporter virus tools; 3) Evaluate vaccine-induced immune responses and HNV-specific mAbs and nbs; and 4) Validate the PPZ-MNP platform with another paramyxovirus antigen.

Period of Performance: March 1, 2024 - February 28, 2029

Abstract

Henipaviruses are single-stranded, negative-sense enveloped RNA viruses of the paramyxovirus family. Two henipaviruses, Nipah virus (NiV) and Hendra virus (HeV), cause a systemic and often fatal respiratory and/or encephalitic disease in humans and ten other mammalian species. Importantly, NiV and HeV are significant biothreats to humans and economically important livestock in Australia and Southeast Asia. There are currently no vaccines or therapeutics approved for human use. Notably, development of countermeasures for NiV and HeV is hampered by the fact that these viruses require BSL-4 containment, meaning that very few research groups worldwide have access to the required biocontainment facilities to perform preclinical studies with these important human viral pathogens. To address this problem, we are developing a BSL-2 animal model that is based on Cedar virus (CedV), which is a non-pathogenic henipavirus. Specifically, we are employing recombinant Cedar viruses (rCedVs) in which the NiV and HeV fusion (F) and receptor-binding glycoprotein (G) are expressed in the rCedV genome, replacing CedV F and G. Additionally, we have also incorporated our recently developed *in vivo* bioluminescence methodology to longitudinally trace the dynamics and anatomical progression of rCedV-luciferase (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host innate immune response in mice, we have demonstrated sustained replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Importantly, whereas rCedV-luc does not establish stable expression in the brain, both of the chimeric viruses do. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in specific strains of mice. The rCedV-luc platform is thus an authentic henipavirus system that can be used to study henipavirus *in vivo* biology safely and expediently under BSL-2 containment. Our overall hypothesis is that rCedV-luc infection of mice lacking specific innate immune responses represents a BSL-2 platform for the study of henipavirus biology and pathogenesis, as well as for development and testing of anti-viral countermeasures. We will address this hypothesis through three Specific Aims: Aim 1: To optimize the use of immunodeficient mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease; Aim 2: To determine the mechanism of rCedV-NiV neurovirulence; Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Aims involve synergistic collaborations with several other research projects and cores in this U19 program. Successful completion of these Aims will establish the rCedV-luc mouse model as a robust BSL-2 platform for the exploration of henipavirus pathogenesis and countermeasures.

The *Henipavirus* genus of RNA viruses in the family *Paramyxoviridae* contains diverse species, and this group of viruses is ideal for prototype pathogen immunity approaches. Henipaviruses are found naturally in bats in Australia, Asia, and Africa and have a wide host range. These zoonotic pathogens can cause severe illness and death in domestic animals and humans. Prophylactic and therapeutic options for Hendra and Nipah virus infections in man are limited. Anti-Hendra/Nipah human mAbs are expected to be valuable antiviral therapeutics as countermeasures to Hendra and Nipah virus disease in humans. Here, we will isolate panels of naturally occurring human monoclonal antibodies (mAbs) that bind cross-reactively to both Hendra and Nipah virus surface proteins and neutralize both viruses. This effort will focus especially on the mAbs to the fusion (F) proteins. In previous experiments, we have isolated some mAbs for the G protein that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic and therapeutic molecules for humans. We propose here a series of aims that will discover new F mAb and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of Hendra and Nipah virus in preparation for clinical studies. The work will identify and fully characterize a panel of highly promising mAbs with the goal of identifying and selecting lead compounds and advancing their preclinical development. The work is organized in two major Specific Aims: Aim 1) Isolation of human mAbs from patients previously infected with henipavirus. In this Aim, human mAbs will be identified that recognize epitopes that are conserved across henipaviruses and neutralize those viruses at low concentration, with a focus on F-specific mAbs that neutralize virus and inhibit virus-cell fusion. Blood cells from individuals with natural prior exposure to Nipah virus will be used for study. These B cells will be interrogated with several well developed human mAb discovery platforms, including high-throughput single cell sorting and single cell RNAseq techniques, or converted to stable human hybridoma cell lines. B cell line supernatants or recombinant mAbs will be subjected to high-throughput screening to identify Abs that bind to Hendra and Nipah surface proteins and functionally inhibit virus replication. Aim 2: Develop Abs for the treatment of henipavirus infections. MAbs identified in Aim 1 will be tested for their broad recognition of conserved epitopes across all henipaviruses and for their ability to neutralize in culture. We also will investigate the role of Fc effector functions on antiviral activity, and the effect of long half-life Fc mutations that enable use of human mAbs for prophylaxis. Prioritized mAbs then will be tested for therapeutic efficacy in multiple animal models of infection including nonhuman primates. The leads will be selected, and CHO cell lines will be made by Mapp Biopharmaceutical for Ab production, in preparation for cGMP manufacture and IND planning. The work promises to yield a best-in-class mAb combination preparation for broad and potent activity against henipaviruses that can be used to treat or prevent human henipavirus infections.

SPECIFIC AIMS

The COVID-19 pandemic has highlighted the urgent need for rapid drug development and novel antiviral therapies to combat emerging pathogens. Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising solution. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier, making them particularly effective in treating Central Nervous System (CNS) diseases caused by viral infections.

Henipaviruses (HNV) and arenaviruses (ARV) represent significant global public health risks, yet currently lack specific licensed treatments. To address this critical gap, prototype viruses from each viral group have been selected based on their impact. The research strategy developed for this project can be extended to encompass a broader range of viruses within these groups. Specifically, the study focuses on Nipah virus (NiV) and Hendra virus (HeV), both of which cause severe respiratory and CNS illnesses in humans and have alarmingly high mortality rates ranging from 40% to 90%. Additionally, Lassa virus (LASV) and Machupo virus (MACV), both belonging to the Arenavirus genus, are targeted due to their capacity to induce severe illness and fatalities. LASV is responsible for endemic Lassa fever in West Africa, while MACV is associated with Bolivian hemorrhagic fever.

The overarching objective of this study is to develop nanobody-based therapeutic approaches for combating HNV and ARV infections. The key targets for intervention are the viral entry machinery, specifically the glycoproteins G and F for HNV and the glycoprotein complex (GPC) for ARV. Employing a structure-based approach, the research aims to unravel the intricate mechanisms of viral neutralization, enhance nanobody engineering techniques, and design blood-brain barrier-penetrating nanobodies. The underlying hypothesis is that nanobodies can effectively counteract CNS diseases caused by these viruses.

To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody libraries that closely mimic the natural human antibody heavy chain variable domain. Antigen-specific enriched nanobody libraries will be deep-sequenced to ensure comprehensive coverage. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. The project will be conducted with following specific aims.

Aim 1: To identify cross-reactive nanobodies to HNVs. Given their high degree of glycoprotein (F and G) similarity, it feasible to identify cross-reactive neutralizing nanobodies against both HeV and NiV for broad protection. We will employ sequential immunization and antigen panning strategies to identify nanobodies that cross-recognize HeV and NiV. Furthermore, the neutralizing activity of the nanobodies will be evaluated by RP2.

Aim 2: Identification of nanobodies to ARVs. To overcome the challenges posed by the heavily glycosylated and conformationally labile surface glycoprotein (GPC) of Arenaviruses (ARVs), we will develop nanobodies as a therapy option. Nanobodies can potentially penetrate the GPC's glycan shield and neutralize the virus. We will assess individual antigen-specific nanobodies by evaluating their neutralization activity in RP1.

Aim 3: Structural characterization. To gain insight into nanobody epitopes and neutralization mechanisms, we will employ structural characterization techniques such as X-ray crystallography and Electron Microscopy Single Particle Analysis. This structural analysis will be instrumental in guiding the design and optimization of nanobody-based therapeutic interventions.

Aim 4: Enhancing efficacy and CNS bioavailability of nanobodies. We will engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved blood-brain barrier (BBB) penetration. Finally, we will compare the efficacy of the original nanobodies (from Aim 1 and 2) with the engineered nanobodies in either the rCedV-NiV-B chimera mouse model in RP3 (for HNVs) or animal models of ARV developed at UTMB in RP1.

Aim 5: Expanding to other members of the viral groups in Center Phase 2. Building upon the knowledge gained from Aims 1-4, we will extend our research to develop nanobody therapies targeting other members of HNV and ARV, such as *Mojiang virus, Langya virus, Lujo virus, or Chapare virus*. The research strategy developed in the earlier aims will be applied and tested for these additional viral targets.

By pursuing these specific aims, our objective is to advance the development of nanobody-based therapies for HNV and ARV infections. The ultimate goal is to contribute to the development of effective treatments against these viral pathogens and mitigate the global public health risks they pose.

Project Summary (OVERALL)

Emerging and reemerging pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales***. The *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans worldwide with associated high morbidity and mortality. A host of arenaviruses viruses, including Lassa, Machupo, Lujo, and Chapare viruses and the Nairovirus-Crimean-Congo Hemorrhagic Fever Virus and are also included among the World Health Organization's (WHO) List of Priority Pathogens. The zoonotic henipaviruses (HNVs) including Nipah virus (NiV) and Hendra virus (HeV), in the **Paramyxoviridae** family are also on the WHO Priority Pathogens . ~~Also, within the Priority Pathogens list is Nipah virus and henipaviral disease which includes Hendra virus which are zoonotic henipaviruses (HNVs) in the family~~ ~~**Paramyxoviridae**.~~ These HNVs have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease, and are significant biothreats to humans and livestock in South and South East Asia and Australia. All these RNA virus threats to global public health are heightened due to the absence of approved vaccines or therapeutics. There is a clear unmet need for countermeasures to address the threat of natural outbreaks, epidemics, or deliberate release. The Paramyxoviridae and Bunyavirales Vaccines and Antibodies (PABVAX) is a well-integrated Center conducting a set of discovery and translational research programs composed of a Data Management Core, 3 Scientific Cores, and 5 Research Projects (RPs). The synergistic activities of Center partners will be focused on: developing, testing, and translating, prototype subunit vaccines ~~using~~ employing a novel~~,~~ adjuvanted~~,~~ dissolvable, microneedle patch (MNP) vaccine platform; developing new virus and animal model tools; and developing and testing monoclonal antibody and nanobody prototypes to foster pandemic preparedness. The level of ~~certain~~ vaccines and antibody countermeasure advancements among the RPs is a major strength and advantage of this Center. The Center's overall objective is to elucidate key principles for vaccine and antibody-based countermeasures in developing prototype candidates against a selection of these viruses. In the out years of the effort, the Center will exploit these learned key principles in a "plug and play" ~~demonstration~~ approach against related viruses.

Commented [LZ1]: Clarify? Not sure what the intent of this sentence is…

Relevance (OVERALL)

Select zoonotic RNA viruses within the Paramyxoviridae and Bunyavirales ~~are a~~represent a continuous threat to global publich health ~~continuous infectious disease and potentially pandemic threats to global public health because of~~due to their ease of dissemination and/or ~~abilities to~~transmissibility ~~transmit~~ from person-to-person ~~,~~ and ~~produce~~ result in significant morbidity and mortality, ~~and require~~thus requiring special actions for public health preparedness. These viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. There is a clear unmet need for vaccines and antibody-based therapeutics to address these threats that can arise from natural outbreaks, epidemics, or bio-weaponization and deliberate release.

George,
An org chart is attached as well as abstracts/specific aims for the cores and research projects and overall for the center goals. (all but RP1).

Core C: Microneedle Patch Vaccines (UMD; Alexander Andrianov/UPitt; Louis Falo/Emrullah Korkmas)
Core D: Early and IND-Enabling Translational Research for Vaccines and mAbs (MappBio; Larry Zeitlin/Dafna Abelson- WSU; Bonnie Gunn-UTMB; Tom Geisbert)
Core E: Animal Model Development and Preclinical Evaluation (UTMB; Tom Geisbert/Courtney Woolsey)
RP1: Antigen Design and Testing of Arena virus and Nairovirus Vaccines (UTMB; Bob Cross- WSU; Bonnie Gunn)
RP2: Vaccines and Antibodies to Henipaviruses (USUHS; Chris Broder/Amaya Moushimi/Antony Dimitrov)
RP3: Cedar henipavirus Animal Model Development (USUHS; Brian Schaefer)
RP4: Monoclonal Antibodies Against Henipaviruses, Arenaviruses, and Nairoviruses (VUMC; Jim Crowe)
RP5: Nanovody Therapeutics Against Henipaviruses and Arenaviruses (OSU; Kai Xu/GSU; Jianliang Xu)

Let me know if this helps or you need anything else.

Best,
Sherry

Subject: Re: Data Mgmt Core Final Documents - UTMB/USUHS U19

Hi Sherry,

The following documents are not needed for the data management core:

- Resource sharing plan - I'm providing the data management sharing plan instead for the final submission.
- Authentication of key biologicals - don't have any.

For an Abstract, I would need the organizational chart for the entire proposal to integrate what was asked for earlier.
Based on other U19, this is what my abstract will include:

- Aims " Aim 1 will..... In Aim 2 we will....". And include 1-2 sentences following each aim to elaborate a little.
- Overall goal
- **Mention of Cores and RPs to emphasize synergy**
- End with a statement about how the team of experts at UTMB has been assembled

I can skip the synergy part for now, add it based on the organizational chart if we have one, or pull from the methods from core and RPs.

Please advise.

Best,
George

Subject: Data Mgmt Core Final Documents - UTMB/USUHS U19

Hello Dr. Golovko,
This is a reminder of the documents that we still need to get from you for Core B (Data Mgmt) on the UTMB/USUHS U19 application. Our administrative review is this coming Thursday, June 1, so we will need all of the items listed below in final form by **EOB tomorrow, Wednesday, May 31**.

- Abstract – 30 lines
- Resource sharing plan
- Authentication of key biologicals

For the final application, please provide the following by **EOB Monday June 5** *(hard deadline!).*

- Research Strategy + Bibliography

Please let me know if you have any questions about these or have any concerns about getting them back to us by the deadlines.
Thank you,

Sherry L. Haller, PhD

OMB No. 0925-0001 and 0925-0002 (Rev. 10/2021 Approved Through 09/30/2024)

BIOGRAPHICAL SKETCH

NAME: Schaefer, Brian Charles

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Professor of Microbiology and Immunology, and Director (Interim), Emerging Infectious Diseases Graduate Program

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE *(if applicable)*	Completion Date MM/YYYY	FIELD OF STUDY
Massachusetts Institute of Technology	B.S.	1989	Biology
Harvard University	PhD	1995	Immunology
Harvard Univ/Dana Farber Cancer Institute	(Postdoc)	1995-1996	Tumor Virology
National Jewish Medical and Research Center	(Postdoc)	1996-2002	Immunology

A. Personal Statement

My group has historically focused on two major research programs. Our longest-standing program involves elucidation of mechanisms of signal transduction in immune cells and regulation of immune cell effector function, with a particular emphasis on the pathway that connects the T cell receptor (TCR) signaling to the transcription factor, NF-κB. This work has also stimulated our studies of the function of an understudied CARD protein, CARD19, which was originally (incorrectly) identified as a negative regulator of TCR signaling to NF-κB. These studies have resulted in numerous publications that define novel signaling mechanisms in the CARD11-BCL10-MALT1 signaling cascade and additional pathways. Our second major area of research is centered on immune responses in the central nervous system. Our initial work in this area involved elucidation of the role of the immune response initiated by traumatic brain injury, particularly NF-κB-mediated inflammatory responses. However, we have now shifted our emphasis to translational research on immune responses to neurotropic viruses, with an overall goal of developing immunotherapy strategies that are broadly effective against this dangerous class of human pathogens. This work is focused on lyssaviruses and henipaviruses, due to their neurotropic nature and propensity to cause severe human disease with a very high fatality rate. Our use of bioluminescence imaging to track viral replication has been a particularly important innovation for this work, as it allows us to collect highly granular data regarding viral spread and amplification from individual animals in a longitudinal manner. Specific current projects include a DoD-funded translational study in which we are defining the utility of a novel, mAb-based anti-lyssavirus immunotherapy against rabies strains circulating in Europe and Africa, and a study to develop novel henipavirus therapies (both are collaborations with Dr. Christopher Broder's group).

I am ideally suited to be PI of RP3: *Cedar henipavirus animal model*, as my group has established the only mouse model of Cedar virus infection (to our knowledge), and we now have several years of experience in the development of this very important BSL-2 animal model to investigate mechanisms of henipavirus pathogenesis, and to test efficacy of novel therapies. The following are notable ongoing projects:

HU00011920118 (**PI: Schaefer**), USU Center for Global Health Engagement
09/30/2019 – 09/29/2022 (NCE to 9/30/23)
"Efficacy testing of a novel human monoclonal antibody therapy for late-stage rabies/lyssavirus infection"

U19 AI142764-01 (PI:Broder; **Schaefer Co-I**), NIH/NIAID
03/01/2019 – 02/29/2024
"Advancement of Vaccines and Therapies for Henipaviruses"

R01 AI125552 (**PI: Schaefer**). NIH/NIAID
06/01/2017 – 05/31/2022 (NCE to 5/31/2024)
“T cell receptor-activated autophagy as a regulator of T cell effector responses”

HU00011921048 (**PI: Schaefer**), USU Multi-domain Operations Research (MDO)
02/28/2023 - 09/30/2025
“Defining the mechanism of enhancement of the pathogen-directed host adaptive immune response following anti-lyssavirus monoclonal antibody therapy”

B. Positions, Scientific Appointments, and Honors

Positions

2017 - current	Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2009 - 2017	Associate Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2002 - 2009	Assistant Professor in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
1996 - 2002	Post-doctoral Research Associate, Howard Hughes Medical Research Institute, National Jewish Medical and Research Center, Denver, CO.
1995 - 1996	Research Fellow in Pathology, Harvard University, Dana-Farber Cancer Institute

Professional Memberships and Service

2011 - 2016	NIH CMIB (Cell and Molecular Immunology-B) study section for review of R01/R21 grants (Ad hoc member Feb & May 2011, Feb & May 2013, Feb 2014, Feb 2015, May 2016)
2008, 2021	ZRG1 CB-D 30 Confocal Microscopy Shared Instrumentation NIH Study Section (Ad hoc member)
2006 - current	American Society for Cell Biology (ASCB)
2006 - current	American Association of Immunologists (AAI)
2006 - 2007	ZRG1 IMM-L 29 L, DBBD Minority and Disability Predoctoral Fellowship NIH Study Section (Ad hoc member)
2005-2006	ZRG1 F07 Immunology Fellowship and AREA NIH Study Section (Ad hoc member)

Honors

2016	Uniformed Services University Henry Wu Award for excellence in basic science research
2005 - 2008	Dana Foundation Program in Brain and Immuno-Imaging
2004 - 2006	Kimmel Scholar - Sidney Kimmel Foundation for Cancer Research
2000 - 2002	Leukemia and Lymphoma Society Special Fellowship
1989 - 1992	Office of Naval Research Graduate Research Fellowship
1989	Phi Beta Kappa
(1989)	National Science Foundation Graduate Research Fellowship (Declined)

Patents

2007	US Patent 7,169,570: *Method to Identify Regulators of Cellular Activation Using Bcl10* – BC Schaefer, JW Kappler and P Marrack

Mouse strains developed

2001	C57BL/6-Tg(UBC-GFP)30Scha/J: Ubiquitously expressed EGFP transgene on a pure C57BL/6 background. Repository strain at Jackson Laboratory (stock# 004353). This strain has been used and cited in hundreds of publications.

C. Contributions to Science

1. My Ph.D. thesis studies involved identification of the molecular mechanisms controlling distinct latency-associated Epstein Barr virus (EBV) transcriptional programs. Prior to my dissertation work, it was known that there were three forms of EBV latency which displayed two distinct phenotypes with regard to expression of EBV nuclear antigens (EBNAs): Type III latency is characterized by expression of all six EBV nuclear antigens (EBNA1-EBNA6) whereas Type I and Type II latency is characterized by expression of EBNA1 only. The molecular basis restricted EBNA expression in Types I and II latency was not known. My work demonstrated the existence of a novel EBV promoter "Qp," responsible for driving exclusive expression of EBNA1 in Types I and II latency. My studies also showed that the choice between latency programs was contingent on whether the Type III latency promoter, Cp, is methylated in the host cell. Collectively, this work contributed significantly to the current understanding of regulation of EBV latency, which is relevant to elucidating how EBV persists for life in immunocompetent individuals, how EBV emerges as a life-threatening pathogen in specific immunodeficiencies, and how specific programs of EBV latency may be related to EBV-associated tumors, such as Burkitt lymphoma.

    ‡Cited >85 times.

2. My early work as an independent investigator involved determining whether NF-κB signaling proteins undergo molecular redistribution in response to TCR signaling. Previous work had shown that several different signaling molecules are recruited to "supramolecular activation clusters (SMACs)," membrane-proximal enrichments of signaling proteins that form on the cytoplasmic face of the antigen-engaged TCR. An assumption in the field, prior to our work, was that SMAC recruitment would be a shared feature of all cytoplasmic proteins important in TCR signaling. Surprisingly, our investigations demonstrated that NF-κB signaling proteins, including Bcl10 and Malt, redistribute to punctate cytoplasmic structures, which we named POLKADOTS. Our ongoing signal transduction work has involved mechanistic studies connecting the POLKADOTS signalosome to TCR activation of NF-κB. Key findings include demonstration that (i) TCR activation of NF-κB is *digital*. In other words, in contrast to pharmacological stimulation of NF-κB (PMA + ionomycin), which results in graded activation of NF-κB as the stimulus is increased, increasing TCR ligand changes only the *number* of T cells that respond, but not the *intensity* of the response; (ii) polyubiquitination of Bcl10 leads to recruitment to pre-existing p62 "speckles," forming the POLKADOTS signalosome; (iii) the POLKADOTS signalosome is required for activation of the IKK complex; (iv) the POLKADOTS signalosome contemporaneously directs a signal dampening activity that involves a highly novel regulatory mechanism: *selective* autophagy of Bcl10, which results in degradation of Bcl10, but not its direct binding parther, Malt1; (v) effector T cells form POLKADOTS signalosomes and use autophagy to degrade Bcl10, whereas naïve T cells use a distinct mechanism of NF-κB activation that appears to be independent of p62, involving recruitment of signaling proteins to SMACs. Collectively, these contributions provide key mechanistic details regarding how signals are transmitted from the TCR to the NF-κB transcription factor. Most recently, we have collaborated with Drs. Wolfgang Losert and Arpita Upadhyaya, biophysicists at the

University of Maryland, to define biophysical features of TCR-mediated activation and degradation of Bcl10. Our study with Dr. Losert in PLOS Computational biology has shown that the regulated polymerization and degradation of Bcl10 has characteristics of an excitable system, providing new insights regarding the digital behavior of this signaling module.

3. During our studies on TCR signaling to NF-κB, we became interested in the understudied CARD protein, CARD19. Although CARD19 was initially described as a cytoplasmic negative regulator of TCR signaling to NF-κB, we found that this work was based on analysis of a partially spliced cDNA clone, and that the conclusions of this initial study were therefore spurious. Our work with a properly spliced CARD19 cDNA showed that CARD19 is a mitochondrial protein that plays no role in TCR activation of NF-κB. Our latest work has shown that CARD19 interacts with the mitochondrial cristae organizing system (MICOS), and that it plays a role in determining cristae morphology. Notably, 3 of the 7 current publications focused on CARD19 were generated by my laboratory or as a collaboration with my group. We are currently performing further studies to determine whether CARD19 regulates other aspects of mitochondrial function via its interaction with MICOS components.

   a. Rios KE, Kashyap AK, Maynard SK, Washington M, Paul S and **Schaefer BC**. CARD19, the protein formerly known as BinCARD, is a mitochondrial protein that does not regulate Bcl10-dependent NF-κB activation after TCR engagement. Cell. Immunol., 2020; 356:104179.
   b. Bjanes E, Sillas RG, Matsuda R, Demarco B, Fettrelet T, DeLaney AA, Rodriguez Lopez EM, Grubaugh D, Wynosky-Dolfi M, Philip NH, Krespan E, Tovar D, Joannas L, Beiting DP, Henao-Meija J, **Schaefer BC**, Chen KW, Broz P, and Brodsky I. Genetic targeting of Card19 is linked to disrupted NINJ1 expression, impaired cell lysis, and increased susceptibility to Yersinia infection. PLoS Pathog. 2021;17(10):e1009967.
   c. Rios KE, Zhou M, Lott N, Beauregard C, McDaniel DP, Conrads TP, and **Schaefer BC**. CARD19 interacts with mitochondrial contact site and cristae organizing system constituent proteins and regulates cristae morphology. Cells, 2022 11(7):1175.

4. A second major research focus in my lab is the study of immune responses in the central nervous system. Our initial studies focused on inflammatory responses in traumatic brain injury (TBI), using mice as a model system: The first study demonstrated that the gene expression program induced by mild vs. severe TBI is remarkably similar, with the main distinction being that the expression of certain inflammatory genes remains persistently elevated in severe TBI. The second study presented evidence that the anti-inflammatory drug salsalate is a candidate therapy for TBI, reducing inflammation and improving functional recovery, as assessed by behavior assays. Our more recent work has focused on developing novel animal models and immunotherapies for neurotropic viral infections. Our published work on this project includes a description of our methodology for longitudinal tracing of lyssavirus infections and a description of isolation and in vitro characterization of two anti-lyssavirus neutralizing mAbs.

   a. *Lagraoui M, Latoche JR, Cartwright NG, Sukumar G, Dalgard CL, **Schaefer BC**. Controlled cortical impact and craniotomy induce strikingly similar profiles of inflammatory gene expression, but with distinct kinetics. Front Neurol. 2012; 3:155.
      ***Cited >100 times**

   b. Lagraoui M, Sukumar G, Latoche JR, Maynard S, Dalgard CL, **Schaefer BC**. Salsalate treatment following traumatic brain injury reduces inflammation and promotes a neuroprotective and neurogenic transcriptional response with concomitant functional recovery. Brain, Behavior and Immunity. 2017; 61:96-109.
   c. Mastraccio KE, Huaman C, Warrilow D, Smith GA, Craig SB, Weir DL, Laing ED, Smith IL, Broder CC, and **Schaefer BC**. Establishment of a longitudinal pre-clinical model of lyssavirus infection. J. Virol. Methods. 2020; 281:113882.
   d. Weir DL, Coggins SA, Vu B, Coertse J, Yan L, Smith I, Laing ED, Markotter S, Broder CC and **Schaefer BC**. Isolation and Characterization of Cross-Reactive Human Monoclonal Antibodies That Potently Neutralize Australian Bat Lyssavirus Variants and Other Phylogroup 1 Lyssaviruses. Viruses. 2021; 13:391.

5. A distinct area of emphasis in my career has been the development of new tools for research and the optimization of existing tools. Among many publications in this area, I have edited a protocols book and written a review on methodology for identification of cDNA ends by RACE (which included an optimized protocol). I produced a C57BL/6 transgenic mouse strain ubiquitously expressing GFP, which has been a highly utilized tool for cell transfer studies. I also generated a set of retroviral vectors for rapid and reliable creation of stable cell lines. My lab has published optimized protocols for visualizing NF-κB signaling intermediates via confocal microscopy, and for quantifying NF-κB activation using imaging flow cytometry. We have most recently described our methodology for using bioluminescence imaging to semi-quantitatively trace lyssavirus infection in laboratory mice. A central goal of this work is to facilitate progress across the biomedical research community, through the development and distribution of better tools and clear explanation of how to reliably execute challenging techniques.

A. Personal Statement

The main objective of this ReVAMPP proposal is to support Pandemic Preparedness through the study and advancement of broadly effective countermeasures for pathogenic henipaviruses and bunyaviruses, through advanced machine learning-enabled design of prototype pathogen vaccines and antibodies. I will serve as co-investigator, with **Thomas Geisbert** (Project-Lead) of **Research Project 5 (RP5): Animal models and vaccine evaluation.** I have researched enveloped virus-host cell interactions for 34 years. 1999, I established a collaborative international group of experts in Hendra and Nipah virus biology, and over an 11-year period I was the PI of two multi-component, international, NIAID, U01 Cooperative Agreements, and the Co-PI of a third U01 with RP5 Lead (Geisbert); all focused on Nipah virus and Hendra virus research. Collaborative henipavirus work includes structural biochemistry on the viral G and F glycoproteins including most recently with **David Veesler,** Overall Center Co-PI; animal models and *in vivo* pathogenesis, and the development and testing of vaccines and therapeutics; the discovery of the entry receptors for Hendra and Nipah (ephrin-B2/B3) and the development of the feline, ferret and African green monkey models (with **Geisbert**) of Hendra and Nipah pathogenesis; development of antiviral mouse and human monoclonal antibodies (mAb) including mAb m102.4 that successfully completed a Phase 1 trial in Australia (2020) and to date has been used by emergency protocol in 17 people in Australia and 1 person in the US for Hendra/Nipah post-exposure treatment; developed the Hendra/Nipah subunit vaccine based on soluble Hendra G (HeV-sG); one version called Equivac® HeV (Zoetis, Inc.), the first commercialized vaccine to a BSL-4 agent. The HeV-sG vaccine is in Phase I trial in the US (Auro Vaccines/PATH/CEPI). More recently I developed a reverse genetics platform for generating recombinant Cedar henipavirus (rCedV) that can be utilized at BSL-2 for both high-throughput antiviral drug discovery and rCedV chimeras for performing rapid neutralization tests for Nipah and Hendra. I have the expertise in many aspects of the henipavirus-related project goals, and for the past 24 years I have led both basic and translational research projects in a broad area of study on Nipah and Hendra virus. My lab's role will be focused on the development of new reporter viruses with a focus on the recently discovered Langya henipavirus as a new 'prototype henipavirus' distinct from the Nipah/Hendra/Cedar henipaviruses; and my lab will use these new tools, and existing and recently developed platforms to assess new henipavirus vaccines and neutralizing antibodies that will be developed by the Center's Scientific Cores and Research Projects.

Ongoing and recently completed projects that I would like to highlight:

U19 AI142764. NIAID, Center of Excellence for Translational Research (CETR): Role: PI
03/20/19-02/29/24. "Advancement of Vaccines and Therapies for Henipaviruses"

U19 AI171413. NIAID AViDD: "UTMB-Novartis Alliance for Pandemic Preparedness": PIs: Diagana and Shi.
05/01/2022-04/30/2027; Sub-project 3: Henipaviruses. Role: Co-PI with Geisbert

CRADA; Auro Vaccines, LLC. Egan (PI). CEPI (Coalition for Epidemic Preparedness Innovations): Role: Co-PI
07/01/18-06/30/2023; "A Subunit Vaccine (HeV-sG) to Protect against Nipah and Hendra Diseases"

B. Positions, Scientific Appointments

Positions and Employment

2018-pres.	Chair, Department of Microbiology and Immunology, USU, Bethesda, Maryland.
2006-2018	Director, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.
2005-pres.	Professor, Department of Microbiology and Immunology, Joint appointment, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.
2000-2005	Associate Professor, Department of Microbiology and Immunology, Joint appointment, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.
1996-2000	Assistant Professor, Department of Microbiology and Immunology, Joint appointment, Molecular and Cell Biology Graduate Program, Uniformed Services University, Bethesda, Maryland.
1993-1996	IRTA Fellow, LVD, NIAID, NIH, Bethesda, Maryland.
1990-1992	National Research Council, Research Associate, Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland.

Other Experience and Professional Affiliations

2022-	Member, Virus Expert Panel for Disease X Vaccine Libraries (CEPI).
2018-	Nipah Task Force (CEPI).
2018-	Nipah Therapeutics Protocol Team; ICMR, NIAID, WHO.
2011-	Member, Discontools Nipah Virus Infection Panel Expert Group. Gap analysis. International Federation for Animal Health Europe, Brussels, Belgium.
	Editorial boards, dates since joining: *Journal of Virology-07’*, *Virology-10’*, *Viruses-11’*, *Pathogens-11;* V*irologica Sinica-12’*
2009-	Member, National Veterinary Stockpile Nipah virus Countermeasures Workshop; United States Department of Agriculture. Geelong, Australia.

Honors and Awards

2022	The Carol Johns Medal (highest honor USU faculty can bestow on a fellow faculty member).
2021	Military Health System Research Symposium (MHSRS) 2021 Outstanding Research Accomplishment Team Award. (COVID-19 / SARS-CoV-2 serology research).
2020	Military Health System Research Symposium (MHSRS) 2020 Outstanding Individual Research Accomplishment by an Individual Senior Researcher. (Hendra and Nipah virus countermeasures).
2020	Inaugural, 2020 Federal Laboratory Consortium (FLC) Impact Award.

2019	USU Outstanding Biomedical Graduate Educator Award.
2019	The University of Florida, College of Medicine, “Wall of Fame”.
2019	Dean’s Award for Leadership, University of Florida, College of Medicine.
2019	Federal Laboratory Consortium (FLC) Award for Excellence in Technology Transfer.
2016	The James J. Leonard Award for Excellence in Translational/Clinical Research.
2014	The Cinda Helke Award for Excellence in Graduate Student Advocacy.
2013	The 3rd Sidney Pestka Lecture; 22nd Annual Philadelphia Infection & Immunity Forum.
2013	Federal Laboratory Consortium (FLC) Award for Excellence in Technology Transfer.
2013	Second Finalist for the Australian Infectious Diseases Research Centre Eureka Prize.
2013	The CSIRO Chairman’s Medal. The Commonwealth Scientific and Industrial Research Organisation (CSIRO); Australia's national science agency.
2008	The Henry Wu Award for Excellence in Basic Science Research.
1996	The Fellows Award for Research Excellence, Office of Science Education, NIH
1996-1997	AAAS: Breakthrough of the Year, Science Magazine; and the Newcomb Cleveland Prize
1990-1992	National Research Council Research Associateship Award
1989	Medical Guild Graduate Research Award, University of Florida College of Medicine

- HIV-1 Envelope Glycoprotein Oligomer and Methods of Use. U.S. Pat. No. 8,597658.
- CCR5 DNA, new animal models and therapeutic agents for HIV infection: U.S. Pat. No. 7,151,087.
- Cells expressing both human CD4 and CXCR4 associated with HIV infection: U.S. Pat. No. 6,197,578.
- Compositions and methods for the inhibition of membrane fusion by paramyxoviruses: U.S. Pat. Nos. 7,666,431 and 8,114,410.
- Soluble Forms of Hendra and Nipah Virus G Glycoprotein. Australian Pat. No. 2005327194. U.S. Pat. Nos. 8,865,171; 9,045,532; 9,056,902; 9,533,038, 10,053,495.
- Soluble Forms of Hendra and Nipah Virus F Glycoprotein and Uses Thereof: Australian Patent No. 2013276968. U.S. Pat. Nos. 10,040,825; 10,590,172.
- Human monoclonal antibodies against Hendra and Nipah viruses. U.S. Pat. Nos. 7,988,971; 8,313,746, 8,858,938.
- Antibodies against F glycoprotein of Hendra and Nipah viruses. U.S. Pat. Nos. 9,982,038 and 10,738,104
- Cedar virus and Methods of Use. U.S. Patent No., 10,227,664.
- Recombinant Cedar Virus Chimeras. Provisional. Atty. Dkt. No. 103783-0276.
- Hendra sG: Licensed to Zoetis, Inc. (Pfizer Animal Health). Equivac ® HeV; Nov, 2012, Australia.
- Hendra sG: Licensed to AuroVaccines, Aurobindo Pharma USA., Nipah/Hendra human vaccine candidate.
- Monoclonal antibodies to Henipaviruses. Absolute Antibody Ltd, United Kingdom.
- Soluble Nipah and Hendra virus F and G glycoproteins. The Native Antigen Company Ltd, United Kingdom.

C. Contributions to Science

1. My Ph.D. thesis studies centered on the discovery and characterization of a specific receptor for human plasmin on Group A Streptococci during my rotation project as a first year student. My studies revealed that certain group A streptococci elaborated surface receptors that could bind selectively a key fibrinolytic enzyme, plasmin. The bacterium-bound plasmin remained enzymatically active including its ability to hydrolyze a fibrin clot and could not be inhibited by its physiological regulator, alpha 2-plasmin inhibitor. Since these organisms produced streptokinase producing an active enzyme that can convert plasminogen to plasmin, they could accelerate the destruction of the extracellular matrix environment: a model for the "flesh-eating streptococci".

2. My independent work as a postdoctoral fellow focused on the early stages of HIV-1 envelope glycoprotein mediated membrane fusion as a surrogate model of HIV-1 entry. I established a vaccinia virus-based reporter gene assay for measuring viral (HIV-1) glycoprotein-mediated membrane fusion and generated the first panel of T-cell tropic and Macrophage-tropic HIV-1 envelope glycoprotein (Env) encoding recombinant vaccinia virus vectors and I used these tools to be the first to hypothesize that the cellular tropism of HIV-1 could be explained by specific membrane fusion factors required for the different classes of HIV-1 Envs. I also developed the first soluble and secreted full-length oligomeric HIV-1 gp140 glycoprotein and explored the importance of its native oligomeric structure in terms of its presentation of conformational and virus-neutralizing epitopes through the development and characterization of more than 100 murine monoclonal antibodies.

3. My early studies on the cellular and viral membrane fusion tropism of HIV-1 and the development of a sensitive and specific reporter gene assay of cell-cell membrane fusion facilitated the discovery of the first membrane fusion accessory factor (“fusin”; CXCR4) that I earlier hypothesized existed, and this rapidly led to the discovery by us and others of the second factor for macrophage-tropic Envs (CCR5); the HIV-1 coreceptors. These findings were a significant breakthrough in HIV research leading to numerous new directions in understanding HIV-1 pathogenesis as well as new therapeutic strategies.

a. Feng, Y., **C.C. Broder**, P.E. Kennedy, and E.A. Berger. HIV-1 Entry Cofactor: Functional cDNA Cloning of a Seven-Transmembrane, G Protein-Coupled Receptor. Science. 272:872-877, 1996.

4. My initial work on HIV-1 entry led to further independent studies which focused on follow-up investigations characterizing the roles of the HIV-1 coreceptors in the virus entry process. These studies revealed the interplay between the HIV-1 entry receptors, mapped important domains of the coreceptors involved in HIV-1 Env interaction, and also revealed possible avenues of how an HIV-1 Env might engage and differently utilize the CXCR4 and CCR5 coreceptors for infection. In addition, I also engaged in collaborative follow-up studies exploring the utility of soluble oligomeric HIV-1 envelope glycoproteins as subunit vaccine immunogens (gp140) which I initiated at NIH while a postdoctoral fellow.

a. Chabot, D.J., P-F. Zhang, G.V. Quinnan, and **C.C. Broder***. Mutagenesis of CXCR4 Identifies Important Domains for HIV-1 X4 Isolate Envelope-Mediated Membrane Fusion and Virus Entry and Reveals Cryptic Coreceptor Activity for R5 Isolates. J. Virol. 73:6598-6609, 1999.

d. Zhang, P.F., Cham, F., Dong, M., Choudhary, A., Bouma, P., Zhang, Z., Shao, Y., Feng, Y.R., Wang, L., Mathy, N., Voss, G., **Broder, C.C**., Quinnan, G.V., Jr. Extensively cross-reactive anti-HIV-1 neutralizing antibodies induced by gp140 immunization. PNAS. USA. 104(24):10193-8. 2007.

5. My recent efforts have focused on emerging viruses that impact human and domestic livestock populations; including lyssaviruses, filoviruses, and henipaviruses for the past 23 years. I obtained the first NIAID funded biodefense project providing fiscal support on select agent research to an overseas laboratory (2003; U01 AI056423). I developed the first henipavirus peptide-based fusion inhibitors, subunit vaccines, and neutralizing human and humanized monoclonal antibodies (mAb), and my NIAID grants supported the development of the feline, ferret and African green monkey models of Hendra and Nipah pathogenesis. Henipavirus countermeasures development is a major a focus of my lab and supported by a NIAID U19 CETR. Here, we are developing next-generation mAb therapies and next-generation vaccines and delivery methods against Nipah and Hendra for both human and livestock use. I am also heavily engaged in collaborative virus surveillance activities focusing on henipaviruses, filoviruses, coronaviruses, and others, in wildlife and human populations in more than 10 countries in South Asia, Southeast Asia, West Africa and Southern Africa; using the Luminex xMAP-based platform which has proven to be more sensitive than ELISAs for the detection of antibodies to viral infections. The key feature of our multiplex microsphere immunoassays (MMIA) are the use of my lab's production of recombinant, soluble, native-like, oligomeric viral glycoproteins, designed similar to our HeV-sG subunit vaccine. Our MMIA array presently contains more than 20 different soluble glycoprotein ectodomains. These programs are funded by the NIAID and the Defense Threat Reduction Agency (DTRA), an agency within the US Department of Defense.

A. Personal Statement

As an active researcher in the development of novel therapeutics and vaccine candidates against emerging and re-emerging henipaviruses in relation to pandemic preparedness, I am uniquely qualified to participate as a Co-Investigator in **Research Project 2: Vaccines and antibodies to henipaviruses** of the present U19 application (ReVAMPP). The extensive experience in henipavirus reverse genetics platforms necessary to conduct the proposed studies began in my postdoctoral training, under the guidance and mentorship of **Dr. Christopher Broder**, a leading expert in henipavirus biology. During my fellowship, I rescued and fully characterized a replication competent recombinant Cedar virus (rCedV) as non-reporter and luciferase expressing reporter versions that can safely be utilized at BSL-2. This work resulted in a first co-author publication (see below). In addition, I generated replication competent chimeric viruses as non-reporter and reporter versions that express the envelope glycoproteins of either Nipah virus Bangladesh (NiV-B) (rCedV-NiV-B) or Hendra virus (HeV) (rCedV-HeV) instead of those of CedV. All 6 chimeric viruses were fully characterized in in vitro studies. Together with **Dr. Thomas Geisbert**, at the University of Texas Medical Branch (UTMB), with whom I have a 5-year collaboration, we demonstrated that the chimeras can serve as suitable surrogate viruses for authentic NiV-B or HeV as determined by plaque reduction neutralization tests. Moreover, the fluorescent reporter chimeric viruses were further characterized in a high throughput fluorescence reduction neutralization test (FRNT) to analyze neutralization potencies of sera from henipavirus immunized animals and monoclonal antibodies. This work resulted in a first author manuscript that was very recently published (see below). The FRNT has also been implemented in several neutralization and synergistic neutralization tests that resulted in 2 co-author publications (see below). The highly productive collaborations between Drs. Broder, Geisbert and I underscore the feasibility of the proposed project. The research proposed in this application will not only build on my work developed thus far but also strengthen my scientific portfolio to achieve my long-term goal of vaccine development for priority pathogens.

C. Contributions to Science

1. **Graduate career:** My Ph.D. thesis research involved characterizing the host viral interactions in human cells with a focus on the least characterized non-structural protein, nsP3, from VEEV. I initially constructed a tagged version of nsP3 both as an overexpression construct and in the context of the viral genome. Mass spectrometry analyses revealed that VEEV-nsP3 interacted with multiple host factors. Those of particular interest were chosen for additional studies, namely the kinase IKKβ and the RNA helicases DDX1 and DDX3. I validated that VEEV-nsP3 interacted and complexed with IKKβ, DDX1 and DDX3 and furthermore, siRNA knockdown studies indicated a reliance of these host factors for productive and continuous viral replication. These findings formed the basis of the functional model where VEEV-nsP3 interacts with the host translational machinery via DDX3 to potentially aid in translation of viral proteins that could be part of the replication complex, and that this interaction could be essential in the viral life cycle. This contribution will aid in elucidating the functionality of nsP3 in the viral life cycle as well as to promote the development of host based therapeutic options to treat RNA viral infections or disease. Results from my research were highly relevant as they provided new details and insight in understanding the role of the uncharacterized VEEV protein, nsP3, in

the new world alphavirus life cycle. As such, this work resulted in two first author research publications and one review article (see below). My Ph.D. research on host viral interactions was expanded to include host pathways that were altered during viral infection by utilizing small molecule inhibitors. Such pathways included the host phospho-signaling and the ubiquitin proteasome pathways. I validated, as a collaboration, that the MAPK/ERK signaling pathway was activated and necessary for the infectious process in VEEV infected human cells through utilization of the small molecule inhibitor, Ag-126. This joint effort resulted in a second author publication. In a different study, I had revealed with the use of an FDA approved proteasome inhibitor, Bortezomib that VEEV requires the ubiquitin proteasome pathway in the viral life cycle. My results indicated the likely mechanism was that K48 ubiquitination of VEEV capsid protein may be necessary for the early stages of infection. This study was the first to demonstrate that the capsid protein was post translationally modified with ubiquitin and this resulted in a first author publication (see below). In addition, I had also collaborated to investigate the requirement of the ubiquitin proteasome pathway in the negative stranded RNA virus, RVFV infection. We showed that with Bortezomib treatment, the formation of the characteristic nuclear filaments formed by the virulence factor NSs was abolished, thereby preventing NSs interaction with host repressor proteins SAP30 and mSin3A. This study resulted in a second author publication. Cumulatively, these studies would pave the way for developing host-based therapies and/or repurposing FDA approved drugs to treat these re-emerging diseases.

(2014). The role of IKKbeta in Venezuelan equine encephalitis virus infection. *PLoS One*, *9*(2), e86745. https://doi.org/10.1371/journal.pone.0086745

2. **Postdoctoral career:** My postdoctoral training involved the development and characterization of a recombinant henipavirus platform that can safely be used at BSL-2 to investigate and understand henipavirus infection with respect to pathogenesis, neutralization, drug discovery, therapeutics and vaccine potential. The reverse genetics system for the rCedV platform resulted in a first co-author publication (see below). A collaborative research project entailed the optimization of a replication competent rCedV-Luc for high throughput screening assays to identify small drug like molecules that can target multiple stages in the henipavirus life cycle, which resulted in a first co-author publication (see below). Building on the rCedV platform, I designed and characterized a robust recombinant chimeric henipavirus reverse genetics system to be used as a surrogate system for pathogenic henipaviruses. The envelope glycoproteins of rCedV were replaced with those of either NiV-B (rCedV-NiV-B) or HeV (rCedV-HeV) and non-reporter and reporter versions were generated. I optimized and implemented a rapid high throughput cell-based fluorescence reduction microneutralization assay using rCedV chimeras to determine monoclonal antibody neutralization potencies and detect the presence of neutralizing antibodies and measure neutralizing titers in henipavirus immunized animal sera. This work resulted in a first author manuscript (see below). In a collaborative effort, I generated recombinant henipavirus chimeric virus escape mutants to understand the structure of henipavirus envelope glycoproteins. This collaboration resulted in a co-author manuscript (see below). In addition, my work has been recently presented at multiple meetings such as the Keystone Symposia, Bat Infectious Diseases Symposium, and the World One Health Congress.

NCI-Frederick, NIH, Frederick, MD	Postdoctoral Training	04/2004	Biochemistry, Viral entry

A. Personal Statement

I have been familiar with HeV-sG since its discovery. I am a co-author of the HeV-sG characterization article in JVI 2005. It shows that HeV and NiV as well G-glycoproteins, membrane attached and soluble as well, exist as dimers and dimers of dimers. Under the supervision of Dr. Broder I played a major role in the discovery of ephrin B2 as a functional receptor for Nipah and Hendra viruses, sharing an equal contribution with Dr. Bonaparte in the related PNAS article (2005). I had been also characterizing the binding site of ephrin B2 to HeV and NiV G glycoprotein and found aminoacid residues on ephrin B2 that are critical for the virus receptor binding.

I was a PI (MPI, with Dr. Fouts) of two pre-clinical development programs – one for the HeV-sG as subunit vaccine against henipavirus infections and the other for the human antibody, m102.4, as postexposure treatment against such infections. I am currently involved in the clinical investigation of the HeV-sG subunit vaccine led by Auro Vaccines LLC. I am also actively involved in coordination the work of the research projects and cores within the CETR U19- AI142764 “Advancement of Vaccines and Therapies for Henipaviruses” (Christopher Broder, PI), where I wrote the proposal for RP1 related to the next generation HeV-sG human vaccine. Although the subunit vaccine in its current formulation has an excellent efficacy, its stability at ambient condition and efficacy are expected to be significantly enhanced within RP1 of the above CETR U19, there is still room to explore the immunization efficiency by decreasing the cost of storage and application procedure. Within one of the latest awards we are developing patches of soluble microneedle arrays for intradermal delivery of HeV-sG. The vaccine is expected to be stable at ambient conditions and ready for easy self-administration by pressing the patch to a bare skin place, like on the shoulder. During the past 2 decades I accumulated relevant experience related to GLP, GMP, and partly GCP and believe that I can significantly contribute to the proposed project.

B. Positions, Scientific Appointments, and Honors

2019 –	Senior Scientist, USUHS, Bethesda, MD 20814 / HJF, Bethesda, MD 20817

2006 – 2019 Senior Staff Scientist, Profectus BioSciences, Inc., 6411 Beckley Str., Baltimore, MD 21224
2004 – 2006 Research Associate, Dept. of Microbiology at USUHS, Bethesda, MD 20814
1999 – 2004 Post-Doctoral Fellow, Laboratory of Experimental and Computational Biology, CCR, NCI, NIH, Bldg. 469, Rm. 211, P.O. Box B, Frederick, MD 21702-1201
1995 – 1999 Scientist, L'ORÉAL Tsukuba Center, Tokodai 5-5, Tsukuba, Japan
1992 – 1995 Senior Research Associate, Nagayama Protein Array Project, ERATO, JRDC, Tokodai 5-5, Tsukuba, Japan
1987 – 1993 Research Specialist (Chemist), Faculty of Chemistry, Sofia State University, Sofia, Bulgaria

C. Contributions to Science

1. *Development of HeV-sG as a human subunit vaccine against henipavirus infection.*
Relates to my current activities described above in the Personal Statement.

A. Geisbert TW, Bobb K, Borisevich V, Geisbert JB, Agans KN, Cross RW, Prasad AN, Fenton KA, Yu H, Fouts TR, Broder CC, **Dimitrov AS**. A single dose investigational subunit vaccine for human use against Nipah virus and Hendra virus. **NPJ Vaccines**, 2021 Feb 8;6(1):23. doi: 10.1038/s41541-021-00284-w

2. *Discovery that ephrin B2 is a functional receptor for both HeV and NiV. Characterization of HeV-sG.*
Dr. Broder (USUHS, Bethesda) pioneered the research on HeV and NiV starting the beginning of the century. I joint his group in 2004. Dr. Bossart had already created soluble versions of HeV and NiV G glycoproteins and was spending time on a search for the viral receptors. It was anticipated that both viruses share common receptor indicated by immune response crossreactivity and anti-G antibody crossreactivity, including m102. Dr. Broder suggested me to join in the efforts of receptor discovery. We mainly attempted to co-immunoprecipitate the receptor with soluble G from lysates of permissive and non-permissive cells using coomassie stain, radiolabeling, and different modification. It later became clear that the S-agarose we used for co-IP with the S-tagged soluble G produces a non-specific band overlapping ephrin B2 and, thus, the band was considered false positive. When Matthew Bonaparte joint the team proposed to use gene chip technology developed at his university, SUNY. He sent lysates from permissive and non-permissive cells for analyses. Using the gene chip data he successfully narrowed the possibilities for the receptor down to low 20s. Farther on, narrowing couldn't be justified by the available data. Then, I proposed to purchase plasmids with the identified genes from Origene, transfect non-permissive cells, and find out which gene will render them permissive to HeV or NiV. Thus, ephrin B2 was discovered as receptor for HeV and NiV. Looking back into those data ephrin B3 shows a signal higher than background, but we have ignored it at that time, being excited of ephrin B2 identification.

A. Bonaparte MI, **Dimitrov AS**, Bossart KN, Crameri G, Mungall BA, Bishop KA, Choudhry V, Dimitrov DS, Wang LF, Eaton BT, Broder CC. From the Cover: Ephrin-B2 ligand is a functional receptor for Hendra virus and Nipah virus. **PNAS** 2005; 102: 10652-10657.
B. Bossart KN, Crameri G, **Dimitrov AS**, Mungall BA, Feng YR, Patch JR, Choundhary A, Wang LF, Eaton BT, Broder CC. Receptor Binding, Fusion Inhibition, and Induction of Cross-Reactive Neutralizing Antibodies by a Soluble G Glycoprotein of Hendra Virus. **J. Virol.** 2005; 79: 6690-6702.

3. *Having a contribution in the discovery of m102.4 by identifying its parent m102 as a crossreactive neutralizer.*
Being in the laboratory of Dr. Broder I was using HeV and NiV mediated cell-cell fusion assays to study mutant G glycoproteins created by inactivating glycosylation sites. At that time, Dr. Zhu had found Fab binders to HeV-sG and asked me to test those for inhibitory activities in the cell-cell fusion assay. His Fabs showed different inhibitory potency to HeV and NiV with Fab m102, although not the best against either virus, showing a balanced inhibition to both viruses. Then, Dr. Zhu optimized m102 by in vitro maturation to m102.4.

C. Prado I, Fouts TR, **Dimitrov AS**. (2009) Methods Mol Biol. v. 525 pp. 517-31. “*Neutralization of HIV by antibodies.*”

5. *Studying the mechanism of HIV entry. Applying mAbs to inhibit HIV entry*
While postdoc under the supervision of Dr. Blumenthal, we proposed that HIV-1 Env gp41 destabilizes target cell or its own membrane upon activation of gp120 by CD4 and respective coreceptor, CCR5 or CXCR4, complexes, resulting in fusion or viral inactivation, respectively. In relation to HIV-1 entry to cells we detected intermediates of the fusion process by using conformation specific mAb. Later, at Profectus I worked with anti-HIV antibodies as entry inhibitors. Results from the completed grant awards identify sweet epitopes that are simultaneously targeted by inhibitory antibodies show synergistic effect and an exceptional efficacy in vitro.

RESEARCH & RELATED Senior/Key Person Profile (Expanded)

Additional Senior/Key Person Form Attachments

When submitting senior/key persons in excess of 8 individuals, please attach additional senior/key person forms here. Each additional form attached here, will provide you with the ability to identify another 8 individuals, up to a maximum of 4 attachments (32 people).

The means to obtain a supplementary form is provided here on this form, by the button below. In order to extract, fill, and attach each additional form, simply follow these steps:

- Select the "Select to Extract the R&R Additional Senior/Key Person Form" button, which appears below.
- Save the file using a descriptive name, that will help you remember the content of the supplemental form that you are creating. When assigning a name to the file, please remember to give it the extension ".xfd" (for example, "My_Senior_Key.xfd"). If you do not name your file with the ".xfd" extension you will be unable to open it later, using your PureEdge viewer software.
- Using the "Open Form" tool on your PureEdge viewer, open the new form that you have just saved.
- Enter your additional Senior/Key Person information in this supplemental form. It is essentially the same as the Senior/Key person form that you see in the main body of your application.
- When you have completed entering information in the supplemental form, save it and close it.
- Return to this "Additional Senior/Key Person Form Attachments" page.
- Attach the saved supplemental form, that you just filled in, to one of the blocks provided on this "attachments" form.

Important: Please attach additional Senior/Key Person forms, using the blocks below. Please remember that the files you attach must be Senior/Key Person Pure Edge forms, which were previously extracted using the process outlined above. Attaching any other type of file may result in the inability to submit your application to Grants.gov.

1) Please attach Attachment 1 ☐
2) Please attach Attachment 2 ☐
3) Please attach Attachment 3 ☐
4) Please attach Attachment 4 ☐

TITLE: Cedar henipavirus animal model

Funding announcement: RFA-AI-23-020

Funding Title: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picronaviridae

PRINCIPAL INVESTIGATOR: Brian Schaefer, Ph.D., Site Principal Investigator

Prime PI: Thomas Geisbert, Ph.D., UTMB

Period of Performance: March 1, 2024 - February 28, 2029

Abstract

Henipaviruses are single-stranded, negative-sense enveloped RNA viruses of the paramyxovirus family. Two henipaviruses, Nipah virus (NiV) and Hendra virus (HeV), cause a systemic and often fatal respiratory and/or encephalitic disease in humans and ten other mammalian species. Importantly, NiV and HeV are significant biothreats to humans and economically important livestock in Australia and Southeast Asia. There are currently no vaccines or therapeutics approved for human use. Notably, development of countermeasures for NiV and HeV is hampered by the fact that these viruses require BSL-4 containment, meaning that very few research groups worldwide have access to the required biocontainment facilities to perform preclinical studies with these important human viral pathogens. To address this problem, we are developing a BSL-2 animal model that is based on Cedar virus (CedV), which is a non-pathogenic henipavirus. Specifically, we are employing recombinant Cedar viruses (rCedVs) in which the NiV and HeV fusion (F) and receptor-binding glycoprotein (G) are expressed in the rCedV genome, replacing CedV F and G. Additionally, we have also incorporated our recently developed *in vivo* bioluminescence methodology to longitudinally trace the dynamics and anatomical progression of rCedV-luciferase (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host innate immune response in mice, we have demonstrated sustained replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Importantly, whereas rCedV-luc does not establish stable expression in the brain, both of the chimeric viruses do. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in specific strains of mice. The rCedV-luc platform is thus an authentic henipavirus system that can be used to study henipavirus *in vivo* biology safely and expediently under BSL-2 containment. Our overall hypothesis is that rCedV-luc infection of mice lacking specific innate immune responses represents a BSL-2 platform for the study of henipavirus biology and pathogenesis, as well as for development and testing of anti-viral countermeasures. We will address this hypothesis through three Specific Aims: Aim 1: To optimize the use of immunodeficient mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease; Aim 2: To determine the mechanism of rCedV-NiV neurovirulence; Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Aims involve synergistic collaborations with several other research projects and cores in this U19 program. Successful completion of these Aims will establish the rCedV-luc mouse model as a robust BSL-2 platform for the exploration of henipavirus pathogenesis and countermeasures.

TITLE: Vaccines and antibodies to henipavirus
Funding announcement: RFA-AI-23-020
Funding Title: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picronaviridae
PRINCIPAL INVESTIGATOR: Christopher Broder, Ph.D., Site Principal Investigator
Moushimi Amaya, Ph.D and Antony Dimitrov, Ph.D., Co-investigators
Prime PI: Thomas Geisbert, Ph.D., UTMB
Period of Performance: March 1, 2024 - February 28, 2029

Project Summary/Abstract

Pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among these are the two emerged zoonotic paramyxoviruses: the ‘prototype’ henipaviruses (HNVs); Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. The prototype HNVs have a uniquely broad tropism capable of infecting 18 species across 6 orders of mammals using the conserved ephrin-B2 and -B3 ligands as entry receptors. NiV and HeV infection often results in a systemic and fatal respiratory and/or neurological disease in multiple mammalian species including humans. NiV and henipaviral disease are also included in the WHO List of Priority Pathogens, and they are significant biothreats to humans and livestock in South and South East Asia and Australia. HNVs have two membrane glycoproteins: the attachment glycoprotein (G) and the fusion glycoprotein (F) that are the major targets of neutralizing antibodies and the focus of all vaccine and antiviral monoclonal antibody (mAb) strategies. The most extensively studied HNV vaccine is a soluble recombinant form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including nonhuman primates (NHPs). With no licensed vaccines or treatments available for human use, this project will use the prototype HNVs as a model to develop, test, and translate a novel vaccination platform (a thermostable, needle-free, adaptable, and widely deployable polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP)). Preliminary data demonstrates potent immunogenicity of a PPZ-MNP-HeV-sG vaccine in mice, inducing robust antigen-specific HNV cross-neutralizing antibody and cellular immune responses. The MNP vaccines will be used to evaluate HeV-sG and compare stabilized soluble forms of HNV G and F (sG_{tet} and sF_{stb}) and combinations in challenge studies. A reverse genetics system has been developed to generate recombinant, nonpathogenic Cedar virus (rCedV) and rCedV chimeric virus tools by swapping the G and F glycoproteins with those of NiV/HeV as a rapid, surrogate, BSL-2 high-throughput neutralization platform to be used to rapidly evaluate HNV vaccine responses. Also, divergent and pathogenic zoonotic HNVs have been discovered including the related rodent borne Mòjiāng virus and Langya virus (LayV)), and the divergent bat-borne Angavokely virus (AngV). This project will develop and test the rapid, adaptable and readily deployable MNP vaccine platform together with new virological tools to facilitate the translational nature of this pandemic preparedness approach. Specifically, we will: 1) Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV vaccines; 2) Construct new reporter virus tools; 3) Evaluate vaccine-induced immune responses and HNV-specific mAbs and nbs; and 4) Validate the PPZ-MNP platform with another paramyxovirus antigen.

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Equipment

The laboratories are located in the Department of Microbiology and Immunology at USU.

The following equipment is supplied in the laboratory:

- Epifluorescence microscopy system (Fully-automated Zeiss AxioObserver epifluorescence microscope)
- BioRad BioPlex 200 HTF multiplexing system
- Luminex MagPIX multiplexing system
- BioRad iQ5 real-time PCR system
- Lonza Nucleofector 4D Shuttle – core unit and X-unit
- Coulter Z1-Dual cell counter
- centrifuges: Eppendorf 5425 microfuges (4); Beckman Allegra 25R; Thermo-Fisher Jouan GR4i; various rotors
- inverted microscopes for tissue culture (3)
- gel electrophoresis equipment for protein (7) and DNA (12) gels
- semi-dry protein transfer apparatus (4)
- Perkin-Elmer and Eppendorf thermal cyclers (5)
- ELISA plate readers (2)
- balances (6)
- pH meter (2)
- refrigerators
- freezers (-20 C, -80 C)
- platform orbital shakers (5)
- sonicator with cup horn and microtip
- bacterial shakers (6)
- heating blocks (16)
- waterbaths (14)
- biosafety cabinets (6)
- CO_2-tissue culture incubators (11)
- Thermo-Fisher Locator 4 liquid nitrogen storage tank with electronic monitoring (6)
- GE-ATKA low pressure chromatography systems, including UV detectors and fraction collectors (2)
- CTL S6 Universal Analyzer

The following equipment is supplied as common support equipment within the department:

- Fuji LAS-4010 chemiluminescence/fluorescence CCD camera imaging system
- IVIS in vivo imaging system (equipped to detect luminescence and fluorescence)
- 2D gel electrophoresis system (protein)
- Alpha-Innotech gel documentation system (EtBr-stained gels)
- MilliQ ultra-pure water system
- Nanodrop spectrophotometer
- Luminometer
- Fluorescence plate readers (2)

The University Biomedical Instrumentation Center, USUHS provides other resources and is also located on- site and provides a wide variety of services, including:

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Translational Imaging Facility

- Siemens Inveon SPECT/PET/CT Scanner
- Bruker In-Vivo Xtreme II: supports bioluminescence, X-ray, and direct radioisotopic imaging
- Bruker Biospec 70/20 USR MRI
- Image Guided Therapy 7T MR guided Focused Ultrasound System for neurological applications

Flow Cytometry

- Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers (2)
- 15-parameter FACSAria II FACS sorter, including a 541nm laser upgrade for sorting of RFP-expressing cells
- Amnis Image Stream X Mark II imaging flow cytometer with IDEAS statistical image analysis software
- Bio-Rad Bio-Plex 200 multi-analyte bioassay detection system
- Offline data analysis stations (3) with software packages including: FlowJo, WinList, and ModFit

Microscopy

- Zeiss 710NLO confocal system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm
- Zeiss 700 confocal system with 405/458/488/514/561/633 laser lines
- Zeiss Elyra PS.1 Superresolution microscope for superresolution structured illumination microscopy (SR-SIM), photoactivated localization microscopy (PALM), and direct stochastic optical reconstruction microscopy (dSTORM). System is fully equipped, including the 3D-PALM/dSTORM option.
- Becker-Hickl 2-detector FLIM system (for FRET – attached to Zeiss 710NLO)
- Zeiss AxioExaminer.Z1 upright confocal system with Coherent Chameleon multiphoton laser for in vivo imaging and electrophysiology
- Zeiss AxioImager.M2 upright microscope and MicroBrightField Stereo Investigator software (stereology analysis).
- Leica AF6000 system, including an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control
- Wide-field fluorescence microscopes (3)
- Transmission electron microscope (Philips CM100 transmission EM)
- Ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment)
- Offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph.

Genomics

- Fuji FLA-5000/LAS-3000 chemiluminescence/fluorescence CCD/laser scanning imaging systems
- ABI 9800 Fast Thermal Cycler
- ABI 7500 Real Time PCR System
- ABI 3500xl Genetic Analyzer
- ABI 394 DNA/RNA Synthesizer (2)
- ABI 3900 DNA Synthesizer
- Eppendorf epMotion 5075 VAC Liquid handling robot
- Thermo Scientific Evolution 300 UV/Vis Spectrophotometer
- Systec MediaPrep & Plate Pourer

Proteomics

- Agilent 1100 HPLC (2)
- AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer

- AB SCIEX Q-TOF tandem mass spectrometer
- Genetix QArray2 Micro array printer

Histopathology
- Fee-for-service histology and immunohistochemistry
- Nanozoomer digital slide scanner

Structural Biology
- X-ray crystallography facility with a Rigaku HighFlux HomeLab X-ray diffraction system, including:
    - MicroMax-007 HF, a microfocus rotating anode generator
    - R-AXIS Imaging Plate detector
    - X-stream 2000 cryogenic system
    - AB Sciex 4000 QTRAP LC/MS/MS System

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Facilities and Other Resources

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Broder (PI) is a tenured Professor and Chair of the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Broder, the PI, has had and is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Broder has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Broder's laboratories are divided into 3 rooms totaling 1,440 sq. ft. Both investigators possess routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, water baths, free-standing biosafety cabinets, and CO_2-tissue culture incubators. Additionally, Dr. Broder's lab is equipped with an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), a BioRad iQ5 real-time PCR system, and a Lonza Nucleofector 4D Shuttle. Dr. Broder's lab also includes two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus. Dr.
Broder's lab performs virus based assays that incorporate primarily 2 techniques: plaque assays and neutralization assays. Both of these techniques determine viral concentration and/or viral quantity and require manual counting of plaques/clear areas (plaque assay) or manually counting GFP foci using a fluorescent microscope (neutralization assays). Since a large number of iterations with multiple viruses are performed routinely, Dr. Broder acquired a CTL S6 analyzer, which is an automated plate reader that can read up to 4 fluorescent colors, captures 25 megapixel images and is able to recognize over 11,000 spots per well in a 96-well plate format. The analyzer can efficiently handle a large number of 96-well plates required for assay characterization and development thus allowing for a high-throughput workflow with the use of minimal reagents. Operator bias is also diminished when counting plaques/GFP foci from processed images allowing for consistent, objective and statistically reliable results. Washed formalin fixed 96-well plates are first loaded into the analyzer and the software takes a high quality image of each well. Using the Basic count feature in the software package the user establishes parameters, which is used to enumerate GFP foci in each well of a single 96-well plate or from batch processing multiple plates. The counts can then be exported as an Excel file, which can be used to generate neutralization profiles for example. Conventional plaque assays and virus neutralization assays can take between 5- 7 days to complete, whereas the protocol established with the CTL

S6 analyzer has reduced the time to 3 days. Postdocs, students, and technicians have desks and computers in the laboratory.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomat and staffed with three other veterinarians, a graduate animal husbandry man, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers as well as Apple Mac all within 4 years of life cycle. They are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Broder has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory. The department employs one senior program manager, administrative officer, administrative specialist and a microbiologist. Other personnel can be provided as necessary to support the program.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data.

The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging sytem.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zess 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo mutliphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a RochLightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocus rotating anode generator, an R-AXIS Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

A full-time statistician is available at the University for consultation on data analysis and to help with statistical analysis.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

Facilities and Other Resources

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Schaefer is a tenured Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators, including the Department of Microbiology and Immunology chair, Dr. Christopher Broder, who is an internationally-known virologist (and centrally involved in this proposal).

USU is directly across the street from the main NIH campus and close to Johns Hopkins, the University of Maryland and several other outstanding institutions, facilitating opportunities to establish productive collaborations with world-class investigators. For example, Dr. Schaefer has had a multi-PI U01 grant with Dr. Wolfgang Losert (Dept of Physics, University of Maryland) as the co-PI and Dr. Hari Shroff (NIH/NIBIB) as a collaborator. Dr. Schaefer is also primary PI on a multi-PI R01 from NIAID with Dr. YouWen He at Duke University Medical Center, and Dr. Thomas Conrads (Women's Health Integrated Research Center). Dr. Schaefer and his staff have also collaborated with the Advanced Imaging Center (AIC) at the Howard Hughes Medical Institute (HHMI) for some of their imaging-based research. Overall, the broader scientific environment at USU and the greater Bethesda/Washington D.C. metropolitan region is highly conducive to productive collaborations. Dr. Schaefer has been using these resources to his advantage, and has been very active in establishing collaborative relationships to facilitate his research objectives. Notably, Dr. Schaefer and Dr. Broder have been collaborating for several years on lyssavirus- and henipavirus-related project, and they have a very strong working relationship.

Members of the Schaefer lab participate in a weekly multi-lab Immunology journal club, Immunology data club, virology journal club, and virology data club. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club. Also, members of the Schaefer lab participate in a bi-weekly data presentation/discussion group which meets monthly.

Dr. Schaefer has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., The IVIS® Spectrum CT preclinical in vivo imaging system; Cytek Aurora spectral flow cytometer), and 10x Genomics Visium Spatial Transcriptomics instruments are not overbooked and therefore readily available to laboratory personnel. Dr. Schaefer is also Chair of the USU Biomedical Instrumentation Center (BIC), and thus plays a central role in directing equipment purchases, ensuring that needed technologies are available for the research of the PI and his USU colleagues. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase core facility equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by recent USU purchases of cutting-edge equipment including a Perkin-Elmer IVIS® Spectrum CT preclinical in vivo imaging system, a Zeiss Elyra PS.1 super-resolution microscope, an Agilant Seahorse XPe96 Analyzer, a BD FACSAria Fusion flow sorter, and many other pieces of advanced research equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional.

USU has several Ph.D. programs, including an Emerging Infectious Diseases (EID) program, a Molecular and Cellular Biology (MCB) program and a Neuroscience (NES) program. Dr. Schaefer holds secondary appointments in all three programs and is currently Interim Director of the Emerging Infectious Diseases Graduate Program. Ds. Schaefer has been very active in training graduate students, having trained >10 Ph.D. students. USU recruits strong graduate students, and Dr. Schaefer's students have been very productive, during and beyond their dissertation studies. The availability of talented graduate students is a further resource, promoting productivity and enhancing the overall vibrancy of the scientific environment at USU.

Laboratory: Dr. Schaefer's laboratory area consists of three rooms of 450 sq. ft, 300 sq. ft and 225 sq.ft., and a dedicated microscopy suite of 110 sq. ft. The Schaefer lab contains routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO_2-tissue culture incubators. Additionally, Dr. Schaefer's lab is equipped

with an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope), a BioRad CFX Connect real-time PCR system, a Coulter Z1-Dual cell counter, a DeNovix CellDrop-FL cell counter and a Lonza Nucleofector 4D Shuttle. Postdocs, students, and technicians have desks and computers in the laboratory.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. The facility also includes two preclinical behavior cores (one for mice, one for rats). The facility and the University's animal care and use program is managed by the Department of Laboratory Animal Medicine (DLAR), which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates and lower vertebrates to higher vertebrates including non-human primates and domestic livestock, as well as more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥8GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. Dr. Schaefer's laboratory also has a dedicated workstation for use for analysis of microscopy and in vivo imaging data. Image analysis software in the Dr. Schaefer's lab includes Zeiss Zen, with a digital deconvolution module and numerous tools for quantitative image analysis. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro. Dr. Schaefer also maintains a license for FlowJo software, which can be used on any networked computer in the laboratory. The computers are connected by a central server to each other and to the Internet. A variety of USU-supported software programs are available, including EndNote, Microsoft Office, Adobe Creative Cloud, Geneious Prime and Graph Pad Prism 9.

Office: Drs. Schaefer's office is separate from but proximal to each of his laboratories. Trainees and technicians have desks in the laboratory. Four full-time administrative officers and one part-time administrator are available to provide support within the department.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely meet with BCC consultants regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data.

The USU Biomedical Research Imaging Core (BRIC) houses state-of-the art equipment for pre-clinical studies, including a IVIS® Spectrum CT, a Siemens Inveon SPECT/PET/CT Scanner and a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system. A Scientist and several staff provide technical support and manage the facility.

The USU American Genome Center (TAGC) is one of only four academic genome centers in the United States. It is the Department of Defense operations subsidiary of the Collaborative Health Initiative Research Program (CHIRP) established between the National Heart, Lung, and Blood Institute (NHLBI) and USU. Since inception, TAGC has generated more than 40,000 whole Genome Sequences across 107 research studies sourced from NHLBI, other NIH Institutes, DoD and USU investigators. TAGC is also the sequencing center and genome data analysis center for the APOLLO Cancer Moonshot project, and collaborates for this purpose with the Murtha Cancer Center (MCC) at Walter Reed, the National Cancer Institute, and the Veterans Administration. Through a collaborative relationship with 10x Genomics, USU has early access to newly released platforms such as Visium Spatial Transcriptomics (including improvements to that platform).

The USU TAGC includes a large array of next-generation sequencing instruments including Illumina NovaSeq 6000 systems, Illumina HiSeq X systems, and an Illumina NextSeq 500 system. A 10x Genomics Chromium Connect automated single-cell NGS library workstation is available for automated single cell partitioning, barcoding and NGS library preparation. A 10x Genomics Chromium Controller massively parallel sample partitioning platform is available for barcoding single cell RNA for library preparation and for single cell transcriptome profiling, including CITE-seq workflows. 10x Genomics Visium CyAssist transcriptomic probe transfer system is available to facilitate spatial transcriptomics workflows. Electrophoresis systems include Agilent Fragment Analyzers and a Bio-Rad Experion LabChip Platform. Sequencing platforms are connected to a high-speed network switch for data storage on a petabyte-scale Isilon SAN.

The USU Biomedical Instrumentation Center (BIC) consists of five core equipment facilities for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). Each core is run by a full-time Director with an advanced science background (most hold a PhD) and a high degree of technical expertise. The majority of cores have at least one additional employee to help manage the core and provide guidance and assistance to users.

The BIC Flow Cytometry Core includes three analyzers (Cytek Aurora 5-laser, 64-channel Spectral Analyzer; Becton-Dickinson 5-laser, 30-parameter FACSymphony A5; Becton-Dickinson 4-laser, 15-parameter LSRII) and two sorters (BD FACSAria Fusion 4-laser, 18-parameter flow sorter; BD FACSAria IIIu 4-laser, 17-parameter flow sorter) and an Amnis Image Stream X Mark II imaging flow cytometer. Other equipment includes a Bio-Rad Bio-Plex 200 multi-analyte detection system and an Agilant Seahorse XPe96 Analyzer. The core has several off-line analysis workstations with FlowJo and other data analysis platforms.

The BIC Imaging Core houses a wide array of microscopes, including a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. Other microscopes include aZeiss 980 Confocal with Airyscan2, a Zeiss 700 confocal system, a Zeiss 7 MP Multi-photon Confocal Electrophysiology System, a Zeiss Lightsheet Z.1 and a Zeiss Axioscan Z1 Slide Scanner. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize. For electron microscopy needs, the core is equipped with a JEOL JEM-1011 transmission electron microscope, an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment), and a grid stainer (Leica EM AC20).

The BIC Genomics core includes a 3500 XL Applied Biosystems Genetic Analyzer, a Gene Forge 3900 and an ABI 3900 and DNA Synthesizer, a U-3000 Thermo-Scientific HPLC system, an Agilent 1200 HPLC, a QX200 Droplet Digital PCR System, a Roche LightCycler 480 Real-Time PCR System and an Agilent Capillary Electrophoresis Fragment Analyzer.

The BIC Structural Biology and Proteomics Core includes a GE Healthcare Biacore 3000 Surface Plasmon Resonance instrument, an AB Sciex 4000 QTRAP LC/MS/MS System, an Agilent 1200 HPLC, a Wyatt DynaPro NanoStar Dynamic Light Scattering analyzer, an Art Robbins Instruments Phoenix Crystallization Robot, and a JANSi UVEX Fluorescence Microscope (for crystal inspection).

The BIC Histopathology Core includes a Leica Autostainer XL, a Leica CV 5030 Robotic Coverslipper, a Sakura Tissue-Tek VIP tissue Processor, a Leica CM 3050 S Cryostat, and a Microm HM 325 Microtome.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology.

Antony Dimitrov, Ph.D.

Resource Sharing Plan (to include sharing research data, model organisms and data)

We routinely present data derived from our studies at scientific meetings such as the American Society for Virology (ASV), American Society for Microbiology, Keystone Symposia among others, and when components are completed, invention disclosures filed, and following consultation with our appropriate technology transfer offices, we publish and disclose our findings. We have always made our reagents and data available to other investigators, and when appropriate, complete MTAs in a timely fashion. If research findings we deem sensitive are requested by outside parties, prior to publication mutual non-disclosure agreements will be put in place. In addition, we will have a free exchange of findings and data with all our consultants and collaborators. We will adhere to all institutional, state and federal resource sharing guidelines and agree to share knowledge, research materials, and any other resources necessary and relevant to the particular focus of the grant, recognizing that final authorization will be cleared with all appropriate organizational parties. We will make all data gathered available quickly and in an easy-to-interpret format, adhering to confidentiality regulations, provided that this does not conflict with our local requirements.

Research resources, research tools, research procedures and protocols, and novel materials such as recombinant viruses like VSV and rCedV based reporters for LayV and other emerging viruses that may arise out of the funded studies will be made available to others in the private and public sector as soon as appropriate agreements covering such transfer can be executed, or in the case of project data, shall be published as soon as possible or otherwise shared with other researchers pursuant to NIH policies regarding data sharing.

The USU and HJF Joint Office of Technology Transfer (JOTT) will coordinate all technology transfer activities for data and resources generated by USU and UTMB and Novartis. The JOTT will adhere to all applicable policies, principles, guidelines and procurement rules in making unique research resources readily available for research purposes to qualified individuals and entities, and in ensuring that there is no more than a short–term restriction on publication or public dissemination of data in order for the JOTT to evaluate and file for patent protection on any subject invention that may arise from the funded study. Dissemination of unpublished data that is considered to be proprietary or confidential shall occur pursuant to a suitable confidential disclosure agreement prepared by the JOTT as required. Material transfer agreements, license agreements, and Cooperative Research and Development Agreements (CRADAs), as appropriate, will be used to transfer material property. Material transfer agreements will be established to share resources among the research community for noncommercial research use.

Vertebrate Animals

1. The following mouse strains will be used in this proposal:
   - **i)** **B6-albino-Ifnar1-/- mice**. We maintain a breeding colony of B6-albino Ifnar1-/- mice at Charles River Labs (CRL). We generated these mice by crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the Ifnar1-/- strain (Jackson Laboratory B6(Cg)-Ifnar1<tm1.2Ees>/J, Strain # 028288), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carried the Infar1- allele. This colony is now producing only albino mice that are homozygous Ifnar1-/-.
   - **ii)** **B6-albino-STAT1-/- mice.** We are currently establishing a breeding colony of B6-albino STAT1-/- mice at CRL. We are currently crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the STAT1-/- strain (Jackson Laboratory B6.129S(Cg)-Stat1tm1Dlv/J, Strain # 012606), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carry the STAT1- allele. We anticipate establishing a colony of the desired genotype by early 2024..

   We will use mice for in vivo infection with rCedVs, with many experiments including bioluminescent imaging. Animals are housed in an approved ABSL-2 room and all laboratory and animal care staff follow BSL-2 safety precautions. The total number of required mice (including all mice produced during breeding) is 5440. Experiments will be performed with male and female mice. The PI has an IACUC-approved experimental protocol and an IBC-approved biosafety protocol that details the use of the above strains of mice for the described experiments.

2. The goal of this project is to validate the mouse as a BSL-2 model for henipavirus pathogenesis, and as a platform for development and testing of countermeasures. For this work, we must use an experimental animal model to allow the course of in vivo infection and the host immune response to be studied. There is no in vitro model which can model the complex in vivo dynamics of viral infection, moving between distinct cell types and anatomical locations, or the host immune response to infection. We have chosen to utilize mice due to their ease of care, the existence of well-characterized inbred strains and knockout models, and our preliminary data with rCedVs showing robust and reproducible infection of mice which is highly amenable to statistical analysis. The number of animals to be used is based on power analyses, as detailed in our approved IACUC protocols.
3. Experiments will involve the euthanasia of infected animals experiencing pain or distress. Our IACUC protocols also define a weight loss threshold or a combined disease score criterion as end points for virus-infected animals requiring euthanasia. Animals not euthanized for the above reasons will be euthanized for tissue collection, at time points described in our IACUC protocol. Euthanasia will be performed as described in part 4, below.
4. Mice reaching criteria/endpoints described in 3, above, will be euthanized by ketamine or ketamine-xylazine overdose. This method is consistent with AMVA guidelines.

Site Principal Investigator: Brian Schaefer, Ph.D.

Select Agents

No select agents are used in this research.

We will perform animal studies with recombinant forms of Cedar virus. These viruses are categorized as BSL-2. Dr. Schaefer has an approved BSL-2 biosafety protocol for research with Cedar virus, including in vivo ABSL-2 studies. All members of the Schaefer research group have received specific training in laboratory safety and the proper use and disposal of BSL-2 organisms (and two current laboratory members have certifications for BSL-3). Dr. Schaefer has BSL-2 certified laboratories where work with these agents will be conducted. Animal experiments are conducted in approved ABSL-2 rooms within the USU animal facility, conducted under USU IACUC-approved protocols.

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Select Agents

No select agents are used in this research.

We will generate and characterize recombinant forms of Cedar virus and Vesicular Stomatitis Virus. These viruses are categorized as BSL-2. Drs. Broder and Amaya have approved biosafety protocols for in vitro research with Cedar virus. All members of the Broder lab have received specific training in laboratory safety and the proper use and disposal of BSL-2 organisms. Dr. Broder has BSL-2 certified laboratories where work with these agents will be conducted.

USUHS

Antony Dimitrov, Ph.D.

AUTHENTICATION OF KEY BIOLOGICAL AND/OR CHEMICAL RESOURCES

Molecular biology tools. Oligonucleotides and gene fragments for PCR and cloning will be purchased and verified by internal quality control at Twist Biosciences, Integrated DNA Technologies or Genscript. All clonal products will be validated by whole plasmid sequencing. All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Cells. All cells were originally obtained from ATCC or collaborators and maintained by the PI. They are tested monthly for mycoplasma contamination by two complementary methods (qPCR analysis and Lonza MycoAlert biochemical luminescence-based assay). Cells used will be used from the listed initial passage number for a maximum of 50 passages, and then discarded for a fresh vial from the working freezer stock to prevent any long-term selection of altered cell populations. To avoid cross-contamination between different cell lines, only one cell line is used at a time in a biosafety cabinet. Cell lines are routinely validated using either flow cytometry and/or functional tests.

Recombinant Cedar viruses and recombinant vesicular stomatitis viruses (VSV). Viruses are validated through genome sequences or infectivity/functional tests. SOPs, as detailed documents, for work with either recombinant Cedar virus, recombinant Cedar virus chimeras (encoding either Hendra virus or Nipah virus F and G glycoproteins), and recombinant VSVs have been established in the Broder/Amaya laboratory and all laboratory staff are required to be familiar with this documentation. Rescued recombinant viruses are validated through genome sequencing and compared to the original cloned full length viral genomes. Use of recombinant Cedar virus recombinant Cedar virus chimeras has been approved at USU.

Antibodies. Antibodies are tested for specificity as follows: (1) For antibodies used repeatedly in the PI’s lab, the staining/blotting performance of new antibody lots are compared against previous lots; (2) For new antibodies, banding/staining patterns are compared against published data; (3) Whenever possible, new antibodies are also validated using objective controls, such as cells known to lack the protein of interest (e.g., knockout cells) or cells engineered to over-express an epitope-tagged form of the molecule (i.e., staining by the new antibody is compared side-by-side with staining by the epitope-tag antibody).

Commercial chemical reagents. Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

Rigor and Reproducibility

The Broder laboratory employs quality systems to ensure rigor, reproducibility, and robust and unbiased results in all experiments. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility.

USUHS

Site Principal Investigator: Brian Schaefer, Ph.D.

Authentication of Key Biological and Chemical Resources

The reagents that are used in the Schaefer lab are routinely authenticated as follows:

Expression constructs: All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Antibodies: Antibodies are tested for specificity as follows: (1) For antibodies used repeatedly, the staining/blotting performance of new antibody lots are compared against previous lots; (2) For new antibodies, banding/staining patterns are compared against published data; (3) Whenever possible, new antibodies are also validated using objective controls, such as cells known to lack the protein of interest (e.g., knockout cells) or cells engineered to over-express an epitope-tagged form of the molecule (i.e., staining by the new antibody is compared side-by-side with staining by the epitope-tag antibody).

Cell lines: Cell lines are routinely validated using flow cytometry for key cell surface markers and/or functional tests. Cell lines transfected for virus production are validated via measuring titers of virus in the resultant supernatants.

Viruses: Viruses are validated through a combination of genome sequencing, infectivity and functional testing. Rescued recombinant viruses are validated through genome sequencing, with comparison to the original cloned full length viral genomes.

Mice: Every new litter of knockout animals is PCR screened for both the wild-type and inactivated allele, with validated wild-type and knockout control DNAs included in every screen. For transgenic animals, presence of the transgene is PCR verified in every litter, with validated controls included in the screen. Additional screens include periodic western blotting and/or FACS analysis of tissues/cells from knockout animals, to validate that PCR-identified knockouts indeed fail to express the protein product of the inactivated gene.

Commercial chemical reagents: Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

Budget Justification – RP3 – Schaefer

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Key Personnel:

Brian. C. Schaefer, Ph.D. (Site Principal Investigator, 1.2 calendar months, 10% effort) is a Professor of Microbiology and Immunology at USUHS. His expertise is in cellular immunology, animal models of immune responses in the central nervous system and applying advanced imaging methods to biological questions. He and Dr. Broder have been collaborating for nearly a decade on creating animal models and investigating therapeutic interventions for neurotropic viral infections. The preliminary data in this application resulted from this collaboration, through an NIH-funded U19 grant (with aims that do not overlap the aims of this proposal). Dr. Schaefer will direct all animal studies in this project, managing and advising staff and overseeing data collection and data analysis. Dr. Schaefer will manage the overall experimental direction, the writing and editing of manuscripts for publication and the preparation of progress reports and other administrative functions related to this project, with assistance from the Senior Staff Scientist. (Dr. Schaefer is a full-time Federal employee. Hence, no salary is requested for this project).

Other Personnel

†**To be named** (Scientist II, 9 calendar months, 75% effort). A Scientist with experience in animal models and transcriptomics analysis will be recruited for this project. This Scientist will supervise animal research studies, coordinate, conduct and supervise data analyses for transcriptomics studies. The scientist will also coordinate overall data analysis and will participate with Dr. Schaefer in preparation of manuscripts for funding and in preparing progress reports and performing other administrative tasks related to the conduct of this project. The Scientist II will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**To be named** (Postdoctoral fellow, 12 calendar months, 100% effort). A Postdoctoral fellow with experience in animal research and virology will be recruited for this project. The Postdoctoral fellow will perform approximately half of the animal experiments proposed for this study. The Postdoctoral fellow will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**Celeste Huaman** (Graduate Student, 12 calendar months,100% effort) will perform approximately half of the proposed in vivo experiments described in this proposal. Ms. Huaman is a senior graduate student in Dr. Schaefer's lab, who has been working collaboratively with members of the Broder lab on this project. Notably, Ms. Huaman generated the majority of preliminary data in this proposal, and has extensive experience in all procedures and analysis techniques required for the execution of the proposed experiments. Ms. Huaman worked in Dr. Schaefer's lab as a Research Assitant II for 5 years before joining the USU Emerging Infectious Diseases graduate program, and she acquired a very deep technical skill set during that time. Ms. Huaman completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas State University in 2021, and she has trained most current laboratory staff in proper BSL-2 technique. Ms. Huaman is currently employed by the Henry M. Jackson Foundation, and salary support is requested for her on this project.

†**Caitlyn Clouse** (Research Assistant II, 9 calendar months, 75% effort) will provide general technical support, performing routine tissue culture, ordering reagents, and maintaining databases, as required for the project. Ms. Clouse will also perform genotyping of animals breeding at Charles River Lab and she will maintain detailed records of animal genotypes. She will also assist the postdoctoral fellow and Ms. Huaman with all animal experiments. Ms. Clouse completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas llent technical support, including assistance to Ms. Huaman in gathering the preliminary data for this project. Ms. Clouse is an employee of the Henry M. Jackson Foundation and we are requesting salary support for her on this project.

[†]**Camille Alba** (Research Associate, The American Genome Center (TAGC), 1.85 calendar months, 15.4% effort) will be responsible for leading the collaborative performance task for this study. She will oversee performance of library preparation, library quality assessment, library clustering and whole genome sequencing of the samples across the entire project. She will report Illumina NovaSeq platform performance metrics to the collaborating staff scientist and oversee data transfer batches. Ms. Alba is employed as a Henry Jackson Foundation employee therefore salary support is requested.

[†]A merit increase has been added to years 2-5 of the personnel budget to account for salary increases for Henry M. Jackson Foundation personnel.

Equipment:

An ultralow (-80 C) freezer, ThermoFisher Scientific Model TSX60086A ($12,123), is needed for storage of the many RNA samples, viral stocks and frozen tissues (for sectioning) and slides with frozen sections. Dr. Schaefer's current -80 freezers are filled to capacity.

Travel: (Year 1)

Funds are requested to attend two domestic scientific conferences or one international conference. This travel is for data presentation, exchange of ideas with colleagues, and for keeping up-to-date regarding the latest research findings relevant to the proposed project. Meeting attendance and data presentation is a key component of postdoctoral and graduate student training.

Materials and Supplies:

For the laboratory to successfully complete the experiments, the project will need to procure the following reagents and supplies:

General Laboratory Supplies

Serological pipettes, microscope slides and coverslips, pipet tips, microcentrifuge tubes, sterile conical tubes, ultracentrifuge tubes, syringes, needles, gloves, respirators, gowns, buffers, flasks, plates, etc.

Materials

Trizol reagents, RNAse-free DNAse, RNAse-free water and buffers, Reverse Transcriptase, Taq Polymerase, qPCR master mix, RNAse-free consumables for tissue homogenization, magnetic beads for cell sorting, tissue culture media, fetal bovine serum, antibiotics, etc

Real-time PCR probes

DNA oligonucleotide

Labeled antibodies for histology and flow cytometry

Animal costs (procurement and husbandry):

Animal Breeding at Charles River Labs

The breeding of experimental mice at USU is contracted to Charles River Labs (CRL). All aspects of animal care and breeding are managed by CRL, while genotyping of progeny is performed by Dr. Schaefer's group, using biosamples collected and shipped by CRL. We maintain a colony of B6-albino Ifnar1-/- mice and B6-albion STAT1-/- mice in our breeding colony at CRL. For this project, we expect to maintain 12 breeding cages and 12 progeny cages to supply the animals needed for the proposed experiments. ($1.80/cage/day x 24 cages x 365 days = $15,768 + Transportation charges $1,500 = $20,768).

Animal Husbandry at USU

Animal facility (DLAR) mouse per diems:
USU DLAR FY24 per diem for biohazardous mice is $4.78/cage/day. We expect to have an average of 8 experimental cages housed in the facility (8 cages x 365 days x $4.78/cage/day = $13,957.60/yr)

Translational Imaging Core (BRIC):
BRIC – IVIS Spectrum CT bioluminescence imaging (9 hr/week x 52 weeks/yr x $50/hr = $23,400/yr)

Biomedical Instrumentation Core (BIC):
BIC – flow cytometry (4 hr/week x 52 weeks/yr x $36/hr = $7,488/year).
BIC – confocal microscopy (2 hr/week x 52 weeks/yr x $30/hr =$3,120/year)

The American Genome Center (TAGC):

Transcriptomics studies performed at the USU American Genome Center

Total RNAseq on brain slices from 32 animals/year x $300 per animal = $9,600/year

Supplies for Visium Spatial Gene Expression:

Visium CytAssist Spatial Gene Expression for FFPE, Mouse Transcriptome 6.5mm slides (quantity of 16 per year) $24,500/year

Visium CytAssist Tissue Slide Cassettes = $1,800/year

Dual INdex Kit TS set A = $620/year

S1 Novaseq Flow cells (for spatial transcriptomics sequencing), 2 flow cells/year = $8,600/year

Supplies for Single-cell RNAseq:

Chromium Next GEM Automated Single Cell 3' Library and Gel Bead Kit v3.1 = $27,130/year

Chromium Next GEM Automated Chip G Single Cell Kit = $630/year

S1 Novaseq Flow cells (for single-cell RNAseq), 1 flow cell/year = $4,300/year

Publication costs: (Year 2)
We estimate 2 manuscripts per year for an average cost of $2,500 per publication. This cost estimate is based on our average fee paid per open access journal publication for the last 3 years.

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Budget Justification - RP 2 - Broder

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Key Personnel:

Christopher Broder, Ph.D., (Principal Investigator, 1.2 calendar months, 10% effort), is a Professor of Microbiology and Immunology at USUHS and will serve as PI on the proposed project. He is a leading expert in henipavirus biology and genetics, as well as development of glycoprotein-based vaccines and monoclonal antibody-based therapeutics against these viruses; many tested in collaboration with Dr. Thomas Geisbert (Project Lead on this application). Dr. Broder has more than 15 years of collaborative research projects with Dr. Geisbert focused on henipaviruses and together have published on a variety of henipavirus countermeasures including the use of recombinant CedVs. Dr. Broder's group recently developed the reverse genetics platform for designing and rescue of recombinant Cedar henipaviruses (rCedV) that can be utilized at BSL-2, some of which have been successfully used in drug library HTS assays and one report on the successful use of Cedar virus in antiviral drug discovery for henipaviruses including Nipah (NiV), Hendra (HeV) and CedV has been published in collaboration with Dr. Geisbert. Dr. Broder's group generated and characterized the recombinant Cedar chimeric viruses that were used to generate the preliminary data for this application. He will oversee all aspects of the recombinant Cedar chimeric virus construction and characterization. In addition, he and Dr. Amaya will collaborate on the design of all experiments and the preparation of progress reports and manuscripts. Dr. Broder is a federal employee and no salary support is requested.

Moushimi Amaya, Ph.D., (Co-investigator, 2.0 calendar months, 16.67% effort). Dr. Amaya is an experienced biochemist and molecular virologist with expertise in a variety of areas including gene cloning and expression and mutagenesis specifically with viruses and viral culture and propagation, and viral protein purification and analysis. She has considerable experience in henipavirus reverse genetics systems. Using the rCedV platform, Dr. Amaya designed, generated and characterized replication competent chimeric viruses as non-reporter and reporter versions that express the envelope glycoproteins of either NiV-Bangladesh (NiV-B) (rCedV-NiV-B) or HeV (rCedV-HeV) instead of those of CedV. In a collaborative effort, Drs. Amaya, Broder and Geisbert demonstrated that the chimeras can serve as suitable surrogate viruses for authentic NiV and HeV viruses. Dr. Amaya developed and characterized the fluorescent reporter chimeric viruses in a high throughput fluorescence reduction neutralization test (FRNT) to analyze neutralization potencies of sera from henipavirus immunized animals and monoclonal antibodies. She will design, oversee and conduct the research plans related to the generation and characterization of the rCedV chimeric viruses and VSV reporter viruses outlined in this proposal. She will develop, perform quality assurance and test the new chimeric viruses for use in henipavirus neutralization assays. Dr. Amaya is a federal employee and no salary support is requested.

Antony S. Dimitrov, Ph.D., (Co-investigator, 6.0 calendar months, 50% effort). In addition to Dr. Dimitrov's duty to the day-to-day operations of this ReVAMPP and the Admin Core, he will oversee and conduct the research plans related to the production and characterization of all rCedV chimeric viruses and VSV reporter viruses; including generation, quality control, and in vitro cell-based studies. Dr. Dimitrov is highly familiar with all scientific and translational development activities of the proposed ReVAMPP. He was a former member of Broder laboratory and played major roles in the development and biochemical characterization of the HeV-sG subunit glycoprotein (JVI 2005), the discovery of the NiV and HeV entry receptor ephrin B2 (PNAS 2005) and in the development, characterization and efficacy testing of the first neutralizing human monoclonal antibody to NiV and HeV, the latter studies conducted with Profectus Biosciences in collaboration with Dr. Geisbert. When at Profectus Bio, Dr. Dimitrov led their program in the pre-clinical development of HeV-sG as a subunit vaccine and the human antibody, m102.4, for treatment of henipavirus infections. Dr. Dimitrov is an employee of the Henry M. Jackson Foundation and salary support is requested.

Other Personnel

TBD (Research Assistant, 12.0 calendar months, 100% effort). This individual will provide technical laboratory support for this project. In addition, this individual will also be responsible for ordering supplies, organizing shipments, and other laboratory support as instructed by the senior staff. As an employee of the Henry M. Jackson Foundation salary support is requested for this individual.

Lianying Yan (Linda) (Manager/Lead Research Associate 3, 6 calendar months, 50% effort) has been in Dr. Broder's laboratory since 2003 and is well-versed in all aspects of the research in his laboratory. Ms. Yan is a highly trained molecular biologist skilled in expression construct design, screening techniques, and stable cell line development for protein expression using immunoprecipitation and Western blot techniques. Ms. Yan is highly experienced in designing soluble and secreted viral glycoprotein constructs and establishing stable cell-lines to express and produce, purify and characterize the proteins using protocols that include Bio-Plex bead coupling and assay development. She is also expert in confocal and fluorescent microscopy techniques and has been co-author of several manuscripts. Ms. Yan is an employee of the Henry M. Jackson Foundation and salary support is requested.

Madison Thammavong (Research Assistant I, 4 calendar months, 33% effort). Mr. Thammavong will assist Ms. Yan in the production of proteins. He will be trained as a back-up support with various laboratory responsibilities. Mr. Thammavong is an employee of the Henry M. Jackson Foundation and salary support is requested.

Kimberly Boxley, (4.0 calendar months, 33% effort), serves as the Center Financial and Post-Award Administrative Manager. Ms. Boxley, is currently a Program Manager III with the Henry M. Jackson Foundation and her office is located adjacent to Dr. Broder within the Department of Microbiology, USU. Ms. Boxley has been working in grants management for over 15 years and successfully completed the Grants Management Certificate Program (GMCP) from Management Concepts in both the federal and pass-thru tracks. She is enrolled in the Program Management Program (PMP) at the Program Management Institute. She currently manages a department portfolio of approximately $32M in direct funded research awarded during the last 3 years. Her day to day grants management includes budget analysis, employee supervision, training of project managers, forecasting burn rates and compliance issues. Ms. Boxley is an employee of the Henry M. Jackson Foundation and salary support is requested.

Supplies

The costs for materials and supplies are based on historical and current supply needs for these types of studies and on current costs for these supplies. The research teams will be engaged with numerous recombinant gene cloning strategies to produce new expression plasmids and recombinant viral stocks. Several large genomic segments will need to be synthesized and the final clones of all these viral genomes assembled and cloned into expression plasmids.

There will be five different chimeric virus stocks that will need to be prepared, qualified, stored and characterized: three rCedV chimeric viruses and two VSV reporter virus stocks. Piloting and rescuing these new viruses will require significant amounts of materials for all the plasmid preparations and transfection reagents and the multiple anticipated variations in plasmid ratios to achieve virus rescues. We estimate $2000 per construct for gene synthesis and sequencing and $4000 per construct for reagents. Once rescued and cloned each virus genome (the viral stock) will have to be deep sequenced. In addition, the proposed studies will require a significant amount of both cell line and virus culture as well consumables, disposables and reagents (enzyme substrate for the luciferase reporter assays) for the serum neutralization tests with rCedV chimeric reporter viruses. The reporter viruses will be designed and rescued within the first 2 years. The budget for supplies includes molecular biology reagents as well as bacterial culture media and supplements, although reagents and chemicals will be needed to run the assays with the newly created reporter chimeric viruses.

Categories of supplies:

Cell and virus culture media, sera and reagents
Molecular biology reagents; enzymes, primers, plasmid purification kits, ligation kits, gene synthesis, whole plasmid sequencing, virus genome sequencing
Chemicals,
Consumables; flasks, plates, pipettes, gloves, tips

Steady-Glo® Luciferase Assay System for in vitro luciferase assays
CTL S6 analyzer (Fluorescent neutralization tests) and Promega GloMax (luciferase based assays)
Other miscellaneous expenses

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Hello Sherry,

Most of our documents are pretty good draft's. Maybe minor editorial changes from our grants office.

1. Key Person Biosketches – 5 pages, NIH format– please address your role and expertise for this U19 in personal statement **(Attached) Dr. Broder would like to make some revisions to his.**
2. Key Person Information (including person to be contacted on matters for this application for your institution) **Attached.**
3. Site Information **Attached**
4. Abstract/Project Summary (30 lines) **Attached**
5. Facilities & Resources (Word doc) **pdf documents attached**
6. Equipment (Word doc) **pdf documents attached**
7. Resource Sharing Plan (Word doc). **pdf document attached for Broder, will send document for Schaefer**
8. Vertebrate Animals (Word doc *as applicable*) **pdf attached**
9. Select Agent Research Plan (*as applicable*) **pdf attached**
10. Authentication of Key Biological/Chemical Resources **pdf attached**
11. Budget (SF424) & Justification (Word doc) – *please include justification for Core A effort as well*
    - Project Leads at least 1.2 person months effort **attached, 1.2 cal months verified, no Core A effort; pdf attached of justification**
12. Signed Letter of Intent/Consortium Agreement- for projects that include only effort but no salary or other costs, we will provide a collaborative agreement for signature instead. **this will be provided by grants office no later than June 2, 2023**
13. Specific Aims- 1 page *(draft received 5/18/23 for RP2; draft received 5/12/23 for RP3)*
14. Research Strategy: 12 pages for Research Projects **pdf for Broder attached (draft); will send**

document for Schaefer

Thanks much.....Kim

Subject: ReVAMPP RP2/RP3 Document Reminder

Hello Kim,

This is a reminder as you are working on collecting the required documents for RP2 and RP3 on Dr. Geisbert and Dr. Broder's ReVAMPP U19 application. If you need us to resend any templates for the documents below, please let us know as soon as possible so we can get that over to you. Otherwise, we hope to receive final or near final versions of everything listed below (expect strategy and aims, final due May 26) by end of day **Monday, May 22**.

1. Key Person Biosketches – 5 pages, NIH format– please address your role and expertise for this U19 in personal statement
2. Key Person Information (including person to be contacted on matters for this application for your institution)
3. Site Information
4. Abstract/Project Summary (30 lines)
5. Facilities & Resources (Word doc)
6. Equipment (Word doc)
7. Resource Sharing Plan (Word doc)
8. Vertebrate Animals (Word doc *as applicable*)
9. Human Subjects Study Record (*as applicable*)
10. Select Agent Research Plan (*as applicable*)

11. Authentication of Key Biological/Chemical Resources
12. Budget (SF424) & Justification (Word doc) – *please include justification for Core A effort as well*
    1. 5 years
    2. Project Leads at least 1.2 person months effort, Scientific Core Leads at least 0.6 person months effort, Data Mgmt. Core Lead at least 1.2 person months effort
    3. NIH salary cap, M&O, travel, publications, service fees, indirects, etc.
13. Signed Letter of Intent/Consortium Agreement- for projects that include only effort but no salary or other costs, we will provide a collaborative agreement for signature instead.
14. Specific Aims- 1 page *(draft received 5/18/23 for RP2; draft received 5/12/23 for RP3)*
15. Research Strategy: 12 pages for Research Projects; 6 pages for Scientific and Data Mgmt. Cores
    1. Milestone Plan: Annual Go/No Go's to be met by end of Y3 (Phase I); Gantt chart/Timeline, PhI/PhII
    2. Tie in Industry Expertise
    3. Address Regulatory Barriers
    4. Bibliography (no page limit)

Please let us know if you have any questions or concerns about meeting this deadline for any of these documents. If you have anything completed, feel free to send us what you have ready, so we may begin our review process and start uploading documents to the application.

Thank you!

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. The threat is further heightened for these agents due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these agents. Threats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches **which can be adapted across members of each viral family in a "plug-and-play" manner**. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. (2) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses Specifically, we will:

AIM 1: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.

AIM 2: Develop novel arenavirus and nairovirus vaccination approaches:

2.1 Subunit immunogens and MNP vaccination: Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus.

2.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments: Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

SPECIFIC AIMS

The emergence and reemergence of pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Notable examples are the two emerged zoonotic paramyxoviruses, the ‘prototype’ henipaviruses; Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. NiV and HeV have a broad host tropism capable of infecting 18 animal species across 6 orders of mammals using the highly conserved ephrin-B2 and -B3 ligands as entry receptors. NiV and HeV infections result in a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans. They are significant biothreats to humans and economically important livestock in Australia and South East Asia. Henipaviruses have two membrane glycoproteins: the attachment glycoprotein (G) and the fusion glycoprotein (F) that are the major targets of neutralizing antibodies and the focus of all vaccine strategies. The most extensively studied NiV/HeV vaccine has been the soluble recombinant G glycoprotein of HeV (HeV-sG), which can provide complete protection against lethal challenge by either NiV or HeV in four animal species including nonhuman primates (NHPs). We have recently tested the immunogenicity of HeV-sG delivered using an advanced dissolvable microneedle patch (MNP) technology. Preliminary data reveal potent NiV/HeV neutralizing antibody responses and this new approach may offer a novel, highly stable and rapid vaccination modality. In parallel, we have extensively characterized the nonpathogenic henipavirus, Cedar virus (CedV); develop a reverse genetics platform, generated recombinant CedV (rCedV) and rCedV chimeras by swapping G and F glycoproteins for the respective NiV or HeV G and F, and developed a surrogate BSL-2 virus neutralization platform. More recently, novel henipaviruses, including genetically related Mòjiāng virus and Langya virus (LayV) have been discovered, and in contrast to HeV/NiV, both appear to be rodent borne and do not use ephrin ligands as entry receptors, and each has infected humans causing disease. Further, a most recently discovered bat-borne and divergent henipavirus, Angavokely virus, from wild Madagascar fruit bats, has also been described. Here, we propose to develop the MNA patch delivery platform, create LayV and other reporter virus tools to complement the HeV/NiV chimera tool, and use these approaches to developed high throughput BSL-2 based virus neutralization platforms to evaluate the MNP subunit vaccine approach; and apply the MNP vaccine patch technology to other emerging and/or potential zoonotic paramyxovirus pathogens. Specifically, we will:

Aim 1: Develop and evaluate sG_{tet} and sF_{stb} prototype henipavirus subunit vaccine candidates by dissolvable MNP vaccination.

We will compare NiV vaccine immunogens (sGtet and sFstb) and HeV (HeV-sFstb) to HeV-sG in heterologous challenge studies using Nipah-Bangladesh and Hendra-Redlands viruses when delivered by microneedle vaccine patch. Immunogenicity will be tested in mice and NiV/HeV neutralizing potencies evaluated. Challenge studies will be conducted in ferrets. Antivirus humoral responses will be evaluated by,,,,, (Gunn). Selected best-in-class vaccine candidate(s) will be evaluated in the NHP NiV/HeV model.

Aim 2: Rescue recombinant Langya virus (rLayV) and LayV glycoprotein reporter virus platforms.

We will generate the new henipavirus LayV as an additional ‘prototype’ henipavirus using reverse genetics. Recombinant LayV (and reporter-gene versions) will be constructed and virus rescue procedures will be conducted by the Scientific Core at UTMB to rLayV. Alternate, virus tools will also be generated using reporter-gene versions and rCedV chimeras encoding the LayV F and G. Rescued viruses will be characterized in cell-based assays. The rLayV virus will be examined in vivo (animal model development) within the Center Core.

Aim 3: Evaluate antibodies and nanobodies to henipaviruses developed by the Center’s RPs.

Henipavirus tools and high-throughput virus neutralization platforms will be utilized to test and evaluate MNP vaccine induced immune sera and individual virus specific monoclonal antibodies against henipaviruses discovered and/or developed by the research projects in the Center. (Needs defining here, RP4 and 5, and also AngV F/G mab discovery – Genovac)

Aim 4: Adapt the MNP vaccination approach in Center Phase 2 to other paramyxoviruses.

Here, we will develop, characterize, and validate this *plug-and-play* polyphosphazene (PPZ) adjuvanted dissolvable MNP platform with different recombinant paramyxovirus glycoprotein antigens.

Specific Aims

Henipaviruses are single-stranded, negative-sense enveloped RNA viruses of the paramyxovirus family[1]. Two henipaviruses, Nipah virus (NiV) and Hendra virus (HeV), cause a systemic and often fatal respiratory and/or encephalitic disease in humans and ten other mammalian species[2-4]. Importantly, NiV and HeV are significant biothreats to humans and economically important livestock in Australia and Southeast Asia[5]. There are currently no vaccines or therapeutics approved for human use. Notably, development of countermeasures for NiV and HeV is hampered by the fact that these viruses require BSL-4 containment, meaning that very few research groups worldwide have access to the required biocontainment facilities to perform preclinical studies with these important human viral pathogens[6].

To address this problem, we are developing a BSL-2 animal model that is based on Cedar virus (CedV), which is a non-pathogenic henipavirus[7]. Specifically, we have engineered recombinant Cedar viruses (rCedVs) in which the NiV and HeV fusion (F) and receptor-binding glycoprotein (G) are expressed in the rCedV genome, replacing CedV F and G. Additionally, we have also incorporated our recently developed *in vivo* bioluminescence methodology[8, 9] to longitudinally trace the dynamics and anatomical progression of rCedV-luciferase (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, we have demonstrated sustained replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Importantly, whereas rCedV-luc does not establish stable expression in the brain, both of the chimeric viruses do. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. The rCedV-luc platform is thus an authentic henipavirus system that can be used to study henipavirus *in vivo* biology safely and expediently under BSL-2 containment. Our **overall hypothesis** is that rCedV-luc infection of mice lacking interferon responses represents a BSL-2 platform for the study of henipavirus biology and pathogenesis, as well as for development and testing of anti-viral countermeasures. We will address this hypothesis through three Specific Aims:

Aim 1: To optimize the use of Stat1-/- mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease. Hypothesis: *Infection of Stat1-/- mice with recombinant rCedVs will recapitulate major hallmarks of pathogenic NiV and HeV infections in humans*. We will establish a breeding colony of Stat1-/- mice on a B6-albino background. We will infect Stat1-/- mice with rCedV-luc chimeras. We will use flow cytometry, spatial transcriptomics approaches and histological methods to define cell types infected, gene expression changes and immune phenotypes that characterize pathological (Stat1-/- model; rCedV-luc chimeras) vs. non-pathological (Ifnar1-/- model; rCedV-luc) infections.

Commented [BS1]: -Collaboration with Core D (systems serology - Gunn)
-Collab with RP2 (other rCedV chimeras)
-Possible exploration of hamster infection (rCedV-NiV-luc), using much larger dose than what was used for UTMB studies to determine if (1) efficient CNS infection can be achieved and (2) if CNS infection is highly correlated with lethality. Hamsters may represent a rCedV lethal model employing a host that is not immunocompromised. Limitations: few specific analysis tools (mAbs in particular) for the hamster model.

Aim 2: To determine the mechanism of rCedV-NiV neurovirulence in the Stat1-/- mouse model. Hypothesis: *CNS infection by rCedV chimeras requires functional interaction between G and host ephrin B3; neurovirulence is a property shared by henipaviruses in the absence of host IFN-dependent defenses*. We will evaluate whether interaction between NiV/HeV G and host ephrin B3 is required for neurotropism. We will employ direct injection of rCedV into the brains of Stat1-/- mice to determine whether neurological disease is a property shared by brain-resident henipaviruses in the absence of a host interferon response.

Commented [BS2]: -Collab with RP2 (rCedV-NiV ephrin B3 binding mutant)

Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Hypothesis: *G- and F-directed mAb-based therapeutics will demonstrate Fc-dependent efficacy against CNS-resident henipavirus*. Stat1-/- mice infected with rCedV chimeras will be treated with anti-G and anti-F mAbs and nanobodies. We will employ the approaches of Aim 1 to determine the immunological basis of any observed mAb therapeutic effects. We will also specifically investigate the role of mAb-FcR interactions for therapeutic efficacy.

Commented [BS3]: -Collaboration with RP5, nanobodies
- Collaboration with Core D (systems serology - Gunn)

HeV and NiV are emerging human and livestock pathogens with a high fatality rate, demonstrated human-to-human transmission, and a worrisome recent history of outbreaks in proximity to densely populated areas, including Kerala, India[10-12]. There is thus an urgent need to develop novel therapeutics directed against these viruses. However, work with HeV and NiV requires BSL-4 containment, severely limiting translational research efforts. Through the development and investigation of this longitudinal BSL-2 animal model of authentic and pathological henipavirus infection, we will greatly facilitate future development and preclinical validation of therapeutics directed against these deadly human pathogens.

SPECIFIC AIMS

The COVID-19 pandemic has highlighted the need for fast drug development technologies and new antiviral drugs to address emerging pathogens. One promising approach is the use of nanobodies, which are antigen-binding entities derived from camelid animals' heavy chain-only antibodies. Nanobodies are small (15 kDa), retain full antigen specificity, and can recognize inaccessible epitopes while crossing tissues and blood-brain barriers, making them potential antiviral drugs with high cross-reactivity against multiple viral pathogens.

Henipaviruses and arenaviruses are two viral families that pose severe public health risks worldwide, causing encephalitis and hemorrhagic fever. Currently, there are no licensed treatments that specifically target these viruses, so effective treatments are urgently needed. To address this issue, four prototype viruses were selected from each of the Henipavirus and Arenavirus genera based on their significant impact on public health and the lack of effective treatments against them. This research strategy can be generalized and applied to more members of these two viral groups.

The study focuses on two Henipavirus prototypes: Nipah virus (NiV) and Hendra virus (HeV), which have caused outbreaks in Asia and Australia, respectively, and are responsible for severe respiratory and central nervous system (CNS) illnesses in humans. These viruses have high mortality rates ranging from 40% to 90%. Similarly, two prototypic viruses of the Arenavirus genus that can cause severe illness and death in humans are focused in this study, Lassa virus (LASV) and Machupo virus (MACV). LASV is responsible for causing Lassa fever, which is endemic in West Africa and can lead to hemorrhagic fever, while MACV is responsible for causing Bolivian hemorrhagic fever. These viruses are a global public health threat due to their geographical distribution and diversity.

To develop nanobody-based therapies against Henipaviruses and Arenaviruses, the study proposes to target the viruses' key entry machinery, including the G and F glycoproteins of HNV and the GPC of arenavirus. The study will use a structure-based strategy to understand viral neutralization mechanisms and facilitate nanobody enhancement engineering and design blood-brain barrier-penetrating nanobodies. The hypothesis is that nanobodies will serve as a useful countermeasure against CNS diseases caused by these viruses. The study will leverage three nanobody development platforms: camelid animals, nanomouse, and low-immunogenic human nanobody libraries, which closely resemble the natural human antibody heavy chain variable domain. These libraries will enable the quick identification of nanobody leads that require minimal optimization for clinical use. The study will carry out this project with three specific aims.

Aim 1: To identify cross-reactive nanobodies to Henipaviruses. Given their high degree of glycoprotein (F and G) similarity, it feasible to identify cross-reactive neutralizing nanobodies against both HeV and NiV for broad protection. We will use both immunization in camelids and nanomice and a recently generated naive human nanobody library for nanobody production. We will employ sequential immunization and antigen panning strategies to identify nanobodies that cross-recognize HeV and NiV. Enriched libraries will be deep-sequenced to ensure comprehensive coverage. Finally, candidate nanobodies will be evaluated for specificity by ELISA and neutralizing activity by RP2.

Aim 2: Identification of nanobodies to Arenaviruses. Arenaviruses, such as Old World LASV and New World MACV, contain a heavily glycosylated and conformationally labile surface glycoprotein (GPC), making it challenging to generate monoclonal antibody therapies using conventional antibodies. To overcome this, we plan to develop nanobodies as a therapy option. Nanobodies, being smaller in size, could potentially penetrate the glycan surface of GPC and neutralize the virus. We will generate nanobodies by immunizing camelids and nanomice with a stabilized trimeric GPC immunogen, and also use a naive human nanobody library for screening neutralizing nanobodies. Individual nanobodies will be assessed for target specificity by binding and neutralization activity in RP1.

Aim 3: Nanobody characterization and structure-based engineering. We will first conduct an affinity test for all identified nanobody neutralizers and correlate their affinity and neutralization potency. Using the structure-based analysis, using X-ray crystallography and Electron Microscopy Single Particle Analysis, of nanobody epitopes and neutralization mechanisms, we will rationally design to improve the therapeutic efficacy and engineer the combination of nanobodies that target multiple epitopes. We will also design a nanobody therapy that targets the central nervous system (CNS) by coupling with transferrin receptor 1 (TfR1) for efficient blood-brain barrier (BBB) penetration. Finally, we will evaluate the efficacy of the engineered nanobodies in an in vivo rCedV-NiV-B chimera mouse model in RP3.

SPECIFIC AIMS - Core A (Administrative Core), University of Texas Medical Branch at Galveston

The Administrative Core will function as a critical component of the Research and Development of Vaccines and Monocolonal Antibodies for Pandemic Preparedness (ReVAMPP) “Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center” (PABVAX) by providing support for the implementation of an integrated, product-oriented research program composed of major research projects and core facilities. The Core will be responsible for the overall management and coordination of PABVAX activities, including governance and financial and operational management to facilitate the execution of the ReVAMPP network-wide strategic research goals and Center plans to develop countermeasures for Paramyxoviridae and Bunyavirales infections.

The Specific Aims of the Administrative Core are to:

Aim 1: Manage, coordinate, and supervise all Center activities.

Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core will provide organizational and programmatic structure to promote research productivity and scientific interactions in support of the development of countermeasures for Parmyxoviridae and Buynavirales. The Administrative Core will guide the refinement of policies governing PABVAX operations and will ensure compliance with requirements for the responsible conduct of research activities, particularly those involving select agents, vertebrate animals, and human subjects. The Core will coordinate all activities of the Scientific Advisory Board and will oversee the management of Center financial resources.

Aim 2. Provide regulatory expertise as needed for implementing translational research activities.

Regulatory guidance will be provided by the Administrative Core from institutional experts who will assist PABVAX researchers in overcoming nonclinical regulatory barriers.

Aim 3: Coordinate seamless communication within the Center, with NIAID program staff, and throughout the ReVAMPP Network.

The Administrative Core will assure continuous communication within the Center by organizing regular meetings with all Core members and Research Project personnel and will facilitate the dissemination of information among Center scientists, institutional officials, and external stakeholders. The Administrative Core will be in direct contact with each component of the Center to continually review research progress and to maintain detailed, up-to-date records; the core will exploit this relationship to generate all written reports to assure timely delivery of information to NIAID program staff and to complete all annual continuation applications. In conjunction with the ReVAMPP Coordinating and Data Sharing Center (CDSC), the Administrative Core will also coordinate interactions with ReVAMPP network participants to facilitate network-wide communication of Center activities.

Aim 4: Lead collaborative efforts with the CDSC and the ReVAMPP Network to ensure program compliance.

The Administrative Core will be responsible for maintaining communication with the ReVAMPP CDSC to lead and coordinate the Center’s collaborative obligations to the ReVAMPP Network. Further program compliance will be assured through the organization of annual ReVAMPP network-wide meetings for Center personnel, as well as the annual ReVAMPP Center progress meetings for PABVAX personnel and Scientific Advisory Board Members.

Data Management Core: Specific Aims

The Data Management Core (DMC) aims to design a secure, scalable, and redundant data storage and transfer infrastructure that will serve as the central knowledge vault for all research projects and cores. DMC will establish a robust mechanism for "raw" HIPAA-compliant data collection generated by all groups and performs routine quality control activities focusing on 6 dimensions: completeness, accuracy, consistency, validity, uniqueness, and integrity. After a thorough cleaning and error resolution, the data will populate the local RAID6 redundant instance of the SQL server, completely mimicking the Immport system, which will be used for data sharing with the coordinating center and worldwide research communities. Pure and organized data will conform to the FAIR data principles to follow the Findability, Accessibility, Interoperability, and Reuse of digital assets. DMC will utilize the HIPAA-compliant Microsoft SharePoint cloud located behind the secure UTMB firewall to organize a data lake with a dedicated vault for each research project and core. Individual vaults will undergo automatic data assessment routines to identify outliers, gaps in data, and errors and report to individual vault stakeholders. All inconsistencies will be resolved during the organized monthly meetings between stakeholders and the data management group. The data will be prepared to be further deposited to the MariaDB instance following Import schema and table structures. DMC team has already established a similar infrastructure in the West African Center for Emergent Infectious Disease and has experience and contacts developed with the Immport admin team to achieve this goal. DMC core will also assist in the bioinformatics, data science, and statistical analysis required at any project stage. With years of experience in clinical biomedical informatics working with Big Data EMR, our team will help with in-silico validation and external data integration to supplement the research activities of all groups. To implement the proposed infrastructure, we propose the following aims:

Aim 1: **Establish a Robust Data Management System**
1.1 Develop a secure, user-friendly data management system using HIPAA-compliant tools like Microsoft OneDrive and SharePoint Server to store, organize, manage, and share research data.
1.2 Standardize data formats, metadata, and documentation to ensure consistency, interoperability, and reusability. This will involve creating data dictionaries, templates, and guidelines for data entry and quality control.
1.3 Design vault specific PowerBI dashboard that allows continuous monitoring of the state of the data for each of the project and core
Aim 2: **Facilitate Data Sharing and Training**
2.1 Develop tools and platforms for data sharing, collaboration, and communication among project research teams, including data sharing agreements, data access portals, and workshops.
2.2 Provide training and technical assistance to research teams on data management best practices
2.3 Maximize the dissemination and reuse of research data in line with the NIH FAIR mission through strategies such as publishing datasets in public repositories and creating data citation policies.
Aim 3: **Ensure Data Quality Control and Security**
Implement rigorous data quality assurance and control measures to maintain research data's accuracy, completeness, and validity. Ensure data security and compliance with relevant regulations to protect sensitive data from unauthorized access, disclosure, or loss. This will involve regular risk assessments, data backup and encryption, and access controls. Data quality will be assessed across several dimensions: accuracy, completeness, consistency, timeliness, validity, and uniqueness. Accuracy and validity ensure the data correctly represents real-world entities and conforms to HIPAA and FAIR rules, while completeness and uniqueness check for comprehensive data without repetitions. Consistency and timeliness checks will ensure uniform representation across different sources and the data's relevance to the required time point.

Core C - Microneedle Patch Core (Falo, Andrianov, Korkmaz): SPECIFIC AIMS

The ***goal*** of the *Microneedle Patch (MNP) Core* is to develop, characterize, and validate our *plug-and-play* polyphosphazene (PPZ) adjuvanted dissolvable MNP platforms with different recombinant viral glycoprotein antigens that will be developed in the Research Projects (RPs: RP1 and RP2). The MNP Core will develop and batch release PPZ MNP vaccine platforms with RP1- and RP2-specific viral antigens based on the well-defined quantitative release criteria of their validated physicochemical and immunological properties. Ultimately, these PPZ MNP vaccine platforms will enable the development of clinically translatable, highly protective vaccines against several prototype viral pathogens from multiple viral families, including *Arenaviruses (Lassa, Machupo, Lujo, and Chapare viruses)*, *Nairoviruses (Crimean-Congo hemorrhagic fever-CCHF and Kasokero viruses)*, and *Paramyxoviruses (Nipah, Hendra, and Langya viruses)*, through studies outlined in RP1 and RP2.

The MNP Core leverages our unique and broadly deployable vaccination approach enabled by a synergistic combination of plug-and-play, clinically feasible *immunoadjuvant* and *skin-targeted vaccine delivery* platforms, for which we have well-established formulation/production and quality control protocols. Our unique vaccination strategy will effectively harness the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs incorporating recombinant viral glycoprotein antigens and PPZ adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The RP-specific *recombinant viral glycoprotein antigens* will drive the generation of virus-specific protective immune responses. *The PPZ macromolecules* will serve as an immunoadjuvant nanoassembly that will provide many immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. *Dissolvable MNPs* will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. ***Our preliminary data strongly support these innovative features of our skin-targeted vaccination strategy.*** Collectively, our PPZ MNP-based skin immunization technology *1)* brings key immunogenicity advantages over conventional immunization routes (intramuscular and subcutaneous) by targeting the highly efficient endogenous immune circuitry of the skin to significantly improve vaccine-specific immune responses, and *2)* shifts vaccination from traditional needle-and-syringe administration of heat-sensitive vaccines by trained healthcare workers to highly effective, widely deployable, needle-free, thermostable, and self-administered vaccines for more effective, sustainable, and equitable mass vaccination campaigns. Ultimately, our clinically translatable PPZ MNP vaccine platforms are readily adaptable to develop efficacious and broadly deployable vaccines against emerging and re-emerging viruses, including those with RP1- and RP2-specific recombinant viral glycoprotein antigens.

Building on our strong preliminary data with PPZ MNP platforms with different antigens, our expertise with MNPs, PPZ adjuvants, skin-targeted vaccines, and murine immunogenicity studies, as well as complementary expertise provided by Core D, we will develop, extensively characterize, immunologically evaluate, and batch release PPZ MNP platforms with RP-specific antigens to enable the development of effective, safe, broadly deployable, and clinically translatable vaccines against the prototype viruses outlined in RP1 and RP2. Our cohesive research support plan involves two Specific Aims in the MNP Core as IND-enabling studies with RP-specific viral antigens:

Specific Aim 1: To Develop And Characterize PPZ MNP Vaccines. We have comprehensive experience with the translational development of PPZ adjuvants and dissolvable MNPs that we have advanced to human clinical trials. *AIM 1* is geared toward the development and physicochemical characterization of PPZ MNP platforms with RP1- and RP2-specific antigens (drug substances or antigens will be extensively characterized in Core D) based on standard operating procedures (SOPs) established for formulation and quality control (QC) of PPZ-complexed antigens and vaccine-loaded MNPs. Ultimately, PPZ MNP platforms with project-specific antigens (drug product) will be batch released based on the quantitative release/pass criteria of their physicochemical features to enable reproducible targeting of the vaccine components to the skin for efficacious immunization.

Specific Aim 2: To Validate The Correlates Of Protection Of PPZ MNP Vaccines In Mice. We have expertise with the evaluation of the correlates of PPZ MNP vaccine-induced protection through murine studies. *AIM 2* is planned toward the evaluation of vaccine-induced humoral (antigen-specific serum binding antibodies [IgM, total IgG, IgG1, IgG2, and IgA] and virus-specific neutralization activity of vaccine-induced serum antibodies via an *in vitro* neutralization assay) and cellular (polyfunctional antigen-specific T-cell responses in vaccine-draining lymph nodes and spleens) immune responses in mice immunized with PPZ MNP vaccine platforms with project-specific viral antigens. Ultimately, PPZ MNP vaccine platforms with RP1- and RP2-specific viral antigens will be advanced to RPs based on the quantitative immunological release/pass criteria to enable the optimal induction of effective, robust, and long-lived virus-specific protective immune responses in studies outlined in RP1 and RP2.

Core C - Microneedle Patch Core (Falo, Andrianov, Korkmaz): RESEARCH SUPPORT PLAN

1. Significance

The threat of emerging and re-emerging infectious diseases highlights the need for continued improvement of vaccination strategies to enable more effective, sustainable, and equitable global immunization campaigns(1-3). Development of efficacious, safe, low-cost, user-friendly, broadly deployable, and rapidly adaptable vaccination platforms, with emerging vaccine adjuvants and vaccine delivery systems, as well as their proactive validation with vaccines against prototype pathogens are of great significance to maximize pandemic preparedness(4-6). The Microneedle Patch (MNP) Core brings together the transformative project components, ***1)*** *skin immunization*, ***2)*** Polyphosphazene (*PPZ) adjuvant*, and ***3)*** *dissolvable MNPs*, with the rationally designed antigens that will be developed in research projects (RPs) against high-priority pathogens (**Fig.1**) to enable the achievement of the goals of the overall project, as well as to support the translational development of a next-generation immunization strategy. Our cohesive project plan designed around these key project components will yield IND-enabling results for PPZ MNP platforms, with RP-specific viral antigens, which will facilitate their rational clinical translation. Ultimately, PPZ MNP platforms will help obviate the existing bottlenecks in the vaccine efficacy, compliance, storage, acceptance, and distribution for more widespread global immunization campaigns.

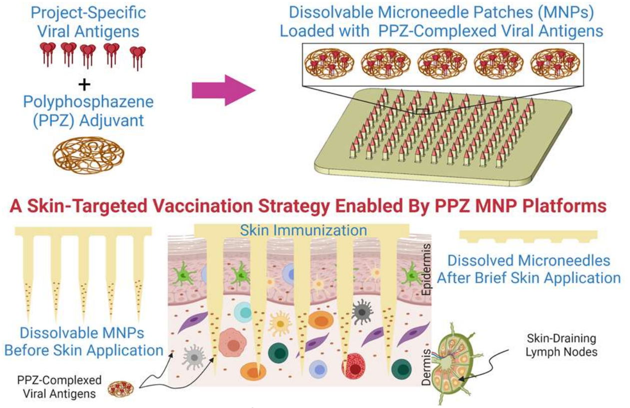

Fig. 1. A paradigm-shifting immunization strategy using heat-stable, self-administered, and widely deployable dissolvable MNPs integrating PPZ-complexed project-specific antigens.

Skin Immunization. Rapidly increasing experimental and clinical evidence strongly supports the notion that skin vaccination offers key biological benefits over conventional vaccination routes (intramuscular and subcutaneous) to induce significantly improved vaccine-specific protective immunity(7-11). The skin offers an immunocompetent tissue microenvironment that hosts a high density of professional antigen-presenting cells (APCs) and immune-accessory cells, with broad immune functions, as well as a rich network of lymphatic vessels that facilitate the continuous immune communications with the skin-draining lymph node(12-15). Unlike the immunologically inert features of muscle and subcutaneous tissues that consist of a substantially lower density of APCs than the skin tissue, the highly efficient immune networks of the skin drive the generation of strong and long-lasting antigen-specific immune responses, enabling more effective immunization compared with conventional intramuscular and subcutaneous vaccination strategies(7-10, 12-14). We and others have demonstrated that skin immunization is capable of inducing strong and long-lasting immune responses in both systemic and mucosal compartments, which are superior to those induced by conventional needle immunization via parenteral routes(9, 10, 16-18). *We have unique expertise with skin immunization and propose to exploit the established advantages of the skin immune system in the MNP Core to enable the development of effective, safe, and broadly deployable skin-targeted vaccines, with the project-specific viral antigens that will be extensively characterized in Core D.*

PPZ Immunoadjuvants. Recombinant subunit protein antigens are often complemented with vaccine adjuvants to mount robust, strong, and durable protective immune responses(19-21). PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs(22-24). PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, without the need for sophisticated formulation processes, and form nanoassemblies with virus-mimicking dimensions (60-100 nm)(25, 26). Mounting clinical and experimental evidence supports that PPZ macromolecules serve as a potent and safe adjuvant that provides several immune-potentiating features, including increased antigen uptake, multivalent antigen presentation, and multifaceted innate immunity stimulation to enhance vaccine-induced protective immune responses (22-28). We and others have demonstrated through animal studies that PPZ adjuvants, especially the most commonly used PPZ adjuvants*, clinical-stage poly[di(carboxylato-phenoxy)phosphazene] (PCPP)* and its structural homologue *poly[di(carboxylato-ethylphenoxy) phosphazene] (PCEP)*, significantly augment vaccine immunogenicity, enable antigen dose-sparing, and achieve long-lasting protection in live viral challenge studies(28-30). *We will leverage our comprehensive experience with the translational development of PPZ adjuvants in the MNP Core to enable the development of effective and rapidly deployable PPZ MNP vaccine platforms, with the RP-specific antigens.*

Dissolvable MNPs. Effective and reproducible delivery of vaccine components to the highly immunoresponsive cutaneous microenvironments is pivotal for efficacious skin immunization strategies(12, 13, 31-33). Dissolvable

MNPs have emerged as a clinically feasible delivery platform that can administer vaccines to the immunologically rich milieu of the skin in a safe, patient-friendly, and consistent manner(12, 13, 32). We have previously shown that microneedles of our dissolvable MNPs physically penetrate the outermost skin layers and actively deposit vaccine components in a defined three-dimensional (3D) space within the skin, eliminating the delivery efficiency, formulation, and precision complexities associated with other skin-targeted vaccine delivery approaches(12, 16, 33-35). Importantly, we and others have introduced dissolvable MNPs in human clinical trials in studies that are establishing the feasibility of MNP-based biomolecule delivery to human skin (*NCT02192021, NCT05377905*). Further, the immunogenicity and logistic benefits of self-administered, temperature-stable MNP vaccines over needle-and-syringe delivery of heat-sensitive vaccines by trained healthcare workers have been demonstrated by several laboratories, including our own laboratory(12, 13, 32). Collectively, our dissolving MNPs offer a widely applicable vaccine delivery platform to enable more effective, sustainable, and equitable global immunization campaigns against infectious pathogens. *We will exploit our unique expertise with the development of clinically feasible dissolvable MNPs in the MNP Core to enable the development of effective, safe, and widely deployable skin-targeted vaccines (drug products), with the project-specific viral antigens (drug substances from Core D).*

Together, the MNP Core will deliver PPZ MNP vaccine platforms with project-specific viral antigens, with the goal of unlocking the full potential of the cutaneous immune system to capacitate the development clinically viable vaccines for effective, safe, and widespread immunization against high-priority viruses.

2. Innovation

The MNP Core will exploit our transformative, rapidly translatable, self-administered, needle-free, thermostable, and widely applicable vaccination strategy consisting of next-generation vaccination platforms, such as emerging PPZ adjuvants and dissolvable MNP-based skin-targeted vaccine delivery systems, to enable the translational development of novel, highly protective vaccines against several prototype viral pathogens outlined in RPs. Key factors contributing to the innovation of the MNP Core include:

- *The skin tissue* is a more potent vaccination site than conventional vaccination routes, including muscle and subcutaneous tissue, since it contains a more immunoresponsive environment than the latter tissues.
- *PPZ macromolecules* are next-generation immunoadjuvants that are compatible with dissolvable MNPs. Importantly, PPZ macromolecules offer remarkable immune-potentiating features, including increased antigen uptake and stability, multivalent antigen presentation, and efficient skin innate immune stimulation to enhance both humoral and cellular protective immune responses induced by vaccine antigens.
- *Dissolvable MNPs* are a next-generation vaccine delivery system that offers a needle-free, thermostable, self-applied, and broadly deployable platform that can reproducibly target vaccine components (antigen and adjuvant) to the immunologically rich milieu of the skin. Importantly, we will leverage our unique and clinically tested dissolvable MNPs to enable precise and reproducible delivery of PPZ-complexed project-specific antigens to the highly immunocompetent cutaneous layers for the optimal induction of protective humoral and cellular immunity. Dissolvable MNPs will not only improve the vaccine immunogenicity and efficacy but also eliminate the need for needles, syringes, medical expertise, and cold-chain dependence to reduce cost, and to improve vaccine storage and distribution for increased vaccine coverage.
- Translational feasibility is enabled by our next-generation vaccination strategy synergistically combining the clinically tested PPZ adjuvants and dissolvable MNPs with project-specific viral antigens. The success of our translational efforts will be ensured by the clinical product development (GMP Manufacturing, GLP Testing, Target Product Profiles) support that will be provided by highly experienced investigators of Mapp Biopharmaceutical (Core D), Emergent Biosolutions and Moderna (see the attached letters of support).

The outcome of this project will be IND-enabling results for PPZ MNP platforms, with RP-specific antigens, which will facilitate the clinical translation of a paradigm-shifting vaccination strategy against high-priority pathogens.

3. Experimental Plan

3.1. Studies Supporting The Feasibility Of The MNP Core

Our published (12, 13, 16, 33-35) and preliminary data demonstrate our expertise with the proposed activities in the MNP Core and herein we show representative data supporting that we have the expertise to enable the development of PPZ MNP vaccine platforms with various antigens.

Over the past decade, the research teams of Dr. Falo and Dr. Korkmaz at UPITT have pioneered the translational development, analysis, and human application of dissolvable MNPs for effective skin-targeted delivery of diverse biocargos, including vaccine components (antigen + adjuvant). **Fig.2** shows representative MNPs designed and developed at the UPITT, and their skin-targeted vaccine delivery performance. These user-friendly MNPs consist of micron-scale, obelisk-shaped, ultra-sharp (<1 μm in tip radii) protrusions with filleted bases, which maximize biocargo volume and microneedle strength for consistent delivery of vaccine components to the defined skin layers. Our MNPs are manufactured from water-soluble materials that are designated as safe for human use (categorized as GRAS) by the FDA. Upon a brief (~5 min) cutaneous application, these high-quality MNPs **(Fig.2B)** penetrate the highly host-protective cutaneous layers, quickly dissolve **(Fig.2C)** in the aqueous skin environments upon penetration, and effectively deliver the integrated vaccine components to the immune-responsive layers in murine **(Fig.2D-F)** and human **(Fig.2G-I)** skin. *<u>We will exploit this expertise to develop PPZ MNP platforms with RP-specific viral antigens based on established guidelines and inspection checklists, which we are now using for creation and quality control of MNPs that are being tested in our own investigator-initiated clinical trials.</u>*

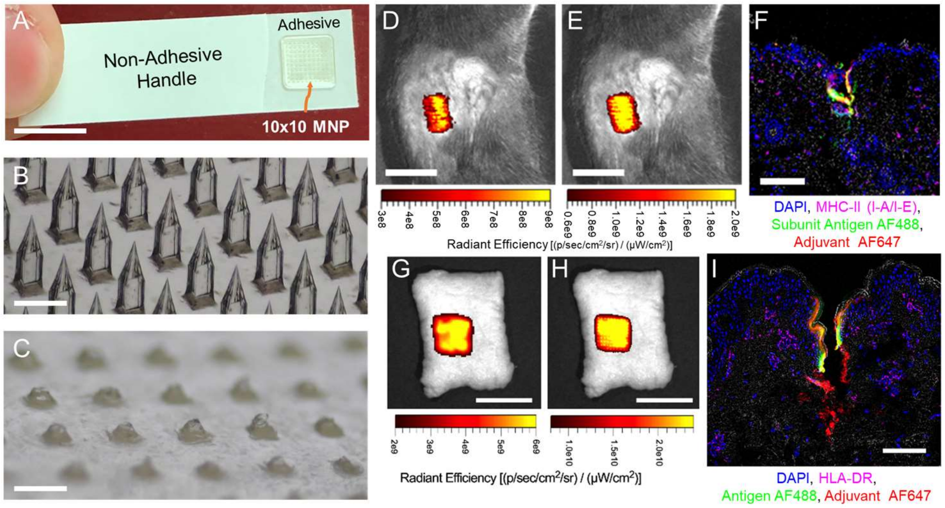

Fig. 2. Engineering dissolvable MNPs for cutaneous vaccination. **A)** Patient-friendly skin-targeted vaccine delivery platform with dissolvable MNPs. <u>Scale bar (SB) = 10 mm</u>. Microscopy images of MNPs **B)** before and **C)** after application to the skin demonstrate efficient dissolution of microneedles. <u>SBs = 500 μm</u>. Effective delivery of fluorescent labeled vaccine components (subunit antigen AF488 and adjuvant AF647) to **(D-E)** murine skin *in vivo* and **(G-H)** human skin *ex vivo* using MNPs. <u>SBs = 10 mm</u>. MNP-based precise delivery of these fluorescent labeled vaccine components to the immunologically rich milieu of the **F)** murine skin *in vivo* and **I)** human skin *ex vivo*. <u>SBs = 100 μm</u>.

Our published data have consistently demonstrated that vaccine delivery via our high-quality MNPs is effective in eliciting robust, potent, and durable antigen-specific systemic adaptive immune responses that are often superior to those generated by traditional intramuscular and subcutaneous vaccination approaches(16, 34, 35). Importantly, as part of our ongoing collaboration with Dr. Broder, Dr. Geisbert, and Dr. Andrianov, we have initiated the development of PPZ-MNP vaccine candidates against henipahviruses. The research team of Dr. Andrianov has pioneered the design and development of PPZ adjuvants to boost vaccine-induced immunity, and has validated the successful formulation of PPZ with soluble recombinant G glycoprotein of Hendra Virus (HeV-sG). *<u>In the MNP Core, we will exploit this expertise to develop PPZ vaccine complexes with RP-specific viral antigens based on the established guidelines and inspection checklists of PPZ adjuvants.</u>* We have then formulated the antigen HeV-sG, the PPZ adjuvant PCEP, the two water-soluble biomaterials, carboxymethyl cellulose and trehalose (GRAS), into dissolvable MNPs, and have tested the immunogenicity of these MNPs incorporating PCEP and HeV-sG. **Fig.3** demonstrates our unpublished representative data with regard to the ***immunogenicity*** [<u>*Humoral:*</u> (Antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro* by the FRNT assay) and <u>*Cellular:*</u> (Polyfunctional T-cell responses by *in vitro* stimulation of isolated cells with antigenic peptides, followed by intracellular cytokine staining (ICS) and flow cytometry) responses] and ***temperature stability*** [Ag-specific

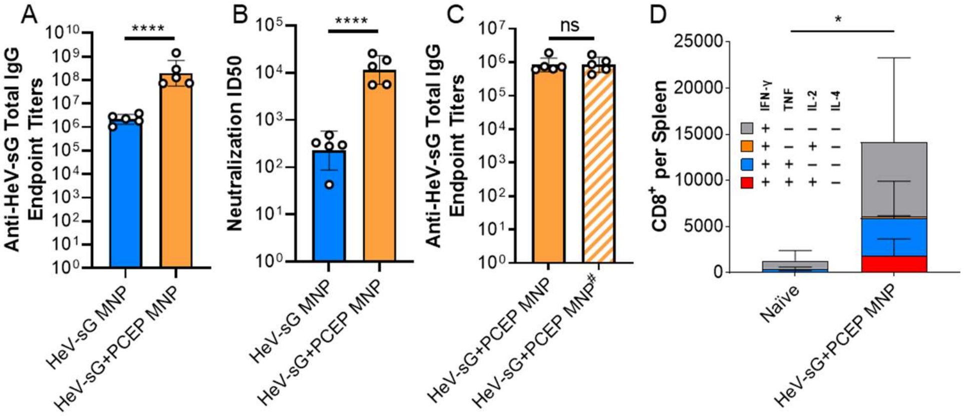

Fig.3. Antigen-specific humoral and cellular responses elicited by PPZ MNP vaccines. Mice were immunized using MNPs loaded with HeV-sG (5 μg)±PCEP (50 μg) MNPs on days 0 and 21. **A)** Anti-HeV-sG total IgG endpoint titers at Week 5 after primary vaccination. **B)** HeV-sG-specific neutralizing antibody titers (ID_{50}) from mice 5 weeks after primary immunization. **C)** Mice were immunized by HeV-sG±PCEP MNPs that were freshly prepared, or stored for 1 month at room temperature after fabrication(HeV-sG±PCEP MNP$^{\#}$), and serum anti-HeV-sG total IgG levels were measured 2 weeks later as an indicator of the retention of immunogenicity. **D)** Mice were immunized by HeV-sG±PCEP MNPs in multiple times and 5 days after the boost, splenocytes were obtained via single-cell suspension and stimulated with an antigenic pool of peptides, followed by intracellular cytokine staining and flow cytometry, to assess systemic cellular responses in terms frequencies of HeV-sG-specific $CD8^+$ T cells in spleen.

binding antibody levels by ELISA after storage of vaccine MNPs for an extended period of time without refrigeration] assessment of PPZ MNP platforms with HeV-sG. These results strongly support the key features of our innovative skin-targeted vaccination strategy and demonstrate that ***1)*** our dissolvable MNPs can effectively deliver the HeV-sG antigen, with or without the PPZ adjuvant PCEP, to immunoresponsive skin microenvironments to induce robust, durable antigen-specific protective immune responses; ***2)*** co-delivery of the rationally selected adjuvant PCEP with HeV-sG in MNPs significantly improves the immunogenicity of HeV-sG; and ***3)*** Dissolvable MNP-embedded vaccines retain the immunogenicity for an extended period of time (at least a month) without a need for expensive "cold-chain". _More comprehensive data demonstrating the feasibility of PPZ MNP platform with HeV-sG are presented in the RP2._ Importantly, we have demonstrated the broad applicability of our PPZ MNP platforms with different viral antigens, such as HeV-sG, Sudan ebolavirus glycoprotein (SUDV GP), Influenza Hemagglutinin (HA) protein, and SARS-CoV-2 Spike (S) protein through animal studies. **Fig.4** shows the relevant representative data that further demonstrate our experience with PPZ MNP platforms, as well as support that skin immunization with PPZ MNPs results in potent immune responses that are superior to those elicited by vaccination with traditional intramuscular (IM) injection of the traditional adjuvant Alum-complexed antigens. _In the MNP Core, we will exploit this expertise to validate the immunogenicity of PPZ MNP platforms with RP-specific antigens in mice._

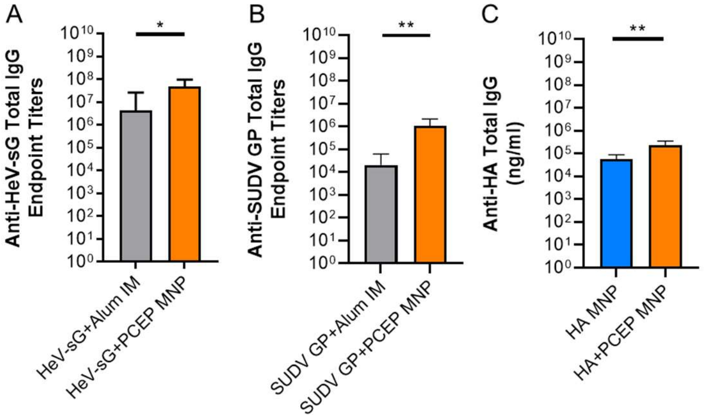

Fig.4. Antibody levels induced by PPZ MNP vaccine platforms incorporating different viral antigens in mice after prime-boost immunization. A) Anti-HeV-sG, **B)** Anti-SUDV GP, and **C)** Anti-HA total IgG levels.

Collectively, the MNP Core will exploit the expertise of our investigators at the UPITT and UMD in PPZ adjuvants, dissolvable MNPs, skin-targeted vaccines, and immunogenicity studies in murine models to develop and batch release the PPZ MNP platforms (drug products) with RP-specific antigens (drug substances from Core D).

3.2. Experimental Design and Methods

Our cohesive research support plan involves two Specific Aims in the MNP Core to provide the RP1 and RP2 with the physicochemically and immunologically validated PPZ MNP platforms, with RP-specific antigens.

Specific Aim 1: To Develop And Characterize PPZ MNP Vaccines. The ***objective*** of *AIM 1* is to fabricate and characterize dissolvable MNPs integrating PPZ-complexed project-specific antigens ***(drug substances will be released from Core D)*** using the standard operating procedures and analysis methods developed at the UMD and UPITT for PPZ-complexed antigens and vaccine-loaded dissolvable MNPs, respectively.

The research team of Dr. Andrianov will formulate project-specific viral antigens with PPZ immunoadjuvants and validate the physicochemical properties of PPZ-complexed antigens for successful incorporation into dissolvable MNPs and for subsequent animal studies. PPZ adjuvants, ***PCPP and PCEP***, will be formulated with project-specific antigens by mixing them in aqueous solutions in the absence of agglomeration, which results in formation of stable supramolecular nanoassemblies **(Fig.5A),** effectively displaying multiple copies of antigen. To validate the physicochemical properties of PPZ-complexed antigens, _antigen-PPZ binding_ [asymmetric field flow fractionation (AF4) method and isothermal titration calorimetry (ITC)], _hydrodynamic diameter_ [dynamic light scattering (DLS)], _short-term stability_ [DLS], and _antigenic integrity and stability_ [dose-dependent ELISA with specific antibodies from RPs.] will be tested and PPZ-antigen formulations will be released based on the pass criteria: **1) Antigen-PPZ binding strength:** <10% unbound antigen and similar Kd values to viral antigen alone, **2) Hydrodynamic diameter:** Z-average diameter of 60-100 nm, **3) Biological integrity:** <1% loss in antigenicity after PPZ formulation, **4) Stability**: <2% aggregation of PPZ complex by volume and <5% loss in antigenic integrity after incubation at temperatures simulating storage conditions.

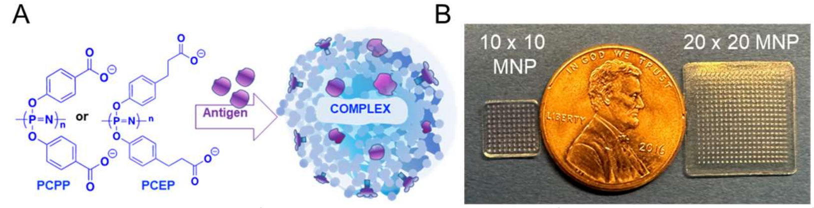

Fig.5. Development of PPZ MNP vaccine platforms. A) Antigen self-assembles with PPZ into supramolecular nanocomplexes (~60-100 nm), and **B)** Different patch sizes of MNPs for small animal (10 x 10 MNP)- and large animal (20 x 20 MNP)-studies.

The research teams of Dr. Korkmaz and Dr. Falo will manufacture PPZ MNP platforms with project-specific antigens and validate the physicochemical properties of these PPZ MNP vaccines for subsequent animal studies. Dissolvable MNPs integrating PPZ-complexed RP-specific antigens released from Core D will be fabricated in the Bioengineering Laboratory of the Department of Dermatology in the University of Pittsburgh School of Medicine (UPSOM) using the established methods well described in our publications. This Bioengineering Laboratory is fully equipped for reproducible manufacturing of high-quality MNPs up to 10,000 MNPs per day. Notably, the manufacturing strategy is flexible to allow precisely and reproducibly dictate needle geometries and their spatial distribution, as well as patch sizes **(Fig.5B)** to achieve different doses of integrated biocargos to enable various studies with small animals, large animals, and humans. Importantly, we have devised standard manufacturing and QC procedures for biocargo-loaded MNPs and outlined these SOPs in our FDA-approved IND (Falo-IND#122488), which we have been using for production and QC of MNPs that are being tested in our investigator-initiated clinical trials (*NCT02192021, NCT05377905*). In the MNP Core, PPZ-MNP platforms, with our clinically validated obelisk-shaped microneedle designs, will be manufactured using our scalable spin-casing strategy with high-precision MNP molds to incorporate RP-specific viral antigens in strict compliance with clinical protocols and will be batch released with our well-established pass criteria. Two different patch sizes of MNPs **(Fig.5B)** will be considered for animal studies. While small MNPs (10x10 obelisk-shaped microneedles – *the total needle volume of 2.4 µl*) will be utilized for small animal studies, large MNPs (20x20 microneedles with the same needle design and same spatial distribution in a larger patch area – *the total needle volume of 9.6 µl*) will be released with the validated properties to facilitate the large-animal studies. To validate the physicochemical properties of PPZ MNP vaccines, *geometric integrity* [advanced microscopy], *mechanical integrity* [standard insertion tests on a force measurement setup (Mark-100 ESM 303)], *vaccine loading accuracy and reproducibility* [Fluorescence spectrometry of MNPs integrating fluorescent-labeled vaccine], *biological integrity* [DLS, AF4 or ITC for antigen-adjuvant complex and antigen-specific ELISA for antigen], *endotoxin content* [the limulus lysate test], *vaccine stability* [DLS, AF4 or ITC for antigen-adjuvant complex and antigen-specific ELISA for antigen after storage], *and skin delivery performance* [Fluorescence spectrometry and advanced microscopy with the skin applied MNPs to quantify the remaining vaccine components and the dissolution volume of microneedles] of PPZ MNP vaccines will be evaluated and PPZ MNP vaccine platforms with project-specific vaccines will then be batch released based on the quantitative pass criteria: **1) Geometric integrity and accuracy:** >95% high-quality microneedles across a PPZ MNP vaccine and <10% deviation from the target geometric values, **2) Structural integrity:** Factor of safety (FOS) > 2 (FOS = Failure forces/penetration forces), **3) Vaccine loading accuracy/reproducibility:** 10% deviation from the mean of theoretical amounts and <10% standard deviation of the mean value. **4) Biological integrity:** No significant ($p>0.05$) aggregation of adjuvant-antigen complexes and no significant loss ($p>0.05$) of antigenicity with respect to those of fresh antigen and fresh PPZ-antigen complexes, **5) Endotoxin content:** < 1 endotoxin unit per PPZ MNP vaccine, provided that the endotoxin content of RP-specific antigens is relatively low, **6) Thermostability:** No significant ($p>0.05$) aggregation of PPZ-antigen complexes and no significant loss ($p>0.05$) of antigenicity after storage at elevated temperatures. **7) Skin delivery performance**: <10% of remaining materials in terms volume and <15% of remaining materials in terms of vaccine after 20 min murine skin application *in vivo* and 20 min the RP-specific animal-skin application *ex vivo*.

Completion of AIM 1 for each batch of PPZ MNP vaccines will be achieved when PPZ-antigen complexes and PPZ MNP vaccine platforms, with project-specific antigens, meet with the aforementioned QC pass criteria.

Specific Aim 2: *To Validate The Correlates Of Protection Of PPZ MNP Vaccines In Mice*. The ***objective*** of *AIM 2* is to evaluate the humoral and cellular responses induced by physicochemically validated PPZ MNP vaccines from *AIM 1* in mice to immunologically validate these novel vaccine technologies with project-specific antigens before advancing them to RP1 and RP2 for the translational development of highly protective vaccines against several prototype viral pathogens.

The research teams of Dr. Falo and Dr. Korkmaz have comprehensive experience with the assessment of the immunogenicity of MNP vaccines through murine studies(16). We will leverage this expertise to determine the immunogenicity of ***PCPP (50 and 100 µg per MNP)*** and ***PCEP (50 and 100 µg per MNP)*** MNP platforms with ***project-specific viral antigens (5 and 10 µg per MNP)*** in mice. These antigen and adjuvant doses were chosen based on our preliminary studies with PPZ MNP HeV-sG vaccine in which the selected doses were found to elicit potent and robust immune responses. We will optimize the doses of antigens and adjuvants for the lead PPZ MNP vaccines to advance them to RPs by using different MNP patch sizes. ***C57BL/6 mice (both female and male)*** will be immunized in ***two different immunization regimens (single dose or prime-boost fashion with a three-week interval between two doses)***. Naïve or unimmunized mice will serve as negative controls. Mice immunized with the intramuscular injection of Alum-complexed RP-specific antigens will be our positive controls. To complete the initial immunogenicity evaluation of physicochemically validated PPZ MNP vaccines, effector immune responses to PPZ MNP vaccines will be determined to rapidly advance the physicochemically and immunologically validated PPZ MNP vaccines to RP1 and RP2. _To investigate humoral responses_, blood samples will be collected on Week 2 and Week 5 after primary immunization. Serum antigen-specific antibody levels (IgM, total IgG, IgG1, IgG2c, and IgA) will be measured by ELISA and virus-specific neutralization capacity of these antibodies will be determined by an *in vitro* neutralization assay (**Fig.3)**. _To evaluate cellular responses,_ mice will be sacrificed five days after the final vaccine dose, vaccine-draining lymph nodes and spleens will be isolated and their single cell suspensions will be obtained. These cells will be stimulated with a pool of antigenic peptides (custom-synthesized PepTivators for RP-specific antigens), followed by intracellular cytokine staining and by multi-color flow cytometry to determine antigen-specific polyfunctional cellular responses (IFN-γ, TNF-α, IL-2, IL-4, IL-17: $CD4^+$ and $CD8^+$ T-cell responses) **(Fig.3)**. _Upon this initial evaluation, both physicochemically and immunologically validated PPZ-MNP vaccines, with RP-specific antigens, will be advanced to RPs, for which if necessary larger size MNPs will be used to achieve the target antigen and adjuvant doses._

The durability of vaccine-induced immune responses and the temperature stability of PPZ MNP vaccines will also be tested in the MNP Core through murine studies using the lead PPZ MNP vaccine platforms that will be advanced to RPs. _To evaluate the longevity of humoral responses_, blood samples will be collected on Week 2, Week 5, Week 8, and then monthly for at least a year. Serum antigen-specific antibody levels and virus-specific neutralization capacity of these antibodies will be determined as described above. _To determine the memory T-cell responses_, mice will be boosted 6 months and 1 year after the primary immunization and then sacrificed five days after the booster dose, vaccine-draining lymph nodes, spleens, and other relevant tissues will be isolated and antigen-specific polyfunctional T-cell responses will be assessed as described above. _To test the stability of PPZ MNP vaccines_, the afromentioned physicochemical and immunological evaluation of PPZ MNP vaccines will be repeated with the lead PPZ MNP vaccine platforms stored at room temperature and 40°C for an extended period of time (1-, 3-, 6-, and 12-month storage), and the results will be compared with those obtained with fresh PPZ MNP platforms. These long-term validation studies of our novel vaccine technology will facilitate the clinical translation of PPZ MNP vaccines, with the further support from Core D, Emergent Biosolutions and Moderna.

Completion of AIM 2 will be marked when both physicochemically and immunologically validated PPZ MNP platforms with RP-specific antigens are advanced to RPs, as well as when the durability of PPZ MNP vaccine-induced immune responses and the thermostability of PPZ MNP vaccines are comprehensively characterized.

Expectations, Potential Issues, and Alternative Strategies. Based on our supporting data, we expect that our established PPZ formulation and MNP manufacturing methods will result in high-quality PPZ MNP vaccine platforms with project-specific viral antigens, which will meet all of our QC pass criteria. In the unlikely event that PPZ MNP vaccines fail to pass the physicochemical validation tests, PPZ and MNP formulations, and processing conditions will be altered to further optimize the PPZ MNP vaccine formulations. Based on our strong preliminary data, we also expect that PPZ MNP vaccines will induce robust and potent antigen-specific immune responses. We expect no insurmountable technical issues with our immunological assays since all of the proposed assays has been validated in our laboratories. One potential issue is the availability of antigen-specific peptide pools to pulse cells for assaying T-cell responses. In the event that custom-synthesized PepTivators may take too long to obtain, we will pulse these cells with the whole protein or use stably transduced dendritic cells (DC2.4) for restimulation. To accommodate the potential dose variations between mice and other animals that will be used in RPs, we will modify the patch size and/or number (if necessary, also the frequency of MNP applications).

Statistical Considerations. To demonstrate the reproducibility of our results with PPZ-MNP vaccines in both sexes, experiments in *AIM 2* will be independently repeated with *female and male* mice. If treatment effects and trends differ significantly between sexes, experiments will be repeated to confirm sex-based differences and reproducibility. To eliminate age as a confounding variable, young adult aged-matched mice (8-14 weeks) will be used for all experiments, and mice will be randomly assigned to masked groups. The aforementioned established QC procedures will eliminate confounding effects of batch-to-batch variability of PPZ MNP vaccine platforms. The statistical aspects will be considered for all aspects of the project. For the experiments involving multiple groups with outcomes at a single time point, results will be analyzed by one-way ANOVA followed by Tukey's multiple comparisons. For time-course experiments, results will be analyzed by two-way mixed ANOVA, followed by one-way ANOVA on treatment effect and Tukey's multiple comparisons. Power analyses were conducted using our preliminary data with PCEP MNP HeV-sG vaccine with significance level $\alpha<0.05$, power $(1-\beta) = 0.8$, and $k=3$-6 pairwise comparisons (for 3-4 groups), minimum sample sizes for statistical significance were determined to be $N = 5$ mice and $N = 6$ mice per group for each independent experiment (at least two independent experiments) for humoral and cellular responses, respectively.

CORE D (Abelson, Geisbert, Gunn and Zeitlin)

EARLY AND IND-ENABLING TRANSLATIONAL RESEARCH FOR VACCINES AND MABS

Core D will leverage the relationship between vaccines and antibodies to optimize the translational activities performed by the Janus team (just a placeholder – *i.e.* duality of vaccines and mAbs). Vaccines and antibodies are inextricably linked:

1. mAbs can help define protective epitopes for a vaccine
2. mAbs can help establish correlates of protection for vaccines
3. Vaccine antigens can be used to discover mAbs
4. mAbs can provide an alternative to a vaccine in immunocompromised populations and in emergency situations where immediate protection is required (*i.e*. there isn’t sufficient time to allow natural host immunity to develop from vaccination)

Developing mAb countermeasures and vaccines simultaneously will allow us to take advantage of natural synergies between the two types of interventions and more efficiently advance superior prototypes (Table 1).

Table 1: Vaccine and mAb translational efforts

Family	Prototype (Y1-3)	Test case (Y4-5)
Arenaviruses	Lassa (Old world), Junin (New world)	Lujo (Old world), Machupo (New world)
Nairoviruses	CCHF	Kasokero, Dugbe
Paramyxoviruses	Nipah, Hendra	Langya, Angavokely and/or Mojiang

Aim 1: Manufacture vaccine antigens and mAbs in support of the RPs and Cores

Small and larger scale (*e.g.* sufficient for stability testing and NHP dosing) will be performed by Mapp Biopharmaceutical and Geneovac to support the efforts of the other Scientific Cores and the Research Projects.

Aim 2: Lead optimization, stability, manufacturability testing, and early process development of subunit vaccines.

Optimization of the lead subunit vaccines (and adjuvants) will result in stable subunit vaccines with favorable manufacturability characteristics. Small scale manufacturing and early-stage process development will be performed. As vaccines are regulated by CBER, all activities will be performed consistent with regulatory expectations for this branch of the

FDA. The Core's vaccine industrial partners' input (Emergent and Moderna) will be integrated into the translational development efforts.

***Aim 3: Identification of correlates of protection, lead optimization, stability and manufacturability testing of mAbs*.**
Together with Dr. Gunn, engineered mAbs (altered N-glycans, Fc mutations for effector functions and extended half-life, multimeric formats and nanobodies from RPx) will be evaluated to correlate mechanisms of action with maximal efficacy. This work, in conjunction with stability and manufacturability assessment, will identify a lead prototype format to transition to early process development. The goal will be to identify a single prototype for long-term intramuscular prophylaxis as well as for intravenous post-exposure prophylaxis and therapy. As mAbs are regulated by CDER, performance of all activities will be as per regulatory expectations.

The PIs of Core D bring decades of experience with preclinical translational efforts on vaccines and mAb countermeasures and are long time collaborators with the other scientists involved in the project.

Core D will work closely with Cores C and E and the Research Projects to coordinate and integrate the translational research being performed in development of the Janus prototypes.

Subject: UTMB/USUHS ReVAMPP Specific Aims draft - DUE Friday 5/12

Good afternoon,

Drs. Geisbert and Broder have requested a one-page rough draft of the Specific Aims page for each Research Project and Core to help with their development of the Overall Research Strategy. Please send your draft by 12pm CST this Friday (5/12).

Thank you,
Sonja

Sonja J. Stutz, MS

ANIMAL MODEL DEVELOPMENT AND PRECLINICAL EVALUATION (SCIENTIFIC CORE E)

1. SPECIFIC AIMS

The main objectives of the Animal Model Development and Preclinical Evaluation Core are to optimize and/or develop animal models for Paramyxoviridae and Bunyavirales and to evaluate vaccines and treatments identified in RP1, RP2, RP4, RP5, and Cores C and D against Paramyxoviridae and Bunyavirales under BSL-3 and/or BSL-4 containment.

The Specific Aims of the Animal Model Development and Preclinical Evaluation Core are to:

Aim 1: Provide resources including a secure repository of well characterized seed stocks of henipaviruses, arenaviruses, and nairoviruses and develop and rescue recombinant viruses.

Aim 2: Develop and/or optimize animal models of henipavirus, arenavirus, and nairovirus infection that faithfully reproduce human disease.

Aim 3: Provide technical expertise and conduct *in vitro* assays.

Aim 4: Provide technical expertise and perform vaccinations, animal challenges, treatments, clinical pathology assays, virology assays, necropsies, and histopathological analysis of tissues.

The Aims will be achieved by the following specific functions to be carried out by the Animal Model Development and Preclinical Evaluation Core PI and personnel:

1. Maintain records of well characterized Paramyxovirus and Bunyavirales seed stocks including background history, passage history, genomic information, periodic monitoring of titer, mycoplasma testing, endotoxin testing, and sterility testing.
2. In collaboration with RP2 develop a reverse genetics system to rescue recombinant Langya virus (do we also propose other viruses?).
3. Perform *in vitro* virus neutralization assays; optimize assays for new viruses.
4. Develop and/or optimize animal models for strains or variants of henipaviruses, arenaviruses, and nairoviruses to fill gaps where no models exist; make these models available to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers.
5. Generate tools including inactivated samples from infected animals and immune reagents obtained from animal studies and provide to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers.
6. Assist Center Investigators in designing animal studies, prepare animal protocols, and obtain IACUC approval of animal studies.
7. Perform animal challenges using well characterized henipavirus, arenavirus, and nairovirus seed stocks to support RP1, RP2, RP4, RP5, and Cores C and D.
8. Perform vaccination and treatment of animals with vaccines and treatments provided by RP1, RP2, RP4, RP5, and Cores C and D.
9. Perform all duties associated with animal challenge studies including monitoring of animals, collection of samples, and necropsies.
10. Perform clinical pathology assays including hematology and clinical chemistry assays.
11. Perform virology assays on blood and/or tissue samples collected from infected animals including viral load by plaque assay and RT-PCR.
12. Perform gross pathology analysis on all animals at necropsy.
13. Perform histopathologic and immunohistochemical analysis on tissues from animals collected at necropsy.
14. Provide all data generated in Core E to Data Management Core B.

The RNA virus that causes the Crimean Congo Hemorrhagic Fever (CCHF) is a tick-borne pathogen of the *Nairovirus* genus, family *Bunyaviridae*. Unlike many zoonotic viruses that are only passed between animals and humans, the CCHF virus can also be transmitted from human to human with an overall mortality rate approaching 30%. Currently, there are no atomic structures for any CCHF virus proteins or for any *Nairovirus* proteins. A critical component of the virus is the envelope Gn glycoprotein, which contains a C-terminal cytoplasmic tail. In other *Bunyaviridae* viruses, the Gn tail has been implicated in host-pathogen interaction and viral assembly. Here we report the NMR structure of the CCHF virus Gn cytoplasmic tail, residues 729–805. The structure contains a pair of tightly arranged dual $\beta\beta\alpha$ zinc fingers similar to those found in the *Hantavirus* genus, with which it shares about 12% sequence identity. Unlike Hantavirus zinc fingers, however, the CCHF virus zinc fingers bind viral RNA and contain contiguous clusters of conserved surface electrostatics. Our results provide insight into a likely role of the CCHF virus Gn zinc fingers in *Nairovirus* assembly.

Recent outbreaks of the Crimean Congo Hemorrhagic Fever (CCHF)[2] virus along with the reported ability of the virus to transfer between humans have raised concerns of a widespread pandemic (1). The virus is transmitted to humans by tick bite or by direct handling of infected animal meat or blood (1, 2). Infection causes a hemorrhagic fever and myalgia resulting in mortality rates approaching 30% (1–3). The virus contains an antisense RNA genome divided into three segments, and named according to lengths as the S, M, and L (for Small, Medium, and Large) segments (4). The viral proteins are the nucleocapsid protein, two membrane glycoproteins Gn and Gc (also referred to as G1 and G2 in other *Bunyaviridae*) (5, 6), a nonstructural protein (NSm) (7), and an RNA polymerase (4). In the mature virion, the Gn glycoprotein contains a 176 residue ectodomain followed by a 24 residue transmembrane region and terminates in a long cytoplasmic tail consisting of ~100 residues (5, 7).

Recent results from other related *Bunyaviridae* viruses suggest the role of the Gn tail in viral assembly. For example, alanine mutagenesis of the cytoplasmic tails of Uukuniemi virus (genus *Phlebovirus*) (8) and Bunyamwera virus (genus *Orthobunyavirus*) (9) affect the ability of virus-like particles (VLPs) to effectively incorporate ribonucleoproteins, thus intimating a role for Gn tails in genome packaging. More recently, the Gn tail of Puumala virus (genus *Hantavirus*) was shown to co-immunoprecipitate with the Puumala nucleocapsid protein (10). These results suggest that the CCHF virus Gn tail plays an equally important role in viral assembly of genus *Nairovirus*.

The sequence of the CCHF virus cytoplasmic tail is somewhat variable in Nairoviruses (~24% identity) and even more so when compared with other Bunyaviruses (12% identity with Hantavirus Gn tails). However, one characteristic feature present in four of the five genera of *Bunyaviridae* is a conserved dual **C**-X-**C**-X-**H**-X-**C** motifs of cysteine and histidine residues with X representing any amino acid (Fig. 1). Others have suggested that the high cysteine content of the CCHF virus Gn tail could be due to extensive disulfide bonding (5). Recently, we reported that the cysteines in the Andes hantavirus Gn tail fold into a novel arrangement of back-to-back classical $\beta\beta\alpha$ zinc fingers (11). Despite low sequence identity between the Gn tail of Nairoviruses and Hantaviruses, the spacing of the dual CCHC motif in the CCHF virus most closely resembles that of Hantaviruses, suggesting the presence of a similar dual zinc finger structure. To test this hypothesis, we determined the NMR structure of the CCHF virus Gn cytoplasmic tail from residues 729–805. We report here the first known atomic structure of any protein component of the CCHF virus and demonstrate that the high cysteine content of the Gn cytoplasmic tail is partly due to the presence of dual, back to back $\beta\beta\alpha$-type zinc fingers similar to those found in Hantaviruses. Unlike Hantaviral zinc fingers, however, the electrostatic surface of the CCHF virus zinc finger reveals a clear distribution of conserved electrostatic charges. Moreover, we demonstrate using electrophoretic mobility shift assays (EMSA) that these conserved electrostatics may play a role in forming a surface for binding viral

[2] The abbreviations used are: CCHF, Crimean Congo Hemorrhagic Fever; EMSA, electrophoretic mobility shift assay; GB1, the B1 domain of *Streptococcus* protein G; HSQC, heteronuclear single-quantum coherence spectroscopy; NOE, nuclear Overhauser effect; R_1, longitudinal or spin-lattice relaxation rate; R_2, transverse or spin-spin relaxation rate; ZF1, first CCHC zinc binding array, residues 736–756; ZF2, second CCHC zinc binding array, residues 761–780.

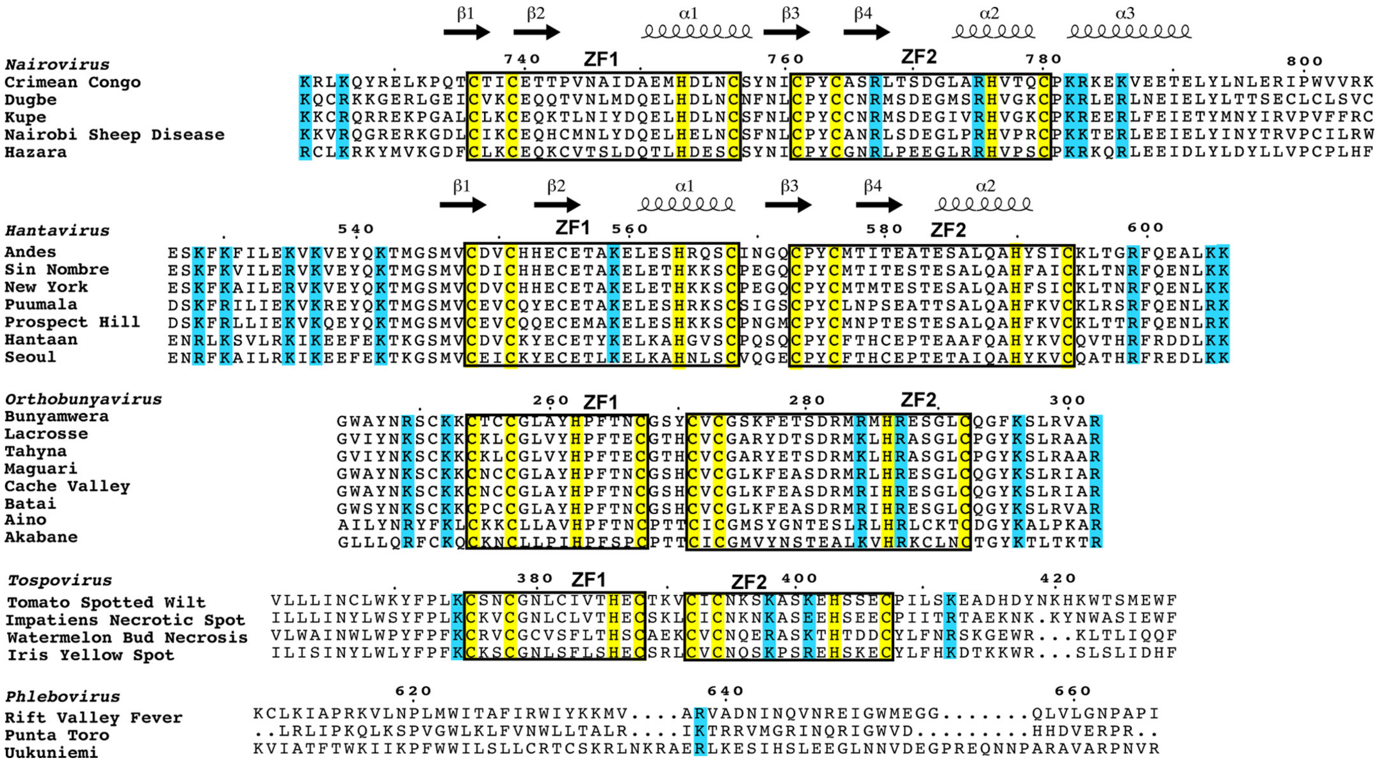

FIGURE 1. **Sequence alignment of the Gn tails of representative members of family *Bunyaviridae*.** *Bunyaviridae* is comprised of five genera: Nairovirus, Hantavirus, Orthobunyavirus, Tospovirus, and Phlebovirus. The conserved CCHC-zinc finger motifs (*boxed*) are present in four of the five genera, with Phlebovirus the lone exception. Another recurring feature is the clustering of conserved basic residues (*in blue*) in the vicinity of the CCHC-motifs. Notably, these basic residues overlap with ZF2 in Nairovirus, Orthobunyavirus, and Tospovirus, but are located outside ZF2 in Hantavirus.

RNA. Together, these data provide insight into the role of the Gn tail in *Nairovirus* assembly.

EXPERIMENTAL PROCEDURES

Protein Expression and Purification—Various constructs of the CCHF virus (strain SPU103/87) Gn cytoplasmic region (spanning residues 719–819) were subcloned from a synthetic gene (GenScript) into the expression vectors pDZ1 and pDZ3 (12), which expressed His$_6$-tagged GB1 fusion proteins with TEV protease cleavage sites. For NMR structure determination, the soluble Gn construct spanning residues 729–805 (Gn$^{729-805}$) was expressed and purified under native conditions following the method reported previously for the Andes hantavirus zinc finger domain (11). Briefly, ^{15}N- and ^{15}N/^{13}C-labeled proteins were expressed in *Escherichia coli* BL21(DE3) grown in 1 liter M9 minimal media supplemented with 0.1 mM $ZnSO_4$ before and after induction. Cells were grown at 37 °C, induced with 1 mM isopropyl-β-D-thiogalactopyranoside at A_{600} ~0.8, and cell growth was continued in a 15 °C shaker incubator overnight (to a final A_{600} ~2.0). Cells were harvested by centrifugation, resuspended in buffer A (20 mM Tris-HCl pH 8.0, 20 mM NaCl, 1 mM DTT, 0.1 mM $ZnSO_4$), and lysed by sonication. Cellular debris was removed by centrifugation, and to the supernatant was added one-tenth volume of 1% polyethyleneimine (pH 8) to precipitate the nucleic acids. Following centrifugation, the supernatant was bound to a 40 ml of Q column (GE Healthcare) and eluted with a 280 ml linear gradient of buffer B (20 mM Tris-HCl, pH 8.0, 0.5 M NaCl, 1 mM DTT, 1 mM $ZnSO_4$). For TEV protease digestion, fractions containing the fusion protein were pooled and dialyzed at 25 °C overnight in buffer (50 mM Tris-HCl pH 8.0, 20 mM NaCl, 1 mM DTT, 1 mM $ZnSO_4$) with 0.16 mg recombinant TEV protease (13) per 10 ml of fusion protein. The TEV digestion mixture was dialyzed back into buffer A and passed again through a 40 ml Q column (GE Healthcare). The GB1 tag (theoretical pI of 5.6) was retained on the column while Gn$^{729-805}$ (theoretical pI of 8.6) was present in the flow-through. The 50 ml flow-through fraction was concentrated using Ultra-15 centrifugal filters (Amicon) and dialyzed in NMR buffer (10 mM $NaPO_4$ pH 7.0, 10 mM NaCl, 1 mM DTT, 0.1 mM $ZnSO_4$). The Gn$^{729-805}$ construct retained three residues (Gly-His-Met) cloning artifacts at the N terminus.

NMR Spectroscopy—NMR data were acquired at 25 °C using a Bruker Avance 800 MHz spectrometer equipped with a cryoprobe, processed with NMRPipe (14), and analyzed with NMRView (15). Backbone assignments were obtained from two-dimensional ^{1}H-^{15}N HSQC (16) and three-dimensional HNCA (17), CBCA(CO)NH (17), and HNCACB (18). Secondary structures were identified from the Cα, Cβ, and Hα chemical shifts (19). Side chain assignments were obtained from two-dimensional ^{1}H-^{13}C HMQC (20), three-dimensional HBHA(CO)NH (21), and three-dimensional ^{13}C-edited HMQC-NOESY (22) (t_{mix} = 120 ms). The histidine ring nitrogen atoms coordinated to Zn^{2+} ions were identified from two-dimensional ^{15}N HMQC (23) using a nitrogen sweep width of 160–230 ppm. NOE (nuclear Overhauser effect) crosspeaks were identified from three-dimensional ^{15}N-edited NOESY-

HSQC (24) (t_{mix} = 120 ms) and three-dimensional ^{13}C-edited HMQC-NOESY (22) (t_{mix} = 120 ms).

Backbone ^{15}N relaxation parameters were acquired on a 0.5 mM ^{15}N-labeled sample in NMR buffer. The steady-state heteronuclear {^1H}-^{15}N NOE was acquired as a pair of two-dimensional datasets in an interleaved manner (where portions of each two-dimensional spectrum were acquired sequentially until both datasets were completed) (25). The first two-dimensional dataset contained a 3-s proton saturation (achieved with a series of 120° pulses) whereas the second two-dimensional dataset contained a 3-s delay. The heteronuclear {^1H}-^{15}N NOE was calculated as the ratio of the intensities for each peak in the two datasets. Each two-dimensional dataset was acquired with 2048 (^1H) × 128 (^{15}N) complex points, 32 scans per point, and a 5 s recycle delay. Error bars were estimated using the standard deviation of the background signal of each spectrum. The ^{15}N backbone relaxation rates R_1 and R_2 were acquired as described (26). The time delays used to determine R_1 were 10, 60, 120, 240*, 400, 900, and 1100 ms, and the time delays used to determine R_2 were 20, 40*, 50, 60, 70, 90, 100, 120, and 150 ms (asterisk denotes spectra acquired in duplicate to estimate reproducibility). Peak intensities were obtained from NMRView (15) and fitted using GNUPLOT (27). Deviations from fitting were reported as error bars. Because of peak overlap, residues 749, 787, 791, and 796 were not used in the analysis.

Structure Calculation—The protocol used for NMR structure calculation has been described previously (11). Briefly, unique NOE distance restraints were classified into upper bounds of 2.7, 3.5, 4.5, and 5.5 Å and lower bound of 1.8 Å based on peak volumes. Backbone dihedral angles in the α-helical regions identified by the secondary Cα, Cβ, and Hα chemical shifts (19) were restrained to φ (−60 ± 20°) and ψ (−40 ± 20°). Initial structures were generated using CYANA (28), followed by molecular dynamics and simulated annealing in AMBER7 (29); first *in vacuo*, then with the generalized Born (GB) potential. Initial structural calculations were performed in CYANA without the Zn^{2+} restraints to confirm that the zinc finger domain will fold from NOE-derived restraints only. Once the topology of the Zn^{2+}-coordinated residues were confirmed, subsequent CYANA structure calculations used distance restraints that imposed tetrahedral Zn^{2+}-coordination to Cys and His residues (22). Iterative cycles of AMBER calculations followed by refinement of NMR-derived restraints were performed until the structures converged with low restraint violations and good statistics in the Ramachandran plot. A family of twenty lowest energy structures were analyzed using PROCHECK (30) and molecular graphics were generated using PYMOL (31). The surface electrostatic potentials were calculated using APBS (32) and visualized in PYMOL (31).

In Vitro Transcription—A DNA oligonucleotide representing the M genomic segment panhandle was assembled by PCR primer extension and used for *in vitro* transcription. *In vitro* transcription was carried out following manufacturer's protocol (MAXIscript Kit, Ambion). Briefly, a 20-μl reaction was carried out for 1.5 h (37°) and terminated by adding 2 μl 0.25 M EDTA and heating to 90° followed by rapid cooling on ice. Reaction mixtures were then treated with DNase I and subjected to ethanol precipitation. The RNA transcripts were resuspended in RNase-free ddH_2O and analyzed for purity on a native 12% acrylamide gel stained with SYBR Green II dye (Invitrogen).

RNA Binding Assays—To assess protein-RNA binding by gel electrophoresis, RNA transcripts were incubated on ice for 15 min with increasing amounts of either CCHF virus $Gn^{729-805}$ or Andes hantavirus $G1^{543-599}$ in binding buffer (30 mM $NaPO_4$, 30 mM NaCl, pH 7.4). Samples were mixed with one-half volume 50% glycerol and loaded onto a native 12% acrylamide Tris borate gel. The gel was run in a cooling water bath at 90 V for 1 h in Tris borate buffer, pH 8.3 and visualized by staining with SYBR Green II dye. For nucleic acid size determination, each gel included a 100 bp DNA ladder (NEB, NO467S).

CD Spectroscopy—CD spectra were collected in triplicate at 25° on a JASCO J-815 Spectro-polarimeter using a scanning speed of 50 nm/min. Protein concentrations were kept at 1 μM in buffer (10 μM $NaPO_4$, 10 μM NaCl, 0.1 mM $ZnSO_4$). EDTA and $ZnSO_4$ titrations were applied to the same sample.

RESULTS

Protein Expression and Purification—Our previous work with Hantavirus glycoprotein cytoplasmic tails indicates expression of the tail is toxic to *E. coli* (11). Therefore, all constructs of the CCHF virus Gn cytoplasmic tail were expressed as GB1 fusion proteins. The GB1 tag contained His_6 for nickel affinity purification and a TEV protease cleavage site to recover the native Gn zinc finger domain. The fusion protein was expressed in soluble form in *E. coli*, purified under native conditions, and digested with TEV protease to obtain the Gn zinc finger domain. Longer constructs comprising the entire predicted cytoplasmic tail ($Gn^{719-819}$) expressed as insoluble inclusion bodies. $Gn^{729-819}$, which was missing the first ten residues following the transmembrane region, expressed as soluble protein but with low yield. $Gn^{729-805}$ represented the longest construct containing the conserved $\mathbf{C}$-X_2-$\mathbf{C}$-X_{11-12}-$\mathbf{H}$-X_3-$\mathbf{C}$ (where X is any amino acid) that also expressed in high enough yield to give high resolution NMR data.

Zn^{2+} Is Required for Proper Folding—To examine the reliance of Zn^{2+}-coordination on the proper folding of the CCHF virus Gn tail, we recorded the two-dimensional ^{15}N HSQC of the $Gn^{729-805}$ in the presence of 4 mM EDTA (Fig. 2*A*). The spectrum in the presence of EDTA is collapsed between ppm values of 6.5 and 8.6, whereas the folded spectrum in the absence of EDTA is well dispersed between 6.5 and 9.3 ppm. Narrowing of the spectrum suggests a loss of tertiary structure upon removal of Zn^{2+}, indicating the requirement for Zn^{2+} binding in folding of the domain. A similar titration using circular dichroism (CD) spectroscopy demonstrates that the presence of EDTA causes a downward spectral shift, indicating a transition toward an unfolded protein (Fig. 2*B*). Here we also demonstrate that the addition of Zn^{2+} ion back into the sample recovers the trace of the original native spectrum. Therefore, Zn^{2+} is required for proper folding of the CCHF virus Gn tail.

NMR Structure Determination—CCHF virus $Gn^{729-805}$ showed a well dispersed two-dimensional ^1H-^{15}N HSQC (Fig. 3*A*). Complete backbone assignments were obtained from three-dimensional HNCA, CBCA(CO)NH, HNCACB, and ^{15}N-edited NOESY-HSQC. The C^{α}, H^{α}, and C^{β} secondary chemical shifts (Fig. 3*B*) showed the presence of three short

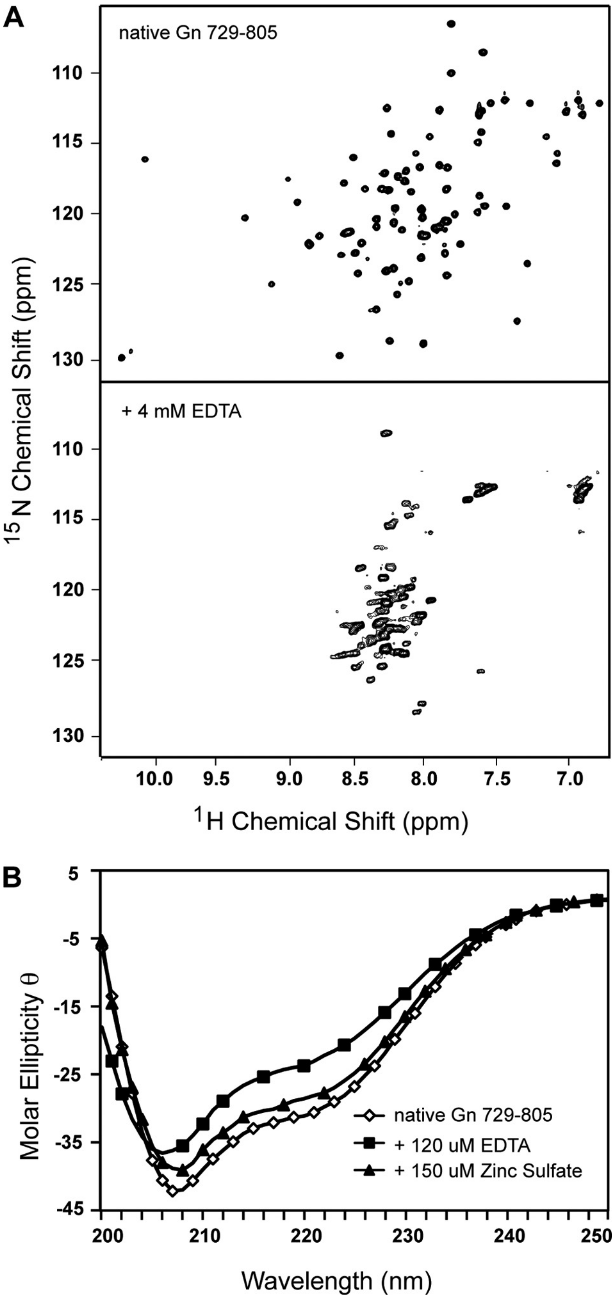

FIGURE 2. **CCHF virus Gn zinc finger domain (residues 729–805) relies on Zn^{2+} for proper folding.** Addition of 4 mM EDTA to a sample of ^{15}N-labeled $Gn^{729-805}$ effectively narrows the HSQC spectrum into a characteristic of an unfolded protein (*A*). Likewise, addition of a metal chelator causes a downward shift at 208 nm in the CD spectra toward random coil (Y axis: molar ellipticity θ per residue, deg·cm^2 dmol^{-1}residue^{-1} × 10^4) (*B*). Titration of zinc sulfate back into the sample recovers the original CD trace (*B*).

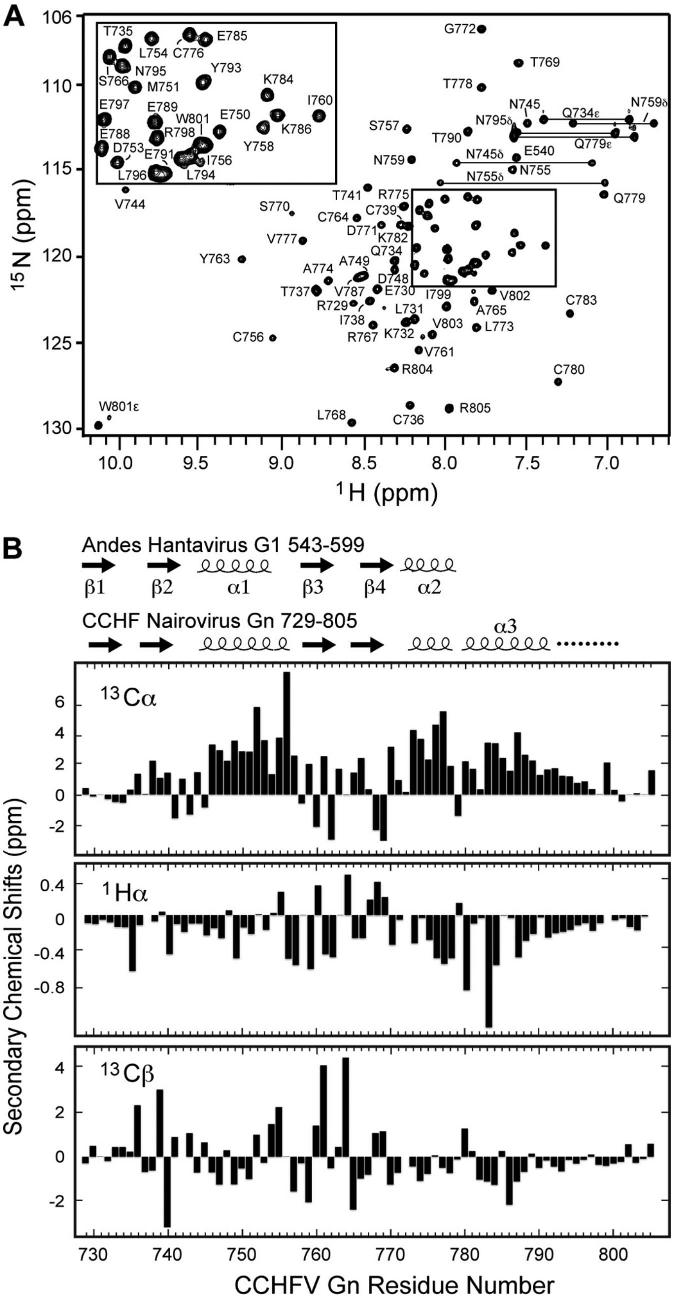

FIGURE 3. The CCHF virus Gn zinc finger yielded a well dispersed two-dimensional ^{1}H-^{15}N HSQC spectrum (*A*). The smaller peak in the tryptophan (*W801*) side-chain suggested a minor conformation of the tryptophan ring possibly due to ring flip-flop. Secondary chemical shifts for ^{13}Cα, ^{1}Hα, and ^{13}Cβ suggest the presence of three short α helices interspersed with two short β hairpins (*B*).

α-helices with an intervening random coil region between the second and third helix. Two more regions in random coil orientations flanked the central sequence of the domain as indicated by the heteronuclear {^{1}H}-^{15}N NOE (Fig. 4*C*). Side chain assignments were completed using two-dimensional ^{1}H-^{13}C HMQC, three-dimensional HBHA(CO)NH, and three-dimensional ^{13}C edited HMQC-NOESY. There were six invariant cysteine and two histidine residues (His-752 and His-776) in $Gn^{729-805}$ (Fig. 1), all of which were involved in Zn^{2+} coordination. Long distance NOE's confirmed that His-752 and His-776 were involved in Zn^{2+} coordination. Notably, His-752 Hϵ1 shares an NOE with Cys^{736} Hβ′s. Likewise, His-776 Hϵ1 and Hδ2 share NOEs with Cys-761 and Cys-780 Hβ′s. A two-dimensional ^{15}N HMQC (23) spectrum showed that His-752 and His-776 coordinated Zn^{2+} through the Nδ1 and Nϵ2 atoms (supplemental Fig. S1), respectively. Manual analysis of three-dimensional ^{15}N- and ^{13}C-edited NOESY spectra identified 1193 unambiguous interproton NOE distance restraints. The NOE restraints together with 26 φ and 26 ψ dihedral angle restraints and zinc coordination restrains (Table 1) were used in structure calculation and refinement in CYANA and

AMBER. The 20 low energy NMR structures of Gn$^{729-805}$ converged into a family of structures (Fig. 5) with low restraint violations and good Ramachandran plot statistics (Table 1).

Structure of CCHF Virus Zinc Finger—The NMR structure of Gn$^{729-805}$ reveals a rigid, compact three-helix structure with four short β-strands (Fig. 5). The structure contains a pair of tightly associated, back to back ββα zinc fingers connected by a short four residue linker (Ser^{757}-Ile^{760}) (Fig. 5). The first CCHC-zinc finger array (ZF1) consists of a Zn^{2+} ion coordinated to residues Cys-736, Cys-739, His-752, and Cys-756 and forms the classical ββα zinc finger fold. Cys-736 and Cys-739 form part of a short β-hairpin. Thr-737 and Ile-738 form a loop with Cys-736 and Cys-739 on either side of the hairpin. The structure contains helix α1 formed by Ile-747 to Ser-757 that folds back toward the β-hairpin, forming the ββα zinc finger fold. Cys-756 forms the fourth Zn^{2+}-coordinating residue and is located on the same surface of helix α3 with His-752.

Likewise, the second CCHC-zinc finger array (ZF2) consists of a second Zn^{2+} ion coordinated to residues Cys-761, Cys-764, His-776, and Cys-780 into a classical ββα zinc finger fold. Cys-761 and Cys-764 are positioned on either side of a short β-hairpin. Pro-762 and Tyr-763 form a loop between Cys-761 and Cys-764. The structure is followed by a short helix α2 formed by Leu773-Cys-780 and folded back toward the β-hairpin, forming the ββα zinc finger fold. His-776 is located toward the middle of helix α3, and the final coordinating cysteine (Cys-780) is located at the end of helix α3. Although ZF2 also resembles the classical ββα fold, a minor difference exists when compared with ZF1. The helix α2 of ZF2 is shorter than helix α1 by three residues. This is due to the presence of helix breakers Gly-772 and Pro-781 located at either end of helix α2.

Unlike many classical ββα zinc fingers which form independently folded domains like "beads-on-a-string," the two CCHF virus zinc fingers were tightly stuck together, with over 65 NOEs observed between ZF1 and ZF2. These NOEs fix the relative orientation of ZF1 with respect to ZF2. Among these NOEs, the strongest were observed between Met-751 (ZF1) and Tyr-763 (ZF2), Cys-739 (ZF1) and Ala-774 (ZF2), His-752 (ZF1) and Val-777 (ZF2), and Thr-741 (ZF1) and Val-777 (ZF2).

In addition to the two classical ββα fold zinc fingers, the structure contains an additional helix, helix α3, formed by Lys-782 to Glu-791 that packs against the dual zinc finger fold. A hydrophobic interaction between Val-744 of ZF1 and Val-787 keeps helix α3 pinned to the core structure. The orientation of helix α3 to ZF2 is partially determined by the helix breaker Pro-781, the residue immediately following ZF2. Pro-781 is 100% identical among Nairoviruses (Fig. 1) and serves as a kink between helix α2 and α3. Strong Cys Cα to Pro-718 Cδ NOEs indicated a trans proline isomer. The C-terminal 13 residues (Leu-792 to Lys-805) are primarily unstructured. NOEs between Ile-799 Cγ2 and Met-751 Cγ indicate the unstructured tail is pinned to the rest of the structure.

The ^{15}N backbone relaxation rates (R_1 and R_2) as well as the heteronuclear {^{1}H}-^{15}N NOE (Fig. 4) showed that the ZF1, linker (residue 757–760), and ZF2 regions behave with nearly similar amide backbone dynamics. The average R_1 values for ZF1, ZF2 and linker regions were well within each other, with values of 1.60 (+ 0.15), 1.81 (+ 0.40), and 1.65 (+ 0.04) s^{-1}, respectively (Fig. 4*A*). ZF1 and the linker had essentially similar R_1 values, however, within ZF2, the R_1 values increased for residues 770 and 771 of the loop connecting β4 and α2, indicating increased mobility of this region. Likewise, the average R_2 values for ZF1, ZF2, and linker regions were similar to each other, with values of 13.8 (+ 1.8), 13.8 (+ 1.8), and 15.6 (+ 3.1) s^{-1}, respectively. Interestingly, the first linker residue, Ser-756, showed increased R_2 without a corresponding increase in R_1, which suggested chemical exchange on the μs-ms timescale for

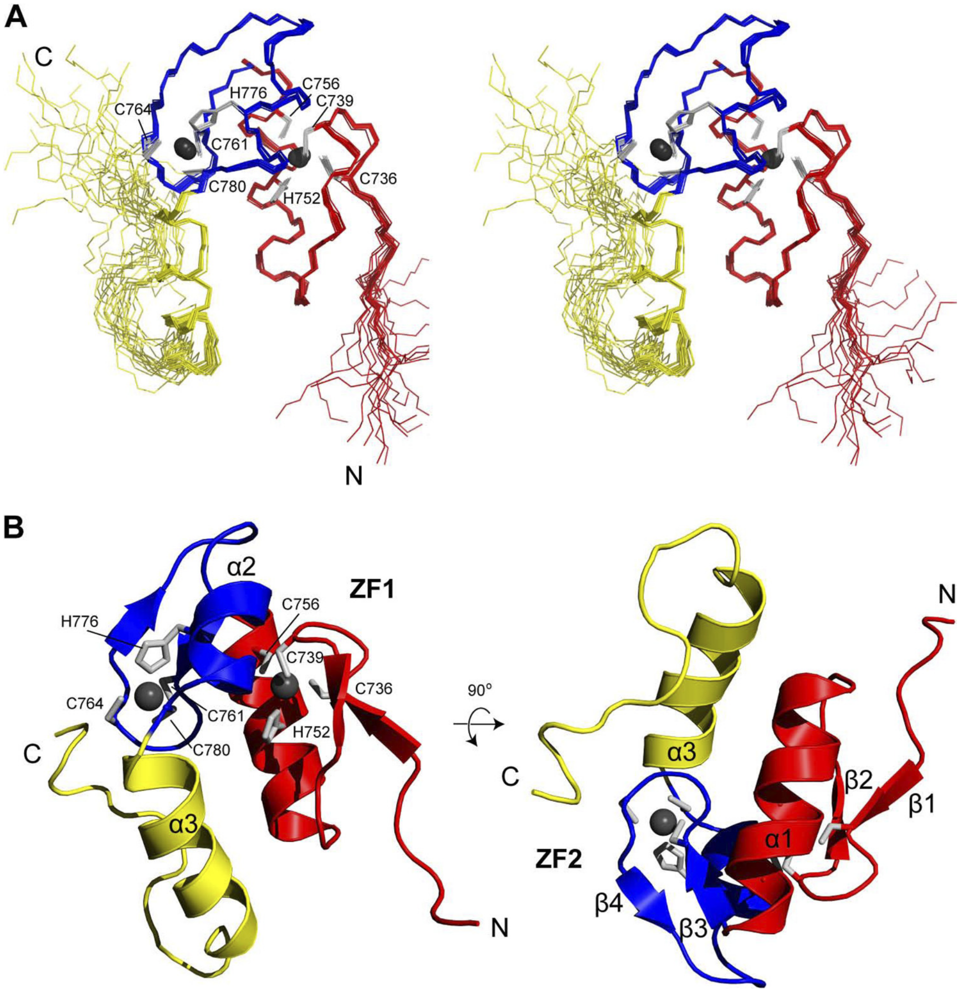

FIGURE 5. **NMR structure of CCHF virus Gn tail zinc finger.** Stereoview of the superposition of 20 lowest energy NMR structures of CCHF virus Gn zinc finger (*A*). CCHF virus Gn zinc finger domain folds into a compact three-helix structure consisting of two back-to-back $\beta\beta\alpha$ zinc fingers with helix $\alpha3$ pinned underneath the core zinc finger structure (*B*).

Ser-756. The average heteronuclear $\{^1H\}$-^{15}N NOE for the ZF1, linker and ZF2 regions was 0.8 (Fig. 4*C*), indicating reduced flexibility for the dual zinc finger domain including the linker region. In brief, the NMR amide backbone relaxation parameters (Fig. 4) confirmed that the two zinc fingers essentially tumble as one entity, that the linker between the two zinc fingers was rigid and tumble at the same rate as the zinc fingers, and that the loops and tails were flexible.

CCHF Virus Zinc Finger Contains Conserved Electrostatic Surfaces—Analysis of the surface electrostatics of the CCHF virus $Gn^{729-805}$ reveals clustering of positive and negatively charged surfaces on opposite faces of the structure (Fig. 6). Surface residues Glu-740, Glu-750, and Asp-753 of ZF1 converge with surface residues Glu-789 and Glu-791 of helix $\alpha3$ and Glu-797 of the C-terminal unstructured region to form a large, nearly contiguous negatively charged surface. Similarly, Arg-767 and Arg-775 of ZF2 converge with Lys-782, Lys-784, and Lys-786 of helix $\alpha3$ and Arg-798 of the C-terminal unstructured region to form a large contiguous positively charged surface. Of the charged surface residues, only Glu-750, Glu-797, Lys-784, and Arg-798 are not conserved in Nairoviruses. Most of the surface electrostatics, therefore, is a conserved feature of the Nairoviruses zinc finger domain.

CCHF Virus Gn Tail Binds RNA—RNA electrophoretic mobility shift binding assays (EMSA) were carried out using two different proteins: the zinc finger domain of CCHF virus consisting of $Gn^{729-805}$, and the zinc finger domain $G1^{534-599}$ of the related Andes hantavirus. The RNA sequences used in the EMSA were a 58-mer RNA of the Andes hantavirus and a 51-mer RNA of the CCHF virus (Fig. 7*A*). Both RNA sequences contain 23–26 nucleotides at the 5′ and 3′ termini of the M genomic segments of the Andes and CCHF viruses, and these 5′ and 3′ strands are complementary to each other and are expected to form into hairpin-like panhandle structures (Fig. 7*A*). On a 12% native acrylamide gel, the Andes hantavirus RNA traveled as a single band consistent with a 58-mer hairpin (Fig. 7*B*), however, the CCHF virus 51-mer RNA migrated as two bands, a higher molecular weight form and a lower band migrating at a size consistent with a 51-mer hairpin (Fig. 7*B*). Incubation of the Andes hantavirus protein with the 58-mer RNA failed to affect the migration of RNA (Fig. 7*B*). The RNA bands in the presence of the Andes hantavirus protein were similar to the free RNA band (Fig. 7*B*). However, incubation of the CCHF virus zinc finger protein notably affected the migration of the CCHF virus RNA, as demonstrated by the appearance of an additional band (marked with *asterisk*, Fig. 7*B*)

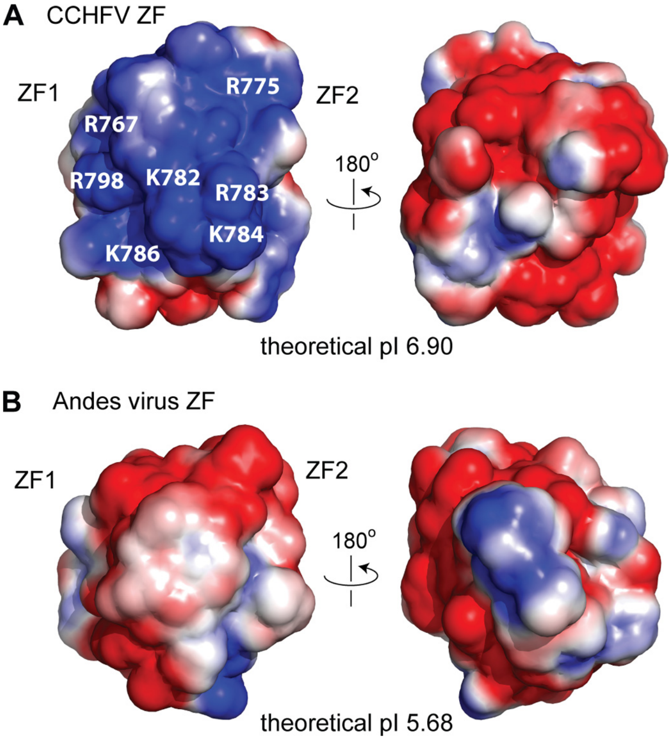

FIGURE 6. **Comparison of the surface electrostatics of the CCHF virus (*A*) and Andes hantavirus (*B*) zinc fingers.** Analysis of the surface electrostatics of the CCHF virus Gn zinc finger reveals a contiguous cluster of basic charges (colored *blue*) that cover the entire half of the structure (*A*). Rotating the structure 180° reveals an equally large cluster of acidic charges (colored *red*) on the opposite face (*A*). Surface electrostatics of the Andes hantavirus zinc fingers (PDB 2K9H) in the same orientation as the CCHF virus structure (*B*). Notably, the clustering of conserved basic surface in Nairovirus (*A*) is absent in Hantavirus (*B*).

migrating between the hairpin and the higher MW form of the CCHF virus RNA. The protein-RNA complex band was most likely formed between the zinc finger protein and the RNA hairpin. Because the 51-mer CCHFV RNA existed in two forms (the hairpin and the higher MW form), the relative amounts of each form must be in equilibrium and binding of the CCHFV zinc finger protein to the hairpin RNA will also affect the amount of the RNA B form as seen in Fig. 7*B*. We are designing new RNA sequences that will only form hairpins for future studies of the protein-RNA interaction of the CCHF virus zinc finger. Nevertheless, the main conclusion from the EMSA results demonstrated that the CCHF Nairovirus Gn tail (residues 729–805) interacted with RNA whereas the Andes hantavirus G1 tail (residues 534–599) did not.

To test our hypothesis that conserved basic residues in the CCHF virus zinc finger protein may be involved in RNA binding, point mutations were introduced in conserved lysine and arginine residues into aspartic acid and the mutant proteins were used in EMSA. The point mutants K783D, K786D, and R767D retained the ability to bind RNA suggesting these basic residues may not be critical in RNA binding (supplemental Fig. S2*A*). However, the K782D mutation disrupted the protein-RNA interaction, as its shift pattern resembles that of RNA alone. Coincidentally, Lys-782 is located at the kink between helix $\alpha 2$ and $\alpha 3$, and is pointed away from the zinc finger domain (supplemental Fig. S2*B*), suggesting that the kink between helix $\alpha 2$ and $\alpha 3$ may be important for RNA binding interaction of the CCHF virus Gn zinc finger.

DISCUSSION

We report here that an envelope glycoprotein of a Nairovirus contains a dual CCHC-type zinc finger (Figs. 2–5) domain that

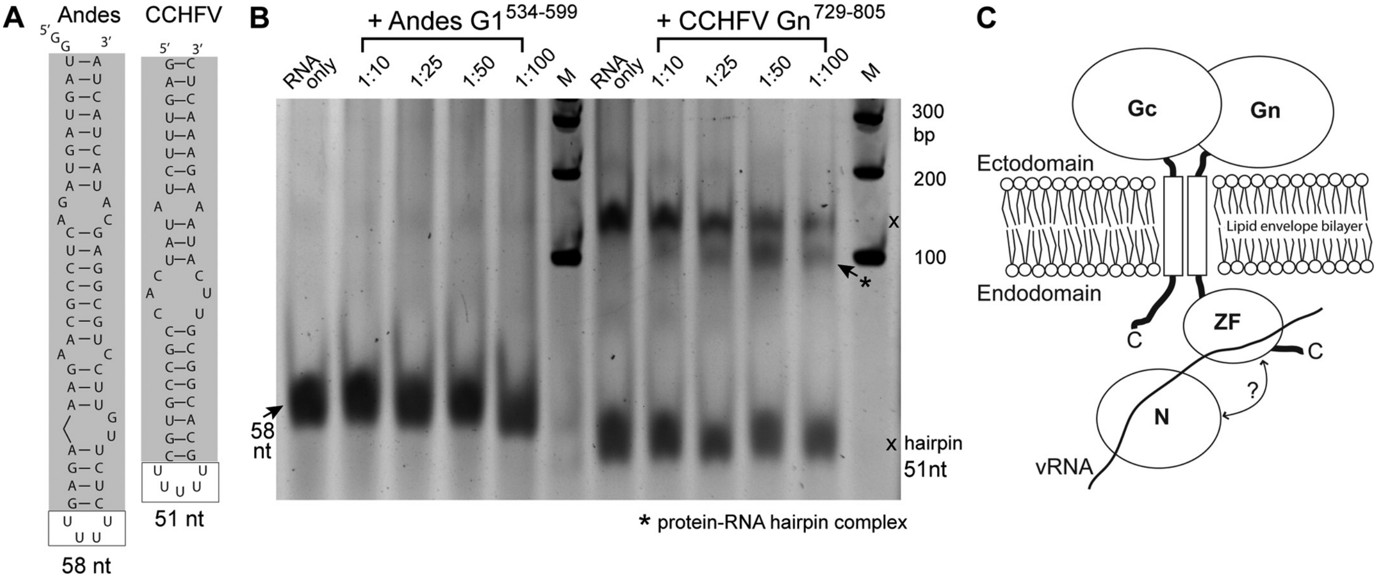

FIGURE 7. **RNA electrophoretic mobility shift assay comparing the Andes Hantavirus and the CCHF virus zinc fingers.** RNA sequences used in the EMSA: Andes Hantavirus RNA (58 nt) and CCHF virus RNA (51 nt) (*A*). CCHF virus RNA traveled in two forms (marked with ×), lower band consistent with a 51-nt hairpin form, and a higher molecular weight band above 100 bp (*B*). While the Andes hantavirus zinc finger fails to alter the mobility of Andes hantavirus RNA, increasing the amount of CCHF virus zinc finger causes the appearance of an additional band (marked with *) for the CCHF virus RNA, thus suggesting a protein-RNA complex (*B*). Each lane contained 0.24 μmol RNA, proteins came from 0.4 mM stock diluted accordingly (*B*). Surface electrostatics combined with EMSA results of the Gn tail provide mechanistic insight into RNP packaging (*C*). We propose a model in which packaging consists of a zinc finger-RNA complex. Studies in related viruses suggest a nucleocapsid, Gn tail interaction, presented here as a possible additional packaging site (*C*).

binds RNA. Although zinc fingers have been known in viruses, in particular, the HIV-1 nucleocapsid protein zinc fingers (33) are critical in RNA packaging and viral assembly, zinc fingers are rarely found in viral envelope glycoproteins. Including the zinc finger in this report, there are currently only three known structures of viral envelope glycoprotein zinc fingers. First is the zinc finger of the Hantavirus G1 envelope glycoprotein (11), and second is the zinc finger of the Junin virus envelope glycoprotein (34) (also an RNA virus, of family *Arenaviridae*). In all three cases, the cytoplasmic tails of the envelope glycoproteins contain the zinc finger domains. The Junin virus zinc fingers (34) form a unique fold that do not show any structural nor sequence similarity with the Nairovirus and Hantavirus zinc fingers. Although the Nairovirus and the Hantavirus zinc fingers (11), which both belong to family *Bunyaviridae* (Fig. 1), show an overall similar global fold (supplemental Fig. S3), they also have major structural differences (Fig. 6) and properties (Fig. 7).

Key Differences between Nairovirus and Hantavirus Gn Zinc Fingers—Examination of the surface electrostatics of the CCHF virus Gn tail reveals key differences when compared with the Andes hantavirus structure (Fig. 6). Whereas the CCHF Gn tail displays sharp clustering of conserved charges that form a large contiguous swath on the protein surface, the Andes hantavirus zinc fingers display charges that are predominately negative and apparently randomly dispersed (Fig. 6). The variation in charge conservation is also evident in the sequence analysis (supplemental Fig. S3). Whereas the spacing of CCHC motif is mostly conserved, the spacing between conserved charges is highly variable. The CCHF virus displays conserved negative charges on ZF1 and conserved positive charges on ZF2. The Andes hantavirus sequence, however, displays clustering of conserved positive charges on the sequences flanking the negatively charged core zinc finger structure.

Moreover, the CCHF virus Gn tail contains a structural motif that is absent in the Andes hantavirus structure. Helices $\alpha 2$ and $\alpha 3$ (Fig. 3*B*), residues Leu-773 to Leu-792, form a helix-kink-helix motif due the positioning of the conserved helix breaker Pro-781. While not an uncommon motif, this structural aspect in the CCHF Gn tail forms the core scaffold for a large positively charged surface partly composed of the conserved charges at Arg-775, Lys-782, and Lys-786 (Fig. 6*A*). By contrast, the Andes hantavirus structure contains neither the corresponding proline nor the charges to support a similar motif (Fig. 1). Instead, it contains the non-conserved helix breaker Gly-598 followed by conserved charges exclusively on the C-terminal end of ZF2 (Fig. 1). In this respect, the surface electrostatics of the CCHF virus Gn tail may more closely resemble that of Orthobunyaviruses, with conserved helix breakers flanked by conserved basic charges (Fig. 1). Perhaps not coincidentally, Nairoviruses and Orthobunyaviruses are both arthropod-borne, whereas Hantaviruses are rodent-borne (3). Overall, the general preservation of the fold indicates that the dual zinc finger motif plays a general but important role in the life cycle of both Nairoviruses and Hantaviruses. However, the major differences in the surface electrostatics of the CCHF virus and Hantavirus cytoplasmic tail structures (Fig. 6) also suggests that while general, the function of the tail may be species specific.

Proposed Role in Viral Assembly—Given the data available regarding the *Bunyaviridae* Gn role in viral assembly (8–10), it is likely that the surface electrostatics play an important role in assembly of the CCHF virus, presumably via direct interaction with some component of the ribonucleoprotein. The large positively charged surface of the Gn tail would suggest RNA binding, as is the traditional role for zinc fingers in retroviruses (33, 35). Our EMSA results (Fig. 7) suggest that this may in fact be the case. Using increasing amounts of $\mathrm{Gn}^{729-805}$ revealed the migration of an additional RNA band (Fig. 7*B*), which likely represents a protein-RNA complex consisting of $\mathrm{Gn}^{729-805}$ and the hairpin-like M segment panhandle. While the observed complex is weakly bound and therefore likely to be nonspecific, these results suggest RNA interaction mediated by some of the conserved residues in the Gn tail. Additionally, these results suggest the possibility of an interaction between the Gn tail and the RNA component of the ribonucleoproteins (Fig. 7*C*). A reverse genetics system for studying the CCHF virus has only recently been developed (36), thus allowing testing of this model in the future.

In summary, we present the NMR structure of a zinc finger domain in the Gn tail of the CCHF virus. Currently, this is the only available atomic structure for a protein component of the Nairovirus genus. The global fold of this zinc finger is similar to that of the Hantavirus zinc finger, which represents a unique fold of two classical-type $\beta\beta\alpha$-zinc fingers that are stuck together (in contrast, individual classical $\beta\beta\alpha$-zinc fingers behave as independent domains, like beads-on-a-string). We also demonstrated that the CCHF virus Gn tail binds RNA *in vitro*, thus suggesting the possibility of an interaction between the Gn tail with the viral RNA. Taken together, our results contribute novel mechanistic insight toward understanding the CCHF virus life cycle.

Enveloped viruses utilize the membranous compartments of the host cell for the assembly and budding of new virion particles. In this report, we have investigated the biogenesis and trafficking of the envelope glycoprotein (GP-C) of the Junín arenavirus. The mature GP-C complex is unusual in that it retains a stable signal peptide (SSP) as an essential component in association with the typical receptor-binding (G1) and transmembrane fusion (G2) subunits. We demonstrate that, in the absence of SSP, the G1-G2 precursor is restricted to the endoplasmic reticulum (ER). This constraint is relieved by coexpression of SSP in *trans*, allowing transit of the assembled GP-C complex through the Golgi and to the cell surface, the site of arenavirus budding. Transport of a chimeric CD4 glycoprotein bearing the transmembrane and cytoplasmic domains of G2 is similarly regulated by SSP association. Truncations to the cytoplasmic domain of G2 abrogate SSP association yet now permit transport of the G1-G2 precursor to the cell surface. Thus, the cytoplasmic domain of G2 is an important determinant for both ER localization and its control through SSP binding. Alanine mutations to either of two dibasic amino acid motifs in the G2 cytoplasmic domain can also mobilize the G1-G2 precursor for transit through the Golgi. Taken together, our results suggest that SSP binding masks endogenous ER localization signals in the cytoplasmic domain of G2 to ensure that only the fully assembled, tripartite GP-C complex is transported for virion assembly. This quality control process points to an important role of SSP in the structure and function of the arenavirus envelope glycoprotein.

Arenaviruses are endemic in rodent populations worldwide (53), and infection can be transmitted to humans to cause severe acute hemorrhagic fevers (44, 51). Recurring outbreaks are common in regions of arenavirus endemicity, and therapeutic options to combat arenavirus infection are limited. Phylogenetic analyses divide the arenaviruses into the Old World species, such as Lassa fever and lymphocytic choriomeningitis (LCM) viruses, and the New World species, such as Junín and Machupo viruses. Up to 300,000 infections with Lassa fever virus occur annually in Africa (45), and outbreaks of New World viruses in the Americas are sporadic but routine (51). Recently, infections by LCM virus in transplant recipients have been reported (8). In the absence of effective prophylaxis and treatment, the hemorrhagic fever arenaviruses remain an urgent public health concern.

The arenaviruses are enveloped viruses whose genomes consist of two single-stranded RNA molecules, each of which encodes the ambisense expression of two of the four viral proteins (5, 9). The viral envelope glycoprotein (GP-C) is translated from a genomic-sense mRNA generated from the short (S) genomic RNA, whereas the nucleocapsid protein is translated from the antigenomic-sense mRNA. Similarly, the viral matrix protein (Z) and RNA-dependent RNA polymerase are encoded in an ambisense orientation by the long (L) RNA. During biogenesis, arenaviral particles assemble and bud at the plasma membrane (49, 60). Viral entry into target cells is initiated by GP-C binding to cell surface receptors followed by endocytosis of the virion into smooth vesicles (2). Although α-dystroglycan serves as a binding receptor for the Old World arenaviruses (6), the receptor utilized by the major New World group of arenaviruses is unknown (59). GP-C-mediated membrane fusion is activated upon acidification of the maturing endosome (2, 7, 13, 14) to deposit the virion core into the cell cytoplasm and initiate replication.

The arenavirus envelope glycoprotein complex consists of three noncovalently associated subunits derived from the GP-C precursor: in addition to the typical receptor-binding (G1) and transmembrane fusion (G2) subunits, the complex contains a stable signal peptide (SSP) subunit (4, 18, 65) (Fig. 1). The 58-amino-acid SSP is generated by the cellular signal peptidase and subsequently myristoylated (65). The mature G1 and G2 subunits are generated upon cleavage by the cellular SKI-1/S1P protease (1, 35, 38) in the early Golgi compartment (3). This proteolytic maturation event is essential for membrane fusion activity. The arenavirus G2 is a member of the class I group of viral fusion proteins (25, 64) that orchestrate membrane fusion through the triggered formation of a stable six-helix bundle core (references 16, 17, 32, and 63 and references therein).

A tripartite envelope glycoprotein complex is unusual among viral envelope glycoproteins, and the role of the unique arenavirus SSP subunit has not been fully defined. In the GP-C complex, SSP exists as a transmembrane protein, likely in a type II topology with an extended luminal C terminus (19, 23). The N terminus is modified by myristoylation, which is important for efficient membrane fusion activity (65). Recombinant GP-C constructs in which SSP is replaced by a conventional

FIG. 1. Schematic representation of the Junín virus GP-C glycoprotein and G2 cytoplasmic domain sequences. Amino acids of the Junín virus envelope glycoprotein are numbered from the initiating methionine, and cysteine residues (|) and potential glycosylation sites (Y) are marked. The SSP and SKI-1/S1P cleavage sites and the resulting SSP, G1, and G2 subunits are indicated. Within G2, the C-terminal transmembrane (TM) and cytoplasmic (cyto) domains are shown, as are the N- and C-terminal heptad repeat regions (light-gray shading). A comparison of G2 cytoplasmic domain sequences among arenavirus species is detailed below the schematic. Sequences include the New World isolates Junín (D10072), Tacaribe (M20304), Pichindé (*U*77601), Machupo (AY129248), and Sabiá (YP_089665) and Old World isolates Lassa-Nigeria (X52400), Mopeia (M33879), and LCMV-Armstrong (M20869). The sites used to generate truncations in the Junín virus cytoplasmic tail are indicated by angle brackets and dibasic amino acid sequences are underlined.

signal peptide do not undergo significant proteolytic maturation by the SKI-1/S1P protease (18, 65). In the Old World Lassa fever arenavirus, this defect can be rescued by coexpression of SSP in *trans* (18).

In the present report, we examine the biogenesis of the GP-C complex of the Junín virus, a member of the New World Tacaribe complex of arenaviruses that is responsible for recurring outbreaks of hemorrhagic fever in the pampas grasslands of Argentina. We show that SSP association is required for transport of the G1-G2 precursor from the endoplasmic reticulum (ER) and thereby for proteolytic maturation in the Golgi. In the absence of SSP, the G1-G2 precursor is constrained to the ER by dibasic amino acid sequences in the cytoplasmic domain of G2. Association with SSP overcomes this block to permit transit of the fully assembled complex through the Golgi and to the cell surface. Moreover, our studies suggest that, in addition to modulating trafficking of GP-C, SSP association may also be important for the membrane fusion activity of the GP-C complex. The unique roles for SSP in the arenavirus life cycle may suggest novel strategies towards the prevention and treatment of arenaviral disease.

MATERIALS AND METHODS

Molecular reagents, recombinant vaccinia viruses, and monoclonal antibodies. The GP-C coding region from the pathogenic Junín virus strain MC2 (28) was provided by Victor Romanowski (Universidad Nacional de La Plata, Argentina) and introduced into the mammalian expression vector pcDNA3.1+ as described previously (65). For *trans*-complementation studies (18), the CD4sp-GPC construct in which SSP was replaced by the conventional signal peptide of CD4 (65) was coexpressed with an SSP construct in which a stop codon was introduced following the C-terminal SSP amino acid T58 (SSP-term). A chimeric glycoprotein (CD4ecto) bearing the CD4 signal peptide and ectodomain fused to the transmembrane and cytoplasmic domains of G2 was constructed using the human CD4 cDNA (41) obtained through the National Institutes of Health (NIH) AIDS Research and Reference Reagent Program. Mutations were introduced by QuikChange mutagenesis (Stratagene), and PCR was used to generate truncations and chimeric plasmids. For the cytoplasmic-domain truncation series and in a control cleavage-defective GP-C plasmid (cd-GPC) (65), a C-terminal 15-amino-acid S-peptide (Spep) affinity tag (34) was introduced to facilitate biochemical analysis (65). All constructs were verified by DNA sequencing, and three independent clones typically were tested to ensure consistent phenotypes.

Optimal expression of the Junín virus GP-C gene and its derivatives in Vero 76 cells was achieved using the bacteriophage T7 promoter of the pcDNA3.1 vector and infection by a recombinant vaccinia virus expressing the T7 polymerase (vTF7-3) (24). The vaccinia virus vCB21R-lacZ expressing the β-galactosidase gene under the control of the T7 promoter was used in our analysis of cell-cell fusion (47). These recombinant vaccinia virus reagents were provided by T. Fuerst and B. Moss and C. Broder, P. Kennedy, and E. Berger, respectively, through the NIH AIDS Research and Reference Reagent Program.

Mouse monoclonal antibodies (MAbs) QC03-BF11 (BF11) and GB03-BE08 (BE08) (54), directed against the G1 subunit of GP-C, were kindly provided by Tom Ksiasek and Tony Sanchez (Special Pathogens Branch, CDC, Atlanta, Georgia). The anti-CD4 ectodomain MAb SIM.2 (43, 48) was obtained through the NIH AIDS Research and Reference Reagent Program.

Expression of GP-C and its derivatives. The glycoproteins were expressed and characterized as previously described (64, 65). Briefly, Vero 76 cells were infected with the recombinant vaccinia virus vTF7-3 (24) at a multiplicity of 2 in Dulbecco's minimal essential medium containing 2% fetal bovine serum (FBS) and 10 μM cytosine arabinoside (araC) (31). After 30 min, the cells were washed and transfected with the GP-C expression plasmid using Lipofectamine 2000 reagent (Invitrogen). Metabolic labeling using 32 to 50 μCi/ml of ^{35}S-ProMix (Amersham Pharmacia Biotech) was initiated 6 h posttransfection in methionine- and cysteine-free medium containing 10% dialyzed FBS and 10 μM araC and was continued for 12 to 16 h. Cultures were then washed in physiological buffered saline (PBS) and lysed using cold Tris-saline buffer (50 mM Tris-HCl and 150 mM NaCl, pH 7.5) containing 1% Triton X-100 nonionic detergent and protease inhibitors (1 μg/ml each of aprotinin, leupeptin, and pepstatin). The expressed glycoproteins were isolated from cleared lysates by immunoprecipitation using either the G1-directed MAbs or the CD4-directed MAb SIM.2 and protein A-Sepharose (Sigma). In some experiments, glycoproteins containing the C-terminal Spep affinity tag were isolated using S-protein agarose (Novagen). Isolated glycoproteins were deglycosylated using peptide:*N*-glycosidase F (PNGase F; New England Biolabs). Proteins were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis using NuPAGE 4 to 12% bis-Tris gels (Invitrogen) and the recommended sample buffer containing lithium dodecyl sulfate and reducing agent. Molecular size markers included ^{14}C-methylated Rainbow proteins (Amersham Pharmacia Biotech). Radiolabeled proteins were imaged using a Fuji FLA-3000G imager and analyzed using ImageGauge software (Fuji).

For immunoprecipitation of cell surface glycoproteins, monolayers of metabolically labeled cells were incubated with MAb BE08 or SIM.2 in ice-cold PBS containing 2% FBS and 0.1% NaN_3 for 2 h. Following extensive washing, cells were resuspended by scraping in PBS and lysed as described above. Immune complexes were isolated from cleared lysates using protein A-Sepharose.

Flow cytometry. Vero 76 cells expressing GP-C or its derivatives were labeled using the G1-specific MAb BE08 (54) and a secondary fluorescein isothiocyanate-conjugated goat anti-mouse antibody (Jackson ImmunoResearch). CD4 was detected using a fluorescein isothiocyanate-conjugated mouse anti-CD4 MAb (BD Biosciences). Cells were subsequently stained using propidium iodide (1 μg/ml) and then fixed in 2% formaldehyde (64). Populations were analyzed using a FACSCalibur flow cytometer and CellQuest software (BD Biosciences).

GP-C-mediated cell-cell fusion. The β-galactosidase fusion reporter assay (47) was used to characterize the ability of the envelope glycoproteins to mediate pH-dependent cell-cell fusion (64, 65). Briefly, Vero cells infected with vTF7-3 and expressing the envelope glycoprotein were cocultured with reporter cells infected with vCB21R-lacZ, a recombinant vaccinia virus expressing β-galactosidase under the control of the T7 promoter. The reporter cells were obtained by incubating Vero 76 cells with vCB21R-lacZ at a multiplicity of 2 and allowing the infection to proceed overnight in the presence of 100 μg/ml rifampin (31). The GP-C-expressing cells and reporter cells were cocultured in medium containing both araC and rifampin for 5 h and then subjected to a 30-min pulse of neutral or acidic (pH 5.0) medium. β-Galactosidase expression is induced upon fusion of the effector and reporter cells and was detected, after 5 h of continued cultivation at neutral pH, in cell lysates (Tropix) using the chemiluminescent substrate GalactoLite Plus (Tropix). Cell-cell fusion was quantified using a Tropix TR717 microplate luminometer.

Confocal microscopy. Cells expressing GP-C glycoproteins were harvested by trypsinization 6 h after transfection and reseeded to 8-well chambered cover glasses (Lab Tek II) in medium containing 10 μM araC. After 18 h, cultures were washed in PBS and fixed with 4% formaldehyde for 10 min at room temperature. Following washing and quenching with 50 mM Tris (pH 7.4) in PBS, cultures were either permeabilized in PBS containing 0.1% Triton X-100 and blocked in the same buffer containing 5% FBS (for intracellular staining) or simply blocked in the absence of detergent (for cell surface staining). GP-C glycoproteins were detected using the G1-directed MAb BF11 and an Alexa Fluor 488-conjugated anti-mouse antibody (Molecular Probes) in the appropriate blocking buffer. The Golgi marker giantin was detected using a rabbit polyclonal antiserum (Covance Research Products) and an Alexa Fluor 568-conjugated anti-rabbit antibody (Molecular Probes). Chambers were covered with Slow Fade Gold (Molecular Probes) and visualized using an inverted Nikon TE-300 microscope. Fluorescence was examined using a Bio-Rad Radiance 2000 confocal laser scanning microscope and images were merged using Lasersharp software (Bio-Rad).

RESULTS

SSP association is required for proteolytic maturation. The arenavirus SSP is distinct from conventional signal peptides in that it is retained as an essential subunit of the mature GP-C envelope glycoprotein complex and mediates functions beyond translocation of the nascent polypeptide to the ER (18, 20, 65). We previously showed that a recombinant Junín virus GP-C glycoprotein in which SSP was replaced by the conventional signal peptide of human CD4 (CD4sp-GPC) was unable to undergo efficient maturation by the SKI-1/S1P protease (65), extending similar observations with GP-C of the Old World Lassa fever virus (18). In this Old World virus, the deficiency in proteolytic cleavage in the absence of SSP was reversed by coexpression of SSP in *trans* (18).

To investigate the role of SSP in the proteolytic maturation of the Junín virus GP-C, we determined whether the coexpression of SSP in *trans* could likewise rescue cleavage. In these studies, the Junín virus CD4sp-GPC construct was cotransfected with the SSP-term plasmid encoding the 58-amino-acid SSP. Optimal expression in Vero cells was dependent on T7 RNA polymerase provided by the recombinant vaccinia virus vTF7-3 (24). Cells were metabolically labeled, and GP-C glycoproteins were immunoprecipitated using the G1-directed MAb BE08 (54). Baseline studies were performed using the native GP-C glycoprotein that included its endogenous SSP. Expression of the native glycoprotein resulted in the isolation of a 60-kDa G1-G2 precursor glycoprotein and a heterodisperse smear of G1 and G2 subunits (30 to 35 kDa) (Fig. 2A, top panel). These mature subunits are best resolved following deglycosylation by PNGase F to yield 22- and 27-kDa polypeptides, respectively (bottom panel). The G1 and G2 subunits were absent upon expression of an SKI-1/S1P cleavage-defective glycoprotein (cd-GPC) (65). A GP-C precursor glycoprotein bearing SSP is often detected as a minor species, suggesting incomplete signal peptidase cleavage in transfected cells (20, 23, 65). As previously reported (18, 20, 23, 65), SSP was coprecipitated as part of the wild-type and cleavage-defective GP-C complexes (Fig. 2A, top panel).

Expression of the CD4sp-GPC glycoprotein in the absence of SSP generated the 60-kDa G1-G2 precursor (Fig. 2A, top panel, −SSP) and considerably lesser amounts of the cleaved glycoproteins (bottom panel). By contrast, expression of SSP in *trans* (+SSP) enabled efficient cleavage of the G1-G2 precursor glycoprotein to produce mature G1 and G2 subunits (bottom panel). The relative efficiency of proteolytic maturation of CD4sp-GPC in *trans* was similar to that of the native GP-C glycoprotein. Furthermore, SSP was coprecipitated with the CD4sp-GPC complex (top panel). Thus, coexpression of SSP appears to rescue wild-type assembly and proteolytic processing in the New World Junín virus CD4sp-GPC complex.

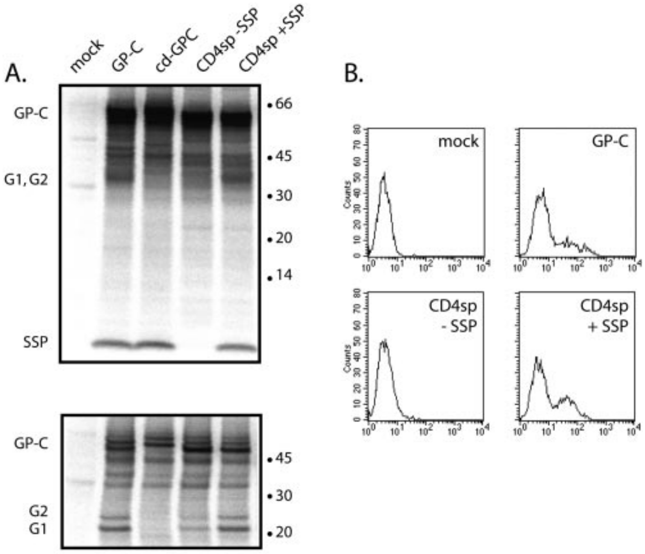

FIG. 2. Coexpression of SSP in *trans* rescues SKI-1/S1P cleavage and cell surface expression of the G1-G2 precursor. (A) Metabolically labeled glycoproteins were immunoprecipitated using the G1-specific MAb BE08 and separated on NuPAGE 4-to-12% bis-Tris gels. The wild-type (GP-C) and SKI-1/S1P cleavage-defective (cd-GPC) glycoproteins are shown for comparison with the CD4sp-GPC construct encoding the conventional signal peptide of human CD4. CD4sp-GPC was expressed alone (−SSP) or with SSP (+SSP). In the bottom panel, the glycoproteins have been treated with PNGase F to resolve G1 and G2 polypeptides. The deglycosylated GP-C polypeptides reveal both the G1-G2 precursor and, in SSP-containing constructs, the pre-GP-C precursor (65); additional species that migrate more slowly than the G1-G2 precursor and with the pre-GP-C precursor are likely products of incomplete deglycosylation. cd-GPC contains a C-terminal S-peptide affinity tag and migrates slightly slower than the other G1-G2 precursors. Known GP-C species are labeled at left; minor unidentified bands are also present. The ^{14}C-labeled protein markers (Amersham Biosciences) are indicated (in kilodaltons). (B) Cell surface expression of GP-C in Vero cells was determined by flow cytometry using the G1-specific MAb BE08 (54). The cell population was subsequently stained using propidium iodide (1 μg/ml) to exclude dead cells. Cells were fixed using 2% formaldehyde and analyzed using a FACSCalibur flow cytometer (BD Biosciences). The histograms plot cell number (counts) versus the fluorescence intensity of MAb binding. Background staining of mock-transfected cells is shown to identify nonexpressing cells in the transfected cell populations.

SSP rescues cell-cell fusion activity in *trans*. To determine whether the *trans*-complemented complex was also able to mediate pH-dependent membrane fusion, we cocultured cells expressing GP-C glycoproteins with Vero target cells infected with the fusion reporter vaccinia virus vCB21R-LacZ expressing the β-galactosidase gene under control of the T7 promoter (47). In this assay, activation of GP-C-mediated membrane fusion by acidic pH (5.0) results in syncytium formation between the effector and reporter cells and expression of β-galactosidase; the enzymatic activity is then monitored using a chemiluminescent substrate (64). As shown in Fig. 3, pH-dependent cell-cell fusion is readily detected using the native GP-C glycoprotein and absent in the cleavage-defective cd-GPC mutant. Cells expressing the CD4sp-GPC glycoprotein in the absence of SSP were unable to mediate cell-cell fusion

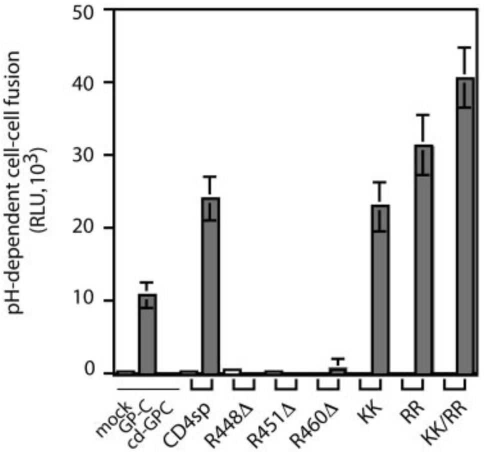

FIG. 3. pH-dependent cell-cell fusion activity. pH-dependent fusion was detected using the recombinant vaccinia virus-based β-galactosidase reporter assay (47) as previously described (64, 65). β-Galactosidase activity was quantitated using the chemiluminescent substrate GalactoLite Plus (Tropix). Relative light unit (RLU) measurements from cultures treated at pH 5.0 are shown after subtraction of background levels from neutral-pH cultures (average background, 1,500 RLU). Control conditions are shown in the underlined bars at left (mock, wild-type GP-C, and cd-GPC). Note that CD4sp-GPC constructs are bracketed in pairs (below the axis) representing the absence (open bars) and presence (gray bars) of SSP. Some bars are not discernible on the scale of the graph. All conclusions were replicated using X-Gal (5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside) staining of parallel cocultures.

(Fig. 3, CD4sp, first of the bracketed pairs of bars). By contrast, coexpression of SSP reconstituted pH-dependent cell-cell fusion activity in the *trans*-complemented CD4sp-GPC complex (second of bracketed pairs of bars) to levels greater than those seen with the native GP-C glycoprotein. Thus, expression of SSP in *trans* can fully restore membrane fusion activity to the Junín virus G1-G2 precursor glycoprotein.

SSP association is required for exit from the ER. To investigate the role of SSP in the biogenesis of GP-C, we examined the intracellular localization of the complex by confocal microscopy. In these experiments, Vero cells expressing the wild-type and CD4sp-GPC glycoproteins were fixed, permeabilized, and immunochemically stained using the anti-G1 MAb BF11 (54) and an Alexa Fluor 488-conjugated secondary antibody. Nonpermeabilized cells were similarly stained to detect GP-C accumulation on the cell surface. As shown in Fig. 4, the native GP-C glycoprotein accumulated in the ER and Golgi-like perinuclear structures (GP-C, permeabilized) and on the cell surface (GP-C, surface). Localization to the Golgi apparatus was confirmed using a rabbit polyclonal antibody directed against an integral Golgi membrane protein, giantin (40), and a secondary Alexa Fluor 568-conjugated antibody. Colocalization of GP-C with the Golgi marker is visualized in yellow in the merged images. Expression of CD4sp-GPC in the presence of SSP resulted in a pattern of localization and transport to the cell surface similar to that of native GP-C (Fig. 4, CD4sp, +SSP). These findings highlight the reconstitution of the GP-C complex upon *trans* complementation with SSP.

In the absence of SSP, however, the G1-G2 precursor of CD4sp-GPC exhibited a diffuse reticulate pattern of intracellular expression consistent with retention in the ER (Fig. 4, CD4sp, −SSP). Notably absent was any concentration of GP-C staining to a morphologically defined Golgi apparatus or specific colocalization with the antigiantin MAb (merged image). The orange in the merged image likely reflects the spatial coincidence of green and red fluorescence rather than specific colocalization to a definable Golgi structure. Also absent was any staining of CD4sp-GPC on the cell surface (surface). The lack of transport to the cell surface is not due to the absence of proteolytic cleavage per se, because the cleavage-site-defective cd-GPC mutant is transported to the cell surface as the wild-type glycoprotein (not shown) (1, 35). Nor did we detect punctate staining in the ER that might suggest misfolding of the G1-G2 precursor in the absence of SSP. The difference in trafficking of the G1-G2 precursor to the Golgi in the presence or absence of SSP likely accounts for the effect of *trans* complementation on proteolytic cleavage (Fig. 2A), consistent with the activation of SKI-1/S1P protease in the *cis*-medial Golgi compartment (10, 21).

Next, we examined the role of SSP in the transport of the GP-C complex to the cell surface by using flow cytometry and the G1-specific MAb BE08. In cell cultures transiently expressing the wild-type GP-C glycoprotein, a clear population of GP-C-expressing cells was evident (Fig. 2B, top right). A comparison of cells expressing CD4sp-GPC in the presence or absence of SSP revealed that the GP-C glycoproteins were present on the cell surface only upon coexpression of SSP (bottom panels). Cell surface accumulation of the *trans*-complemented CD4sp-GPC glycoprotein was comparable to that of the native GP-C glycoprotein. Taken together, these results demonstrate that SSP is essential for GP-C transport to the Golgi and the cell surface. In the absence of SSP, the G1-G2 precursor is localized to the ER.

Transit of a CD4 chimera bearing G2 sequences. To further investigate the role of the G2 subunit in ER localization and the role of SSP in regulating transit to the cell surface, we determined whether control by SSP and the G2 subunit might be transferable to a heterologous cell surface protein. Because the ectodomain of human CD4 forms a soluble and secreted protein (11, 58), we fused the CD4 signal peptide and ectodomain to the transmembrane and cytoplasmic regions of G2. In the CD4ecto construct, the C terminus of soluble CD4 (TPV_{372}) (11) was spliced at the G2 ectodomain sequence TPL_{420}, three residues upstream of D_{424}, that nominally defines the junction with the transmembrane domain.

Cells expressing the CD4ecto chimera or native CD4 were metabolically labeled, and cell lysates were immunoprecipitated using the anti-CD4 ectodomain MAb SIM.2. The CD4ecto chimera was expressed as a 55-kDa glycoprotein that comigrated with native CD4 (Fig. 5A, left panel). Upon coexpression, SSP was found to coprecipitate with CD4ecto (Fig. 5A, left panel). This association was specific to G2 sequences in the CD4ecto glycoprotein; SSP did not bind to native CD4 (when coexpressed) (not shown). Thus, the transmembrane and cytoplasmic domains of G2 are sufficient for SSP binding.

Importantly, transport of the CD4ecto chimera through the Golgi apparatus and to the cell surface was dependent on coexpression of SSP. As shown by immunochemical staining using SIM.2 MAb and confocal microscopy (Fig. 4, CD4ecto, permeabilized), the chimeric glycoprotein was largely con-

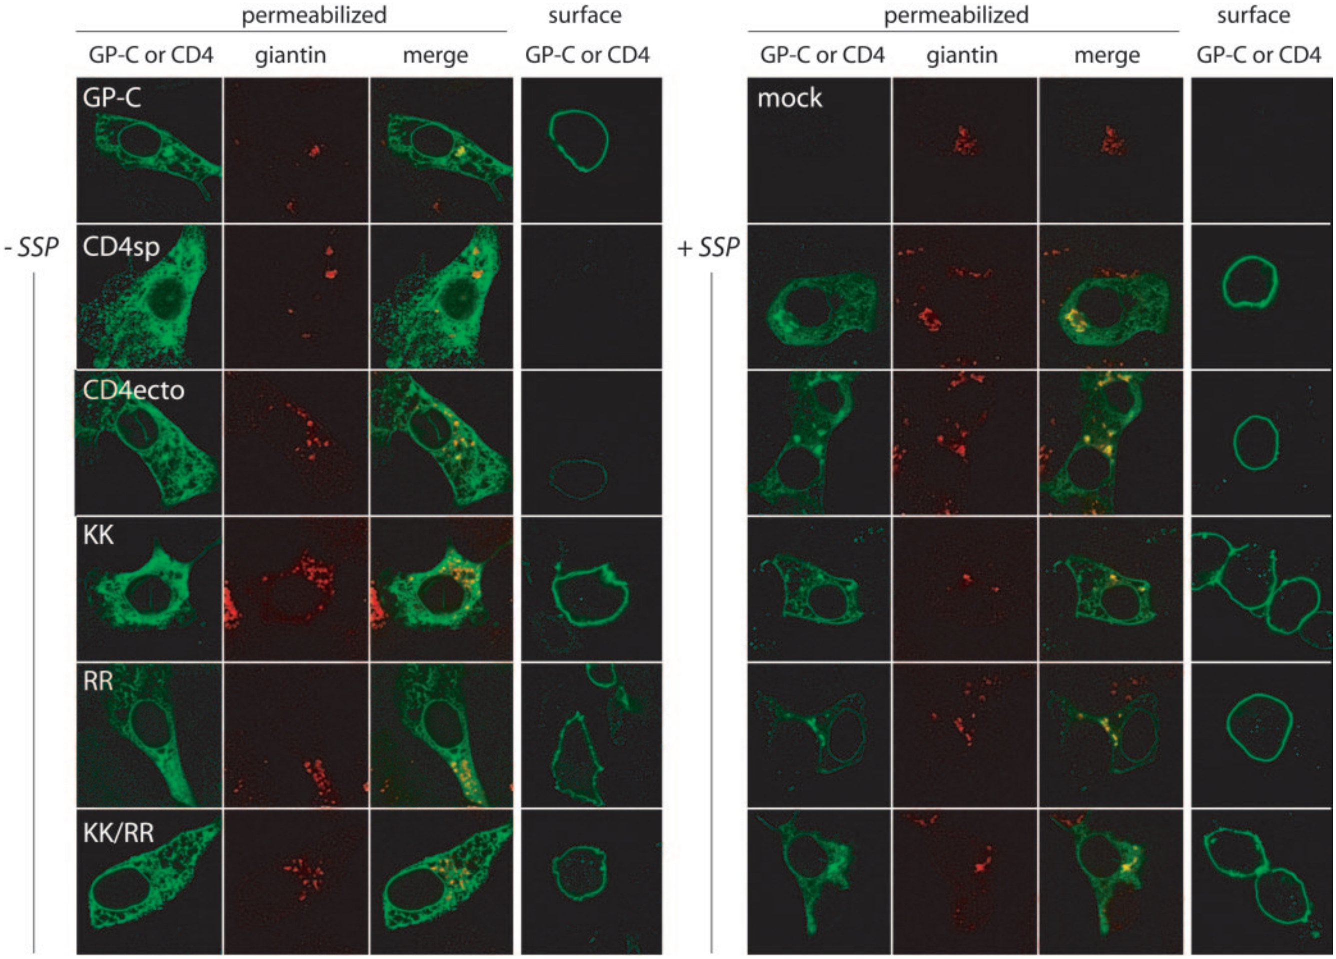

FIG. 4. Intracellular and cell surface visualization of glycoproteins. Confocal images were obtained as described in Materials and Methods. Permeabilized cells were stained in green using either the MAb BF11 (GP-C) or, for CD4ecto, SIM.2 (CD4). Golgi structures were identified using a rabbit polyclonal antiserum and stained in red. Merged images (merge) were created using Lasersharp software. Nonpermeabilized cells (surface) were stained in green using either MAb BF11 or SIM.2. The expressed glycoproteins are indicated in white letters superimposed on the leftmost images. The top row depicts cells expressing native GP-C or mock-transfected cells (all infected with the recombinant vaccinia virus vTF7-3). In subsequent rows, the glycoproteins were expressed either in the absence (−SSP) or presence (+SSP) of SSP. In some images, the Golgi apparatus is vesiculated and dispersed, perhaps due to infection of the cells by vaccinia virus.

strained to the ER in the absence of SSP and failed to colocalize with the Golgi apparatus (−SSP). In addition, only trace amounts of the CD4ecto glycoprotein were detected in the absence of SSP on the cell surface, either through confocal microscopy (Fig. 4, surface) or flow cytometry (Fig. 5B, −SSP). Thus, fusion to the G2 transmembrane and cytoplasmic domains prevented transport of the CD4 ectodomain from the ER.

By contrast, coexpression with SSP resulted in significant localization of CD4ecto in the Golgi (Fig. 4, +SSP) and expression on the cell surface (surface). Mobilization of the chimeric glycoprotein by SSP was confirmed by flow cytometry (Fig. 5B, +SSP). Furthermore, immunoprecipitation studies of CD4ecto expression on the cell surface (Fig. 5A, right panel) identified the surface moiety as the complex of CD4ecto and SSP. Together, these findings demonstrated that the essential elements of ER localization and its control by SSP binding can be recapitulated in a chimeric CD4ecto glycoprotein bearing the transmembrane and cytoplasmic domains of G2.

Analysis of C-terminal truncations in the G2 cytoplasmic domain. Among transmembrane proteins that are retained in the ER, specific localization signals are often encoded within the cytoplasmic domain (references 22, 37, and 62 and references therein). In order to define the determinants in G2 that are required for ER localization, we constructed a series of C-terminal truncations in the cytoplasmic domain of G2. Three arginine residues, spaced 4, 7, and 17 amino acids from the nominal transmembrane domain, were used as endpoints in the truncations (Fig. 1). These positively charged termini were chosen to facilitate anchoring of the truncated CD4sp-GPC glycoprotein in the membrane. The arginine codons were fused to those encoding an S-peptide affinity tag (34) to facilitate analysis of the G2 moiety (65). Metabolically labeled glycoprotein was isolated using the Spep affinity tag and S-protein agarose (Novagen). The truncated CD4sp-GPC glycoproteins (R448Δ, R451Δ, and R460Δ) were well expressed in Vero cells yet failed to coprecipitate significant amounts of SSP (Fig. 6A, top panel). Nonetheless, all three truncated glycoproteins were

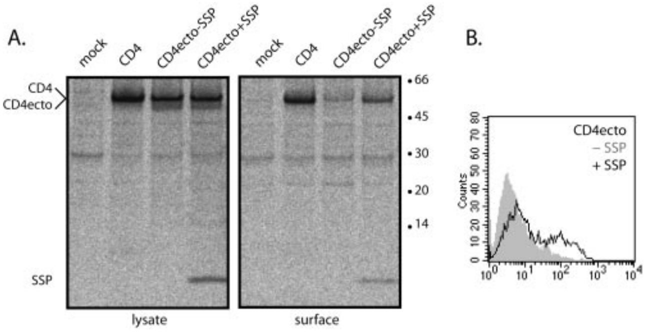

FIG. 5. The chimeric CD4 glycoprotein bearing the transmembrane and cytoplasmic domains of G2 requires SSP for transport to the cell surface. (A) The chimeric CD4ecto construct was expressed alone (−SSP) or with SSP (+SSP) and metabolically labeled. Intact cells were incubated with the anti-CD4 MAb SIM.2 (43, 48) and the cell surface glycoproteins were subsequently isolated from cleared cell lysates using protein A-Sepharose (surface). Intracellular CD4ecto glycoprotein was immunoprecipitated from the post-protein A-Sepharose supernatant using additional SIM.2 MAb (lysate). Mock- and human CD4-transfected cells served as controls. Molecular size markers (in kilodaltons) are as described in the legend to Fig. 2A. (B) Flow cytometry using SIM.2 MAb was otherwise performed as described in the legend to Fig. 2B, and results are plotted similarly. The filled gray (−SSP) and open (+SSP) histograms are overlaid.

subjected to SKI-1/S1P cleavage, in the presence or absence of SSP, to produce truncated and affinity-tagged G2 moieties (Fig. 6A, bottom panel). The relative migrations of the truncated G2 polypeptides correspond to their expected molecular weights but cause them to overlap with the intact G1 polypeptide. The association between G1 and the truncated G2 subunits was separately confirmed by coimmunoprecipitation using a MAb directed to G1 (not shown). By contrast, similar truncations in G2 of the Old World LCM virus were reported to prevent SKI-1/S1P cleavage (35).

Flow cytometry was used to determine whether the truncated Junín virus glycoproteins were also transported to the cell surface without SSP. As shown in Fig. 6B, all three truncation mutants were expressed on the cell surface in the absence of SSP, at levels comparable to the *trans*-complemented CD4sp-GPC glycoprotein (Fig. 2B). Truncations in the context of CD4ecto likewise enabled transport from the ER (not shown). In the LCM virus (35), the truncated GP-C was also expressed on the cell surface. Taken together, these results suggest that amino acid sequences within the cytoplasmic domain of G2 are important in constraining the G1-G2 precursor to the ER. The cytoplasmic region is also important for SSP association.

We have demonstrated that GP-C glycoproteins bearing truncations in the cytoplasmic domain of G2 can be proteolytically processed and transported to the cell surface in the absence of SSP. Surprisingly, however, none of the truncated complexes was able to mediate pH-dependent cell-cell fusion (Fig. 3). It is possible that this failure may be due to insufficient cleavage or transport of the truncated glycoproteins. Alternatively, the failure may reflect a requirement for either SSP or the cytoplasmic domain of G2 for membrane fusion activity.

Dibasic amino acid sequences participate in ER localization. Sequence analysis of the G2 cytoplasmic domain revealed conserved motifs that may be involved in protein trafficking and ER localization. In particular, dibasic amino acid sequences such as the canonical KKXX and RXR motifs are widely utilized in the retrieval of transmembrane proteins to the ER (see references 22, 37, and 62 and references therein). The cytoplasmic domain of Junín virus G2 contains two related dibasic sequences: KKPT$_{479}$ and a C-terminal RRGH$_{485}$. Variants of these sequences appear in other arenavirus G2 proteins (Fig. 1). To assess the potential role of these sequences in ER localization, we mutated the two basic amino acids at each site to alanines, both individually (KK and RR glycoproteins) and as the double mutant (KK/RR).

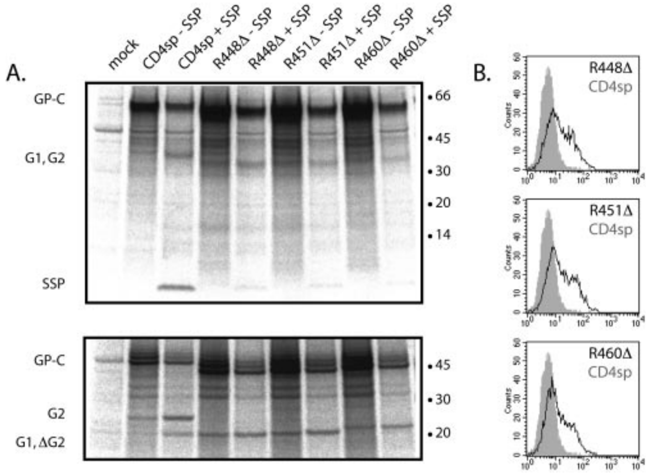

FIG. 6. Truncations to the cytoplasmic domain of G2 ablate SSP binding yet enable transport to the cell surface. (A) The wild-type and truncated CD4sp-GPC glycoproteins (R448Δ, R451Δ, and R460Δ) were expressed alone (−SSP) or with SSP (+SSP). Metabolically labeled glycoproteins were precipitated using the C-terminal Spep affinity tag and S-protein agarose (Novagen) and analyzed as described in the legend to Fig. 2. The G1 and G2 glycoproteins are best resolved following deglycosylation with PNGase F (bottom). Note that the truncated G2 moieties (ΔG2) migrate near the wild-type G1 polypeptide; coassociation between G1 and ΔG2 was formally demonstrated by immunoprecipitation using anti-G1 MAb BF11, which coprecipitated ΔG2 (not shown). Although coprecipitation of SSP was markedly reduced with the truncated glycoproteins, trace amounts could be discerned upon darkening of the image (not shown). This low level of SSP association is judged to be insignificant, as the properties of the truncated glycoproteins are independent of SSP coexpression. Molecular size markers (in kilodaltons) are as described in the legend to Fig. 2A. (B) Cell surface expression of the truncated glycoproteins was determined by flow cytometry as described in the legend to Fig. 2B, and results are plotted similarly. Note that expression of the wild-type CD4sp-GPC glycoprotein (gray histograms in all three panels) is compared with that of the truncations (open histograms), all in the absence of SSP.

Immunoprecipitation studies of metabolically labeled whole-cell lysates revealed that all of the mutant CD4sp-GPC glycoproteins were able to associate with SSP (Fig. 7A, top panel). Neither of the dibasic sequences was essential for SSP binding. *trans* complementation with SSP enabled wild-type levels of cell surface expression (Fig. 7B, +SSP) and efficient pH-dependent cell-cell fusion (Fig. 3), arguing against significant adverse effects of the mutations on overall protein folding.

In the absence of SSP, importantly, both the single and double mutants were now capable of transport to the cell

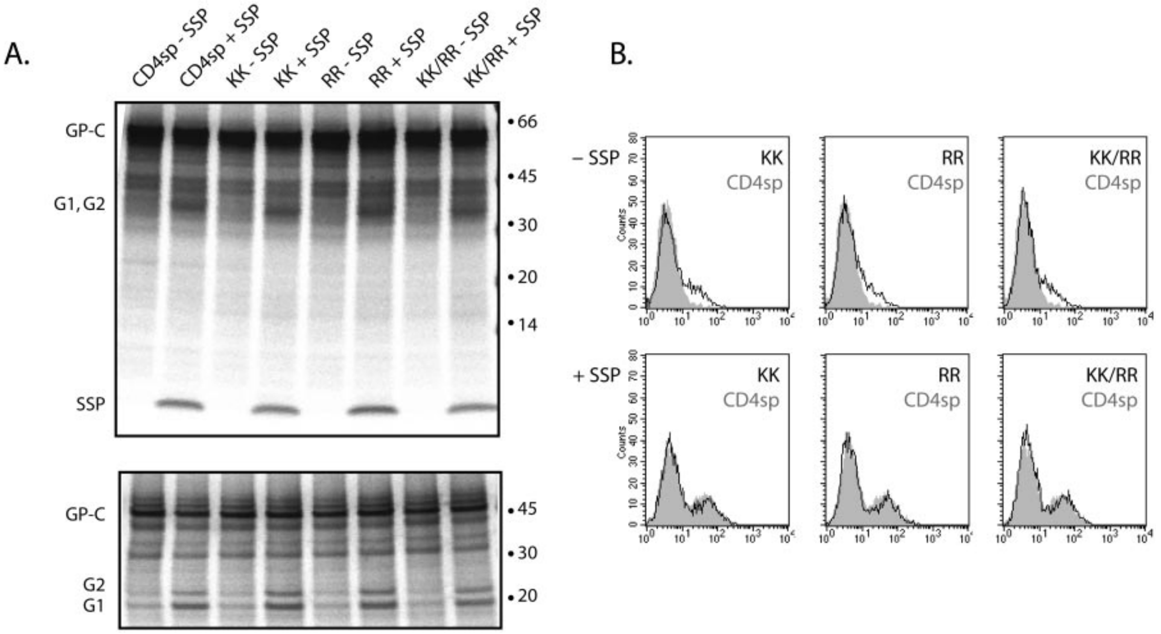

FIG. 7. Alanine mutations to dibasic amino acid motifs enable transport from the ER. (A) CD4sp-GPC constructs containing KK, RR, and double KK/RR mutations were expressed alone (−SSP) or with SSP (+SSP). Metabolically labeled glycoproteins were immunoprecipitated and analyzed as described in the legend to Fig. 2A. Molecular size markers (in kilodaltons) are as described in the legend to Fig. 2A. (B) Flow cytometry was performed as described in the legend to Fig. 2B, and results are plotted similarly. Note that the top panels compare expression of the CD4sp-GPC glycoprotein (gray histograms in all panels) with that of the mutants (open histograms) in the absence of SSP. Expression with SSP is shown in the bottom panels.

surface. This phenotype was evident upon confocal microscopic analysis of nonpermeabilized cells (Fig. 4, surface), although specific localization in the Golgi was difficult to discern (green and merged images). Flow-cytometric studies of cell surface expression indicated that both the single and double mutations provided modest, albeit significant, relief of ER retention (Fig. 7B, −SSP). Evidence for enhanced SKI-1/S1P cleavage of the mutant glycoproteins was, however, difficult to discern in whole-cell lysates, above the residual level of cleavage in the wild-type glycoprotein (Fig. 7A, bottom panel). It is possible that the cleaved species in the wild-type G1-G2 glycoprotein reflect transient residence in the Golgi, prior to retrieval to the ER. In the Old World Lassa fever virus glycoprotein, where cleaved products are not observed in the absence of SSP (18), retrieval of the G1-G2 precursor may be more rapid. Nonetheless, mobilization of the mutant glycoproteins to the cell surface was consistently observed and distinct from the strict intracellular retention seen with the wild-type glycoprotein. Both KK and RR mutations appeared to be comparably efficacious, and no synergy was observed in the double KK/RR mutant. However, none of the mutant glycoproteins was able to mediate cell-cell fusion in the absence of SSP (Fig. 3). This defect is not attributable to the amino acid substitutions per se, as wild-type levels of fusion were restored upon *trans* complementation with SSP.

To confirm that the mutations are sufficient for significant mobilization of the G1-G2 precursor in the absence of SSP, we examined the glycoprotein by immunoprecipitation from the cell surface (Fig. 8). These experiments confirmed significant expression of the dibasic sequence mutants on the cell surface and demonstrated a preponderance of the proteolytically processed G1-G2 complex, reflecting access to the SKI-1/S1P protease in the Golgi. The efficiency of cleavage in the mutant glycoproteins was relatively unaffected by the presence or absence of SSP (60% cleaved versus 40% cleaved, respectively).

Taken together, these studies identify the two dibasic amino

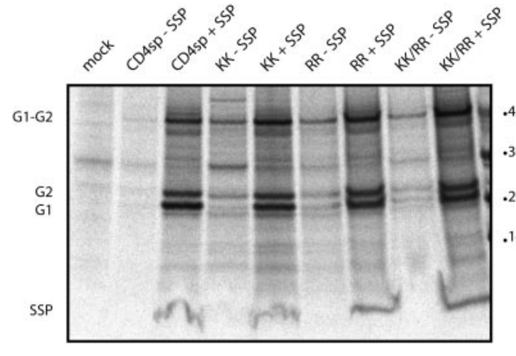

FIG. 8. Cell surface expression of dibasic amino acid motif CD4sp-GPC mutants. Intact cells expressing the constructs shown in Fig. 7 were incubated with the G1-specific MAb BE08, and the cell surface GP-C glycoproteins were isolated from cleared cell lysates using protein A-Sepharose and deglycosylated. The relative amounts of G1, G2, and G1-G2 precursor in each lane were quantitated from the phosphorimage using Image Gauge software (Fuji), and the efficiency of cleavage was determined as the sum of G1 plus G2 relative to total of all forms. Distortion of the SSP band is due to the detergents used in PNGase F treatment. Molecular size markers (in kilodaltons) are as described in the legend to Fig. 2A.

acid sequences (KKPT$_{479}$ and RRGH$_{485}$) as important determinants of ER localization in the absence of SSP. Alanine mutations at either or both of these sites result in partial relief from ER retention and enable transport to the cell surface in the absence of SSP. On the other hand, these mutations do not completely obviate the requirement for SSP association in transport of the G1-G2 precursor (Fig. 8). Quantitative analysis of the glycoproteins indicated that, whereas the mutations were able to increase cell surface expression at least 10-fold, coexpression of SSP resulted in an additional 10-fold increase in all mutants, to the levels of the wild-type glycoprotein. These findings are consistent with our results from confocal microscopy and flow cytometry studies (Fig. 4 and 7). Thus, constraints on the trafficking of the G1-G2 precursor include the dibasic sequence motifs in the cytoplasmic domain of G2 but also involve additional structural elements provided upon full assembly with SSP.

DISCUSSION

The regulation of trafficking through intracellular membranous compartments is central to the biogenesis of membrane glycoproteins (15, 22). Quality control mechanisms for protein folding and assembly are proposed to operate through checkpoints on exit from the ER and through bidirectional transport to and from the Golgi apparatus. Viruses make use of these cellular pathways in the biosynthesis, assembly, and release of new virion particles (15). In our studies, we have characterized the biogenesis of the arenavirus envelope glycoprotein and the requirement for tripartite assembly to enable transport of the GP-C complex from the ER. Without the association of SSP, the wild-type G1-G2 precursor remains localized to the ER. We show that localization is mediated by the cytoplasmic domain of G2 and that the control of trafficking by SSP association is transferable to a chimeric CD4 molecule bearing the G2 transmembrane and cytoplasmic domains. Conversely, regulation of intracellular transport of the GP-C complex does not require G1 or the ectodomain of G2.

Our studies demonstrate that ER localization is mediated in part through dibasic amino acid sequences in the cytoplasmic domain of G2. Alanine mutations to either of two dibasic motifs provide partial relief from ER localization and enable expression of the proteolytically cleaved G1-G2 complex on the cell surface. Upon exit from the ER and transit through the Golgi, the mutant G1-G2 precursor is now fully susceptible to proteolytic maturation by SKI-1/S1P protease. Thus, absent ER localization signals, the arenavirus GP-C precursor can undergo proteolytic maturation much as do the precursor glycoproteins of other class I viral fusion proteins.

Dibasic amino acid sequences are known to mediate ER localization through retrograde transport (retrieval) from the Golgi (references 22, 37, and 62 and references therein). The specific dibasic sequences we have identified as important for ER localization in the Junín virus G2 glycoprotein do not match precisely either of the canonical ER retrieval motifs: the C-terminal KKXX or internal RXR sequences. Although the internal KK sequence studied here is conserved among the New World arenaviruses, the C-terminal RRXX sequence shows considerable variation (Fig. 1). Among the Old World viruses, only the C-terminal motif is identifiable. However, variants to the canonical motifs are also common in other ER-localized transmembrane proteins (46, 55, 62) and the efficiency of retention by these sequences is often highly context dependent (26, 57, 66). Many details regarding the mechanisms and molecular determinants involved in ER-Golgi trafficking remain unresolved.

It is noteworthy that a viral envelope glycoprotein destined for the cell surface should encode an ER localization signal. For cellular transmembrane proteins that traverse the Golgi and beyond, dibasic ER localization motifs are commonly found to control the assembly and trafficking of heteromultimeric membrane protein complexes (12, 33, 39, 42, 67; reviewed in references 22 and 46). These endogenous signals prevent transport of the individual subunits and are overcome upon assembly of the multimeric complex. This quality control mechanism ensures that only the fully and properly assembled complex is transported from the ER. In the biogenesis of the Junín virus GP-C complex, we propose an analogous role for SSP association—namely, to mask endogenous ER localization signals in the cytoplasmic domain of G2 and thus enable transport of only the fully assembled tripartite complex.

This strategy for assembly-dependent control of viral envelope glycoprotein trafficking is likely not unique to the arenaviruses. The bunyavirus G$_C$ glycoprotein also contains a noncanonical basic amino acid cluster that may be involved in ER localization (29). In these viruses, transport of G$_C$ from the ER requires association with a second envelope glycoprotein, G$_N$ (30, 36), which in turn retains the G$_C$-G$_N$ complex in the Golgi (27, 29, 56), the site of virus budding. Together, these observations highlight the use of cellular ER-Golgi trafficking mechanisms during the viral life cycle to control the assembly and transport of multimeric envelope glycoprotein complexes.

Despite mutations that enable the transport of the G1-G2 complex in the absence of SSP, wild-type levels of trafficking were not restored by point mutations to the dibasic amino acid sequences or by truncations in the cytoplasmic domain (not shown). It is possible that additional constraints on GP-C transport lie within the transmembrane domain of G2. Moreover, it is likely that the association with SSP remains essential for the integrity of the GP-C complex. The SSP subunit has uniquely evolved within the arenaviruses for purposes other than simply to relieve ER retention of an envelope glycoprotein precursor. It is telling, then, that despite the accumulation of cleaved G1-G2 complex on the cell surface, none of the glycoproteins lacking SSP is able to mediate membrane fusion (Fig. 3). Notably, GP-C glycoproteins bearing mutations at the dibasic amino acid motifs are unable to promote fusion in the absence of SSP yet are restored to full activity by coexpression of SSP. This defect in fusion is likely not due to the lower levels of cell surface glycoprotein in the absence of SSP, as robust fusion is observed with comparably low levels of cleaved wild-type glycoprotein (see Fig. 6 of reference 64). Rather, we suggest that SSP may be directly involved in modulating pH-dependent membrane fusion by the GP-C complex.

In addition, the G1-G2 complex lacking SSP is not myristoylated. GP-C complexes in which myristoylation is blocked by a G2A mutation are less able to mediate cell-cell fusion than the wild-type glycoprotein (65), perhaps due to alterations in trafficking to specific membrane microdomains (52, 61). The G2A glycoprotein, however, retains 30% of the wild-type fusion activity, significantly more than the present G1-G2 complexes in the absence of SSP. This comparison suggests defects beyond the lack of acylation in G1-G2 complexes lacking SSP. Separately, myristoylation may also be important during virion assembly in facilitating the colocalization of GP-C with the myristoylated Z matrix protein (50).

Further studies will no doubt delineate the additional roles of the unique SSP subunit in the arenavirus life cycle. Unique solutions embodied in the assembly, trafficking, and membrane fusion activity of the arenavirus GP-C complex may suggest novel approaches for intervention towards the prevention and treatment of arenavirus hemorrhagic fevers.

ACKNOWLEDGMENTS

We are grateful to Victor Romanowski (Universidad Nacional de La Plata, Argentina) for his interest and expertise in initiating our collaborative studies of the Junín virus and to Tony Sanchez and Tom Ksiazek (Centers for Disease Control and Prevention, Atlanta, Georgia) for providing Junín virus GP-C MAbs. Additional reagents were obtained from the NIH AIDS Research and Reference Reagent Program through the contributions of T. Fuerst, B. Moss, C. Broder, P. Kennedy, E. Berger, R. Axel, and J. Hildreth. We also thank Lou Herritt for her technical assistance in confocal microscopy at the Molecular Histology and Fluorescence Imaging Core (D. Lurie, Director). Finally, we thank Meg Trahey for useful discussions during the course of the work and for editorial comments.

Confocal microscopy was supported by NIH COBRE grants RR01760 and RR15583. The work was supported by NIH research grant AI059355.

Received 1 September 2006/Accepted 23 November 2006

A variety of rational approaches to attenuate growth and virulence of vesicular stomatitis virus (VSV) have been described previously. These include gene shuffling, truncation of the cytoplasmic tail of the G protein, and generation of noncytopathic M gene mutants. When separately introduced into recombinant VSV (rVSV), these mutations gave rise to viruses distinguished from their "wild-type" progenitor by diminished reproductive capacity in cell culture and/or reduced cytopathology and decreased pathogenicity in vivo. However, histopathology data from an exploratory nonhuman primate neurovirulence study indicated that some of these attenuated viruses could still cause significant levels of neurological injury. In this study, additional attenuated rVSV variants were generated by combination of the above-named three distinct classes of mutation. The resulting combination mutants were characterized by plaque size and growth kinetics in cell culture, and virulence was assessed by determination of the intracranial (IC) 50% lethal dose (LD_{50}) in mice. Compared to virus having only one type of attenuating mutation, all of the mutation combinations examined gave rise to virus with smaller plaque phenotypes, delayed growth kinetics, and 10- to 500-fold-lower peak titers in cell culture. A similar pattern of attenuation was also observed following IC inoculation of mice, where differences in LD_{50} of many orders of magnitude between viruses containing one and two types of attenuating mutation were sometimes seen. The results show synergistic rather than cumulative increases in attenuation and demonstrate a new approach to the attenuation of VSV and possibly other viruses.

Vesicular stomatitis virus (VSV) is a member of the *Vesiculovirus* genus of the family *Rhabdoviridae*. The negative-sense virus genome is 11,162 nucleotides long and contains five genes in the order 3′ N-P-M-G-L 5′, encoding the five major viral proteins (1, 3). The bullet-shaped VSV particle (160 nm by 80 nm) contains a ribonucleoprotein core (nucleocapsid) composed of genomic RNA closely associated with N protein and a RNA polymerase composed of a complex of L and P proteins enveloped in a host cell-derived plasma membrane (4, 18, 19, 44, 53, 56). Following uptake of the virus particle by susceptible cells, nucleocapsid and viral RNA polymerase are released into the cytoplasm and viral mRNA transcription ensues. A 3′-5′ gradient of viral mRNA transcription leads to abundant N protein expression and successively decreasing levels of P, M, G, and L proteins (1, 3, 15, 19, 27, 57). This gene expression gradient provides virus proteins in a suitable ratio for subsequent viral genome replication and assembly of mature virus particles. Virus replication in cell culture is rapid, and virus progeny are detectable 5 to 6 h postinfection.

Since the initial recovery of infectious recombinant VSV (rVSV) from genomic cDNA (39, 61), effort has been directed towards the development of rVSV as a vaccine vector targeting a variety of different human pathogens, including human immunodeficiency virus type 1 (HIV-1) (25, 31–34, 48–51). The major advantages of rVSV vaccine vectors and their immunogenicity and protective efficacy in animal models have been described in detail previously (12). However, VSV is both neurotropic and neurovirulent in mice (54, 58, 60) and can cause neurological disease when injected directly into the brain of cows and horses (24). The original rVSV Indiana serotype vector ($rVSV_{IN}$) developed by J. Rose and colleagues was less pathogenic following intranasal inoculation in mice than the cell culture-adapted virus from which it was derived, but the neurovirulence (NV) potential of this vector following direct intracranial (IC) inoculation was not known. To address this question, an exploratory nonhuman primate (NHP) NV study based on the methodology used for NV testing of mumps vaccine seed lots was carried out. In that pilot study, wild-type (wt) VSV_{IN} and $rVSV_{IN}$ caused clinical signs of severe neurological disease following intrathalamic inoculation of animals; two additional rVSV vectors expressing the HIV-1 Gag protein did not cause any clinical signs of disease, but histological examination of the central nervous system (CNS) in these animals revealed evidence of necrotic and inflammatory lesions (30). These findings indicated that $rVSV_{IN}$ vectors would require further attenuation before being considered suitable for clinical evaluation.

When it became possible to recover infectious VSV from genomic cDNA (39, 61), directed approaches to study rVSV attenuation were adopted. One attenuation strategy known as gene shuffling involves rearranging the natural gene order of VSV, which alters normal levels of gene expression (2, 60). Viruses modified by gene rearrangement often grow poorly in vitro and are typically less virulent in vivo (21–23, 42, 60).

A different attenuation strategy involves truncation of the

29-amino-acid cytoplasmic tail (CT) region of the virus G protein (50, 55). Viruses with shortened CTs have slower growth rates, reach lower peak titers in vitro, and are less pathogenic in mice than unaltered viruses (49). Because N gene shuffles and G protein CT truncations involve gene translocations and deletion of part of the G gene, respectively, mutants generated by these strategies have a stable attenuation phenotype-genotype (23, 55).

A third attenuation strategy relies on nucleotide substitutions within the M gene that ablate expression of two in-frame overlapping polypeptides initiated downstream from the M protein translation start codon (29). Viruses that do not express these polypeptides demonstrate reduced cytopathology in a variety of cell lines and are highly attenuated in mice. Consequently, mutants that do not express these polypeptides have been called noncytopathic M mutants (M_{NCP}).

In this study, we sought to explore and define strategies that would allow step-wise increases in $rVSV_{IN}$ vector attenuation to levels beyond those previously described, thereby increasing the range of attenuated vectors from which to generate an ideal $rVSV_{IN}$–HIV-1 vaccine vector for future clinical evaluation. To achieve this we combined G protein CT truncations with either N gene shuffles or M_{NCP} gene mutations. Growth characteristics of the resulting $rVSV_{IN}$ combination mutants were studied in vitro, and their neurovirulence was assessed in a mouse IC 50% lethal dose (LD_{50}) model to determine degree and relative order of vector attenuation.

MATERIALS AND METHODS

Cells and virus. Vero and baby hamster kidney (BHK) cell lines were obtained from the American Type Culture Collection and propagated under conditions of 37°C and 5% CO_2 in Dulbecco's modified Eagle's medium containing 10% fetal bovine serum, sodium pyruvate (20 mM), and gentamicin (50 μg/ml). The tissue culture-adapted San Juan strain of the VSV Indiana serotype (VSV_{IN}), a recombinant form of VSV_{IN} ($rVSV_{IN}$) (39), $rVSV_{IN}$ expressing HIV-1 Gag protein ($rVSV_{IN}$ gag5), and two attenuated forms of $rVSV_{IN}$ gag5 ($rVSV_{IN}$CT1 gag5 and $rVSV_{IN}$CT9 gag5) were kindly provided by J. Rose (Yale University, New Haven, CT). A modified form of vaccinia virus Ankara (MVA) that expressed bacteriophage T7 RNA polymerase (MVA-T7) (62) was obtained from Bernard Moss (National Institutes of Health, Bethesda, Maryland) and further modified to express T7 RNA polymerase under the control of an early transcription promoter (38).

Virus propagation, purification, and titration. Virus was routinely amplified on BHK cell monolayers and titrated on Vero cell monolayers. For virus amplification BHK cells were infected at a multiplicity of infection (MOI) of 0.001 to 0.05 PFU/cell. Virus inoculum was adsorbed for 15 min at room temperature (RT) followed by 30 min at 37°C. Additional growth medium was then added, and cells were incubated at 37°C until they became rounded and detached from the flask. Infected cell supernatant was clarified by centrifugation for 10 min at 3,000 × *g*. The virus suspension was then flash frozen in an ethanol-dry ice bath and stored at −80°C prior to titration. Where necessary, virus was further purified from infected cell supernatant by centrifugation through 10% (wt/vol) sucrose in 1× phosphate-buffered saline (PBS). Briefly, ~20 ml of clarified cell supernatant was underlaid with 12 to 15 ml of 10% (wt/vol) sucrose in a Beckmann Ultraclear tube followed by centrifugation at 28,000 rpm in a Beckmann SW-28 rotor for 1.5 h at 4°C. Following centrifugation, supernatant was aspirated, the virus pellet was resuspended in PBS, and the virus suspension was flash frozen and stored at −80°C prior to plaque assay.

For virus titration by plaque assay, freshly confluent Vero cell monolayers in six-well plates were infected with 0.1-ml aliquots from serial 10-fold dilutions of rVSV in growth medium. An additional 0.4 ml of medium was added to each well to prevent cell desiccation, and virus was adsorbed for 15 min at RT followed by 30 min at 37°C. The virus inoculum was then removed, and cell monolayers were overlaid with 3 ml of 0.8% (wt/vol) agarose (SeaPlaque; Cambrex Bio Science Rockland, Inc., Rockland, ME) in growth medium. After 10 min at RT to allow the agarose to solidify, cells were incubated at 37°C in 5% CO_2 for 1 to 4 days for plaque development. The agarose overlay was then removed, monolayers were rinsed once with 2 ml of PBS, and cells were stained and fixed in 0.5 ml of 70% methanol containing 2% crystal violet for 5 min at RT. Plaques were counted after removal of excess stain under running water.

Generation of attenuated $rVSV_{IN}$ genome cDNAs. The generation of both CT1 and CT9 mutants has been previously described in detail (49, 55). The corresponding rVSV genomic cDNAs were generously provided by J. Rose (Yale University, New Haven, CT) and were used in the derivation of the combination mutants described below.

A method for gene translocation within $rVSV_{IN}$ genomic cDNA has been described in detail previously (2, 60). A different method of N gene translocation was used in this study. Briefly, the N gene was first deleted from $rVSV_{IN}$ genomic cDNA by replacing the natural BsaAI-XbaI genome fragment (Fig. 1) with a DNA fragment that was generated by in vitro ligation of two PCR products, one stretching from the BsaAI site in the plasmid vector to the exact 3′ end of the virus leader sequence (positive sense) and the other spanning the region from the transcription start signal of the P gene to the downstream XbaI site. Precise ligation of DNA containing the virus leader sequence, with DNA containing the exact 3′ end of the P gene, was achieved by addition of BsmBI sites to PCR primers. The N gene was then reinserted into the ΔN genome cDNA between the P and M genes (N2), between the M and G genes (N3), and between the G and L genes (N4) by use of a similar approach. For generation of the N2 genome cDNA, a PCR product spanning the entire N gene and 3′ CT intergenic dinucleotide was ligated to flanking PCR fragments in vitro; one DNA fragment stretched from the unique XbaI site to the 3′ end of the P gene and contained the P/M intergenic dinucleotide GT. A second DNA fragment spanned the entire M gene to the unique MluI site in the G gene. Addition of BsmBI sites to the 3′ and 5′ ends of the P and M gene fragments, respectively, and to 3′ and 5′ ends of the N gene fragment allowed all three DNA fragments to be ligated in vitro and then cloned into the XbaI and MluI sites of the ΔN genome cDNA. The N3 cDNA genome was constructed in a similar fashion. A PCR fragment spanning the region from the unique XbaI site in the P gene to the end of the M gene, including the 3′ CT intergenic dinucleotide, was ligated to a PCR fragment spanning the entire N gene, a 3′ CT intergenic dinucleotide, and the first 32 nucleotides of the G gene containing the unique MluI site. Both DNAs were ligated through BsmBI sites at the 3′ end of the P/M fragment and the 5′ end of the N gene fragment. This DNA fragment was then cloned into the unique XbaI and MluI sites of the ΔN cDNA genome. For generation of the N4 genome cDNA, a PCR product spanning the entire N gene was joined with flanking PCR products, one stretching from the unique MluI site to the end of the G gene, including the 3′ CT intergenic dinucleotide, and the other containing the G/L intergenic dinucleotide CT and the region from the 5′ end of the L gene to the unique HpaI site. All three fragments were joined by the addition of BsmBI sites to the 3′ and 5′ ends of the G and L gene fragments, respectively, and to the 3′ and 5′ ends of the N gene DNA fragment. The resulting contiguous DNA fragment was then cloned into the MluI and HpaI sites of the ΔN cDNA genome.

A plasmid cDNA containing the M_{NCP} gene in the $rVSV_{IN}$ backbone was generously provided by Michael Whitt (University of Tennessee, Nashville) (29). The M_{NCP} gag5 and M_{NCP}CT1 gag5 vectors were generated by cloning a DNA fragment that spanned the mutant M_{NCP} gene and part of the P gene into the unique XbaI-MluI sites of $rVSV_{IN}$ cDNAs (generously provided by J. Rose, Yale University, New Haven, CT) containing either the HIV-1 Gag gene inserted between the G and L genes ($rVSV_{IN}$ gag5) or the HIV-1 Gag gene inserted between a truncated (CT1) form of the G gene and the L gene ($rVSV_{IN}$CT1 gag5).

Four N gene shuffle-CT combination mutants (N2CT9, N2CT1, N3CT9, and N3CT1) were generated by swapping the G genes from the N2 and N3 cDNAs with the CT1 and CT9 truncated forms of the G gene via unique flanking MluI and HpaI sites.

Recovery of $rVSV_{IN}$ from cDNA. Infectious virus was recovered from genomic cDNA following transfection of BHK cells with a mixture of plasmids expressing VSV N, P, and L proteins and full-length positive-sense genomic RNA, all under the control of the bacteriophage T7 RNA polymerase transcription promoter (39). For transfection, 95% to 100% confluent BHK cell monolayers in six-well dishes were incubated for 4 h in 3% CO_2 at 32°C in 4.5 ml/well of fresh growth medium. Meanwhile, a plasmid DNA-$CaPO_4$ precipitate was prepared for each cell monolayer by mixing 2 to 4 μg of plasmid containing full-length genomic cDNA, 1.0 μg of N plasmid, 0.5 μg of P plasmid, 0.15 μg of L plasmid, 25 μl of $CaCl_2$ (2.5 M), and water to achieve a 250-μl final volume. The DNA-$CaPO_4$ precipitate was then formed by dropwise addition of 250 μl of 2× BBS (280 mM NaCl, 50 mM BES, 1.5 mM Na_2HPO_4, pH 6.95 to 6.98) with gentle vortexing. The mixture was incubated at RT for 20 min to allow precipitate formation and then added dropwise to cells with gentle swirling. To provide a source of T7 RNA

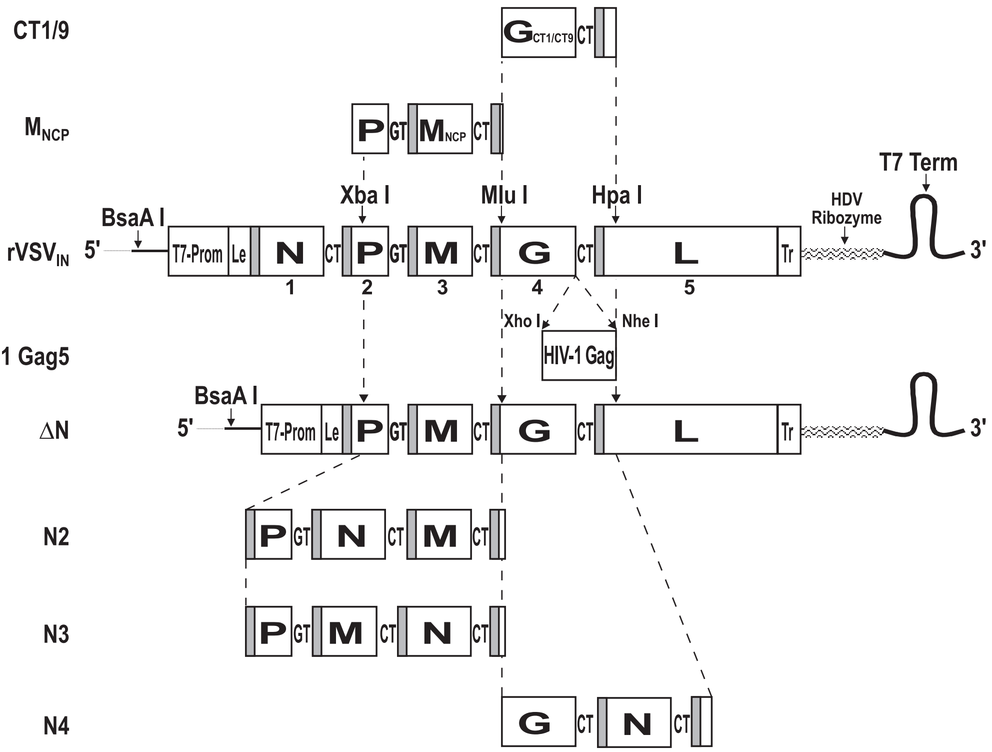

FIG. 1. Construction of $rVSV_{IN}$ mutant cDNA. The BsaAI, XbaI, MluI, and HpaI endonuclease sites used for construction of N gene shuffles and insertion of G genes containing CT truncations and M_{NCP} mutations are indicated with arrows. Virus leader (Le), trailer (Tr), GT, and CT intergenic dinucleotides and transcriptional start signals (shaded boxes) at the beginning of each gene are shown. Synthesis of positive-sense genomic RNA was under control of the T7 RNA polymerase transcription promoter (T7-Prom) and was terminated by a T7 transcription terminator (T7 Term). Hepatitis delta virus ribozyme (HDV Ribozyme) was used to generate the precise viral 3′ end on the positive-sense genomic RNA transcript.

polymerase, MVA-T7-GK16 (38) was then added to each well at an MOI of 3 to 4 PFU/cell along with 20 μg/ml cytosine arabinoside to inhibit amplification of MVA-T7. Cells were then incubated at 32°C in 3% CO_2 for 3 h followed by a 2-h heat shock at 43°C in 3% CO_2 (43). Following heat shock, cells were incubated at 32°C in 3% CO_2 for 18 to 24 h. Transfection medium was then replaced with 2 ml of fresh growth medium containing cytosine arabinoside, and cells were further incubated at 37°C in 5% CO_2 for 48 to 72 h. Transfected cells were then scraped into suspension, gently pipetted repeatedly to reduce cell clumping, and transferred to 95% to 100% confluent Vero cell monolayers in six-well dishes. The following day, cocultures were supplemented with 1 ml of fresh growth medium and incubation was continued for a further 3 to 5 days, during which time VSV cytopathic effect (CPE) became apparent. Rescued virus was then triple plaque purified and further amplified prior to in vitro and in vivo analysis.

In vitro growth studies. For comparison of $rVSV_{IN}$ mutant plaque sizes, plaque assays were performed in duplicate on replicate Vero cell monolayers as described above. For growth kinetics studies, replicate Vero cell monolayers in 25 cm^2 flasks were infected in duplicate at an MOI of 5 PFU/cell. Virus was adsorbed in 0.5 ml of growth medium for 15 min at RT followed by 30 min at 37°C with occasional rocking to prevent cell desiccation. After removal of the inoculum, monolayers were rinsed three times with 5 ml of PBS to remove unbound virus; 5 ml of growth medium was then added to each monolayer, and a 0.5-ml aliquot was immediately removed as a "time h 0" (T_0) sample and replaced with 0.5 ml of fresh medium. Incubation was continued at 37°C in 5% CO_2 for 48 to 72 h, and further samples were taken at T_3 to T_{48}. All samples were flash frozen in ethanol-dry ice and stored at −80°C for titration.

Mouse IC LD_{50} studies. Five-week-old female Swiss Webster mice (Taconic Laboratory Animals and Services, Germantown, NY) were anesthetized and injected IC with log_{10}-fold dilutions of virus in 30 μl PBS (10 mice per dilution, with dilutions adjusted to range around the anticipated LD_{50}). Weight and health status were recorded daily for 2 weeks. Mice becoming either bilaterally paralyzed or showing significant signs of distress or severe illness were sacrificed and recorded as succumbing to VSV disease. The LD_{50} and the 50% paralyzing dose (PD_{50}) were determined by the method of Reed and Muench (45) based on the number of mice that became paralyzed. All animal care and procedures conformed to Institutional Animal Care and Use Committee guidelines. The facilities are fully accredited by the American Association for Accreditation of Laboratory Animal Care.

RESULTS

Recovery of attenuated $rVSV_{IN}$ vectors from genomic cDNA. The complete spectra of $rVSV_{IN}$ vectors recovered from genomic cDNA and subsequently used for in vitro and in vivo attenuation studies are shown in Fig. 2A. Attenuated $rVSV_{IN}$ mutants were generated using three different attenuation strategies and combinations thereof. In one strategy the N gene was translocated (shuffled) to the second, third, and fourth gene positions (N2, N3, and N4, respectively) in the $rVSV_{IN}$ genome. In another strategy, the G protein CT was truncated to either nine (CT9) amino acids or one (CT1) amino acid. A third attenuation strategy abolished expression of two overlapping polypeptides encoded within the M gene open reading frame, generating the M_{NCP} gag5 mutant containing the HIV-1 gag gene at position 5 in the genome. Both the CT9 and N4 mutants contain an additional "empty" transcriptional unit (TU) at the fifth position in the genome. This TU contains an XhoI-NheI cassette flanked by transcription start and stop signals to facilitate insertion and expression of foreign genes (50, 51). Because results from previous murine NV studies (60) and an exploratory NHP NV study (30) indicated that N gene shuffles and G protein CT truncations on their own might not

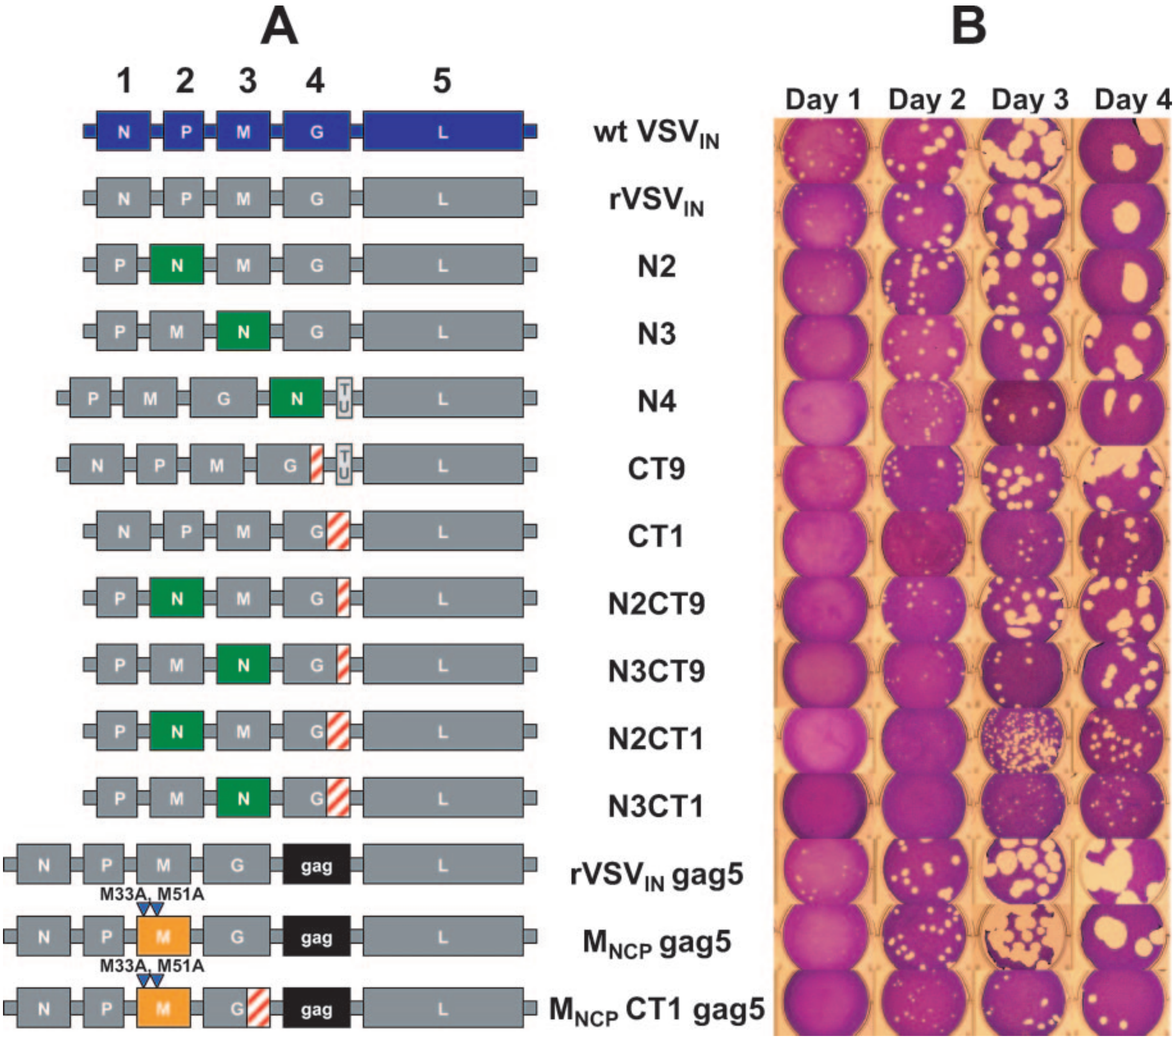

FIG. 2. Genetic organization of rVSV$_{IN}$ mutants and plaque size comparison. (A) Mutants were named to reflect genomic organization and attenuating mutations. The N gene shuffle mutants N2, N3, and N4 were named according to the position of the N gene relative to that of wt VSV$_{IN}$. The G protein CT truncation mutants CT1 and CT9 were named according to the number of amino acids retained in the cytoplasmic tail region of the G protein. Vectors containing noncytopathic M gene mutations (M33A and M51A [triangles]) were named M$_{NCP}$ mutants. Combination mutants were named N2CT1, N3CT1, N2CT9, N3CT9, and M$_{NCP}$CT1 to reflect contributing mutations. An additional empty TU containing transcription start and stop signals but no additional gene was present in N4 and CT9 mutants. The HIV-1 gag gene was present in the fifth position of virus genomes as indicated. (B) Representative plaques produced by wt VSV$_{IN}$ and rVSV$_{IN}$ variants following plaque assay on replicate Vero cell monolayers at 37°C for 1 to 4 days.

attenuate rVSV$_{IN}$ sufficiently for use as a vaccine vector in humans, these mutations were also combined in different configurations in an effort to produce more highly attenuated variants. Most double mutants were generated by combining N gene shuffles with G protein CT9 and CT1 truncations (shuffle-CT mutants), giving rise to N2CT9, N3CT9, N2CT1, and N3CT1 vectors; another double mutant containing the HIV-1 gag gene at position 5 in the genome was generated by combining the G protein CT1 truncation with the M$_{NCP}$ mutations (M$_{NCP}$ CT1 gag5). Even though it was anticipated that the mutant vectors would be more growth attenuated in vitro than the prototype rVSV$_{IN}$ vector developed by J. Rose and colleagues, all single and combination mutants were recoverable from cDNA.

Comparison of rVSV$_{IN}$ mutant plaque size. To gain a first impression on the relative attenuation levels of rVSV$_{IN}$ mutants, plaque sizes on Vero cell monolayers were compared at different times postinfection (Fig. 2B). From this analysis a number of trends emerged. Plaques produced by rVSV$_{IN}$ and wt VSV$_{IN}$ were almost the same size at all time points, indicating that rVSV$_{IN}$ growth was little more attenuated than wt VSV$_{IN}$ growth in cell culture. Virus containing only M$_{NCP}$-attenuating mutations (M$_{NCP}$ gag5) produced a delayed cell CPE, as previously observed (29), that resulted in very small plaques by day 1. At later time points, plaques were only slightly smaller than those made by rVSV$_{IN}$, indicating efficient growth and spread of this mutant in vitro. However, it should be noted that although M$_{NCP}$ plaques were similar in size to

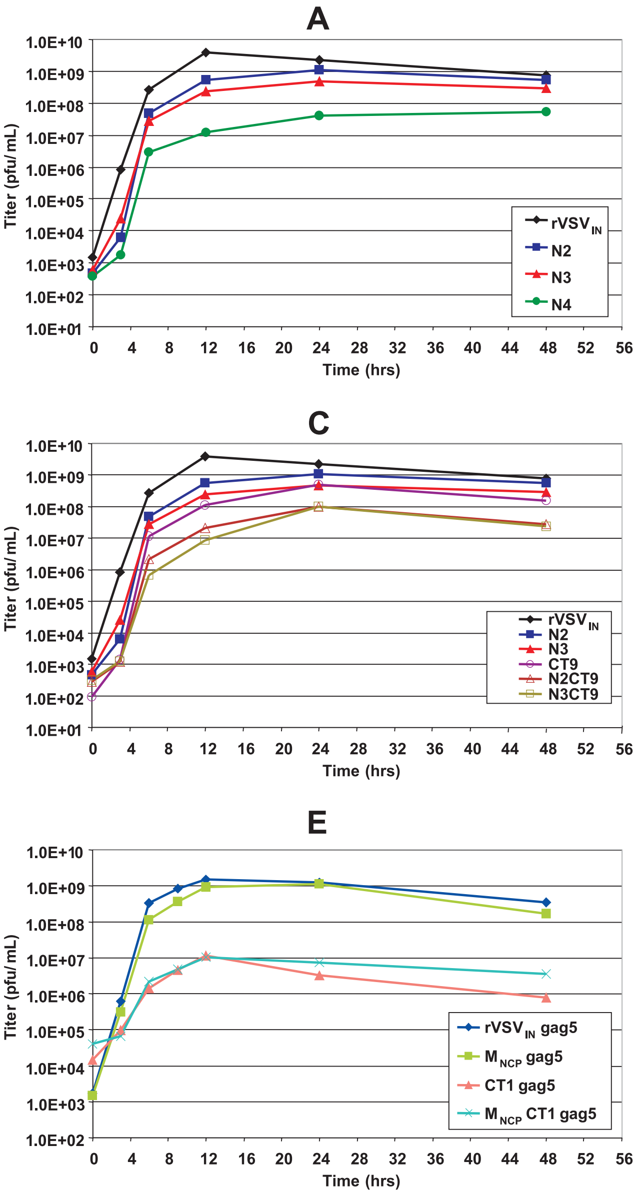

FIG. 3. Growth kinetics of rVSV$_{IN}$ mutants on Vero cell monolayers. Replicate Vero cell monolayers in 25 cm^2 flasks were infected in duplicate at an MOI of 5 PFU/cell. Infected-cell supernatants were collected at intervals postinfection and titrated on Vero cell monolayers. All datum points represent the average titers of samples taken from duplicate infections. Growth curves are shown for mutants containing N gene shuffles (A), CT truncations (B), N gene shuffle-CT truncation combinations (C and D), and M$_{NCP}$ mutations (E).

those made by rVSV$_{IN}$ and rVSV$_{IN}$ gag5 at days 2 to 4, cells within the M$_{NCP}$ gag5 plaques displayed a reduced CPE at all time points. The M$_{NCP}$ CT1 gag5 combination mutant produced plaques that were much smaller than M$_{NCP}$ gag5 plaques and similar in size to those produced by the CT1 virus, indicating that the CT1 truncation was the dominant attenuating mutation affecting virus growth and spread in vitro. Importantly, both CT and N gene shuffle mutants had plaque sizes commensurate with degrees of genetic alteration. For example, CT1 mutants produced smaller plaques than CT9 mutants, and there was a gradient of decreasing plaque size as the N gene was moved further away from the 3′ transcription promoter (N2 to N4), as previously reported (60). When N gene shuffle and CT mutations were combined, plaque size was decreased relative to the results seen with mutants having only one of the two mutations. For example, N2CT1 and N3CT1 produced plaques that were on average smaller than plaques produced by N2, N3, or CT1 mutants at all time intervals. This effect was also seen for N3CT9 but was less notable for N2CT9 except at day 1. Plaque sizes for N shuffle-CT combination mutants also varied incrementally with degree of genetic alteration, and a gradient of decreasing plaque size (N2CT9→N3CT9→N2CT1→N3CT1) was seen. Overall observations of plaque size indicated that the combination of N gene shuffles and CT truncations can attenuate virus incrementally and to a greater degree than either single form of mutation.

In vitro growth kinetics of rVSV$_{IN}$ mutants. We next performed a series of growth kinetic studies measuring the rate and extent of virus growth to further compare relative in vitro attenuation levels among rVSV$_{IN}$ mutants (Fig. 3). As shown in Fig. 3A, the rate of virus growth was reduced in relation to the position (N2 to N4) of the N gene, with a reduction in peak virus titer of 5-fold for N2, 10-fold for N3, and 100-fold for N4 compared to rVSV$_{IN}$ results. The CT9 and CT1 gag5 mutants (Fig. 3B) also had reduced growth rates and reached 10-fold and 100-fold-lower peak titer respectively than rVSV$_{IN}$, in general agreement with previous reports (49, 55). It should be noted that the addition of the HIV-1 gag gene between the G and L genes of rVSV$_{IN}$ did not significantly reduce growth of virus in cell culture and that the CT1 and CT1 gag5 mutants displayed almost identical growth kinetics in vitro (data not shown). More importantly, when N gene shuffles were combined with G protein CT truncations a series of virus mutants was generated that had reduced growth rates and a reduction in peak infectious particle production compared to virus containing either form of mutation alone (Fig. 3C and 3D). Overall, the growth kinetic studies indicated a gradient of increasing virus attenuation (N2CT9→N3CT9→N2CT1→N3CT1) identical to that observed in plaque size comparisons. In this combinatorial approach to virus attenuation, N3CT1 had 1,000-fold-lower peak virus titer than rVSV$_{IN}$ and 50- and 500-fold-lower peak titer than CT1 and N3 mutants, respectively (Fig. 3D). A separate series of growth kinetic studies were performed for the M$_{NCP}$ mutants, as they were originally generated with the HIV-1 gag gene inserted between the G and L genes of the genome(s). As previously described, virus containing the M$_{NCP}$ mutations replicated to a nearly normal peak titer in cell culture (Fig. 3E) but with a delayed onset of CPE in most cell types (29). Unlike the synergistic attenuation of virus growth seen with N gene-CT combination mutants, combining M$_{NCP}$ mutations with the CT1 truncation did not significantly alter growth in cell culture compared to the results seen with the CT1 mutant alone, indicating that the CT1 mutation was the dominant attenuating mutation in vitro.

Assessment of rVSV$_{IN}$ vector neurovirulence in mice. Young mice are much more sensitive to infection with VSV following IC inoculation than following intranasal inoculation (54, 60). Moreover, unlike wt VSV$_{IN}$, attenuated rVSV$_{IN}$ mutants containing either cytoplasmic tail truncations (CT1 and CT9) or N gene shuffles (N2, N3, and N4) do not cause death following intranasal inoculation (25, 60). Therefore, to measure differences in virulence among the attenuated rVSV$_{IN}$ mutants, mice were inoculated IC, and the cumulative animal deaths, time until death, and frequency and severity of paralysis were measured. The LD$_{50}$s and the PD$_{50}$s were calculated based on the method of Reed and Muench and are shown in Fig. 4A. The time to death in animals receiving a lethal dose is shown in Fig. 4B.

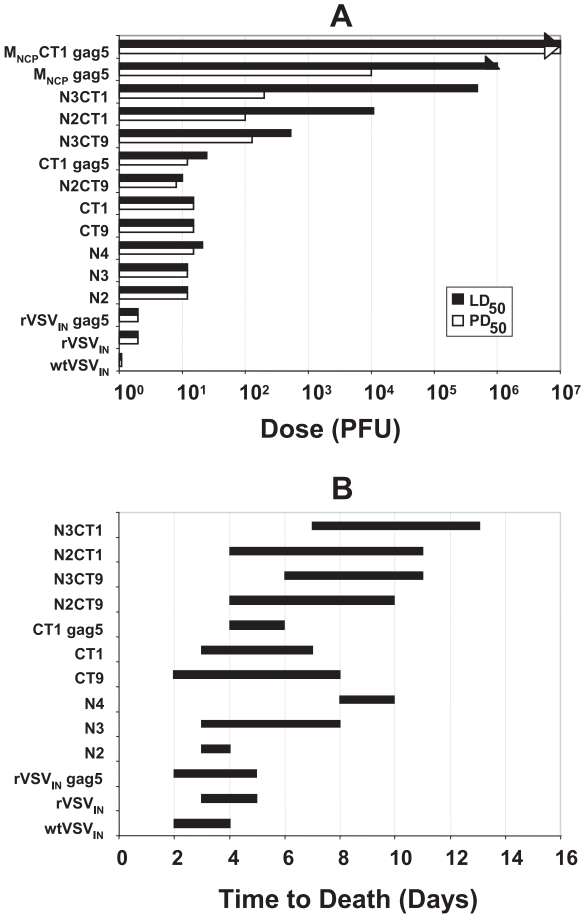

FIG. 4. Neurovirulence properties of rVSV$_{IN}$ mutants in mice following IC inoculation. In a series of experiments, 5-week-old Swiss Webster mice were inoculated IC with log$_{10}$-fold dilutions of virus. Mice were monitored for 2 weeks for mortality and morbidity (paralysis). (A) The LD$_{50}$ and PD$_{50}$ values were determined by the method of Reed and Muench. (B) Time to death was recorded for mice in the group receiving the dose immediately above the determined LD$_{50}$. Arrowheads indicate results in which LD$_{50}$ and PD$_{50}$ were not achieved.

Mice receiving wt VSV$_{IN}$ reproducibly died 2 to 4 days postinoculation, and the LD$_{50}$ was only 1 to 2 PFU. In agreement with plaque size comparisons and growth kinetics studies, rVSV$_{IN}$, with and without HIV gag inserted between the G and L genes, was only marginally more attenuated than wt VSV, with an LD$_{50}$ of approximately 2 to 5 PFU and a slightly delayed onset of death at 2 to 5 days. Viruses containing either CT truncations or N gene shuffles alone were slightly more attenuated than rVSV$_{IN}$, with LD$_{50}$ values of 12 to 21 PFU for CT9, CT1, N2, N3, and N4. Although the LD$_{50}$s of N2, N3, and N4 mutants were similar, there was a respective incremental increase in time to onset of death. However, a dramatic decrease in virulence was seen when the CT1 mutation was combined with N gene shuffles. Most notably, for N3CT1 the LD$_{50}$ increased to $>10^5$ PFU compared to 15 PFU and 12 PFU for CT1 and N3 viruses, respectively, and the LD$_{50}$ for N2CT1 was 1.1×10^4 PFU, demonstrating powerful synergistic attenuation of virulence for these combinations of mutations. Moreover, when animals died at higher doses, onset to death was delayed to 4 to 11 days postinoculation for N2CT1 and 6 to 14 days for N3CT1. To a lesser extent, and consistent with the order of attenuation observed in vitro, synergistic attenuation was also observed for N3CT9, with an LD$_{50}$ of 524 PFU and delayed onset of death. As the least attenuated among the combination mutants in vitro, the LD$_{50}$ dose for N2CT9 was very similar to the LD$_{50}$s for N2 and CT9; however, time to onset of death was delayed compared to that seen with the N2 and CT9 variants.

Many of the mice inoculated with the combination mutants, in particular, N3CT1 and N2CT1, displayed morbidity in the form of paresis and unilateral paralysis, from which they started to recover by week 3 postinfection, without mortality. Thus, the PD_{50}s for N3CT1 and N2CT1 were less than their respective LD_{50}s. Mice receiving the more virulent viruses died quickly without a measurable paralytic phase. Therefore, the PD_{50} and LD_{50} values for these viruses were recorded as being identical. Overall, the gradient of attenuation for the N gene shuffle-CT combination mutants observed in vivo was identical to that observed in vitro.

IC infection with M_{NCP} gag5 primarily caused some mild paralysis (PD_{50} of 10^4 PFU) but not death at up to the highest dose (10^6 PFU) tested, and an LD_{50} dose was not achieved. However, combining the M_{NCP} and CT1 mutations reduced the amount of paralysis compared to the results seen with M_{NCP} gag5 alone such that neither a LD_{50} nor a PD_{50} could be calculated for M_{NCP}CT1 gag5. The very high level of attenuation observed for the M_{NCP} gag and M_{NCP}CT1 gag5 mutants in vivo and the absence of a measurable LD_{50} for both mutants at input levels that were approaching a practical limit for M_{NCP}CT1 gag5 prevented any clear conclusions concerning the synergistic effect of combining the M_{NCP} and CT1 mutations. However, the M_{NCP} mutation was clearly the dominant attenuating mutation in vivo, while the CT1 mutation was clearly dominant in vitro.

DISCUSSION

An exploratory NV study of NHPs indicated that the $rVSV_{IN}$–HIV-1 vaccine vectors pioneered by J. Rose and colleagues retained significant levels of virulence and might be insufficiently attenuated for clinical evaluation (30). The present study was undertaken to investigate strategies for further attenuation of $rVSV_{IN}$ and to identify less-virulent variants that might be more suitable as vaccine vectors for HIV-1 and other pathogens.

Variants containing only a single form of attenuating mutation were more growth attenuated than the prototypic $rVSV_{IN}$ vector in vitro but, except for the M_{NCP} mutant, were still highly neurovirulent when tested in the murine IC NV model. Virus containing only the CT1 mutation also caused significant neuropathology in an exploratory NHP NV study (30). In an effort to further increase $rVSV_{IN}$ vector attenuation, CT truncations were combined with either N gene shuffles or M_{NCP} mutations. Most of the resulting combination mutants were more growth attenuated in vitro than vectors containing either single form of mutation. Growth kinetics studies showed that N2CT1 and N3CT1 reached approximately 500- to 1,000-fold-lower peak titers than $rVSV_{IN}$ and approximately 50- to 500-fold-lower peak titers than N2, N3, or CT1 mutants. Furthermore, the degree of vector attenuation could be altered incrementally depending on the pairing of specific N gene shuffle and CT mutations. For example, the N3CT1 mutant was more growth attenuated than N2CT1, which was more attenuated than N3CT9 and N2CT9 mutants. The gradient of increasing virus attenuation for these combination mutants was N2CT9→N3CT9→N2CT1→N3CT1. The same order of attenuation was also observed in vivo, but differences in attenuation between combination mutants and virus with only one type of attenuating mutation were even more dramatic. The N2, N3, CT9, and CT1 mutants still retained high levels of virulence following IC inoculation of mice (LD_{50}s of 12 to 21 PFU) consistent with previously published data for N gene shuffles (60). In contrast, N gene shuffle-CT combination mutants had incrementally increasing LD_{50}s ranging from 10 PFU for N2CT9 to $>10^5$ PFU for N3CT1. Specifically, attenuation synergy appeared to be greater when the CT1 truncation was combined with N2 and N3 gene shuffles.

The differences in relative attenuation between single and combination mutants observed in vitro probably reflect predominantly virus-specific growth attenuation factors. It is thought that the length of the CT tail of VSV G protein may affect the efficiency of virus budding from the cytoplasmic membrane of infected cells. Shorter CTs reduce the rate of particle formation and peak virus titer produced in vitro, possibly due to impaired CT interaction with viral core proteins (16, 28, 50, 55). The N gene shuffles attenuate virus by a different mechanism. During virus replication, N protein is essential for the encapsidation of nascent genomic RNA, and the resulting nucleocapsid structure is the functional template for mRNA transcription and further genome replication. When the N gene is translocated further away from the single 3′ transcription promoter, N protein expression decreases (60). Consequently, limiting N protein reduces the level of nucleocapsid available for transcription, replication, and subsequent incorporation into virus progeny. When transcription is reduced, all virus proteins are expressed less abundantly, placing additional constraints on the availability of all the components needed for assembly and morphogenesis of virus progeny. When both attenuation strategies are combined, not only are viral nucleocapsid and truncated G protein, along with other virus proteins, limiting for viral morphogenesis but impaired interactions between viral nucleocapsid core and the truncated G protein CT likely also further constrain the efficiency of mature particle formation. In vivo, innate and cellular immune responses are additionally superimposed on these growth-attenuating virus-specific factors and likely contribute to the level of attenuation observed in mice.

Innate immunity is usually rapidly induced in response to viral infection in the periphery and likely also plays an important role in controlling virus replication early (days 1 to 5) following IC inoculation of mice (7, 10, 46). Recently, a role for type I interferon has been proposed for control of attenuated but not pathogenic strains of rabies virus, a relative of VSV, following IC inoculation of mice (59), and it is possible that differences in virulence between attenuated and pathogenic strains of VSV can also be explained by differential stimulation of alpha/beta interferon in the CNS. VSV growth in the brain may also be controlled by the induction of nitric oxide, which can inhibit VSV replication in vitro and in neurons (5, 8, 11, 13, 35–37, 47). Acquired cellular immunity likely also plays an important role in killing some types of infected cells and clearance of virus in the CNS early (days 1 to 8) in the infection (11, 46). In contrast, the humoral immune response does not appear to have a significant role in the control and clearance of VSV from the CNS following direct IC inoculation of mice (7, 11).

In view of the host-specific responses to VSV infection of the CNS described above, it is possible that the more slowly replicating, highly attenuated N gene shuffle-CT truncation combination mutants less efficiently down-regulate innate immune responses, leading to a more potent antiviral state (14). For example, reduced expression of the VSV M protein and associated polypeptides can diminish the efficiency of host cell protein shutoff, allowing more efficient induction of innate immune responses (9, 20, 26, 29). Since the N gene shuffle-CT truncation combination mutants also down-regulate viral gene expression, including the M gene, the innate immune response may be better able to control these viruses. Similar reasoning likely also explains the observed differences between in vitro and in vivo attenuation of M_{NCP} mutants described here. In vitro, the M_{NCP} gag5 and M_{NCP}CT1 gag5 mutants are not subject to innate immune responses, and peak titer is close to that of rVSV gag5 and CT1 gag5, respectively, indicating that the CT1 mutation was the dominant attenuating mutation in vitro. However, both M_{NCP} gag5 and M_{NCP}CT1 gag5 had highly attenuated phenotypes in mice, indicating that the M_{NCP} mutations were dominant in vivo, presumably due to the reduced ability of these viruses to interfere with innate immune responses.

In general, the mouse IC LD_{50} NV model proved to be highly sensitive and capable of discriminating changes in virulence within the range of attenuated rVSV vectors tested in this study. Rodent models have also been used to assess the NV potential of other virus vaccine vectors and some licensed live virus vaccines and vaccine candidates, including smallpox vaccine (40), some yellow fever virus vaccine strains (6), attenuated Venezuelan equine encephalitis virus (41), the Jeryl Lynn strain of mumps virus vaccine (52) and a modified measles virus vaccine strain (17). Interestingly, some of the more highly attenuated rVSV vectors described here produced less morbidity and mortality following IC inoculation than some of the licensed live virus vaccines. However, it should be emphasized that differences in virus biology and the natural susceptibility of different mouse strains to virus infection and replication make direct comparison of attenuation levels among different virus vaccines and candidate vaccines extremely difficult.

In summary, the net effect of combining specific N gene shuffles and G protein CT truncations was a measurable synergistic attenuation of rVSV$_{IN}$ growth in vitro and a dramatic reduction of virulence in the very sensitive mouse IC LD_{50} model. These findings suggest that combining mutations that interfere with viral morphogenesis by impairing interactions between structural proteins with mutations that lead to down-regulation of viral structural protein expression may be a useful general mechanism for synergistic attenuation of rVSV$_{IN}$ and other RNA and DNA viruses. Because of the potential of rVSV$_{IN}$ as a vaccine vector for HIV-1 and other human pathogens, experiments are now under way to confirm attenuation of the combination mutants in NHP NV studies and explore the immunogenicity of these highly attenuated rVSV$_{IN}$ vectors.

ACKNOWLEDGMENTS

We thank J. Rose for providing rVSV$_{IN}$, CT1, and CT9 cDNAs and Michael Whitt for providing cDNA encoding the M_{NCP} gene. We thank Chris Parks and Sue Witko for guidance on virus rescue.

ABSTRACT Truncations of the cytoplasmic tail (CT) of entry proteins of enveloped viruses dramatically increase the infectivity of pseudoviruses (PVs) bearing these proteins. Several mechanisms have been proposed to explain this enhanced entry, including an increase in cell surface expression. However, alternative explanations have also been forwarded, and the underlying mechanisms for the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) S protein remain undetermined. Here, we show that the partial or complete deletion of the CT (residues 19 to 35) does not modify SARS-CoV-2 S protein expression on the cell surface when the S2 subunit is measured, whereas it is significantly increased when the S1 subunit is measured. We also show that the higher level of S1 in these CT-truncated S proteins reflects the decreased dissociation of the S1 subunit from the S2 subunit. In addition, we demonstrate that CT truncation further promotes S protein incorporation into PV particles, as indicated by biochemical analyses and cryo-electron microscopy. Thus, our data show that two distinct mechanisms contribute to the markedly increased infectivity of PVs carrying CT-truncated SARS-CoV-2 S proteins and help clarify the interpretation of the results of studies employing such PVs.

IMPORTANCE Various forms of PVs have been used as tools to evaluate vaccine efficacy and study virus entry steps. When PV infectivity is inherently low, such as that of SARS-CoV-2, a CT-truncated version of the viral entry glycoprotein is widely used to enhance PV infectivity, but the mechanism underlying this enhanced PV infectivity has been unclear. Here, our study identified two mechanisms by which the CT truncation of the SARS-CoV-2 S protein dramatically increases PV infectivity: a reduction of S1 shedding and an increase in S protein incorporation into PV particles. An understanding of these mechanisms can clarify the mechanistic bases for the differences observed among various assays employing such PVs.

KEYWORDS cytoplasmic tail, entry, infectivity, pseudovirus, S protein, S1 shedding, SARS-CoV-2, spike density

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) encodes 15 nonstructural proteins as well as 4 structural proteins. Of these, only the structural proteins, spike (S), membrane (M), envelope (E), and nucleocapsid (N), are incorporated into the virion. The N protein is essential for the encapsidation of the 30 kb positive-sense RNA genome, the M and E proteins contribute to virus assembly and budding via interactions with other viral proteins (1, 2), and the S protein mediates entry into the target cell.

For successful entry, the S protein needs to be activated by two sequential proteolytic cleavages. The first cleavage divides the S protein into the S1 and S2 subunits, of

which S1 binds the receptor angiotensin-converting enzyme 2 (ACE2) and S2 mediates membrane fusion (3). In the case of the first SARS-CoV that emerged 2 decades ago, cleavage at the S1-S2 junction is accomplished in target cells by a cell surface protease, TMPRSS2, or lysosomal proteases, cathepsins (4–8). In contrast, for SARS-CoV-2, cleavage is carried out by furin, a Golgi-resident protease, in infected cells during virus maturation. The second cleavage occurs at a site internal to the S2 subunit, termed the S2′ site, and is carried out by TMPRSS2 or cathepsins for both SARS-CoV and SARS-CoV-2 when they reach the target cells. This second cleavage releases the fusion peptide that is required for subsequent fusion between the cellular and viral membranes (3).

Like SARS-CoV-2, the entry glycoproteins of many viruses are cleaved into the surface and transmembrane subunits prior to virus release from infected cells. For most of these viruses, the two subunits remain associated until the receptor-binding domain (RBD) located in the surface subunit binds the receptor. Receptor binding induces conformational changes in the entry glycoprotein and leads to the dissociation of the surface subunit and subsequent membrane fusion mediated by the transmembrane subunit. In the case of the original Wuhan-Hu-1 strain of SARS-CoV-2, the S1-S2 association is weak, and thus, S1 was easily shed from the spikes (9). To overcome this problem, the virus acquired the D614G mutation early in the pandemic, which stabilized the S1-S2 association and increased virus infectivity (9–12).

Another modification of the SARS-CoV-2 S protein that increases virus infectivity is cytoplasmic tail (CT) truncation. The understanding that CT truncation of viral entry glycoproteins enhances pseudovirus (PV) infectivity originated decades ago from intriguing observations that lentiviruses grown in human T cell lines acquired a premature stop codon in their CTs (13–16). Multiple subsequent studies reported that CT truncations of the entry glycoproteins of various viruses enhanced PV infectivity (17–21). We also showed that a 19-amino-acid truncation of the SARS-CoV S protein enhanced PV infectivity (21). Mechanistic studies showed that CT truncation upregulated the cell surface expression of the entry glycoproteins (20, 22). These observations have been interpreted to suggest that the removal of the endoplasmic reticulum (ER) retention signal present at the carboxy-terminal end of the CT was responsible for the elevated expression on the cell surface. However, other studies did not observe increased expression of the CT-truncated glycoproteins on the cell surface (23, 24). In addition, even if an increase was observed, the degree of the increase was modest, and thus, it is difficult to explain the dramatic changes in PV infectivity. An alternative mechanism, a conformational change in the ectodomain, was also proposed for various enveloped viruses to explain the increased fusogenicity upon CT truncation of their entry glycoproteins (20, 23, 25–27).

Here, we show that CT truncation of the SARS-CoV-2 S protein modestly increases cell surface expression when both S1 and S2 are measured, but no increase is observed when only S2 is detected. When only S1 is detected, however, CT-truncated S protein expression on the cell surface is substantially elevated. Further investigation shows that these differences are contributed by reduced S1 shedding in the CT-truncated S protein. We also demonstrate through biochemical and cryo-electron microscopy (cryo-EM) studies that PVs bearing the CT-truncated S protein exhibit much higher spike densities. Together, our studies show that CT truncation of the S protein enhances PV infectivity by decreasing S1 dissociation and increasing S protein incorporation into PV particles.

RESULTS

Cytoplasmic tail truncation of the S protein does not change SARS-CoV-2 PV production but dramatically enhances PV infectivity. The CT of the SARS-CoV-2 S protein consists of 37 amino acids that contain four motifs, as shown in Fig. 1A: a putative ER retention signal (KXHXX) (28, 29), a charged cluster (KFDEDDSE) (30), and two cysteine-rich motifs (CRMs), CCSCGSCC and SCCSC (30–32). To better understand the role of the CT in SARS-CoV-2 infectivity, we made truncation variants of the S protein (S-dCTs) in which these motifs were sequentially deleted, and we compared them to

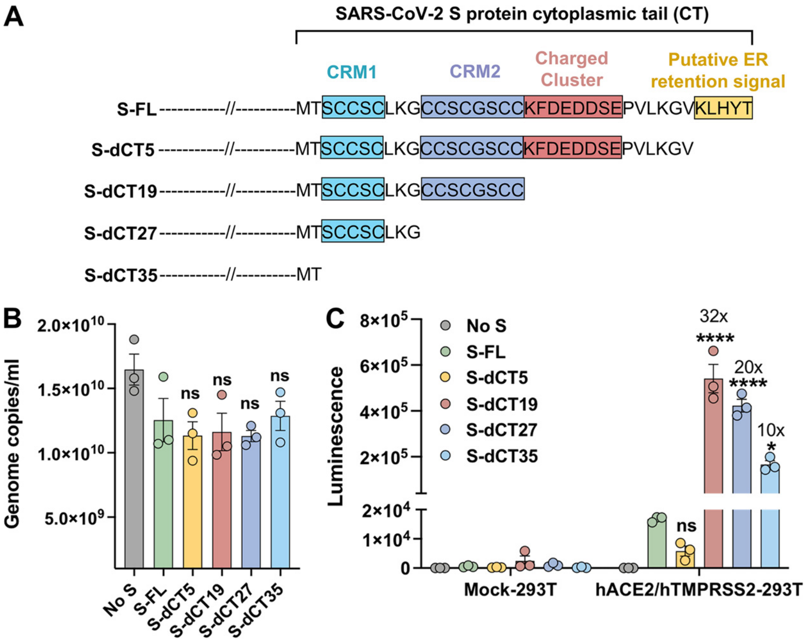

FIG 1 Cytoplasmic tail truncation of the S protein does not change SARS-CoV-2 PV production but dramatically enhances PV infectivity. (A) Diagram representing the CT truncation variants of the S protein used in this study. (B) MLV PVs bearing the full-length S protein (S-FL) or its CT truncation variants (S-dCTs) and expressing firefly luciferase were produced from HEK293T cell transfection, and their titers were quantified by RT-qPCR. (C) Infectivity of the same PVs in parental HEK293T cells or the same cells expressing human ACE2 and TMPRSS2. Cells were infected for 1 h with 5 × 10^8 genome copies per well in a 48-well plate, and infection levels were assessed by measuring luminescence at 24 h postinfection. Panels B and C show mean values ± SEM from three independent experiments conducted with three independently prepared PVs, and statistical significance was calculated by two-way ANOVA using Sidak's multiple-comparison test (*, $P < 0.05$; ****, $P < 0.0001$; ns, not significant). CRM, cysteine-rich motif.

the full-length S protein (S-FL). PVs expressing firefly luciferase (FLuc) and bearing these S-dCTs (PV-dCTs) were produced from HEK293T cell transfection. PVs bearing S-FL (PV-FL) or no S protein were used as controls. To assess the effect of CT truncation on the PV yield, PV titers were quantified by reverse transcription-quantitative PCR (RT-qPCR). Figure 1B shows that these PVs were produced at comparable levels, indicating that CT truncation did not affect PV production.

Next, we assessed their entry efficiency by infecting HEK293T cells stably expressing human ACE2 and TMPRSS2 (hACE2/hTMPRSS2-293T cells) with the same genome copy numbers. HEK293T cells transduced with empty vectors but selected with drugs in the same way as for hACE2/hTMPRSS2-293T cells were used as negative controls for infection (Mock-293T cells). As shown in Fig. 1C, S-dCT5 unexpectedly decreased PV entry compared to S-FL, indicating that the KLHYT motif, a putative ER retention signal, may play its role only in the context of other motifs. In contrast, S-dCT19 increased PV entry by more than 30-fold, which is consistent with previous reports that a deletion of the last 13 to 21 amino acids from the carboxy terminus of the CT enhances PV infectivity (23, 24, 33, 34). S-dCT27 and S-dCT35, which lack one or both CRMs, respectively, also increased PV entry compared to S-FL but to a lesser degree than did S-dCT19, which contains both CRMs (Fig. 1C). Together, these data confirm that CT truncations, except dCT5, substantially enhance the PV entry efficiency and suggest that although the CRMs may play a role in PV infectivity, they are not essential for either PV production or entry.

Cytoplasmic tail truncation does not increase S2 levels but significantly increases S1 levels on the cell surface. Whereas most viruses that are commonly used as a backbone for pseudotyping systems, including human immunodeficiency virus type 1 (HIV-1), murine leukemia virus (MLV), and vesicular stomatitis virus (VSV), bud from the plasma membrane, SARS-CoV-2 buds from the membranes of the ER or the ER-Golgi intermediate compartment (ERGIC) (35). The S protein is therefore designed to be expressed in the intracellular compartments, but when its expression level is high, it is also trafficked to the plasma membrane. Because PV production could benefit from increased S protein expressed on the plasma membrane, we investigated whether CT truncation increased S protein expression on the cell surface. We expressed S-FL and S-dCTs on HEK293T cells via transfection and detected them using convalescent-phase plasma samples derived from coronavirus disease 2019 (COVID-19) patients. Note that whereas all COVID-19 convalescent-phase plasma samples efficiently recognize the S2 subunit, they rarely recognize the S1 subunit (Fig. 2A), likely because the original SARS-CoV-2 did not have much S1 remaining on the virion, owing to its shedding (9). When plasma sample 2, which recognizes both S1 and S2, was used for detection, all S-dCTs, except S-dCT5, were expressed at modestly higher levels than S-FL; albeit modest, the difference was statistically significant (Fig. 2B). However, when plasma sample 9, which recognizes only S2, was used, S-FL and all S-dCTs, except S-dCT5, were expressed at comparable levels (Fig. 2C). Because these data suggest that different S1 levels of S-FL and S-dCTs are responsible for the disparate detection profiles of plasma samples 2 and 9, we also detected S1 alone. To detect only S1, we used hACE2-NN-Ig, the human ACE2 ectodomain that contains enzyme activity-null mutations (H374N and H378N) and is fused to the Fc region of human IgG1 (hIgG1) (21). Figure 2D shows that the S1 levels of S-dCTs, except S-dCT5, detected by hACE2-NN-Ig were approximately 4-fold higher than that of S-FL. These data show that the differences between S-FL and S-dCTs in cell surface expression levels result from their differences in S1, but not S2, contents and that S-dCTs have much higher S1 contents in the spike trimers than S-FL. These data also provide an explanation for the conflicting observations made in previous reports on the cell surface expression of CT-truncated glycoproteins (20, 22–24). Our results demonstrate that depending on which component of the glycoprotein is measured, the expression levels of the CT-truncated glycoproteins could appear to be increased or not increased.

The higher S1 levels observed with S-dCTs than with S-FL prompted us to hypothesize that CT truncation may strengthen the S1-S2 association and, consequently, decrease S1 dissociation from S2. However, because higher hACE2-NN-Ig binding to S-dCTs can result from either a decrease in S1 shedding or an increase in the RBD-up conformation, the conformation that binds the receptor (36–38), we attempted to distinguish these two possibilities by comparing the binding of hACE2-NN-Ig to that of an antibody recognizing the N-terminal domain (NTD) of S1. As this antibody binds the NTD, its binding is unlikely to be affected by the change in the RBD conformation. HEK293T cells were transfected with increasing amounts of an S-dCT19 or S-FL plasmid, their cell surface levels of S1 were measured using hACE2-NN-Ig or the NTD antibody, and their S2 levels were measured using plasma sample 9. Both the hACE2-NN-Ig and NTD antibodies detected severalfold-higher levels of S1 in S-dCT19 than in S-FL at all expression levels (Fig. 2E and F), while the S2 levels of S-dCT19 and S-FL were similar when measured using plasma sample 9 (Fig. 2G). The very similar detection profiles with hACE2-NN-Ig and the NTD antibody of S-FL and S-dCT19 suggest that the RBD-up or -down conformation does not significantly contribute to the differences in the S1 levels but that reduced S1 shedding is likely the major source of the observed S1 differences between S-FL and S-dCTs induced by CT truncation.

In contrast to the other S-dCTs, a low level of S-dCT5 was detected on the cell surface when measured using convalescent-phase plasma sample 2 (Fig. 2B). We thus assessed S-dCT5 expression inside the cell. As the relative level of S-dCT5 compared to other S proteins in permeabilized cells was similar to that on the cell surface (Fig. 2H), we further assessed the S-dCT5 level in cell lysates by Western blotting (WB). Because plasma sample 2 does not efficiently detect S protein in cell lysates, while it does in PVs, a polyclonal anti-S antibody was used for blotting. As shown in Fig. 2I, while comparable levels of the uncleaved S band were observed for all S proteins, indicating that S-dCT5 is expressed comparably to the others, much lower levels of the S1 and S2 bands were observed for S-dCT5, suggesting that they may be rapidly degraded once cleaved. Because this antibody detects S1 only very weakly, we used the NTD antibody to better visualize the S1 bands. Figure 2J shows that the S1 bands in all S-dCTs, except

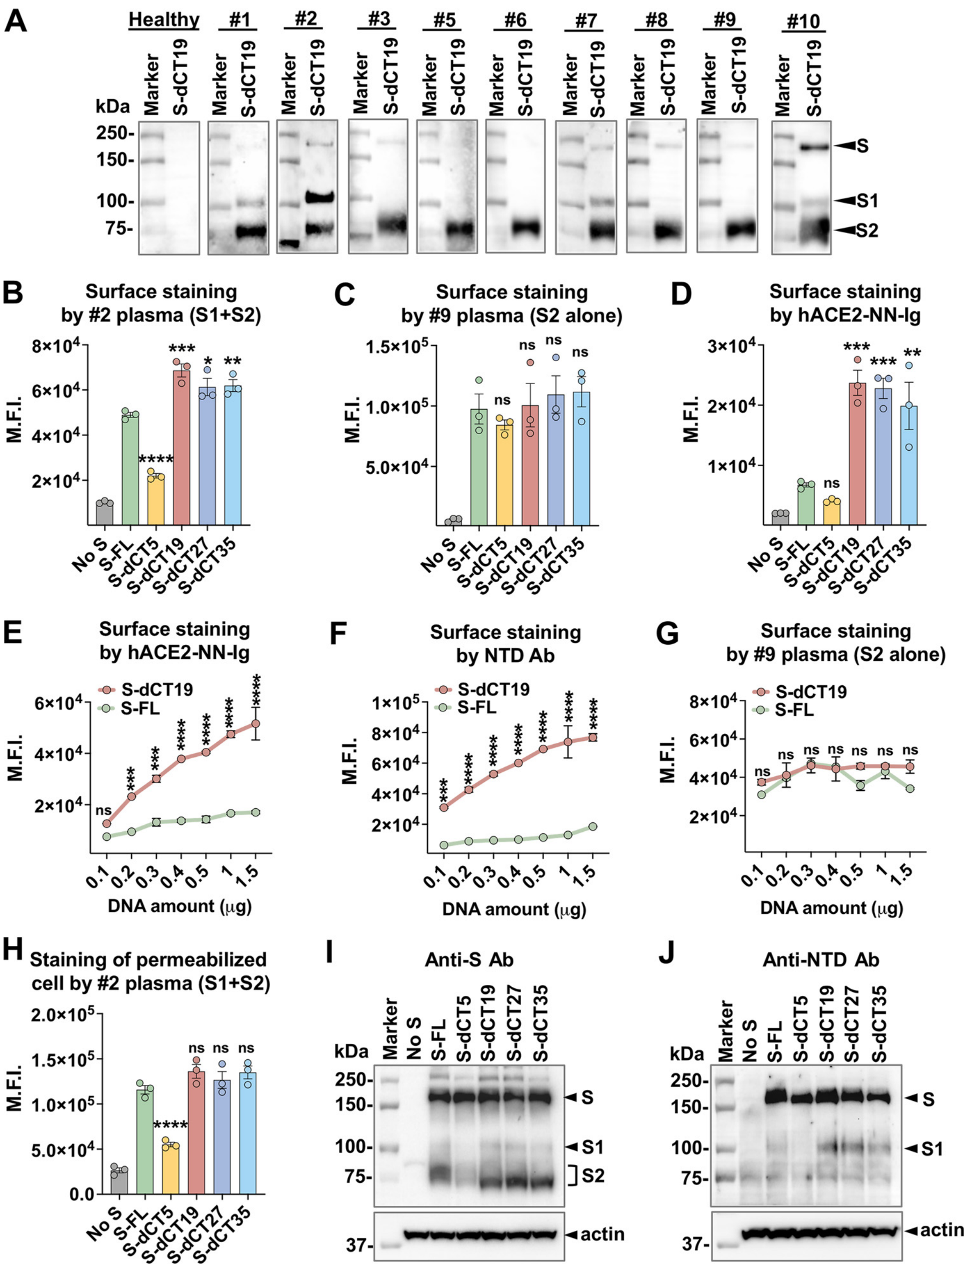

FIG 2 Cytoplasmic tail truncation does not increase S2 levels but significantly increases S1 levels on the cell surface. (A) Ten convalescent-phase plasma samples derived from individuals infected with SARS-CoV-2 early in the pandemic were screened by Western blot analyses for their ability to recognize the S1 and S2 bands of sucrose-pelleted PV-dCT19. (B to D) HEK293T cells grown on 6-well plates were transfected with 0.3 μg of a plasmid encoding the indicated S-FL or S-dCT protein, and their cell surface expression levels were assessed at 42 h posttransfection using plasma sample 2 (at a 1:200 dilution), which recognizes both S1 and S2 (B); plasma sample 9 (at a 1:200 dilution), which recognizes only S2 (C); or 3 μg/mL of hACE2-NN-Ig, which binds only S1 (D). Shown are the mean fluorescence intensity (M.F.I.) values ± SEM from three independent experiments. (E to G) HEK293T cells on 6-well plates were transfected with the indicated amounts of the plasmid encoding S-FL or S-dCT19, and cell surface staining was conducted with 3 μg/mL hACE2-NN-Ig (E), 3 μg/mL NTD antibody (Ab) (F), or plasma sample 9 (at a 1:200 dilution) recognizing only S2 (G). (H) Experiment similar to the one for panel B except that staining was conducted in cells permeabilized with 0.1% saponin. (I and J) S protein expression levels were assessed in cells lysed with dodecyl maltopyranoside and blotted with rabbit anti-S antibody (I) or the same NTD antibody used for panel F (J). The average mean fluorescence intensity values ± SEM from three independent experiments are shown. Statistical significance was analyzed by one-way ANOVA using Dunnett's multiple-comparison test (B to D) or two-way ANOVA using Sidak's multiple-comparison test (E to G) (*, $P < 0.05$; **, $P < 0.005$; ***, $P < 0.0005$; ****, $P < 0.0001$; ns, not significant).

S-dCT5, are stronger than that in S-FL. These data are consistent with our conclusion drawn from cell surface expression and confirm that S-dCTs, except S-dCT5, retain higher levels of S1 than S-FL owing to reduced S1 shedding.

Cytoplasmic tail truncation dramatically enhances functional S protein incorporation into PV particles. As the S protein mediates receptor attachment, the quantity and quality of spike trimers on the virion determine virus and PV infectivity. Thus, we measured the S protein density on PV-FL and PV-dCTs, which were pelleted through a sucrose layer ("sucrose-pelleted PV"), by WB analyses, using plasma sample 2, which recognizes both S1 and S2 (Fig. 2A). When the same numbers of PV particles were analyzed, as supported by the comparable amounts of p30, the MLV Gag protein, the intensities of the S1 and S2 bands of all PV-dCTs, except PV-dCT5, were dramatically increased compared to those of PV-FL (Fig. 3A, left), which were barely detectable only with a much longer exposure of the same blot (Fig. 3A, right). These data demonstrate that CT truncation leads to the much more efficient incorporation of the S protein into PV particles.

To confirm that the increased intensities of the S1 and S2 bands of PV-dCTs assessed by WB analyses (Fig. 3A and B) actually reflect an increased spike density on the virion, we visualized PV-FL and PV-dCT19 by cryo-electron microscopy (cryo-EM). We focused on PV-dCT19 because it exhibits the highest infectivity and virion spike density. Examined by cryo-EM, both PV-FL and PV-dCT19 were quite heterogeneous with respect to their spike densities. Although PV-dCT19 particles generally exhibited higher spike densities than PV-FL particles, to analyze them in a semiquantitative way, we sorted PV-FL and PV-dCT19 cryo-EM particles into high-, medium-, and low (or bald)-spike-coverage groups (Fig. 3C). Three cryo-EM images, each representing the three categories, are shown in Fig. 3C, left. Using these criteria, cryo-EM images of 61 PV-FL and 88 PV-dCT19 particles (see Fig. S1 in the supplemental material) were sorted with four independent counts. Note that we found only one high-density and two medium-density PV-FL particles. Most PV-FL particles belonged to the low-surface-density group. Specifically, 1.3% and 7.1% of the PV-FL particles belonged to the high- and medium-density groups, respectively, while the majority, 91.6%, had low or undetectable levels of spike (Fig. 3D). In contrast, PV-dCT19 virions were more evenly distributed among the high-, medium-, and low-surface-density groups (Fig. 3D): high at 25.4%, medium at 40.6%, and low/bald at 34.0%. These cryo-EM data are consistent with the WB results and clearly demonstrate that PV-FL overall has a much lower virion spike density than does PV-dCT19.

Cytoplasmic tail truncation significantly enhances functional S protein on PV particles. Much higher S1 levels were detected on PV-dCTs (Fig. 3A and B) as well as S-dCTs on the cell surface. To confirm that the higher level of S1 indeed reflects the more efficient retention of S1 on PV-dCTs, we analyzed the S1/S2 ratio of PV-dCTs and PV-FL. Because of the much lower S density of PV-FL, a large amount of PV-FL was compared to a much smaller amount of PV-dCTs in order to detect both the S1 and S2 bands in both PVs. As Fig. 4A and its quantification in Fig. 4B show, the S1/S2 ratio of PV-dCT19 is approximately 2.5-fold higher than that of PV-FL. This result is consistent with the differences that we observed with cell surface-expressed S-FL and S-dCTs (Fig. 2D, E, and F) and again indicates that CT truncation contributes to the greater retention of S1.

To understand the three-dimensional organization of the S protein on the surface of PVs, we performed cryo-EM tomography with PV-FL and PV-dCT19 (Fig. 4 and Fig. S2). On some of the PV surfaces, we were able to distinguish the prefusion trimers, which look like half-blossomed flowers, from the postfusion trimers, which look like thin sticks, as a result of S1 shedding and the conversion of S2 to a helical-bundle conformation (Fig. 4C) (37–39). Sequentially slabbing through the three-dimensional tomogram slices, we observed that most PV-FL particles have extremely low coverage of surface proteins and that the majority of the spike trimers are in the postfusion conformation, with a subset being in the prefusion conformation (Fig. 4D). In contrast, on PV-dCT19, prefusion spikes can be abundantly identified amid closely spaced clusters

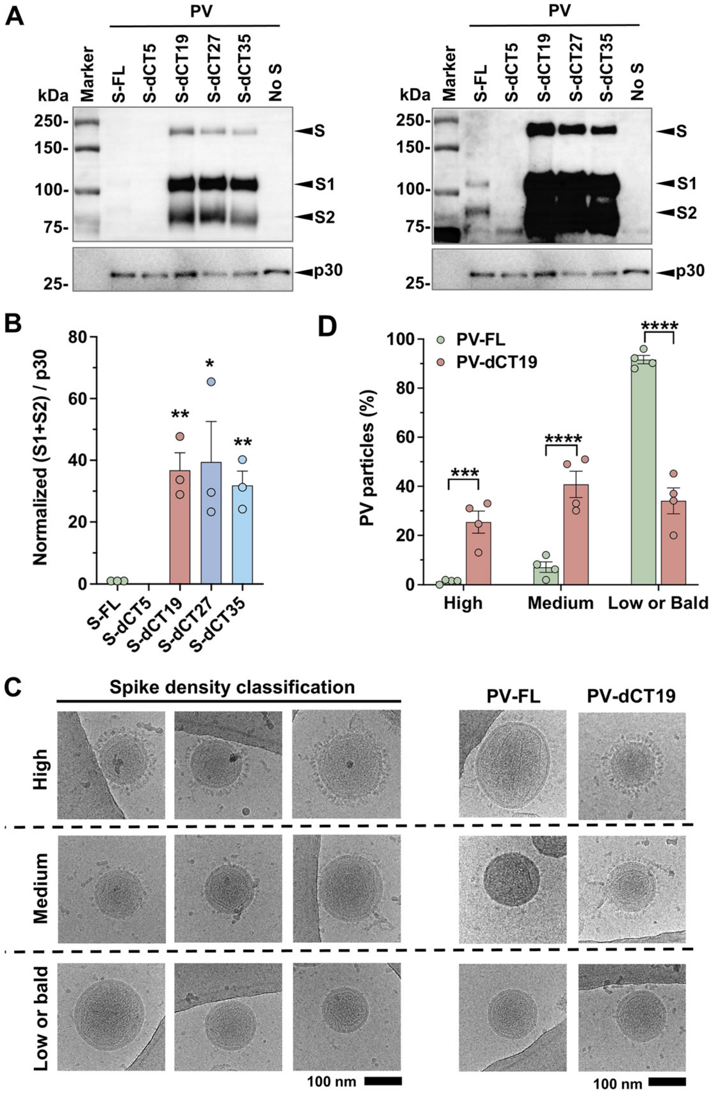

FIG 3 Cytoplasmic tail truncation dramatically enhances S protein incorporation into PV particles. (A) PVs bearing the indicated S variants and produced from HEK293T cell transfection were pelleted through a layer of 30% of sucrose and analyzed by Western blotting. The S, S1, and S2 bands were detected using convalescent-phase plasma sample 2 at a 1:200 dilution. (Left) Blot representative of results from three independent experiments. The S1 and S2 bands of S-FL and S-dCT5 are too weak to be detected. (Right) A much longer exposure of the same blot shown on the left. The S1 and S2 bands of S-FL, but not those of S-dCT5, are visible. (B) Sum of the S1 and S2 band intensities of the Western blot shown in panel A normalized to the intensity of the p30 band in the same blot. Shown are the averages from three independent experiments. (C, left) As both PV-FL and PV-dCT19 exhibit heterogeneous spike densities, to provide an objective guideline for semiquantitative evaluation, three representative cryo-EM images were selected for each of the high-, medium-, and low/bald-spike-density groups. (Right) Images selected separately from PV-FL and PV-dCT19 for each category. Note that there are only one high-density and a few medium-density particles among 61 PV-FL particles. (D) A total of 149 PV particles (61 PV-FL and 88 PV-dCT19 [shown in Fig. S1 in the supplemental material]) were evaluated by four individuals and categorized into the high-, medium-, and low/bald-density groups using the criteria described above for panel C. Mean values ± SEM are shown. Statistical significance was analyzed by an unpaired *t* test (B) and two-way ANOVA using Sidak's multiple-comparison test (D) (*, $P < 0.05$; **, $P < 0.005$; ***, $P < 0.005$; ****, $P < 0.0001$).

of proteins on the PV surface resolved in three dimensions (Fig. 4E). While the high density of protein on the PV-dCT19 particles could mask the presence of some postfusion spikes, and only a portion of the spike conformations are clearly identifiable, many spike trimers appear to be in the prefusion conformation. The higher abundance of prefusion spike trimers on PV-dCT19 is consistent with the presence of intact, functional S-dCTs on the cell surface (Fig. 2) and the high S1/S2 ratios observed in WB

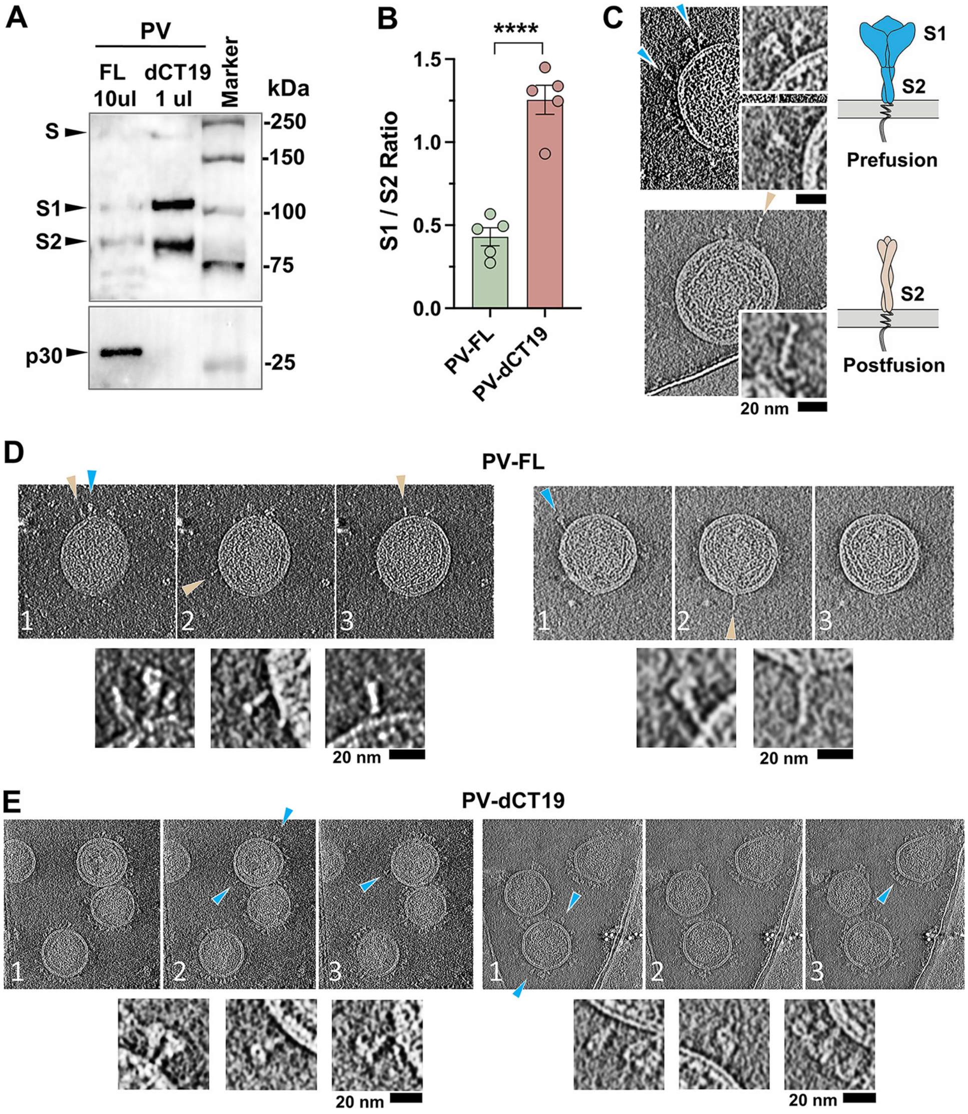

FIG 4 Cytoplasmic tail truncation significantly enhances functional S protein on PV particles. (A) The same PVs shown in Fig. 3A but with PV-FL compared to 10-times-less PV-dCT19 to more accurately measure their S1/S2 ratios. (B) Mean S1/S2 ratios ± SEM of PV-FL and PV-dCT19 analyzed from five Western blots performed with three sets of independently prepared PV batches. Statistical significance was analyzed by an unpaired *t* test (****, $P < 0.0001$). (C) Prefusion (top) (blue arrows) and postfusion (bottom) (light-brown arrow) conformations of spike trimers on sucrose-pelleted PVs examined by cryo-EM tomography. Schematic representations of these two spike conformations are presented at the right. (D) Sequential slices, indicated by the numbers at the bottom left, of PV-FL cryo-electron tomograms, with a mix of prefusion (blue arrows) and postfusion (light-brown arrows) S conformations, enlarged at the bottom. (E) Sequential slices, indicated by the numbers at the bottom left, of PV-dCT19 cryo-electron tomograms, with mostly the prefusion (blue arrows) S conformation, enlarged at the bottom. See also Fig. S2 in the supplemental material.

analyses of PV-dCTs relative to PV-FL (Fig. 4A). Taken together, these data demonstrate that CT truncation enhances S protein incorporation into PVs and S1 retention in the spike, leading to much higher numbers of prefusion spikes on the pseudovirion, thus providing an explanation for the dramatic increase in PV-dCT infectivity.

DISCUSSION

CT truncation of virus entry glycoproteins has been widely used to enhance the infectivity of various PVs. Although several potential explanations were offered, the underlying mechanism for the greatly enhanced PV infectivity is still unclear. Increased cell surface expression of viral glycoproteins upon CT truncation was proposed as an

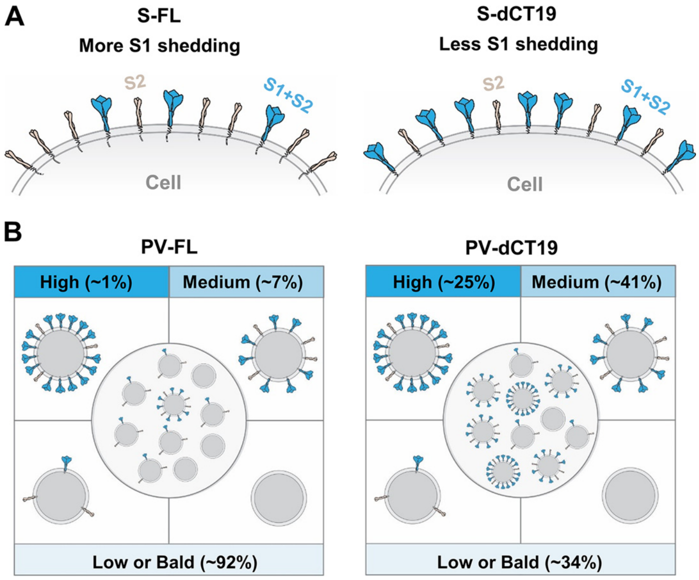

FIG 5 Schematic representation of increased functional spikes on the cell surface and in pseudoviruses upon CT truncation of the S protein. (A) Higher levels of functional S-dCTs are observed on the cell surface, while S2 levels are similar between S-dCTs and S-FL. Functional spikes (in blue), assessed using ACE2-NN-Ig or NTD antibody (Fig. 2D to F), contain both S1 and S2 in the prefusion conformation. Nonfunctional spikes (in light brown), measured using plasma sample 9, which recognizes only S2 (Fig. 2C and G), consist of only S2 in the postfusion conformation. (B) PV-dCTs exhibit much higher levels of functional spikes than PV-FL. The diagrams of four PVs represent those with a high, medium, or low spike density or bald virions. The group of 10 PV particles in the center for PV-FL and PV-dCTs reflects the approximate composition of each PV population with respect to the virion spike density. The proportion of each spike density group in the PV-FL and PV-dCT19 populations was assessed using cryo-EM micrographs (Fig. 3C and D; see also Fig. S1 in the supplemental material).

explanation for the enhanced PV infectivity, but conflicting results were also reported (20, 22–24). Furthermore, even if cell surface expression is increased, the degree of the increase is modest and thus would not be sufficient to explain the dramatic change in PV infectivity. Increased fusogenicity of the glycoproteins induced by CT truncation was also proposed for measles, murine leukemia, vesicular stomatitis, and Nipah viruses (18, 20, 23, 25–27, 33), and a conformational change in the ectodomain induced by inside-out signaling was proposed to explain such increased fusogenicity (20, 25, 27).

Our study here shows that the cell surface expression of CT-truncated SARS-CoV-2 S protein could lead to different outcomes depending on which subunit, S1, S2, or both, is measured (Fig. 5A). If S2 is measured, no significant difference is detected, while a modest increase is observed if both S1 and S2 are measured. However, if only S1 is measured, a much higher S1 level is observed with S-dCT19, -27, and -35 than with S-FL. These data provide an explanation for the conflicting reports on the cell surface expression of the CT-truncated viral entry glycoproteins (20, 22–24).

Our study further identifies two different mechanisms underlying the dramatically increased infectivity of SARS-CoV-2 PVs carrying a CT truncation. Through biochemical and cryo-electron microscopy, we show that CT truncation promotes S protein incorporation into PVs and enhances S1 retention on the S protein. These two events together result in much higher numbers of functional spikes in PV-dCT19, -27, and -35 (Fig. 5B), leading to a dramatic increase in their infectivity. Our results on the increased S1 retention on S-dCTs are consistent with previous reports in which increased fusogenicity upon CT truncation was observed for the entry glycoproteins of various viruses (18, 25–27). Those studies were conducted using syncytium formation assays, and thus, a higher level of the surface subunit of a glycoprotein expressed on the cell surface would have resulted in more efficient syncytium formation. Although further studies are necessary, the increased S1 retention on S-dCTs may arise from the enhanced flexibility of the S2 subunit, which accommodates a more stable S1-S2 interaction.

Our data also show that the differences in spike density induced by CT truncation are much greater in PVs than on the cell surface; while the S2 levels are similar between S-FL and S-dCTs on the cell surface (Fig. 2C), they are much higher in PV-dCTs than in PV-FL (Fig. 3A). A higher spike density in PV-dCTs would be possible if S-dCTs are more enriched in lipid rafts than S-FL because many viruses bud from this microdomain. However, S-dCT27 and S-dCT35 lack some or all of the motifs for palmitoylation, a modification that promotes protein trafficking into lipid rafts (40), and thus, it is unlikely that S-dCTs are enriched in lipid rafts and more efficiently incorporated into the virion. A more likely explanation is that S-dCTs can be more freely incorporated into PVs because they lack the binding motif for Ezrin-Moesin-Radixin proteins that anchor membrane proteins to the cellular cytoskeleton (41). An alternative explanation is that the steric hindrance formed between the structural proteins of PVs (Gag or matrix protein) and the large CT of S-FL makes it difficult to be incorporated into PVs, whereas the smaller CT of S-dCTs allows more efficient incorporation into PVs, as we previously proposed (21).

MATERIALS AND METHODS

Plasmids. The SARS-CoV-2 S protein gene was codon optimized and synthesized by Integrated DNA Technologies based on the protein sequence (Wuhan-Hu-1 strain [GenBank accession number YP_009724390]) and cloned into the pCAGGS vector (42). The genes for cytoplasmic-tail-truncated variants of the SARS-CoV-2 S protein were also synthesized and cloned into the pCAGGS vector. None of these genes contain a tag. The retroviral vector pQCXIX (Clontech), encoding enhanced green fluorescent protein (eGFP) or firefly luciferase (FLuc), and the plasmid expressing the MLV Gag and Pol proteins or the G protein of VSV (VSV-G) were previously described (43). An hTMPRSS2 expressor plasmid was constructed by cloning its residues 1-492 (GenBank accession number NP_005647) into the retroviral vector pQCXIB (44). The hACE2 expressor plasmid was constructed by cloning its residues 20 to 805 (GenBank accession number NM_021804) downstream of the mouse ACE2 signal sequence (MSSSSWLLLSLVAVTTAQS) and the Myc tag sequence into the retroviral vector pQCXIP. The expression plasmid for hACE2-NN-Ig was previously described (45): the hACE2 ectodomain fragment (residues 20 to 615 [GenBank accession number NM_021804]) containing the H374N and H378N mutations was cloned into pcDNA3.1 containing the CD5 signal sequence and the Fc region of human IgG1.

Cells. Human embryonic kidney HEK293T cells were obtained from the ATCC and maintained in high-glucose Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS) at 37°C with 5% CO_2. HEK293T cells transduced to stably express hACE2 and hTMPRSS2 (hACE2/hTMPRSS2-293T cells) or mock transduced (Mock-293T cells) were selected and maintained in medium supplemented with 1 μg/mL puromycin and 10 μg/mL blasticidin (InvivoGen). The transduction vectors for hACE2 and hTMPRSS2 were produced by transfecting pQCXIP-hACE2 or pQCXIB-hTMPRSS2 into HEK293T cells together with the plasmid encoding murine leukemia virus Gag-Pol and the plasmid encoding the G protein of vesicular stomatitis virus. The vector for mock transduction was produced similarly using the empty pQCXIP or pQCXIB plasmid.

MLV PV production and sucrose pelleting. HEK293T cells at ~60% confluence in T75 flasks were transfected using a calcium-phosphate method with 24 μg of total DNA at a ratio of 5:5:1 (by mass) of the retroviral vector pQCXIX encoding eGFP or FLuc, the plasmid expressing MLV Gag and Pol proteins, and the plasmid expressing either the full-length S protein or the truncated version of the S protein of SARS-CoV-2 (Wuhan-Hu-1). Transfected cells were washed at 6 h posttransfection and replenished with 10 mL DMEM supplemented with 10% FBS. The PV-containing culture supernatants were collected at 43 h posttransfection, cleared through 0.45-μm filters, and either immediately aliquoted and stored at −80°C or used for entry experiments.

For sucrose-pelleted PV preparation, 10 mL of the cleared culture supernatants containing PVs precleared by centrifugation in a TX-400 swinging-bucket rotor at 3,000 rpm for 10 min followed by filtration through 0.22-μm filters was loaded onto 2 mL of 30% sucrose (catalog number S7903; Sigma-Aldrich) in NTE buffer (120 mM NaCl, 20 mM Tris, 2 mM EDTA [pH 8.0]) and centrifuged at 50,000 $\times$ g in an SW41 rotor for 2 h at 10°C. The PV pellets were resuspended in 20 μL NTE buffer with gentle shaking on ice and either used immediately or aliquoted and frozen at −80°C.

PV quantification. PVs were quantified by RT-qPCR using primers and a probe that target the cytomegalovirus (CMV) promoter. Culture supernatants containing PVs were treated with 100 μg/mL RNase A for 1 h at 37°C to degrade RNAs that were not packaged inside the virion, and RNA was extracted with TRIzol and GlycoBlue coprecipitant and digested for 30 min at 37°C with DNase I at 1 IU per 1 μg extracted RNA. DNase I was inactivated by incubation for 10 min at 65°C with EDTA added to a final concentration of 5 mM. DNase-treated RNA was reverse transcribed using a high-capacity cDNA reverse transcription kit (catalog number 4374966; Applied Biosystems). qPCR was performed, using Luna universal probe qPCR master mix (catalog number M3004E; New England BioLabs) with a known quantity of the pQCXIX vector (Clontech), to generate standard curves, and data were collected with CFX Manager 3.1 (Bio-Rad). The primers and probe were synthesized by Integrated DNA Technologies (sense primer 5′-TCACGGGGATTTCCAAGTCTC-3′, antisense primer 5′-AATGGGGCGGAGTTGTTACGAC-3′, and probe 5′-FAM [6-carboxyfluorescein]-AAACAAACT-[ZEN]-CCCATTGACGTCA-IBFQ-3′).

PV entry assay in hACE2-hTMPRSS2-293T cells. A PV entry (transduction) assay was performed by incubating Mock-293T or hACE2/hTMPRSS2-293T cells on 48-well plates with PVs (5 × 10^8 genome copies in 200 μL per well) for 1 h at 37°C in a CO_2 incubator. Medium was replaced with DMEM containing 10% FBS. The entry levels of PVs expressing firefly luciferase were assessed by measuring luciferase activity using the Luc-Pair firefly luciferase HS assay kit (catalog number LF009; GeneCopoeia) and reading the plates on the SpectraMax paradigm multimode detection platform using SoftMax Pro 6.3 (Molecular Devices).

Screening of human plasma. Deidentified plasma samples were obtained by the Allergy, Asthma, and Immunology Specialists of South Florida, LLC, in mid-2020 for COVID-19 serotyping, and these were exempt (IRB-20-7580) from human subject research under CFR 45.101(b). These plasma samples were screened by Western blotting at a 1:200 dilution for their ability to recognize the S1 and S2 subunits of the SARS-CoV-2 S protein on sucrose-pelleted PV-dCT19. The blot was visualized using 1:10,000-diluted goat anti-human IgG conjugated with horseradish peroxidase (HRP) (catalog number 109-035-098; Jackson ImmunoResearch).

Cell surface and total expression of the spike protein. HEK293T cells at approximately 70% confluence in 6-well plates were transfected with 0.3 μg, unless indicated otherwise, of the plasmid expressing the indicated S protein variant. Cells were detached at 42 h posttransfection in phosphate-buffered saline (PBS) containing 2 mM EDTA. Approximately 1 × 10^6 cells were fixed with a 2% formaldehyde solution in PBS for 30 min on ice and blocked with PBS containing 2% bovine serum albumin (BSA) (Sigma-Aldrich) and 5% goat serum (Gibco) for 30 min on ice. These cells were then incubated on ice for 90 min in 100 μL of PBS containing either SARS-CoV-2 convalescent-phase plasma at a 1:200 dilution, 3 μg/mL of purified hACE2-NN-Ig (9), or 3 μg/mL of anti-NTD monoclonal antibodies (catalog number SPD-M121; Acro Biosystems), followed by 1:600-diluted anti-hIgG–Alexa Fluor 647 (AF647) (catalog number 109-605-003; Jackson ImmunoResearch). Stained cells were analyzed using an Accuri flow cytometer (BD Biosciences) equipped with the HyperCyt autosampler (IntelliCyt) and ForeCyt 6.2R3 software (IntelliCyt). To measure the total expression levels of the S protein, aliquots of the same cells were permeabilized with 0.1% saponin (Alfa Aesar) in PBS for 10 min at room temperature and subjected to staining on ice as described above.

Western blot analysis of S protein in cell lysates and on pseudovirions. For the detection of S protein bands in the cell lysates, HEK293T cells in 6-well plates were transfected to express S-FL or S-dCT5 and lysed with 0.2 mL of PBS containing 0.5% dodecyl maltopyranoside (Anatrace) and a protease inhibitor cocktail (catalog number A32955; Thermo Scientific). Fifteen microliters of the lysates was analyzed by WB using rabbit anti-S protein antibody (catalog number NR-52947; BEI Resources) at a 1:5,000 dilution or 1 μg/mL of NTD antibody (catalog number SPD-M121; Acro Biosystems) For the analyses of the S protein density on the virion, sucrose-pelleted PVs were analyzed by SDS-PAGE and WB. Unless indicated otherwise, 5 μL PVs was analyzed in each WB analysis. PV proteins were separated on a 4 to 12% Bis-Tris gel (catalog number NW041122; Life Technologies) and transferred to a polyvinylidene difluoride (PVDF) membrane. The membrane was blocked with 5% milk in 1× Tris-buffered saline containing 0.1% Tween 20 for 1 h and blotted with human SARS-CoV-2 convalescent-phase plasma at a 1:200 dilution to detect the S protein bands or 1 μg/mL anti-p30 MLV Gag antibody (catalog number ab130757; Abcam) to detect p30 bands as a PV quantity control. S protein bands were detected using 10 ng/mL mouse anti-human IgG antibody conjugated with polymerized HRP (catalog number 61R-I166AHRP40; Fitzgerald), and p30 bands were detected using 1:10,000-diluted goat anti-mouse IgG–HRP polyclonal antibody (catalog number 115-036-062; Jackson Immuno Laboratory). Bands were visualized using the SuperSignal West Atto ultimate-sensitivity substrate (catalog number A38555; Thermo Scientific), and the band intensities were measured using Image Lab software (Bio-Rad).

Cryo-EM of full-length and dCT19 spike proteins. For cryo-EM samples, 300-mesh R2/2 copper Quantifoil grids (Electron Microscopy Sciences [EMS]) were negatively glow discharged for 30 s. The PV sample (3.5 μL) was applied onto the grid and incubated for 30 s, followed by plunge-freezing into liquid ethane with a Vitrobot Mark IV instrument (100% humidity, 4°C, and 4.5 s per blot). The grids were imaged on an FEI Tecnai T12 120-kV electron microscope.

For cryo-electron tomography, grids were prepared as described above, with the addition of 10-nm gold beads at a ratio of 14:1 (vol/vol) before plunge-freezing. Dose-symmetric tilt series (to ±48° with 3° increments) were collected on a Titan Krios instrument with a K3 detector (total dose of 100 $e^-/Å^2$; 7 frames per angle) and a 20-eV energy filter. The data set was motion corrected with MotionCor2 (46), reconstructed with IMOD (47), denoised with Topaz (48), and processed using ImageJ software.

Statistical analysis. All of the statistical details of specific experiments, which included the statistical tests used, numbers of samples, mean values, standard errors of the means (SEM), and *P* values derived from the indicated tests, are described in the figure legends and shown in the figures. Statistical analyses were conducted utilizing GraphPad Prism version 8.0 (GraphPad Software Inc.). Triplicate and other replicative data are presented as means ± SEM. A *P* value of <0.05 was considered to be statistically significant. For comparisons between two treatments, Student's *t* test (unpaired) was used. For comparisons of each group with the mean of every other group within a data set containing more than two groups, either one-way analysis of variance (ANOVA) with Dunnett's multiple-comparison test or two-way ANOVA with Sidak's multiple-comparison test was used.

Received 6 October 2006/Accepted 31 January 2007

The cytoplasmic tails of the envelope proteins from multiple viruses are known to contain determinants that affect their fusogenic capacities. Here we report that specific residues in the cytoplasmic tail of the Nipah virus fusion protein (NiV-F) modulate its fusogenic activity. Truncation of the cytoplasmic tail of NiV-F greatly inhibited cell-cell fusion. Deletion and alanine scan analysis identified a tribasic KKR motif in the membrane-adjacent region as important for modulating cell-cell fusion. The K1A mutation increased fusion 5.5-fold, while the K2A and R3A mutations decreased fusion 3- to 5-fold. These results were corroborated in a reverse-pseudotyped viral entry assay, where receptor-pseudotyped reporter virus was used to infect cells expressing wild-type or mutant NiV envelope glycoproteins. Differential monoclonal antibody binding data indicated that hyper- or hypofusogenic mutations in the KKR motif affected the ectodomain conformation of NiV-F, which in turn resulted in faster or slower six-helix bundle formation, respectively. However, we also present evidence that the hypofusogenic phenotypes of the K2A and R3A mutants were effected via distinct mechanisms. Interestingly, the K2A mutant was also markedly excluded from lipid rafts, where ~20% of wild-type F and the other mutants can be found. Finally, we found a strong negative correlation between the relative fusogenic capacities of these cytoplasmic-tail mutants and the avidities of NiV-F and NiV-G interactions ($P = 0.007$, $r^2 = 0.82$). In toto, our data suggest that inside-out signaling by specific residues in the cytoplasmic tail of NiV-F can modulate its fusogenicity by multiple distinct mechanisms.

Nipah virus (NiV) and *Hendra virus* (HeV) are deadly emerging zoonotic viruses belonging to the new *Henipavirus* genus within the family *Paramyxoviridae* (66). NiV infections result in respiratory and neurological symptoms, often leading to fatal encephalitis, the primary reason for death in humans (32, 64). Microvascular endothelial cell syncytium formation is a hallmark of NiV infection, associated with endothelial cell death, vascular inflammation, and necrosis (70). The mortality rate of NiV-infected humans ranges from ~40% in the original outbreaks in Malaysia and Singapore in 1999 to 2000 to ~70% in Bangladesh in 2005 (5, 6). The natural reservoir for NiV has been determined to be fruit bats of the genus *Pteropus* (46), and pigs served as the intermediate amplifying host in the original Malaysian-Singaporean outbreaks. Ominously, even though human-to-human transmission was not documented in the original outbreaks, direct bat-to-human and human-to-human transmissions have been reported in the later outbreaks in Bangladesh (5, 6). NiV is classified as a BSL4 pathogen and has also been designated as a select agent because of its bio- or agroterrorism potential. These characteristics of NiV underscore the need for research and treatment development against this perilous pathogen and the need for understanding of the necessary components and mechanisms of virus-cell and cell-cell fusions in order to inhibit viral infection and spread.

For paramyxoviruses, two separate membrane proteins are involved in the fusion process, the attachment protein (H, HN, or G), which binds to the receptor molecule in the target cell membrane, and the fusion protein (F) that actually carries out membrane fusion. For most paramyxoviruses, both F and its homotypic attachment protein are necessary for membrane fusion, except for rare cases like the hyperfusogenic simian virus 5 (SV5) W3A isolate (27, 48). Activation of F is believed to occur through the following three steps: (i) binding of the attachment protein to the receptor, (ii) interaction of the attachment and F proteins (or changes thereof), and (iii) conformational changes in F that mediate membrane fusion. The fusion (F) and attachment (G) envelope glycoproteins in NiV or HeV are both necessary for cell-cell fusion, syncytium formation, and viral entry. G is responsible for binding to its cognate receptor, ephrinB2 (9, 44), and at least for NiV, ephrinB3 can also be used as an alternative receptor (45). The high expression of ephrinB2 on neurons and endothelial cells and the patterns of expression of ephrinB3 in the central nervous system largely account for the cell tropism of NiV and HeV (9, 44, 45). However, much less is known about the components necessary for the subsequent steps in the activation of NiV fusion (NiV-F) or HeV-F protein.

Paramyxovirus F proteins belong to the class I fusion proteins that share several structural and functional characteristics. The structures of the retroviral Moloney murine leukemia virus (MoMuLV) p15E, lentiviral human immunodeficiency virus type 1 (HIV-1) gp41, Ebola virus GP2, paramyxovirus SV5 F, and influenza virus hemagglutinin (HA) fusion proteins have all been shown to have similar trimeric coiled-coil core

structures, suggesting similar membrane fusion mechanisms (8, 14, 20, 72). Class I fusion proteins of enveloped viruses are synthesized as precursors that must be cleaved and hence activated into a metastable conformation that is ready for enabling virus-cell membrane fusion. Typically, cleavage generates a new N terminus that contains a hydrophobic fusion peptide motif. Upon activation of the fusion protein through receptor binding and/or endosomal low pH, the fusion peptide gets inserted into the host cell target membrane. Class I fusion proteins also contain two heptad repeat regions (HR1 and HR2); the C-terminal HR2 region is generally thought to be preformed, but the N-terminal HR1 region is formed only upon fusion peptide insertion (14, 35, 72, 73). Class I fusion proteins function as trimers, and the HR1 and HR2 regions have a strong propensity to fold into coiled-coil domains during six-helix bundle (6HB) formation. The free energy released from fusion protein refolding from the metastable prefusion state to the stable postfusion 6HB state likely drives the virus-host cell membranes together, overcoming the electrostatic repulsion intrinsic to the negatively charged phospholipids' head groups of the two membranes (38, 55).

For NiV and HeV, the fusion protein is cleaved within the endosomal compartment from the precursor F_0 to the F_1 and F_2 subunits (18, 39). Such cleavage is likely required for activation of the F protein into the metastable state. For NiV, after activation into the metastable state, not much is known about the subsequent steps in the triggering of the fusion protein that leads to eventual membrane fusion. We and others have recently reported that N-glycans in both the NiV-F and HeV-F proteins have some effects on protein expression and membrane fusion (3, 15, 40). In addition, we identified N-glycans in NiV-F that both reduce fusion and viral entry and protect the virus against neutralizing antibodies (Abs) (3). These results show some uniqueness of the *Henipavirus* genus fusion proteins. However, little is known about other domains in NiV-F or HeV-F that may have an important role in membrane fusion. Triggering of fusion is usually envisioned to involve primarily the ectodomain of the fusion protein. However, accumulating evidence from retroviral (13, 25, 50, 54), lentiviral (41, 42), and other paramyxoviral (65, 67) envelope (Env) proteins suggests that the Env cytoplasmic tail (CT) is involved in regulating the fusion process.

Multiple reports indicate that fusion mediated by the ectodomain of the retrovirus MoMuLV (2), the lentiviruses simian immunodeficiency virus (SIV) (61) and HIV-1 (71), and the paramyxovirus SV5 (67) fusion proteins can be modulated by inside-out signaling from the CT. Truncation of the long CT of lentiviral Env proteins occurs under certain culture conditions, and increased fusogenicity has been reported for truncated versions of SIV, HIV-1, and HIV-2 Env (16, 31, 41, 60, 61, 76). For the paramyxovirus SV5 F protein, isolates with a short (20-residue) CT (W3A and WR) cause extensive cell-cell fusion, whereas isolates with an extended CT (T1 and SER) cause little or no cell-cell fusion, and truncation of the CT restores fusion to levels seen in W3A and WR isolates (28, 65). For MoMuLV, SIV, and SV5, the hyperfusogenicity caused by truncation of the CT is linked to overall conformational changes in the ectodomain of the protein (2, 61, 67). In MoMuLV and the Mason-Pfizer monkey virus, the CT is even protease cleaved during viral maturation to "prime" the fusion protein for fusogenicity (2, 13). Here we investigated the potential role(s) of the CT of the NiV fusion protein in cell surface expression (CSE), processing, membrane fusion, and viral entry and defined specific residues in a polybasic motif in the CT that can affect the conformation of the ectodomain, fusogenicity, and interaction of the fusion protein with the attachment glycoprotein.

MATERIALS AND METHODS

Expression plasmids and codon optimization. The codon-optimized NiV-G and NiV-F genes were tagged at their C termini with HA and AU1 tags, respectively, as previously described (33). The NiV-HR2-Fc construct was made by fusing the heptad repeat region 2 sequence of NiV-F (amino acids 447 to 488) with the human immunoglobulin G1 Fc constant region as previously described (3, 44). The deletion mutants −T, −T1, −T2, −T3, −T4, −T12, and −T234 and point mutants K1A, K2A, R3A, N4A, and T5A were made by deleting or mutating the codon-optimized wild-type (WT) NiV-F plasmid with appropriately designed primers and the QuikChange site-directed mutagenesis kit (Stratagene, Cedar Creek, TX). All mutations and deletions were confirmed by sequencing the entire open reading frame.

Cell culture. Vero cells were cultured in minimal essential medium alpha with 10% fetal bovine serum (FBS). PK13 and 293T cells were cultured in Dulbecco's modified Eagle's medium with 10% FBS. We obtained 293T and Vero cells from the American Type Culture Collection, and PK13 (porcine fibroblasts) cells were a kind gift from Irvin Chen at the University of California Los Angeles.

Quantitation of cell-cell fusion. Codon-optimized NiV-G and codon-optimized WT or mutant NiV-F expression plasmids (1:1 ratio, 1 μg total) (3, 33) were transfected with 1.5 μg pcDNA3.1 plasmid as filler DNA into 293T or Vero cells growing in 12-well plates at 80% confluence, as indicated. At 12 to 18 h posttransfection, cells were stained with 4′,6′-diamidino-2-phenylindole (DAPI) and syncytium formation was quantified by counting the nuclei in syncytia per ×100 field (at least 10 fields were counted per condition). Syncytia were defined as four or more nuclei visualized within a common cell membrane, as indicated previously (3).

Quantification of NiV-F and NiV-G CSE levels by flow cytometry. Production of antisera from genetically immunized rabbits (with NiV-M and -F or -G expression plasmids) was previously described (44). Sera containing anti-F or anti-G specific activities were used for flow cytometry on NiV-F- or -G-transfected cells at a 1:1,000 dilution. Bound Ab was detected with phycoerythrin-conjugated goat anti-rabbit Abs (Caltag, Burlingame, CA). Antisera were also raised in rabbits immunized with peptides corresponding to amino acids 39 to 57 and 331 to 348 of NiV-F_2 and NiV-G, respectively, as previously described (3, 33). These regions were previously shown to be immunogenic (10). For quantitation of binding of the monoclonal Abs (MAbs), flow cytometry was performed with MAb concentrations of 0.03 to 3 μg/ml. For calculating the binding ratios of any given pair of Abs, data obtained from equal concentrations of the respective Abs were used.

Reverse pseudotype viral entry assay. The ephrinB2 NiV receptor protein was pseudotyped onto a reporter virus, vesicular stomatitis virus (VSV), by transfecting an ephrinB2 expression plasmid into 293T cells and subsequently infecting these cells with recombinant VSV expressing the *Renilla* Luc reporter gene (VSV-ΔG-rLuc), similarly to the procedure described previously for preparation of NiV-F- and -G-pseudotyped VSVrLuc virions (3, 44, 45). ephrinB2 reverse-pseudotyped virions were purified over a 20% sucrose cushion as for NiV-F- and -G-pseudotyped viruses. 293T cells plated in 96-well plates were transfected with NiV-G and WT or mutant NiV-F and, 10 to 12 h later, infected with reverse-pseudotyped virions in phosphate-buffered saline–1% FBS for 2 h at 37°C over a 5-log viral dilution range (10^{-2} to 10^{-6}). After 2 h, cells were washed and 293T cell growth medium was added. At 24 h postinfection, cells were lysed and luciferase activity was measured as relative light units (RLU) with a *Renilla* luciferase detection system (Promega, Madison, WI) and a Veritas microplate luminometer (Turner Biosystems, Sunnyvale, CA). Quantitation of viral genome copies for the ephrinB2 VSV-pseudotyped viral prep was performed exactly as previously described (3). For quantitation of neutralization of viral entry, the reverse-pseudotyped viral entry assay was performed as described above, except in the presence of the indicated amounts of the specified Abs. For the mixed heterotrimer experiments with the K1A and K2A or R3A mutant proteins, the indicated DNA ratios of the expression plasmids for the indicated proteins were transfected into 293T cells 18 h before infection with the reverse-pseudotyped virions.

Western blot analysis of surface NiV-F and NiV-G proteins. Codon-optimized NiV-F and/or NiV-G expression plasmids (1:1 ratios when in combination) were transfected into 293T cells plated in six-well plates (total of 2 μg F and/or G plasmids with 3 μg PCDNA3.1 plasmid as filler DNA/well), as indicated. Cells were either cell surface biotinylated or not (EZ link Sulfo-NHS-LC-Biotin; Pierce, Rockford, IL), as specified, and biotinylated proteins were precipitated with streptavidin-agarose beads (Pierce, Rockford, IL). Twenty percent of the biotinylated cell lysate was subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis and subsequently detected by Western blotting with anti-tag (HA or AU1), anti-F_2, or anti-G peptide Abs, as indicated. Primary and secondary Abs were used at 1:1,000 and 1:20,000 dilutions, respectively, followed by ECL Plus detection (Amersham Biosciences, Piscataway, NJ). For quantification of relative processing levels for the various NiV-F proteins, the ratio of the densitometric units of the F_1 subunit over those of the sum of the precursor F_0 and the F_1 subunits was calculated.

Lipid raft association of NiV-F proteins. 293T cells transfected with WT or mutant NiV-F proteins (as described above) were washed with phosphate-buffered saline and resuspended in TNE buffer (25 mM Tris [pH 7.5], 150 mM NaCl, 5 mM EDTA) containing a protease inhibitor cocktail (Roche, Indianapolis, IN). Cells were Dounce homogenized, and their nuclei were isolated and discarded. Postnuclear supernatants were treated with 1% Triton X-100 for 30 min at 4°C. Cell lysates were then brought up to a 40% OptiPrep (Sigma-Aldrich, St. Louis MO) concentration in 1.2 ml, placed at the bottom of an ultracentrifuge tube, and layered sequentially with 30% (3 ml) and 5% (0.8 ml) OptiPrep layers (in TNE buffer plus protease inhibitors). These discontinuous gradients were centrifuged at 45,000 rpm for 16 h at 4°C in an SW50.1 rotor. After centrifugation, 12 equal fractions were manually collected from the top, protein from 200 μl of each fraction was precipitated by a methanol-chloroform extraction method (69), and each fraction was analyzed by Western blotting. The overall lipid raft domain isolation procedure was similar to that used by Fleming et al. (22).

Production of NiV-HR2-Fc immunoadhesin and fusion inhibition. The NiV-HR2-Fc expression plasmid was transfected into 293T cells, and at 24 h posttransfection, supernatants were collected and concentrated with a Centriplus YM-10 filter (Millipore, Bedford, MA). Protein concentrations were measured by an Fc-specific enzyme-linked immunosorbent assay as previously described (44). For NiV fusion inhibition, the indicated amounts of NiV-HR2-Fc were added to 293T cells transfected with NiV-G and WT or N-glycan mutant NiV-F expression plasmids. Fusion was quantified after overnight incubation as described above.

Fusion kinetics of WT or mutant NiV-F proteins. The fusion kinetics of WT and mutant NiV-F proteins were determined in a β-lactamase reporter cell-cell fusion assay as previously described (3, 34, 53). For better sensitivity, the β-lactamase gene was also codon optimized for mammalian cell expression (Geneart, Inc., Toronto, Ontario, Canada). Fusion-nonpermissive PK13 effector cells were cotransfected with β-lactamase, NiV-G, and WT or mutant NiV-F expression constructs with Lipofectamine 2000. These were then added to 293T target cells labeled with CCF2-AM dye. Effector and target cells were mixed and incubated at 37°C, and cell-cell fusion was detected by analyzing the shift from green to blue fluorescence, indicating β-lactamase cleavage of CCF2. Fluorescence was quantified every 3 min with a CytoFluor Series 4000 Fluorescence multiwell plate reader (PerSeptive Biosystems, Framingham, MA). The results are expressed as the ratio of blue to green fluorescence obtained with NiV-G- and NiV-F-transfected effectors minus the background blue and green fluorescence obtained with empty-vector-transfected cells.

NiV-F–NiV-G coimmunoprecipitation. 293T cells in 10-cm plates were transfected with 20 μg of the indicated NiV-F-G plasmids at a 1:1 ratio with Lipofectamine 2000. At 24 h posttransfection, cells were lysed and cell lysates were subjected to immunoprecipitation as previously described (3, 33), with a 1:100 dilution of anti-NiV-G peptide serum. Coimmunoprecipitated (co-IP) proteins were analyzed by Western blotting with the appropriate anti-tag Ab as described above and then quantified by densitometry with a VersaDoc Imaging System (Bio-Rad, Hercules, CA).

RESULTS

The membrane-proximal region in the CT of the NiV fusion protein plays a role in membrane fusion. The CT of NiV-F can be conveniently divided into four distinct regions, i.e., a membrane-proximal polybasic region (T1), a functional tyrosine-based endocytic motif (YSRL) (18, 39), a highly charged region (T3), and a C-terminal region that is rich in polar residues (T4). To investigate the potential roles that these cytoplasmic regions may play in membrane fusion, protein expression, processing, and transport, we made a series of deletion mutants that lack various regions of the CT, as illustrated in Fig. 1A. The first amino acid of the CT is a glutamic acid and is likely required to demarcate the membrane-spanning domain. Thus, we kept this amino acid in every deletion mutant in order to maximize the likelihood of correct protein folding and expression. We then analyzed the relative levels of CSE and processing of such deletion mutants and compared them to those of WT NiV-F.

Briefly, 293T cells transfected with expression plasmids for WT NiV-F or the indicated mutant proteins were cell surface biotinylated and lysed and cell surface proteins were precipitated with streptavidin beads and then NiV-F detected by Western blotting with the specified Abs (Fig. 1B). Alternatively, we performed flow cytometric analysis on parallel samples of 293T cells expressing WT NiV-F or the deletion mutants with polyclonal anti-NiV-F antiserum 834, which was previously described (3, 33, 45) (Fig. 1D). Both biotinylation and flow cytometric CSE analyses indicated that the deletion mutants were expressed to at least 50% of the WT level and some were even expressed at levels higher than that of the WT. The cell surface biotinylation experiments also showed that the deletion mutants were cleaved and processed more or less at WT levels, with the exception of the deletion mutant missing the entire CT (Fig. 1B, bottom). Interestingly, although this deletion mutant (−T) did not include removal of the C-terminal AU1 tag, the anti-AU1 MAb was not able to detect this protein by Western blotting, perhaps because of the close proximity of the AU1 tag to the detergent-lipid micelles (Fig. 1B, top left part). However, the −T mutant was clearly expressed, as shown by blotting with an anti-F_2 peptide antiserum previously described (3, 33) (Fig. 1B, right part), as well as by flow cytometry (Fig. 1D). Notably, the −T mutant was also not processed efficiently despite being expressed on the cell surface (Fig. 1B, right part).

Cleavage of NiV-F requires active endocytosis and processing by endosomal cathepsin L, which is in part mediated by the YXXΦ endocytic motif in the T2 region (18, 39). Since the AU1 tag contains a putative YXXΦ endocytic motif, we sought to determine if our AU1 tag had any inadvertent effects on the expression or processing of NiV-F. Figure 1C shows that there were no differences in cleavage or processing efficiency between tagged and untagged WT NiV-F (F and F_{NA}, respectively). Interestingly, the untagged version of the T2 mutant ($-T2_{NA}$), which lacks the endogenous YXXΦ motif, also showed no differences from untagged WT NiV-F (F_{NA}), similar to what has been found with the tagged versions (compare Fig. 1B and C).

Next, we asked whether the CT deletion mutations affected the fusogenicity of the NiV-F fusion protein. To normalize for the differences in CSE, we compared the fusion-to-CSE ratios induced by WT NiV-F and the indicated deletion mutants (Fig. 1D). We performed our syncytium-forming assays by transfecting in 0.3 μg of NiV-F and -G per 12-well plate, which was previously determined to result in CSE and fusion with the WT NiV-F protein in the linear range of measurement (3). CSE was measured by flow cytometry as described above, and fusion was determined by counting nuclei inside syncytia (more than

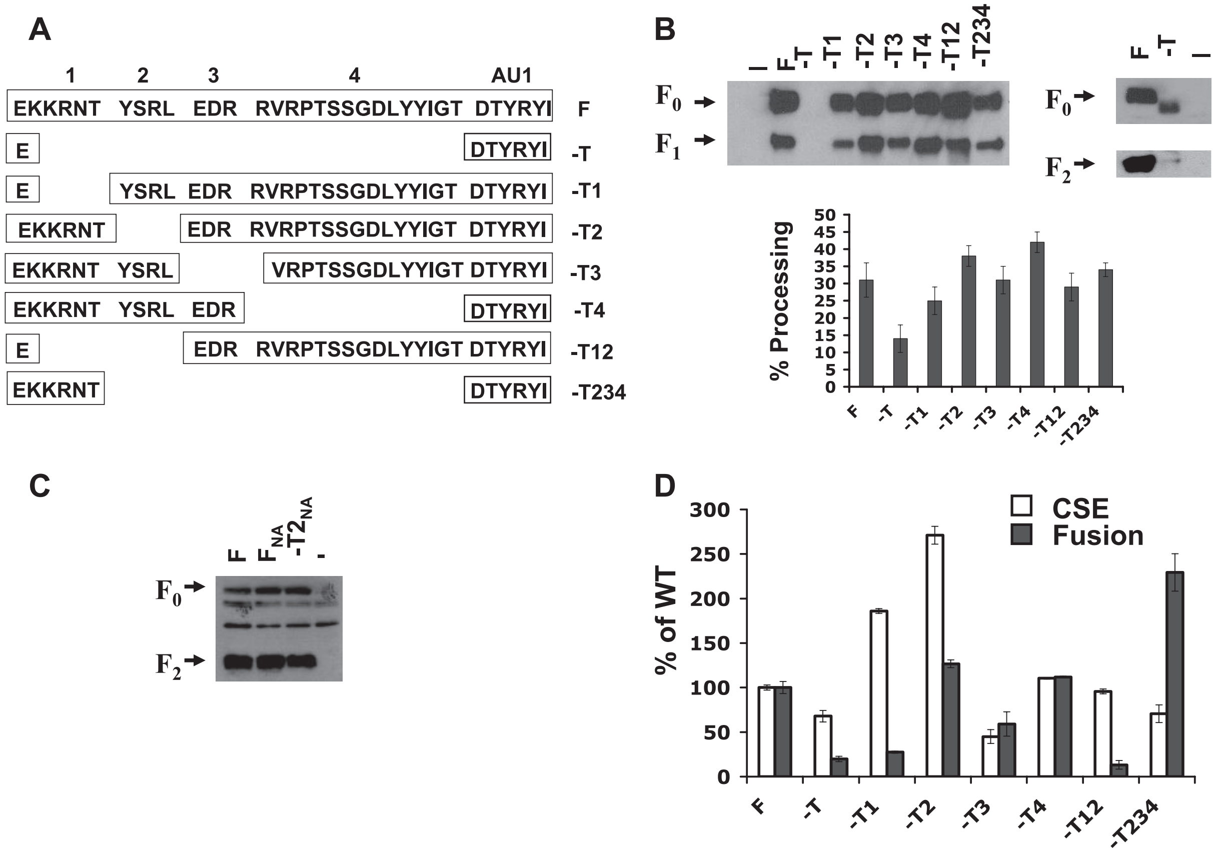

FIG. 1. Analysis of NiV-F CT deletion mutants. (A) Schematic of the NiV-F CT deletion mutants. NiV-F CT was divided into four regions (numbered 1, 2, 3, and 4) as described in the text, and the names of the deletion mutants examined are indicated. (B) Western blot analysis of immunoprecipitated surface WT and mutant NiV-F proteins. Briefly, biotinylated cells were lysed, cell surface biotinylated proteins were precipitated with streptavidin agarose beads, and NiV-F was detected in the biotinylated precipitates by Western blotting with either a monoclonal anti-AU1 tag Ab (left part) or a rabbit anti NiV-F_2 antipeptide Ab (3) (right part). Percent processing was calculated as the densitometric units of the F_1 subunit over those of the sum of the precursor F_0 and the F_1 subunits (bottom part) ($n = 3$). (C) The AU1 tag does not affect cleavage and processing of F. Identical cell surface biotinylation experiments were performed with tagged (F) and untagged versions of WT F (F_{NA}) and the −T2 mutant ($-T2_{NA}$). A rabbit anti NiV-F_2 antipeptide Ab (3) was used to detect NiV-F. (D) Relative levels of CSE and fusion obtained for WT NiV-F and the indicated CT deletion mutants. Fusion was determined by counting nuclei in syncytia per field. At least 10 fields were counted per condition. CSE was determined by flow cytometry with polyclonal anti-NiV-F specific antiserum as described previously (3). Both CSE and fusion levels were separately normalized to levels of WT NiV-F protein, set at 100%. Data shown are averages ± standard errors from three independent experiments.

four nuclei per cell) per microscopic field, respectively. Figure 1D shows the relative CSE and fusogenicity of WT NiV-F and the indicated mutants, and Table 1 (top) shows their corresponding fusion/CSE ratios. Interestingly, all mutants that lacked the membrane-proximal T1 region (−T1 and −T12) were hypofusogenic and had fusion/CSE ratios of less than 0.5 (by definition, that of WT NiV-F is 1.0), while all mutants that retained the T1 region (−T3, −T4, and −T234) had fusion/CSE ratios equal to or higher than that of WT NiV-F, with the exception of the −T2 mutant, which had a fusion/CSE ratio of 0.5. Since the fusion defect in the tailless mutant (−T) was likely due at least partially to its processing defect, it was not included in Table 1 for comparison. These results indicate that the CT, in particular, the membrane-proximal T1 region of the CT, plays an important role in membrane fusion and syncytium formation.

Polybasic KKR motif in the membrane-proximal region of the NiV-F CT modulates NiV-F-induced membrane fusion. To

TABLE 1. Fusion/CSE ratios

Env fusion protein	Fusion/CSE ratio[a]
F	1.0
−T1	0.1
−T2	0.5
−T3	1.3
−T4	1.0
−T12	0.1
−T234	3.2
K1A	5.5
K2A	0.2
R3A	0.3
N4A	0.9
T5A	0.9

[a] The ratio of the normalized fusion and CSE values for each mutant was calculated from the data in Fig. 1D and 2C. By definition, the fusion/CSE ratio for WT NiV-F would be 1.0 (100%/100%). Ratios of >1 indicate increased fusogenicity, while mutants with decreased fusogenicity would have ratios of <1.

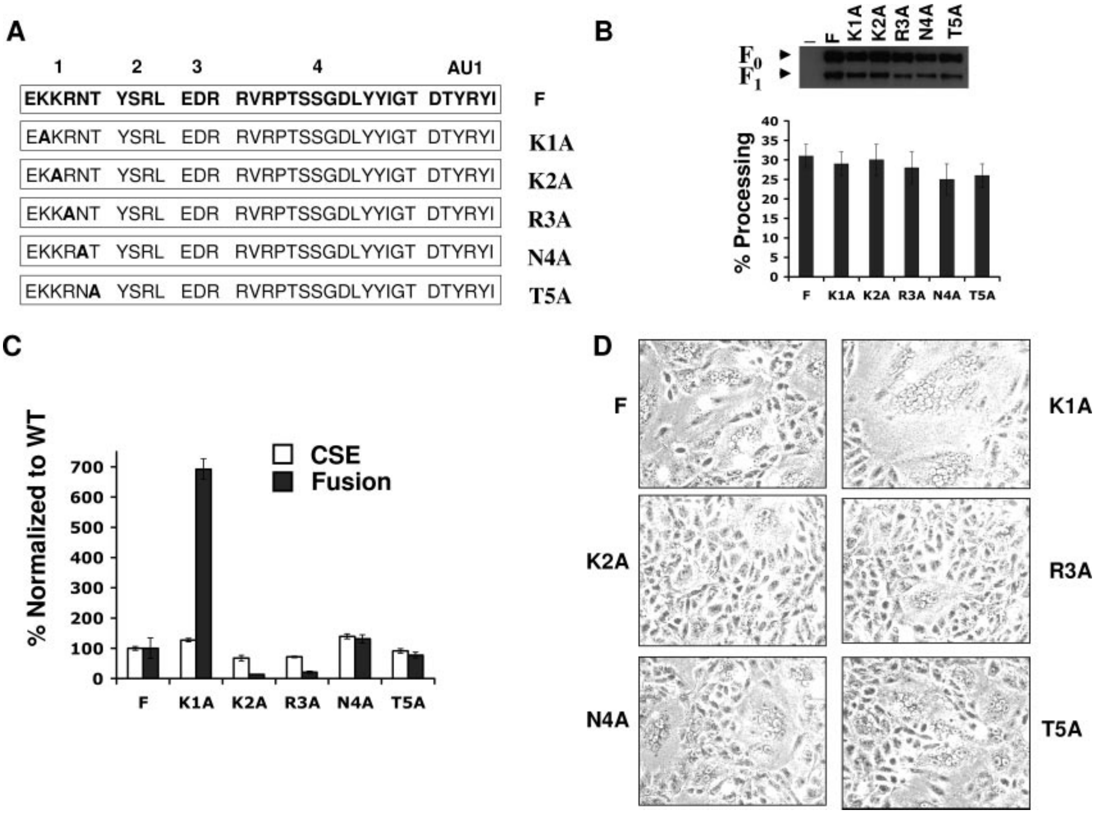

FIG. 2. Analysis of membrane-proximal point mutations in the CTs of NiV-F. (A) Schematic of the NiV-F CT point mutants, showing the sequence of the whole CT, and the positions of the five alanine substitutions in the membrane-proximal region, designated K1A, K2A, R3A, N4A, and T5A. (B) Western blot analysis of immunoprecipitated cell surface biotinylated WT and mutant NiV-F proteins. Surface proteins were analyzed exactly as described in Fig. 1B. Percent processing was also analyzed as described in the legend to Fig. 1B, and the densitometric results are shown graphically. (C) Relative levels of CSE and fusion obtained for WT NiV-F or CT point mutant proteins in 293T cells. Fusion and CSE were determined exactly as for Fig. 1C. Data shown are averages ± standard errors from three independent experiments. (D) Pictures of syncytium formation by the WT NiV-F or the various NiV-F point mutants and WT NiV-G in Vero cells. Representative ×100 fields are shown.

finely map the particular residues within the T1 region that can modulate NiV-F-mediated fusion, we individually mutated each amino acid of the T1 sequence (KKRNT) to an alanine, as depicted in Fig. 2A. 293T cells transfected with an expression plasmid encoding each of the alanine scan mutants were cell surface biotinylated, lysed, precipitated with streptavidin, and subjected to Western blotting to detect NiV-F as described above. All of the alanine scan mutants had levels of CSE and processing similar to those of WT NiV-F (Fig. 2B). Similar levels of CSE of WT and mutant NiV-F proteins were also observed by flow cytometric analyses (Fig. 2C). Next, we determined the fusogenicity of these mutants by quantifying syncytium formation. Representative pictures of syncytia formed by each mutant are shown in Fig. 2D, and the fusion/CSE ratios for WT NiV-F and the indicated mutant were determined (Table 1, bottom). Interestingly, despite WT levels of CSE, mutation of the K1 residue resulted in hyperfusogenicity (fusion/CSE ratio of 5.5) while mutation of the K2 or R3 residue resulted in hypofusogenicity (fusion/CSE ratios of 0.2 and 0.3, respectively) (Table 1, bottom). Mutation of the N4 or T5 residue did not result in any significant change in CSE or fusion (ratio of 0.9) relative to the WT NiV-F protein (Fig. 2C and D and Table 1, bottom). Similar but less dramatic effects on fusogenicity were observed in Vero cells. In summary, these results indicate that the membrane-proximal polybasic KKR sequence in the CT of NiV-F protein can up- or downmodulate its fusogenicity.

Fusion of membrane-proximal NiV-F mutants correlates with entry of ephrinB2-reverse-pseudotyped virus-like particles. Next, we sought to determine if the differences in cell-cell fusion exhibited by the NiV-F CT mutant proteins corresponded to viral entry differences. However, some of these CT mutants were very inefficiently incorporated into our pseudotyped VSV-*Renilla* luciferase (VSVrLuc) reporter viruses, a previously established method for examining NiV envelope-mediated entry (3). To circumvent the problem of variable envelope protein incorporation into VSVrLuc, we developed a novel reverse-pseudotype VSVrLuc entry assay, for which we reverse pseudotyped VSVrLuc with the NiV receptor ephrinB2 (B2-VSVrLuc). We then used these B2-VSVrLuc virions to infect 293T cells previously transfected with equal amounts of mutant or WT NiV-F along with WT NiV-G in a 96-well plate format. Infection of cells expressing HIV Env glycoproteins with viral particles reverse pseudotyped with CD4 and the corresponding coreceptor has been previously reported (36, 56). Figure 3A shows that B2-VSVrLuc viral entry only occurs when cells express both the NiV-F and NiV-G glycoproteins (Fig. 3A). In addition, reverse-

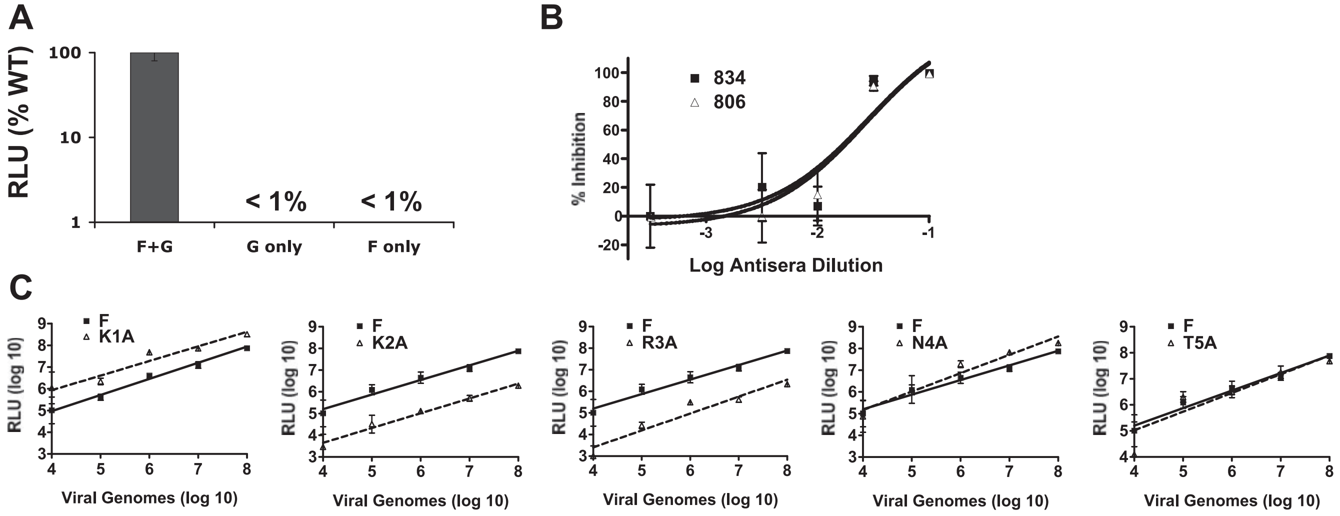

FIG. 3. Reverse-pseudotyped viral entry assay for membrane-proximal CT point mutants. (A) An ephrinB2-pseudotyped VSV-*Renilla* luciferase reporter virus (B2-VSV-rLuc) was used to infect 293T cells previously transfected with expression plasmids for NiV-F–NiV-G, NiV-G alone, or NiV-F alone. Numbers of RLU are shown on a logarithmic scale. (B) Reverse-pseudotyped viral entry into NiV-F- or NiV-G-transfected 293T cells was inhibited by anti-NiV-F and anti-NiV-G specific antisera 834 and 806, respectively. Data are presented as percent inhibition, where 0% represents infection in the absence of any antiserum. The data were normalized as follows. The number of RLU obtained at each serum dilution was calculated as a percentage of the average number of RLU obtained in the absence of any antiserum. Percent inhibition was then calculated as 100% minus the percent infection at each serum dilution. The percent inhibition values were regressed and graphed with GraphPad PRISM. An average of two experiments is shown, with four independent wells per datum point (serum dilution) ± the standard deviation. (C) Relative entry levels of B2-VSV-rLuc virus into 293T cells expressing the WT NiV-G protein and the WT or mutant NiV-F protein. RLU were quantified 24 h postinfection and graphed against the number of viral genomes per milliliter. A single preparation of B2-VSV-rLuc was used for all of the experiments shown. The number of genome copies in the viral preparation was analyzed by reverse transcription-PCR as described in Materials and Methods. The data shown are averages from three independent experiments ± the standard deviations.

pseudotyped viral entry was specifically blocked by previously characterized anti-NiV-F or anti-NiV-G antiserum (3, 33, 44) (Fig. 3B).

We then determined the entry of these B2-VSVrLuc virions into cells expressing WT NiV-G and WT NiV-F or the indicated NiV-F CT point mutants. Entry into K1A-expressing cells was about 8- to 10-fold higher than that of WT NiV-F over several logs of viral input. Conversely, entry into K2A- and R3A-expressing cells was 8- to 30-fold lower than that of WT NiV-F over the same range of viral inputs. Entry levels obtained for the cells expressing the N4A or T5A mutant protein were similar to those expressing WT NiV-F. Thus, our reverse-pseudotype B2-VSVrLuc entry assay results are consistent with our cell-cell fusion results and further demonstrate that the membrane-proximal polybasic KKR motif in the NiV-F CT can modulate virus-cell membrane fusion.

Differential binding and neutralization of hyper- and hypofusogenic NiV-F mutants by distinct novel anti-NiV-F rabbit MAbs. We then asked how specific residues in the KKR region might be modulating fusion. Inside-out signaling from the CT has been reported for other class I enveloped viruses (2, 61), including at least one paramyxovirus (67). We first asked whether any of the KKR alanine mutations affected the overall ectodomain conformation of the NiV-F protein.

We had previously produced conformational polyclonal and monoclonal rabbit Abs by genetically immunizing rabbits with codon-optimized NiV-F and NiV-G and NiV-M expression plasmids (4). We screened a panel of our rabbit MAbs and found two (MAbs 92 and 66) whose epitopes were conformational and distinct. They were conformational because they detected the NiV-F protein in its native state by flow cytometry (Fig. 4A) but not in its denatured form, for example, by Western blot analysis on sodium dodecyl sulfate-polyacrylamide gel electrophoresis (data not shown). They were distinct because Ab 66 bound to NiV-F and HeV-F equivalently while Ab 92 bound to NiV-F approximately10-fold more efficiently than to HeV-F at the same Ab concentrations (Fig. 4A). As a control, polyclonal Ab 834 (3, 33, 44) was used to show that the levels of NiV-F and HeV-F were approximately equally recognized by flow cytometry in the same experiment (Fig. 4A).

Then we measured the relative binding of these Abs to the various WT or mutant NiV-F proteins by flow cytometry. We reasoned that conformational differences in the ectodomain might be revealed by differential binding of these Abs. In order to quantitatively correct for variations in the transfection efficiencies and cell surface protein expression levels of the various mutants from experiment to experiment, we analyzed the binding data obtained by calculating the ratios of the mean fluorescence intensities of pairs of Abs (92-66, 92-834, and 66-834). Figure 4B shows the relative binding ratios of thee Ab combinations for WT NiV-F and the indicated mutants. There was a modest but significant decrease in binding of MAb 92 to the hyperfusogenic K1A mutant, as the 92/834 and 92/66 ratios, but not the 66/834 ratio, were lower than those of the WT NiV-F protein ($P = 0.015$, $P = 0.0005$, and $P = 0.94$, respectively) (Fig. 4B). We also detected an increase in binding of MAb 66 to the hypofusogenic R3A mutant protein, as the 66/834 ratio for this mutant was increased, the 92/66 ratio was decreased, and the 92/834 ratio was unchanged compared to those obtained with the WT NiV-F protein ($P = 0.048$, $P =$

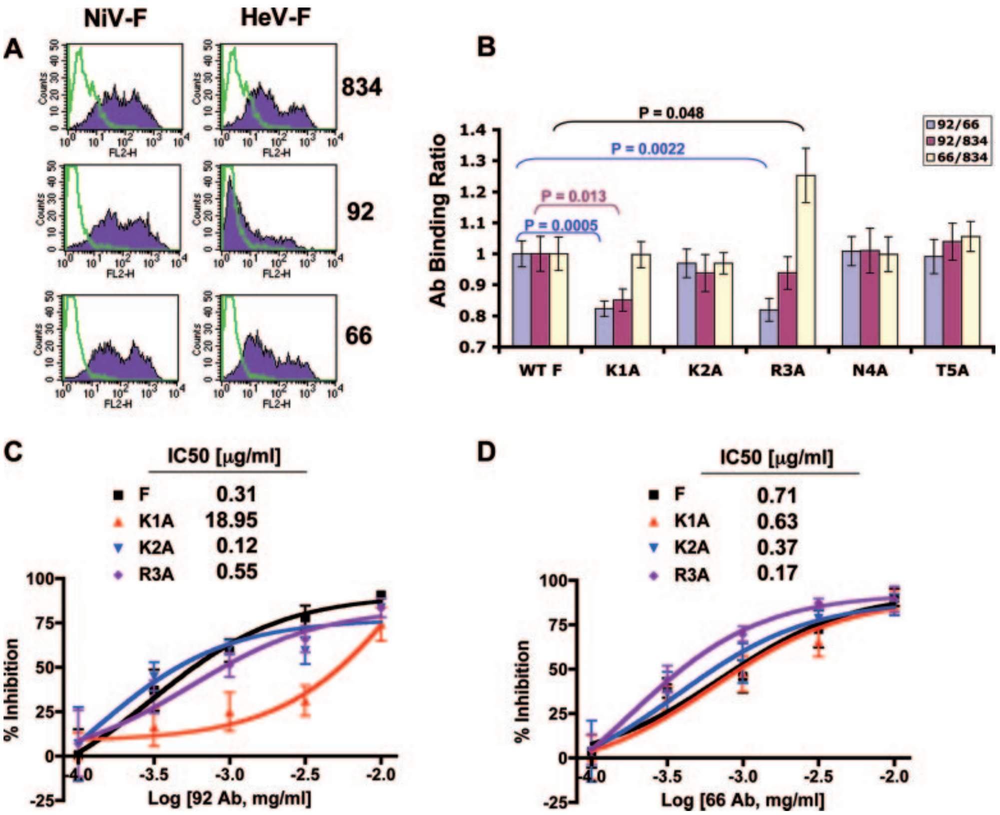

FIG. 4. Specific CT mutants affect the ectodomain conformation as exhibited by differential MAb binding and neutralization. (A) Flow cytometry histograms showing binding of polyclonal anti-NiV-F antiserum 834 or anti-NiV-F MAb 92 or 66 to 293T cells expressing either NiV-F, HeV-F, or neither (pcDNA3 control). Green contours indicate binding of Abs to 293T cells transfected with the pcDNA3.1 backbone only. Overlaid filled purple histograms indicate binding of Abs to NiV-F- or HeV-F-expressing cells, as indicated. (B) MAb binding ratios of pairs of anti-NiV-F Abs. Polyclonal (antiserum 834) or monoclonal (antisera 492 and 66) rabbit Abs were used to stain 293T cells transfected with WT NiV-F or the indicated CT point mutants at a concentration previously determined to be in the linear range of the binding curve. To compare data from repeat experiments and to control for transfection efficiency and differential expression, a set of binding ratios was calculated by dividing the mean fluorescence intensities obtained for the various Abs (92/66, 92/834, and 66/834). The Ab binding ratios for WT NiV-F is necessarily defined as 1. *P* values were calculated with a nonpaired Student *t* test and multiplied by five, which takes into account the Bonferroni correction for the multiple pairwise comparisons (WT versus the five mutants). (C and D) Neutralization of CT mutant proteins by anti-NiV-F Abs. 293T cells expressing the WT NiV-G protein and the WT or mutant NiV-F protein were infected with B2-VSV-rLuc reverse-pseudotyped virus 8 h posttransfection in the presence of increasing amounts of MAb 92 (C) or 66 (D). The amount of viral entry obtained in the absence of anti-NiV-F MAb (artificially represented by the [MAb] = −4.0 datum point) was normalized to 100%, which is equivalent to 0% inhibition. The percent inhibition was then plotted against the logarithm of the Ab concentration. Inhibition curves were regressed, and IC$_{50}$s were calculated with GraphPad PRISM. The data shown are normalized averages from three separate experiments ± the standard deviations.

0.0022, and $P = 0.84$, respectively) (Fig. 4B). All other point mutant proteins did not display a change in Ab binding relative to that of the WT NiV-F protein (*P* values of >0.5) (Fig. 4B). Similar Ab binding ratios were obtained over an Ab concentration range of 0.03 to 3 μg/ml, and the data shown are for 1 μg/ml.

Next, we measured the neutralization capabilities of MAbs 92 and 66 against the various mutant proteins with our reverse-pseudotyped viral entry assay. In general, our neutralization data were consistent with the above-mentioned binding data. For example, since MAb 92 bound relatively less to mutant K1A, we expected that mutant K1A may also be less sensitive to neutralization by MAb 92, and that was indeed the case. Figure 4C shows that the K1A protein was more than 10-fold less sensitive than WT NiV-F to neutralization by MAb 92 (the 50% inhibitory concentrations [IC$_{50}$s] for K1A and WT NiV-F were approximately 19 and 0.3 μg/ml, respectively). In addition, since MAb 66 bound more strongly to mutant R3A, we also expected that the R3A mutant might also be more sensitive to neutralization by MAb 66 than the WT NiV-F. Indeed, we observed that the R3A mutant protein was about fourfold more sensitive to neutralization by MAb 66 than was the WT NiV-F protein, as the IC$_{50}$s for the R3A and WT proteins were approximately 0.17 and 0.71 μg/ml, respectively (Fig. 4D). In toto, our MAb binding and neutralization data show that specific residues in the CT of NiV-F can affect the conformation of its ectodomain.

Association of NiV-F and the hyper- and hypofusogenic mutants with lipid raft domains. Viral envelope glycoproteins are often associated with lipid raft microdomains (22, 26, 43, 47, 62). Such membrane domains are known to have membrane cross-thicknesses greater than those of non-lipid raft cell membrane domains (23, 30) and are enriched in cholesterol and glycosphingolipids. Thus, differential association of WT or mu-

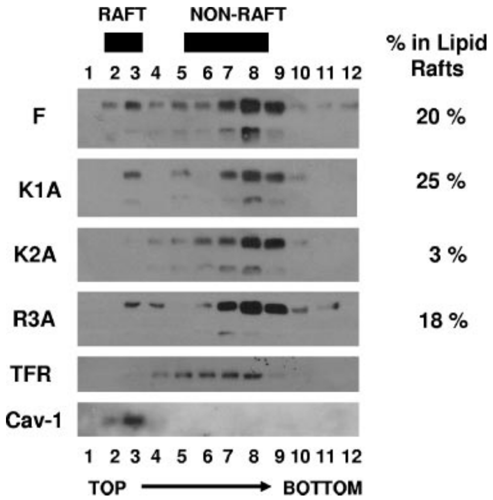

FIG. 5. Association of NiV-F and the hyper- and hypofusogenic mutants with lipid raft domains. Lipid raft fractionations were performed as described in Materials and Methods. Caveolin-1 (Cav-1) and transferrin receptor (TFR) were used as markers for raft (top) and nonraft (bottom) domains, respectively. NiV-F and the indicated mutants were detected by Western blotting with the AU1 Ab. The blots were then stripped and reprobed for Cav-1 and TFR to ensure the integrity of each lipid raft fractionation. Percent NiV-F in lipid rafts was calculated as the percentage of the NiV-F signal observed in the peak Cav-1 fractions (lanes 2 and 3 in most cases) over the sum of signals in the peak Cav-1 and peak TFR fractions (lanes 7 and 8 in most cases) for each sample. This controls for any slight variations between tubes. Representative Cav-1 and TFR blots are shown. The experiment was repeated twice with similar results. Band intensities were quantified by densitometry with a VersaDoc Imaging System (Bio-Rad).

tant NiV-F proteins with lipid raft domains may formally influence the conformation of their ectodomain epitopes, potentially affecting the conformational data in Fig. 4. Therefore, we assessed the relative association of WT and mutant NiV-F proteins with lipid raft domains. First, we observed that a distinct portion (~20%) of the total WT NiV-F protein was associated with lipid raft fractions (Fig. 5), as demonstrated by cofractionation with caveolin-1, a standard marker for lipid raft domains. However, the most of the NiV-F was in nonraft fractions, which were demarcated by the transferrin receptor, a membrane protein known not to be associated with lipid rafts (Fig. 5). With the exception of mutant K2A, all WT and mutant NiV-F proteins were found in both lipid raft and non-lipid raft domains at approximately equal distributions (18 to 25% in lipid raft fractions), indicating that, at least for mutants K1A and R3A, association with lipid rafts did not account for the differences in conformational MAb binding seen in Fig. 4. Interestingly, the hypofusogenic K2A mutant was almost completely absent from the lipid raft fractions, raising the possibility that altered association with lipid raft domains may contribute to its hypofusogenic phenotype and suggesting that mechanistic differences may underlie the hypofusogenic phenotypes of the K2A and R3A mutants.

NiV-F CT fusion mutants are differentially resistant to fusion inhibition by a reagent that prevents 6HB formation and exhibit corresponding rates of fusion kinetics relative to WT NiV-F. Having determined that the specific residues in the CT can affect the ectodomain conformation of NiV-F, we then asked whether the hyper- and hypofusogenic phenotypes exhibited by the NiV-F CT point mutants are mediated by fusion determinants in the ectodomain such as 6HB formation. We have previously shown that a soluble NiV-HR2-Fc protein (HR2 region of NiV-F linked to the Fc constant region of human immunoglobulin G1) inhibits NiV fusion specifically and that the sensitivity of inhibition by this protein inversely correlated with the fusion kinetics of the hyperfusogenic NiV-F N-glycan fusion proteins (3). With the same NiV-HR2-Fc inhibitory reagent, we tested the sensitivity of NiV-F CT mutants or WT NiV-F to fusion inhibition. We observed that the K1A mutant exhibited significantly greater resistance to NiV-HR2-Fc than WT NiV-F for all three concentrations of HR2-Fc tested (Fig. 6A). On the other hand, the K2A mutant exhibited a significantly lower resistance to NiV-HR2-Fc (Fig. 6A), especially when subsaturating amounts of HR2-Fc were

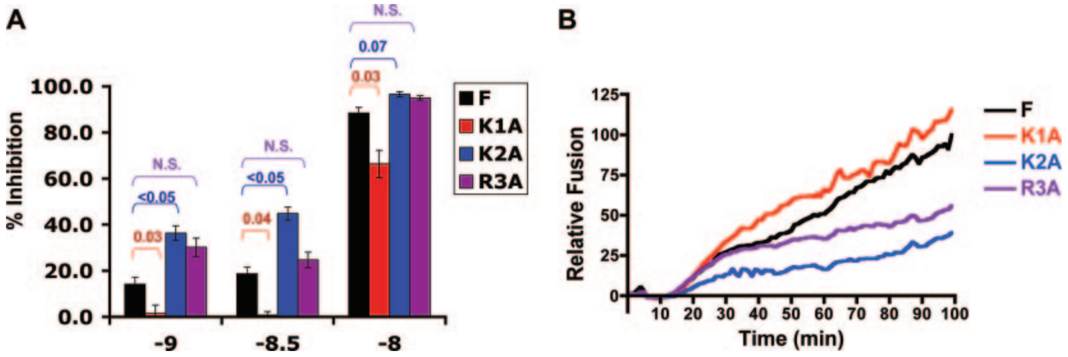

FIG. 6. NiV-F CT fusion mutants are differentially resistant to fusion inhibition by NiV-F HR2-Fc and exhibit corresponding rates of fusion kinetics relative to WT NiV-F. (A) The sensitivity of NiV envelope-mediated fusion to inhibition by NiV-HR2-Fc is shown for WT NiV-F and the indicated CT mutants. For each fusion protein, the amount of fusion in the absence of any inhibitor is set at 0% inhibition. One representative experiment out of two is shown. Error bars indicate standard deviations. *P* values were calculated with the Student *t* test and the Bonferroni correction to account for the multiple pairwise comparisons of significance (F versus K1A, F versus K2A, and F versus R3A). (B) Fusion kinetics of WT or mutant NiV-F protein. NiV-G was expressed with WT NiV-F or the indicated mutants in effector PK13 cells, and the relative rate of fusion was assessed with target 293T cells loaded with CCF2 dye (see Materials and Methods). Relative fusion is the ratio of blue to green fluorescence obtained with NiV-G- and NiV-F-transfected effectors minus the ratio of background blue and green fluorescence obtained with empty-vector (pcDNA3)-transfected cells. Each datum point is an average from three independent experiments.

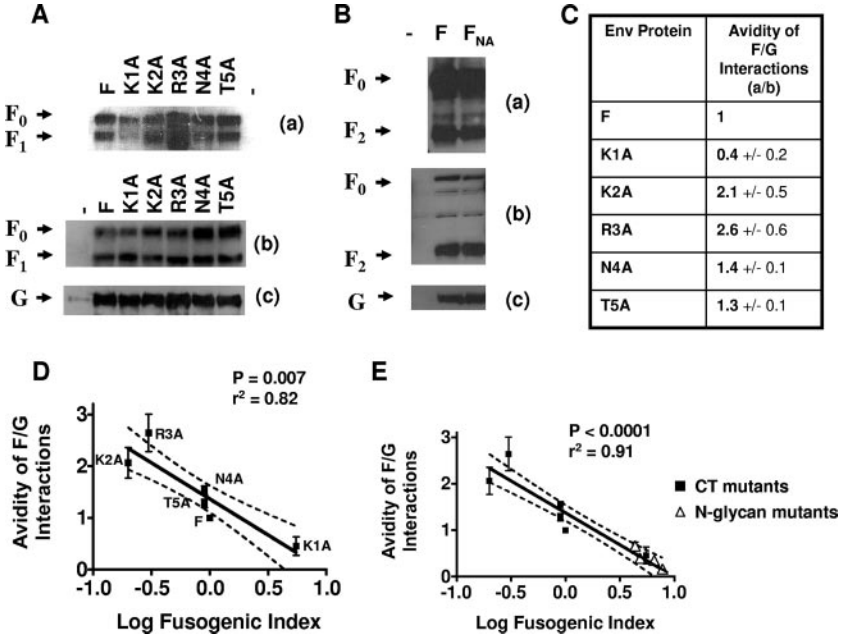

Env Protein	Avidity of F/G Interactions (a/b)
F	1
K1A	0.4 +/- 0.2
K2A	2.1 +/- 0.5
R3A	2.6 +/- 0.6
N4A	1.4 +/- 0.1
T5A	1.3 +/- 0.1

FIG. 7. Fusogenicity of WT NiV-F and the CT mutants inversely correlates with the avidity of F-G interactions. (A) Western blot analysis of co-IP F_0 and F_1 (top part a), immunoprecipitated G (bottom part c), and the relative amounts of F_0 and F_1 present in total cell lysate (middle part b). Cell lysates of 293T cells transfected with WT NiV-G and NiV-F or the indicated CT mutants were immunoprecipitated with rabbit anti-NiV-G specific antisera. The top and middle parts were blotted with mouse anti-AU1 to detect NiV-F, and the bottom part was blotted with mouse anti-HA to detect NiV-G. (B) A coimmunoprecipitation experiment identical to that in panel A was performed with tagged and untagged NiV-F (F and F_{NA}, respectively) but with a rabbit anti-F_2 peptide Ab for detection. Parts a, b, and c are as in panel A. (C) Relative avidities of NiV-F–NiV-G interactions for WT NiV-F and the indicated CT mutants. The amounts of co-IP NiV fusion proteins in panel A were quantified by densitometry as described in the text, with a VersaDoc Imaging System (Bio-Rad). The avidity of F-G interactions is represented by the ratio of the amount of NiV-F protein co-IP with anti-NiV-G antiserum to the relative amount of NiV-F expressed in cell lysates (parts a and b, respectively). The data presented are averages ± standard errors from three experiments. (D) Avidity of the F-G interactions from panel C plotted against the fusion/CSE ratios from Table 1. Pearson correlation analysis was performed with GraphPad PRISM. (E) The avidities of F-G interactions for the multiple N-glycan mutants previously reported by Aguilar et al. (3) were overlaid with the datum points from panel C and plotted together against their respective fusogenic indexes. CT mutants and N-glycan mutants are represented by closed and open symbols, respectively. Pearson correlation analysis was performed with GraphPad PRISM.

used. These results suggested that the rate of 6HB formation contributed to the hyper- and hypofusogenicity of the K1A and K2A mutants, respectively. Interestingly, mutant R3A did not reveal a significant difference in resistance to inhibition by the NiV-HR2-Fc molecule relative to the WT NiV-F protein, suggesting that the hypofusogenic phenotype of the K2A and R3A mutants may be mediated via distinct mechanisms. This is also consistent with our Ab binding data, which suggest that the K2A and R3A mutants differentially affect ectodomain conformation (Fig. 4B).

In order to determine if sensitivity to NiV-HR2-Fc inhibition is actually due to the rate of 6HB formation and, hence, fusion pore formation, we measured fusion kinetics mediated by NiV-F or the indicated CT mutants and WT NiV-G. Real-time fusion kinetics can be measured and quantified with a β-lactamase reporter cell-cell fusion assay that we previously described for analysis of our hyperfusogenic N-glycan NiV-F mutants (3). We found that cells expressing the hyperfusogenic K1A fusion mutant showed faster fusion kinetics and fused to a greater extent than cells expressing WT NiV-F (Fig. 6B). In contrast, the hypofusogenic K2A mutant showed slower fusion kinetics and fused to a lesser extent than cells expressing the WT NiV-F protein (Fig. 6B). Interestingly, although the cells expressing the R3A mutant fused at the same rate as the WT NiV-F protein for the first 40 min, thereafter, their rates of fusion diverged, with the R3A mutant slowing down significantly such that at 100 min, it had fused at less than 50% of the WT NiV-F level (Fig. 6B). The results in Fig. 6A and B strongly suggest a mechanistic difference between the hypofusogenic phenotypes exhibited by the K2A and R3A mutants.

Fusogenicity of NiV-F inversely correlates to the avidity of F-G interactions for the CT mutant proteins. We had previously provided evidence for the attachment protein displacement model for paramyxoviral entry. At least for NiV, the hyperfusogenic N-glycan mutants appear to have weaker interactions between the NiV-F mutants and NiV-G, allowing greater NiV-F–NiV-G dissociation after receptor binding. Thus, fusogenicity inversely correlated to the avidity of F-G interactions for the hyperfusogenic N-glycan NiV-F mutants (3). Here, we asked if the relative avidity of NiV-F–NiV-G associations correlated with the fusogenicity of the CT mutants.

We coexpressed NiV-G with WT NiV-F or the aforementioned mutants in permissive 293T cells and determined the relative avidity of NiV-F and NiV-G interactions by immunoprecipitating whole cell lysates with anti-NiV-G antiserum and detecting the amount of co-IP NiV-F by Western blotting with an AU1 epitope tag Ab (Fig. 7A, part a). The relative amounts of WT and mutant NiV-F were also determined in total cell lysates (Fig. 7A, part b). To normalize for the various expression levels of WT or mutant NiV-F in any single experiment, we calculated the ratio of the level of co-IP NiV-F to the corresponding amount of NiV-F in the total cell lysate. For example, if the amount of co-IP NiV-F was densitometrically quantified at 160 U and the corresponding amount of NiV-F in the cell lysate was 100 U, the F-G co-IP ratio would be 1.6. This ratiometric value was arbitrarily set to 1.0 to indicate the relative avidity of the WT NiV-F–NiV-G interactions (Fig. 7C). On this scale, a value of greater or less than 1.0 would indicate a corresponding increased or decreased avidity in F-G interaction relative to the WT proteins, respectively. Also, we note that the AU1 tag did not affect NiV-F's interaction with G, as the same experiment performed with tagged and untagged NiV-F revealed no difference in the amount of F that can be co-IP with G (Fig. 7B).

When we plotted the relative avidity of NiV-G interactions with WT NiV-F or the indicated CT mutants (Fig. 7C) against their fusogenicities (fusion/CSE ratio) as determined in Table 1, we obtained a significant negative correlation ($r^2 = 0.82$, $P = 0.007$) between the avidity of F-G interaction and the fusogenicity of the NiV-F protein (Fig. 7D). Thus, for example, the NiV-F mutant (K1A) with the lowest relative avidity of F-G interaction (0.4) was also the most fusogenic NiV-F CT mutant examined (fusion/CSE ratio of 5.5), and mutants (K2A and R3A) with the highest relative avidities of F-G interaction (2.1 and 2.6) were the least fusogenic (fusion/CSE ratios of 0.2 and 0.3). These results suggest that the effects of the CT mutants on modulating fusogenicity were linked to the increasing or decreasing avidity of F-G interactions and provide further support for the model (3, 63, 75) where dissociation of the attachment protein from the fusion protein is a rate-limiting step required for fusion peptide exposure and subsequent membrane fusion.

DISCUSSION

Our results implicate the cytoplasmic domain of the NiV fusion protein in modulating fusion through its membrane-proximal polybasic KKR motif in an inside-out signaling manner. Our data also shed some light on the mechanisms by which the KKR motif modulates fusion; specific residues within the KKR motif can modulate the conformation of NiV-F's ectodomain and thus have an effect on fusion kinetics by regulating the rate of 6HB formation and the avidity of the F-G interactions.

The CTs of other paramyxovirus fusion proteins are known to be required for various protein functions, including proper surface expression, membrane fusion, fusion pore enlargement, transition from hemifusion to complete fusion, and/or budding (7, 19, 59, 65, 68), although removal of the CT has resulted in quite distinct phenotypes in different paramyxoviruses, ranging from no effect (12) to fusion pore formation (65) to fusion pore enlargement (19) to syncytium formation (59, 65). In this report, we show that relatively large deletions in the NiV-F CT did not significantly compromise conformational integrity or CSE but can either reduce or enhance fusion (Fig. 1). In addition, while point mutations in the membrane-proximal region had no significant effect on conformational integrity, processing, or CSE, they variably affected fusogenicity (Fig. 2). Indeed, we identified a membrane-proximal polybasic KKR patch in the CT of NiV-F as having the ability to up- or downmodulate fusogenicity. Polybasic residues can also be found near the membrane-spanning region in the CTs of most other paramyxoviruses, but to our knowledge, their function in modulating fusion has not been reported.

Our data show that specific CT mutants with changes in the KKR motif mediate their hyper- or hypofusogenic phenotypes through common mechanisms that have been defined for other class I fusion proteins. For example, the hyperfusogenic V3 loop and CT mutants of the HIV-1 envelope glycoprotein also show faster fusion kinetics and display increased resistance to heptad repeat peptide inhibition (1, 52). In the case of NiV, our results suggest that the hyper- and hypofusogenicity phenotypes of the K1A and K2A mutants are governed by the rate of 6HB formation (Fig. 6A) during fusion pore formation, resulting in increased or decreased fusion kinetics, respectively (Fig. 6B). However, since we did not detect any apparent differences between the R3A mutant and WT NiV-F during 6HB formation and its hypofusogenic phenotype was only manifested in slower fusion kinetics at later time points (Fig. 6B), we speculate that a step post 6HB formation, perhaps fusion pore enlargement, may be affected by the hypofusogenic mutation R3A. The CT of at least one other paramyxovirus, SV5, has been implicated in fusion pore enlargement (19). Our lipid raft results also highlight the mechanistic differences observed between the hypofusogenic K2A and R3A mutants observed in Fig. 4 and 6. The K2A, but not the R3A, mutant displayed differences in lipid raft association compared to the WT NiV-F protein. While many hyper- or hypofusogenic phenotypes in class I viral fusion proteins have been identified, it is uncommon to find a contiguous series of residues within a small patch that have such contrasting contributory roles in fusogenicity.

It remains to be determined how these three basic residues in NiV-F CT actually modulate the kinetics of fusion. Do the KKR mutants stabilize or destabilize the metastable prefusogenic conformation of NiV-F, and/or do they affect subsequent steps in the fusion process? It is also possible that the KKR basic motif may interact with cellular proteins that directly or indirectly modulate the actin cortical cytoskeleton, which is intimately involved in membrane dynamics and curvature during fusion and syncytium formation (37, 49, 51). Dutch and colleagues have previously reported that various transdominant Rho-GTPases can up- or down-regulate HeV fusion (57). Since the ERM (ezrin-radixin-monesin) family of proteins is known to connect the CTs of various membrane proteins to the actin cortical cytoskeleton and the ERM proteins themselves are known to be activated and inactivated by distinct Rho GTPases (21, 29), we speculate that the ERM proteins may connect the CT of NiV-F to the actin cortical cytoskeleton and that modulation of the CT's attachment to the cortical cytoskeleton by the Rho GTPases, or by our various KKR mutants, is what accounts for the hyper- or hypofusogenic phenotypes seen. Intriguingly, ERM proteins preferentially bind CTs of membrane proteins that have isoelectric points higher than 9.0 and that have basic amino acid clusters (29, 74). They also prefer to bind CTs that contain phosphorylated serines and tyrosine motifs (17, 58). NiV-F's CT has an isoelectric point of

9.88, contains a C-terminal tyrosine-rich motif, and contains two basic clusters, i.e., the membrane-proximal KKR cluster that we know affects fusion and an RRVR cluster between regions T3 and T4. In addition, preliminary mass spectrometry analysis indicated that the two C-terminal serines in NiV-F are phosphorylated (unpublished observations). Therefore, it seems plausible that cellular factors such as ERM proteins may connect the CT of NiV-F or HeV-F to the actin cortical cytoskeleton of cells, and the strength and stability of this connection may modulate fusogenicity.

Our data also suggest that the KKR motif modulates fusogenicity via an inside-out signaling mechanism. Differential MAb recognition of the ectodomain correlating with differential neutralization (Fig. 4), faster or slower rates of fusion kinetics affected by the rate of 6HB formation (Fig. 6), and differential effects on the avidity of F-G interactions (Fig. 7) all argue that mutations of these cytoplasmic residues can affect the conformation and subsequent fusogenic function of the ectodomain. Interestingly, data from differential MAb binding, rate of 6HB formation, and fusion kinetics experiments also reveal that distinct mechanisms underlie the similar hypofusogenic phenotypes of the K2A and R3A mutants. For example, while MAbs 92 and 66 clearly bound differentially to the R3A mutant, no difference in K2A binding was observed (Fig. 4B). On the other hand, while K2A was significantly more sensitive to inhibition by HR2-Fc compared to WT NiV-F, R3A was similar in sensitivity to WT NiV-F (Fig. 6A). This equivalent sensitivity to HR2-Fc inhibition is consistent with our real-time fusion kinetics data showing that for the first 40 min, R3A fused at the same rate and to the same extent as WT NiV-F, while K2A fused much more slowly from the very beginning (Fig. 6B). However, after 40 min, R3A began to exhibit slower fusion kinetics and eventually fused to a much lesser extent than WT NiV-F at 100 min. As mentioned above, it is likely that the defect in fusion in the R3A mutant is manifested at a stage post 6HB formation, such as fusion pore enlargement.

We previously suggested that a critical parameter that governs NiV envelope-mediated fusion is the avidity of F and G association, which we quantified by a rigorous coimmunoprecipitation assay (3). Our published data showed a strong and significant negative correlation between the degree of hyperfusogenicity exhibited by a variety of ectodomain N-glycan mutants and the avidity of F and G association. We had therefore favored the attachment protein displacement model of paramyxovirus fusion where the dissociation of G from F after receptor engagement better allows for the conformational changes in F that lead to fusion peptide exposure and membrane fusion. We now provide data to further expand and support this model with both hyper- and hypofusogenic mutants (Fig. 7D). Indeed, as shown in Fig. 7E, when we added our present datum points to the datum points from our hyperfusogenic N-glycan mutants (3), the Pearson correlation became even stronger ($r^2 = 0.91$) and more significant ($P < 0.0001$). These data suggest that F and G dissociation can be a common pathway for the triggering of F regardless of the determinants of fusion in F involved. However, since we performed these studies with receptor-containing 293T cells, we are not able to distinguish whether the differences in F-G association between WT and mutant fusion proteins we have observed occur pre or post receptor binding. True avidity measurements would have to be done with truly receptor-negative cells. In addition, it remains to be determined whether the KKR motif affects the interaction of NiV-F with NiV-G directly and/or via modification of the NiV-F ectodomain's overall conformation. At least for one other paramyxovirus F protein (NDV), the ectodomain HR2 region has been implicated in binding to the attachment protein HN (24); therefore, the effects of NiV-F CT mutants on the avidities of NiV-F–NiV-G interactions observed here may be due to inside-out signaling.

We also note that NiV-F processing is usually increased when G is cotransfected (compare Fig. 7A with Fig. 1B and 2B). Since both F and G are encoded by codon-optimized genes, a potential explanation is that expression of G competes for transcriptional or translational resources, resulting in less overexpression of F; overexpression of F in the absence of G can overwhelm the proteolytic machinery required for F cleavage. However, it would be interesting to determine whether the presence of G, and its association with F, can intrinsically affect F processing, either by modulating its endosomal recycling behavior or changing the conformation of F to make it more accessible to cathepsin L cleavage.

Finally, it remains to be determined how the NiV-F CT actually stabilizes or destabilizes F-G interactions and whether the fusion-modulatory role played by the polybasic motif in the CT of NiV-F is unique for NiV (or the henipaviruses). The studies presented in this report point to the many determinants of fusion in NiV-F and underscore the complexities that regulate the "proper" amount of fusion mediated by NiV-F, which has both fusion-promoting and fusion-inhibiting determinants. Further studies of these determinants will enhance our understanding of the pathobiology of this deadly emerging virus and may reveal more targets for therapeutic intervention.

Single-dose attenuated Vesiculovax vaccines protect primates against Ebola Makona virus

Chad E. Mire[1,2]*, Demetrius Matassov[3]*, Joan B. Geisbert[1,2], Theresa E. Latham[3], Krystle N. Agans[1,2], Rong Xu[4], Ayuko Ota-Setlik[4], Michael A. Egan[4], Karla A. Fenton[1,2], David K. Clarke[3], John H. Eldridge[3,4] & Thomas W. Geisbert[1,2]

The family *Filoviridae* contains three genera, Ebolavirus, Marburgvirus, and Cuevavirus[1]. Some members of the genus, including Zaire ebolavirus (ZEBOV), can cause lethal haemorrhagic fever in humans. During 2014 an unprecedented ZEBOV outbreak occurred in West Africa and is still ongoing, resulting in over 10,000 deaths, and causing global concern of uncontrolled disease. To meet this challenge a rapid-acting vaccine is needed. Many vaccine approaches have shown promise in being able to protect nonhuman primates against ZEBOV[2]. In response to the current ZEBOV outbreak several of these vaccines have been fast tracked for human use. However, it is not known whether any of these vaccines can provide protection against the new outbreak Makona strain of ZEBOV. One of these approaches is a first-generation recombinant vesicular stomatitis virus (rVSV)-based vaccine expressing the ZEBOV glycoprotein (GP) (rVSV/ZEBOV). To address safety concerns associated with this vector, we developed two candidate, further-attenuated rVSV/ZEBOV vaccines. Both attenuated vaccines produced an approximately tenfold lower vaccine-associated viraemia compared to the first-generation vaccine and both provided complete, single-dose protection of macaques from lethal challenge with the Makona outbreak strain of ZEBOV.

Since discovery of the virus in 1976, outbreaks of ZEBOV have been detected sporadically in Africa. With increasing population growth the frequency of human contact with natural virus reservoirs[3] is likely to rise, potentially leading to more catastrophic outbreaks such as the current epidemic in West Africa, thus increasing the need for effective antiviral strategies. A highly effective countermeasure would be a preventive vaccine that can be simply and widely administered to people in regions of virus zoonosis and provide a 'blanket immunity' curtailing any future outbreaks. Also important will be the ability to rapidly combat deliberate misuse of these deadly viruses. Therefore, a preventive vaccine should ideally confer rapid, single-dose protection.

There are currently no licensed filovirus vaccines or post-exposure treatments available for human use. However, there are at least ten different vaccine approaches that have shown the potential to protect nonhuman primates (NHPs) from lethal ZEBOV infection, including platforms based on recombinant adenovirus serotype 5 (rAd5) vectors, combined DNA/rAd5 vectors, combined rAd serotype 26 and 35 vectors, recombinant chimpanzee adenovirus serotype 3 (rChAd3) vectors, combined rChAd3 and modified vaccinia Ankara (MVA) vectors, virus-like particles (VLPs), alphavirus replicons, recombinant human parainfluenza virus 3 (rHPIV3), rabies virus, and recombinant vesicular stomatitis virus (rVSV)[2]. Of the vaccines advancing to phase I trials, the rChAd3 and rVSV vectored vaccines have shown success in single-dose protection of NHPs against ZEBOV challenge; with the caveat that the rChAd3/ZEBOV vaccine requires a boost with an MVA/ZEBOV vector for protection past 6 months[4]. Also, NHPs inoculated with the rChAd3/ZEBOV vaccine were challenged with a ZEBOV seed stock containing a large virus population encoding 8 uridines (U) at a critical transcription editing site in the GP gene[4]. This specific genetic feature typically arises following prolonged passage of ZEBOV in Vero E6 cells and results in higher levels of expression of full-length GP. In contrast, low-passage ZEBOV isolates retain 7U at the GP editing site, resulting in higher levels of secreted GP (sGP) expression, which is associated with greater viral virulence[5–7]. Importantly, studies have shown that rAd-based ZEBOV vaccines that completely protect NHPs against ZEBOV stocks containing high populations of 8U virus are not able to completely protect vaccinated macaques challenged with ZEBOV stocks containing high populations of 7U virus[8].

The first generation rVSV/ZEBOV vaccine that replaces the VSV glycoprotein G with the ZEBOV GP (rVSV/ZEBOVΔG), originally developed by Drs Feldmann and Geisbert[9] and currently licensed by Merck, has demonstrated solid single-dose NHP protection against a low-passage 7U ZEBOV stock[8]. The rVSV/ZEBOVΔG vector has also protected 50% of NHPs when administered shortly after ZEBOV challenge[10], and has demonstrated safety in a NHP neurovirulence model[11]. However, there is a robust post-vaccination viraemia in macaques and a recent phase I trial of the rVSV/ZEBOVΔG vaccine in Geneva was halted due to temporary joint pain in some patients. The level of vaccine-associated viraemia and frequency of adverse events will be more fully documented as data from ongoing phase 3 trials become available for this vector; but the early observation suggest that a further-attenuated rVSV vector may be more desirable for widespread administration in endemic regions of Africa.

To address this possible safety concern we have developed and tested two further-attenuated rVSV/ZEBOV vaccine candidates for efficacy. One of these vaccines is based on an rVSV vector that has advanced through clinical evaluation. It was attenuated by translocating the VSV nucleoprotein (N) gene from position 1 to position 4 in the genome (N4) and truncating the cytoplasmic tail (CT) of the VSV G protein from 29 to 1 amino acids (CT1)[12]. This rVSVN4CT1 vector was modified to maximally express HIV-1 gag from position 1 in the genome (rVSVN4CT1gag1) by positioning the *gag* gene immediately adjacent to the single strong 3′ VSV transcription promoter. The rVSVN4CT1gag1 vector has demonstrated safety in mouse and NHP neurovirulence studies[12,13], and replication is restricted to the IM inoculation site and draining lymph node following vaccination of mice[14]. The rVSVN4CT1gag1 vector has demonstrated safety and immunogenicity in two phase I clinical trials (HVTN 090 and HVTN 087: http://clinicaltrials.gov/) and no post-vaccination viraemia was detected in urine, saliva, and blood of vaccine recipients. The rVSVN4CT1GP1 vector described here (Fig. 1a, N4) is analogous in design to that of the rVSVN4CT1gag1 vaccine and expresses ZEBOV GP from genome position 1. The other attenuated rVSV/ZEBOV

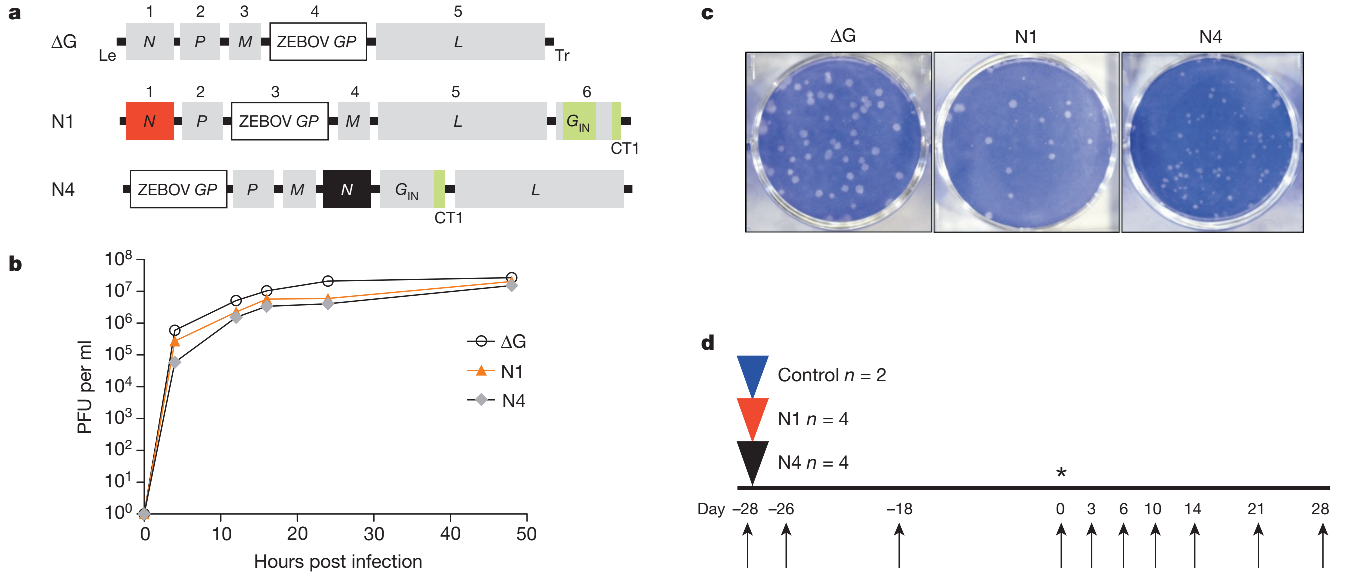

Figure 1 | rVSV/ZEBOV vector design, growth kinetics and vaccine study strategy. **a**, Genome organization comparing ZEBOV GP (Mayinga strain)-expressing rVSV vectors as described in methods. The rVSV/ZEBOVΔG (ΔG) vector had the natural VSV *G* gene replaced with the ZEBOV *GP* at position 4 within the genome. rVSVN1CT1GP3 (N1) vector retained the position of VSV *N* in position 1 (orange box), insertion of ZEBOV *GP* at position 3 and a truncated form of VSV *G* containing the CT1 truncation was inserted at position 6. The rVSVN4CT1GP1 (N4) vector had the insertion of ZEBOV *GP* in position 1, attenuating *N* gene translocation (N4) (black box) and truncated G protein cytoplasmic tail (CT1). Numbers above vector constructs designate genome positions. Virus leader (Le), trailer (Tr), and intergenic regions are shown in black. Shaded regions represent deleted amino acid regions. **b**, Single-cycle growth kinetics comparing the ΔG, N1, and N4 vectors depicted in **a**. Data shown are mean ± s.d. from two biological replicates titrated by plaque assay in triplicate. Titre differences between ΔG and N1 vectors were statistically significant at 4 ($P = 0.0001$), 12 ($P = 0.0055$), and 24 h post infection ($P = 0.0001$). Likewise, ΔG and N4 vector titres were significantly different at 4 ($P = 0.0001$), 12 ($P = 0.0005$), 24 ($P = 0.0001$), and 48 h post infection ($P = 0.0068$). Unpaired *t*-test, $P = 0.05$. **c**, Crystal violet-stained Vero cell monolayers showing plaques generated by the ΔG, N1, and N4 vectors at 48 h post infection. **d**, Flow chart showing the day of vaccination (triangles), days of sampling (arrows), day of challenge (*). Blue triangle, unvaccinated cohort; orange triangle, N1-vaccinated cohort; black triangle, N4-vaccinated cohort.

vaccine described here (rVSVN1CT1GP3), expressing a truncated form of VSV G, was designed to be of intermediate attenuation between rVSVN4CT1GP1 and the first generation rVSV/ZEBOVΔG vaccine (Fig. 1a, N1). Both attenuated rVSV/ZEBOV vectors express GP from the ZEBOV Mayinga strain, as do most other candidate ZEBOV vaccines currently under evaluation. Sequence homology between GPs from the new West African Makona strains analysed to date and the 1976 Mayinga strain is approximately 97%. Although this difference is not likely to affect the protective efficacy of the current ZEBOV vaccines against the heterologous West African strains, it is possible that small changes in sequence could lead to reduced efficacy of a vaccine[15]. It is well established that small variations in sequence and even single amino acid changes in sequence for other viruses including influenza, respiratory syncytial virus, polio, equine infectious anaemia virus, and SIV can reduce vaccine efficacy. Here we assessed the ability of our newly developed next-generation rVSV-based vaccines expressing ZEBOV Mayinga GP to protect against heterologous challenge with the new outbreak Makona strain of ZEBOV in cynomolgus monkeys.

Table 1 | Clinical findings for NHPs challenged with ZEBOV-Guinea

Animal	Vaccine	Day −26*	$PRNT_{50}$†	Clinical signs observed‡	Final outcome

* rVSV viraemia 2 days post vaccination. –, below limit of detection (25 PFU per ml); +, up to 3×10^2 PFU per ml.

† 50% plaque reduction neutralization titre at day of challenge and terminal day presented as day of challenge/terminal day.

‡ Days after ZEBOV challenge are in parentheses. Fever is defined as a temperature more than 1.4 °C above baseline or at least 0.9 °C above baseline and ≥ 39.7 °C. Lymphopenia and thrombocytopenia are defined by a ≥ 35% drop in numbers of lymphocytes and platelets, respectively. ALT, alanine aminotransferase; ALP, alkaline phosphatase; AST, aspartate aminotransferase; GGT, gamma glutamyltransferase. CRP, C-reactive protein: two- to threefold increase,→; 4- to fivefold increase, →→; > 5 fold increase, →→→.

§ No symptoms observed.

Results from an *in vitro* growth kinetics study (Fig. 1b) indicate an approximate tenfold reduction in growth rate early in infection for rVSVN4CT1GP1 relative to rVSV/ZEBOVΔG. Also noted during virus plaque assay were the larger more rapidly forming plaques generated by rVSV/ZEBOVΔG compared to rVSVN4CT1GP1, with rVSVN1CT1GP3 showing intermediate growth and plaque size (Fig. 1c).

We next tested if the further-attenuated rVSV/ZEBOV vaccines could provide NHPs with single-dose protection against challenge with ZEBOV isolated from the current outbreak in Guinea[16]. Groups of four cynomolgus macaques were inoculated intramuscularly with 2×10^{7} plaque-forming units (PFU) of either rVSVN4CT1GP1 or rVSVN1CT1GP3; a group of two control macaques were unvaccinated (Fig. 1d, arrow heads). None of the macaques showed any sign of illness or distress following vaccine administration. Consistent with the statistically significant growth differences between rVSV/ZEBOVΔG and the more attenuated vectors seen during *in vitro* growth kinetics studies, levels of both attenuated vaccine viruses detected in the blood of vaccinated macaques (500 PFU per ml) were 10- to 50-fold lower than those detected for the more replication competent rVSV/ZEBOVΔG[9] (Table 1, day −26). The ZEBOV GP-specific humoral immune response was assessed for all animals before vaccination (Fig. 2a, −28) and after vaccination (Fig. 2a, −18 and 0) by IgG capture ELISA and neutralizing antibody titres (Table 1, plaque 50% reduction neutralization test (PRNT)$_{50}$). Results showed neutralizing titres at terminal days for vaccinated cohorts and detectable circulating levels of anti-ZEBOV GP IgG for both vaccine cohorts after vaccination and before challenge with no detectable levels for the unvaccinated control animals (Fig. 2a). A cell-mediated immune response was also detected in all vaccinated animals by ZEBOV GP-specific interferon gamma (IFN-γ) ELISpot assay 10 days after vaccination (Extended Data Fig. 1a and b).

The eight vaccinated and two unvaccinated control macaques were challenged by intramuscular injection with 1,000 PFU of a low passage 100% 7U Makona strain stock of ZEBOV[16] 28 days after the single injection vaccination (Fig. 1d, asterisk). None of the animals vaccinated with either of the two further-attenuated rVSV/ZEBOV vectors showed any severe signs of illness following challenge with ZEBOV (Table 1), whereas the two unvaccinated control macaques succumbed to disease on days 7 and 8 (Fig. 2b). Circulating infectious ZEBOV was isolated from both of the unvaccinated control macaques on days 3 and 6 post challenge (Fig. 2c, blue) but no circulating infectious ZEBOV could be detected in any of the vaccinated animals. Examination of tissues by immunohistochemistry showed abundant ZEBOV antigen in tissues of the unvaccinated control animals (129 and 276) (Fig. 3a–d) whereas ZEBOV antigen was not detected in tissues of the macaques vaccinated with rVSVN1CT1GP3 (1001100) or rVSVN4CT1GP1 (0807174) (Fig. 3e–h).

Here we show protection against a new West African Makona strain of ZEBOV using a novel filovirus vaccine platform. The large reduction in vaccine-associated viraemia indicates a significant increase of *in vivo* attenuation for these next-generation rVSV/ZEBOV vaccine vectors, which should translate into greater safety and reduced adverse

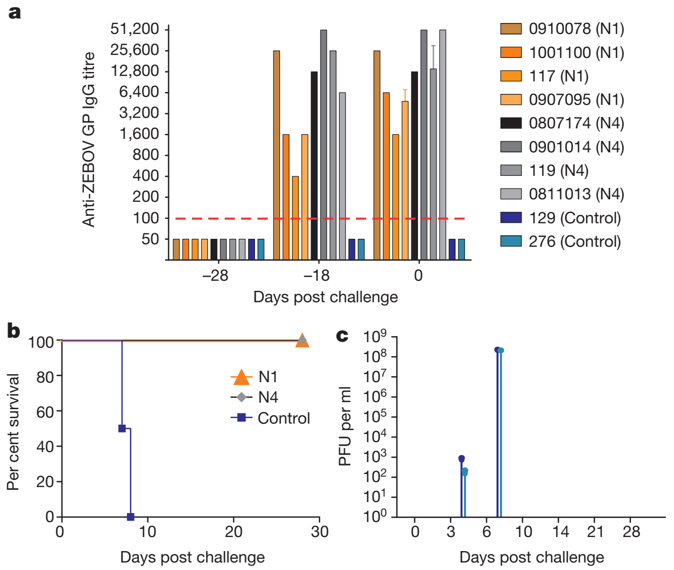

Figure 2 | N1 and N4 vaccination results in circulating anti-ZEBOV GP IgG and protection in cynomolgus macaques. **a**, Reciprocal endpoint dilution titres for circulating IgG against ZEBOV GP for control (blue), N1 (orange), and N4 cohorts (black-grey) on day of vaccination (−28), 10 days post vaccination (−18), and on day of challenge (0). Red dashed line depicts limit of detection for ELISA assay. Error bars represent s.e.m. **b**, Kaplan–Meier survival curve for each cohort post ZEBOV challenge. **c**, Circulating infectious virus load displayed as plaque forming units per ml. Data shown are from individual animals. Lower limit of detection is 25 PFU per ml.

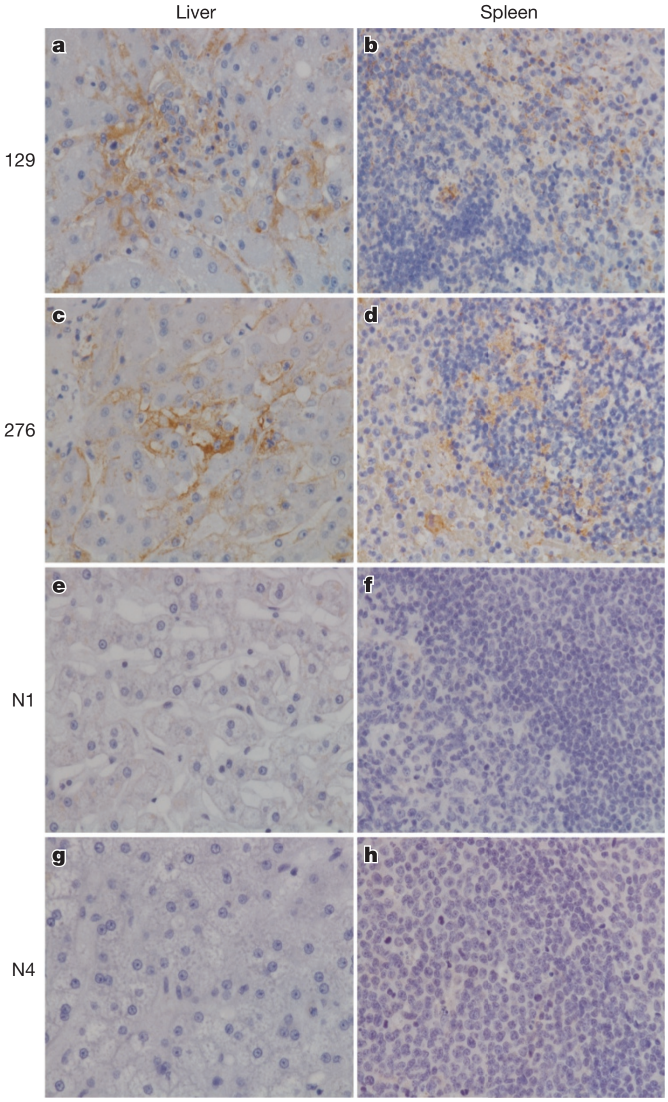

Figure 3 | Comparison of ZEBOV antigen in tissues of cynomolgus macaques either vaccinated or unvaccinated. **a**, **c**, Liver, diffuse cytoplasmic immunolabelling (brown) of sinusoidal lining cells in both ZEBOV-infected control animals. **b**, **d**, Spleen, diffuse cytoplasmic immunolabelling of dendriform mononuclear cells in the red and white pulp of ZEBOV-infected control animals. **e**, **f**, Liver and spleen, respectively, with a lack of immunolabelling from N1 cohort animal 0910078. **g**, **h**, Liver and spleen, respectively, with a lack of immunolabelling from N4 cohort animal 0807174.

events in humans. Importantly, single-dose vaccination of NHPs with highly attenuated forms of rVSV expressing ZEBOV Mayinga GP provides complete protection from heterologous challenge with a highly virulent 7U ZEBOV isolated early during the current West African outbreak[16]. ZEBOV genome sequencing from cases later during the West Africa outbreak has revealed little drift in the GP gene[17,18], suggesting that this vaccine platform could also be efficacious against currently circulating ZEBOV. These findings pave the way for the identification and manufacture of safer, single-dose, high efficacy vaccine(s) to combat current and future filovirus outbreaks in Africa and their potential use as biological weapons.

Acknowledgements We thank V. Borisevich and D. Deer for assistance with clinical pathology assays performed in the GNL BSL-4 laboratory, and the staff of the UTMB Animal Resources Center for animal care. This study was supported by the funds from the Department of Microbiology and Immunology at UTMB to T.W.G. and in part by the Department of Health and Human Services, National Institutes of Health grant R01AI09881701 to J.H.E. and T.W.G.

Author Contributions D.K.C., D.M. and T.E.L. designed the vaccine vectors and did preparative work. J.H.E. M.A.E., A.O.-S. and R.X. designed, conducted, and analysed the *in vitro* vaccine characterization studies. C.E.M., J.H.E., and T.W.G. conceived and designed the NHP study. C.E.M., J.B.G. and T.W.G. performed the NHP vaccination and challenge experiments, and conducted clinical observations of the animals. J.B.G. and K.N.A. performed the clinical pathology assays. J.B.G. performed the ZEBOV infectivity assays. C.E.M., D.M., J.B.G., K.N.A., M.A.E., K.A.F., D.K.C., J.H.E. and T.W.G. analysed the data. K.A.F. performed histologic and immunohistochemical analysis of the data. C.E.M., D.M., D.K.C. and T.W.G. wrote the paper. All authors had access to all of the data and approved the final version of the manuscript.

(twgeisbe@utmb.edu)

METHODS

No statistical methods were used to predetermine sample size.

Generation of N4 and N1 ZEBOV vectors. As described previously[12,19] an rVSV$_{IN}$N4CT1gag1 vector (Indian serotype) expressing HIV-1 gag was used as the backbone for generating the attenuated rVSVN4CT1 vector expressing the Zaire ebolavirus (ZEBOV) glycoprotein (GP). The corresponding rVSV$_{IN}$N4CT1gag1 genomic cDNA was modified by exchanging the gag gene expression cassette via XhoI/NotI restriction sites with an expression cassette encoding a full length ZEBOV GP [1976, Mayinga strain], generating the rVSV$_{IN}$N4CT1-ZEBOVGP1 cDNA (Fig. 1a, N4). The N1 vector was generated by first inserting ZEBOV GP into a VSV-N1ΔG backbone via XhoI/NotI restriction sites within a transcriptional cassette located at position 3 in the genome; followed by the insertion of a PCR fragment containing a portion of VSV *L*, a modified VSV *G* CT1 gene and trailer into the N1 genome at position 6 via the HindIII/RsrII sites, generating the rVSV$_{IN}$N1(G CT1)6-ZEBOVGP3 cDNA (Fig. 1a, N1).

The rVSV-ZEBOV vectors were rescued from genomic cDNA as previously described[20]. Rescued virus was plaque purified and amplified on Vero cell monolayers (ATCC, CCL-81). For animal studies, virus vectors were purified from infected BHK-21(ATCC CCL-10) cell supernatants by centrifugation through a 10% sucrose cushion. Purified virus was resuspended in PBS, pH 7.0, mixed with a sucrose phosphate (SP) stabilizer (7 mM K_2HPO_4, 4 mM KH_2PO_4, 218 mM sucrose), snap frozen in ethanol/dry ice and stored at −80 °C until ready for use.

Growth kinetics study of ΔG, N4 and N1 ZEBOV vectors. Single-step growth curves were performed by adsorbing the N4, N1 and a ΔG control virus to duplicate monolayers of Vero cells (ATCC, CCL-81) in six-well plates at a multiplicity of infection (MOI) of 10 for 15 min at room temperature with continued rocking followed by incubation at 37 °C with 5% CO_2 for 30 min without agitation. The inoculum was aspirated, the cells washed 3× with serum-free Dulbecco's minimal Eagle's medium (DMEM) and then DMEM containing 5% fetal bovine serum (FBS) was added to the plates, which were placed at 32 °C with 5% CO_2. Samples for titration were taken at 4, 8, 12, 16, 24 and 48 h post infection and replaced with the same volume of fresh media. Virus titres were determined in duplicate by plaque assay on Vero cells. Growth curves were performed in triplicate for each virus. Plaque images for each vector were taken at 48 h post infection, after staining with a 1% crystal violet solution. Statistical analysis of rVSV titres were performed using unpaired *t*-test with a 95% confidence level ($P < 0.05$) with the GraphPad Prism program.

Challenge virus. The ZEBOV Makona strain seed stock originated from serum from a fatal case early during the 2014 outbreak in Guékédou, Guinea[16] (NCBI accession number KJ660347) and was passaged twice in Vero E6 cells (ATCC, CRL-1586). The virus stock was deep sequenced as 100% 7U at the GP editing site in the viral genome (see below).

Deep sequencing. Approximately 1 ml of the ZEBOV Makona strain seed stock was removed from the seed stock vial and placed in 5 ml of TRIzol LS and vortexed three times and allowed to sit for 10 min. The 6 ml were then placed into two separate 3 ml Nunc cryo-vials for removal from the BSL-4. RNA was isolated from the TRIzol LS/sample mixture using Zymo Research Direct-zol RNA mini-prep per manufacturer's instructions. Approximately 150 ng of purified RNA were used to make cDNA using the NuGen Ovation RNA-seq 2.0 kit ultimately for the preparation of the double-stranded DNA library using Encore Ion Torrent library prep kit. Sequencing was performed by the UTMB Molecular Core on the Ion Torrent using 318-v2 deep sequencing chips. Sequence analysis was performed using DNA Star Seqman NGen software based on paired-end analysis of 100 base pairs overlaps.

Vaccination and animal challenge. Ten, healthy, filovirus-naive, adult (~3 to 9.5 kg, 7 female and 3 male), Chinese origin cynomolgus macaques (*Macaca fascicularis*) were randomized with Microsoft Excel into two experiment groups of four animals each and a control group of two animals. Animals in one experimental group were vaccinated by intramuscular injection of approximately 2×10^7 PFU of the rVSVN4CT1GP1vaccine while animals in the other experimental group were vaccinated with approximately 2×10^7 PFU of the VSV-N1CT1 ZEBOVGP vaccine. The two control animals were not vaccinated. Four weeks after the single injection vaccination all ten animals were challenged by intramuscular injection with 1,000 PFU of the ZEBOV Makona strain virus. All animals were given physical exams and blood was collected before vaccination, at day 10 after vaccination, at the time of ZEBOV challenge and on days 3, 6, 10, 14, 21 and 28 after ZEBOV challenge (Fig. 1d, arrows). Animals were monitored daily and scored for disease progression with an internal filovirus scoring protocol approved by the UTMB Institutional Animal Care and Use Committee. The scoring changes measured from baseline included posture/activity level, attitude/behaviour, food and water intake, weight, respiration, and disease manifestations such as visible rash, haemorrhage, ecchymosis, or flushed skin. A score of ≥ 9 indicated that an animal met criteria for euthanasia. This study was not blinded.

Anti-ZEBOV GP IgG ELISA. Serum collected at indicated time points was tested for immunoglobulin G (IgG) antibodies against ZEBOV. Enzyme-linked immunosorbent assay (ELISA) using recombinant ZEBOV GPdTM purified protein (Integrated BioTherapeutics, Inc.) was used to detect cross-reactive IgG. ZEBOV GPdTM was diluted to an optimal working concentration of 100 ng per well in 0.1 ml carbonate/bicarbonate buffer (carbonate/bicarbonate buffer with azide tablets from Sigma catalogue number 08058-50TAB-F) and used to coat Immulon 2HB flat bottom ELISA plates (Thermo Labsystem catalogue number 3455) for 18 h at 4 °C. Coated plates were blocked (10% FBS + 1× PBS) for at least 2 h. The serum samples were assayed at twofold dilutions starting at a 1:100 dilution in ELISA diluent (1% heat inactivated fetal bovine serum (HI-FBS), 1× PBS, and 0.2% Tween-20). Samples were incubated for 1 h at room temperature, removed, and plates were washed. Wells were then incubated at room temperature for 1 h with anti-monkey IgG conjugated to horseradish peroxidase (Fitzgerald Industries International) at a 1:2,500 dilution. These wells were washed and then incubated with 2,2'-azine-di(3ethylbenzthiazoline-6-sulfonate) peroxidase substrate system (KPL) at room temperature for approximately 10 min. Reaction was stopped with 1% SDS and read for dilution endpoints at 405 nm on a microplate reader (Molecular Devices Emax system). Absorbance values were normalized by subtraction of background $A_{405\,\mathrm{nm}}$ from uncoated wells for each serum dilution. Antigen-specific serum IgG end-point titres were defined as the reciprocal of the last normalized serum dilution giving an $A_{405\,\mathrm{nm}}$ greater than 0.1.

ZEBOV neutralization assay. Neutralization assays were performed by measuring plaque reduction in a constant virus:serum dilution format as previously described[9]. Briefly, a standard amount of ZEBOV (~100 PFU) was incubated with serial twofold dilutions of the serum sample for 60 min. The mixture was used to inoculate Vero E6 cells (ATCC, CRL-1586) for 60 min. Cells were overlaid with an agar medium, incubated for 7 days, and plaques were counted 48 h after neutral red staining. Endpoint titres were determined by the dilution of serum, which neutralized 50% of the plaques ($PRNT_{50}$).

IFN-γ ELISpot assay. Ninety-six-well flat-bottomed ELISpot plates (Millipore) were coated overnight with a mouse anti-human IFN-γ monoclonal antibody (clone 27; BD-Pharmingen) at a concentration of 10 μg ml^{-1}, after which the plates were washed three times with 1× PBS and then blocked for 2 h with PBS containing 5% heat-inactivated FBS. Heparinized whole blood was collected 10 days after immunization of macaques, and peripheral blood mononuclear cells (PBMCs) were isolated from whole blood by Ficoll-Hypaque density gradient centrifugation, and resuspended in complete R05 culture medium. The isolated macaque PBMCs were washed once with complete R05 culture medium and resuspended in complete R05 culture medium containing either 5 μg ml^{-1} phytohaemagglutinin mucoprotein (Sigma), peptide pools (15-mers overlapping by 11 amino acids; final peptide concentration, 1 μM each) spanning the ZEBOV Mayinga strain GP, or medium alone. The input cell number was 2×10^5 PBMCs per well (2×10^6 PBMCs per ml), and cells were assayed in duplicate wells. Cells were incubated for 18 to 24 h at 37 °C and then removed from the ELISpot plate by first being washed with deionized water and then being washed six times with 1× PBS containing 0.25% Tween 20. Thereafter, plates were treated with a rabbit polyclonal anti-human IFN-γ biotinylated detection antibody (0.65 μg per well; Life Technologies) diluted with 1× PBS containing 1% bovine serum albumin (BSA) and were incubated at 37 °C for 2 h. ELISpot plates were then washed 6 times with 1× PBS containing 0.25% Tween 20, treated with 100 μl per well of streptavidin–horseradish peroxidase conjugate (BD Biosciences) diluted 1:250 with 1× PBS containing 10% FBS and 0.005% Tween 20, and incubated for an additional 1 h at room temperature. Unbound conjugate was removed by rinsing the plate six times with 1× PBS containing 0.25% Tween 20 and three times with 1× PBS. A chromogenic substrate (100 μl per well) (one-step nitroblue tetrazolium/5-bromo-4-chloro-3-indolylphosphate (NBT/BCIP); Pierce) was then added for 3 to 5 min before being rinsed away with water, after which the plates were air dried and the resulting spots counted using an ImmunoSpot reader (CTL Inc.). Peptide-specific IFN-γ ELISpot responses were considered positive if the responses (minus the medium background) were threefold above the medium response and 50 spot-forming cells (SFC) per 10^6 PBMCs. Unpaired *t*-test analysis of IFN-γ ELISpot data was performed on GraphPad Prism version 5.02 software. Two-tailed *P* values less than 0.05 indicated that the tests were statistically significant.

Detection of viraemia. Virus titration of the rVSV vaccine vectors and ZEBOV was performed by plaque assay with Vero E6 cells (ATCC, CRL-1586) from cell culture or serum samples as previously described[9]. Briefly, increasing tenfold dilutions of the samples were adsorbed to Vero E6 monolayers in duplicate wells (200 μl); the limit of detection was 25 PFU per ml.

Haematology and serum biochemistry. Total white blood cell counts, white blood cell differentials, red blood cell counts, platelet counts, haematocrit values, total haemoglobin concentrations, mean cell volumes, mean corpuscular volumes, and mean corpuscular haemoglobin concentrations were analysed from blood collected in tubes containing EDTA using a laser based haematologic analyser (Beckman Coulter). Serum samples were tested for concentrations of albumin, amylase, alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, gamma-glutamyltransferase, glucose, cholesterol, total protein, total bilirubin, blood urea nitrogen, creatine, and C-reactive protein by using a Piccolo point-of-care analyser and Biochemistry Panel Plus analyser discs (Abaxis).

Histopathology and immunohistochemistry. Necropsy was performed on all subjects. Tissue samples of all major organs were collected for histopathological and immunohistochemical examination, immersion-fixed in 10% neutral buffered formalin, and processed for histopathology as previously described[21]. For immunohistochemistry, specific anti-ZEBOV immunoreactivity was detected using an anti-ZEBOV VP40 protein rabbit primary antibody (Integrated BioTherapeutics, Inc.) at a 1:4,000 dilution. In brief, tissue sections were processed for immunohistochemistry using the Dako Autostainer (Dako). Secondary antibody used was biotinylated goat anti-rabbit IgG (Vector Laboratories) at 1:200 followed by Dako LSAB2 streptavidin–horseradish peroxidase (Dako). Slides were developed with Dako DAB chromagen (Dako) and counterstained with haematoxylin. Non-immune rabbit IgG was used as a negative control.

Some food for thought - would appreciate some feedback.

I really like the idea of focusing on the N4CT1 constructs to attenuate the rVSV constructs, particularly for the virus families we're dealing with where neruovirulence of the rVSVs has been shown or could be a limitation.

I coming to think that we should also propose testing other attenuating mutations as in Clarke et al. [attached]

I also like inserting sG constructs.

Additionally, I think it's possible that we could both increase expression of our viral glycoproteins AND attenuate them by truncating and mutating the cytoplasmic tails. IOWS mutate not only the VSV G cytoplasmic tail but also or mutate the cytoplasmic tail of the inserted viral glycoprotein.

This makes a lot of sense [in my mind] for all our prototype pathogens but especially for JUNV - check out the Nunberg paper attached. By truncating the CT of JUNC GPC you eliminate the need for the SSP but more importantly drive the GP to the cell surface.

This draft figure is derived from Tom's Makona paper and shows what I think might be a good grantsmanship approach of not putting all the eggs in one rVSV basket for any one virus.

Abstract: The henipaviruses, Nipah virus (NiV), and Hendra virus (HeV) can cause fatal diseases in humans and animals, whereas Cedar virus is a nonpathogenic henipavirus. Here, using a recombinant Cedar virus (rCedV) reverse genetics platform, the fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-B) or HeV, generating replication-competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without green fluorescent protein (GFP) or luciferase protein genes. The rCedV chimeras induced a Type I interferon response and utilized only ephrin-B2 and ephrin-B3 as entry receptors compared to rCedV. The neutralizing potencies of well-characterized cross-reactive NiV/HeV F and G specific monoclonal antibodies against rCedV-NiV-B-GFP and rCedV-HeV-GFP highly correlated with measurements obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization tests (PRNT). A rapid, high-throughput, and quantitative fluorescence reduction neutralization test (FRNT) using the GFP-encoding chimeras was established, and monoclonal antibody neutralization data derived by FRNT highly correlated with data derived by PRNT. The FRNT assay could also measure serum neutralization titers from henipavirus G glycoprotein immunized animals. These rCedV chimeras are an authentic henipavirus-based surrogate neutralization assay that is rapid, cost-effective, and can be utilized outside high containment.

1. Introduction

The bat-borne highly pathogenic Hendra virus (HeV) and Nipah virus (NiV) are the prototype members of the genus *Henipavirus* within the family *Paramyxoviridae* [1]. HeV and NiV are classified as Biosafety Level-4 (BSL-4) pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia and South and Southeast Asia, respectively. The genus now includes nine other reported henipaviruses; the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV), [2–4] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [5–8]. The recognized or apparent natural reservoir of all isolates of NiV, HeV, and CedV, along with the genomic data of GhV and AngV, are old-world fruit bats of the family *Pteropodidae*.

Whereas the six other reported henipaviruses are, or are likely, of rodent origins, including the isolate LayV. Only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (reviewed in: [9,10]), while LayV was associated with nonfatal febrile illnesses in humans [4]. In contrast, CedV is the only henipavirus isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease, including guinea pigs, ferrets, hamsters [2,11], and African green monkeys (Geisbert, T.W. and Broder, C.C., unpublished). An important distinction between CedV and other henipaviruses lies within the *P* gene, which encodes the phosphoprotein (P), and the *P* gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (reviewed in [12,13]). The CedV *P* gene lacks both RNA editing and does not encode V or W [2,14]. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections [15–18]. All other recognized or proposed henipaviruses have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is hypothesized to be the key factor underlying its nonpathogenic nature in established NiV and HeV animal models. These data permitted the rescue and characterization of recombinant CedV (rCedV) by reverse genetics at BSL-2 containment, and CedV is now recognized as a BSL-2 restricted agent [19–21].

The development of effective countermeasures against NiV and HeV has been a research priority since their discovery [22]. NiV and henipaviral diseases are also included on the WHO's Blueprint List of Priority Pathogens [23], and NiV is among the Coalition for Epidemic Preparedness Innovations (CEPI) list of Priority Diseases needing urgent research and countermeasure development [24,25]. There are currently no licensed NiV/HeV vaccines or antivirals approved for human use, although a licensed vaccine to prevent HeV infection in horses, based on a soluble form of the attachment (G) glycoprotein (sG) from HeV (HeV-sG), was launched in Australia (Equivac® HeV) by Zoetis, Inc., in November 2012 [26]. A NiV vaccine formulated for human use with the HeV-sG immunogen is currently in Phase 1 human clinical trials [27]. As a therapeutic approach development for henipavirus human infection, the human monoclonal antibody (mAb) m102.4, specific to the NiV and HeV G glycoprotein receptor binding site, has completed a Phase I clinical trial in Australia [28]. To date, 18 individuals exposed to either HeV in Australia ($n = 17$) or NiV in the United States ($n = 1$) have received high-dose, post-exposure, m102.4 therapy (15–20 mg/kg) by emergency use protocols and no evidence of virus infection has been reported.

The G glycoprotein (also referred to as the receptor-binding protein (RBP)), together with the fusion (F) glycoprotein on the surface of the henipavirus virion, are the mediators of virus attachment and infection [29]. The RBP determines the cellular tropism of infection. The NiV and HeV G glycoproteins specifically bind to cells expressing the ephrin-B class ligands, ephrin-B2, and ephrin-B3 [30–33]. In contrast, CedV has a uniquely broad ephrin protein tropism and can utilize both B-class and A-class ephrins for cell entry and infection [21,34]. The binding of NiV or HeV G to their ephrin entry receptors on cells triggers a well-characterized activation and refolding of F from a pre- to post-fusion conformation that facilitates the merger of the virion and host cell membranes and subsequent delivery of the viral nucleocapsid into the cell cytoplasm (reviewed in [35]). Importantly, the F and G glycoproteins are also the major viral structural protein targets of neutralizing antibodies and the relevant antigens employed in all henipavirus vaccine strategies [22]. However, for pathogenic henipavirus vaccines or antibody-based countermeasure strategies, the assessment and quantification of neutralizing antibody responses or their potencies against authentic NiV and HeV, which requires BSL-4 containment, can be a major challenge.

Using a rCedV reverse genetics platform, the CedV F and G glycoprotein genes were replaced with those of NiV-B or HeV, and replication-competent chimeric henipaviruses (rCedV-NiV-B and rCedV-HeV) were rescued. Both non-reporter and two reporter gene versions, encoding a green fluorescent protein (GFP) or luciferase protein (Luc), of the rCedV chimeras were also produced. Characterization of the chimeric viruses revealed no significant differences in their replication kinetics or ability to induce a type I IFN response compared to rCedV and possessed the same ephrin B-class entry receptor tropisms as NiV-B and HeV. The neutralization potencies of several well-characterized cross-reactive NiV and HeV F and G specific mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP were highly correlated with those measured using authentic NiV-B and HeV when tested in parallel by a plaque reduction neutralization test (PRNT). A rapid high-throughput and quantitative fluorescence reduction neutralization test (FRNT) using the GFP-encoding chimeras was established that also yielded highly correlated mAb neutralization potencies with those derived by PRNT. The FRNT assay was also suitable for measuring serum neutralization titers from animals immunized with recombinant HeV or NiV soluble G glycoproteins. Taken together, the rCedV chimera platform is an authentic henipavirus-based surrogate neutralization assay for pathogenic henipaviruses that is rapid, cost-effective and can be utilized outside BSL-4 containment.

2. Materials and Methods

2.1. Construction of pOLTV5-rCedV Chimeric Antigenomes

A full description of the synthesis of the rCedV antigenome clone (pOLTV5-rCedV) has previously been described [20]. Here, an optimized version of the pOLTV5-rCedV antigenome clone was designed, and the 3′ end of the T7 minimal promoter ($T7_{min}$) sequence (TAATACGACTCACTATA) was modified by the addition of nucleotides GGGAGA to generate a T7 optimal promoter ($T7_{opt}$) [36]. The $T7_{opt}$ sequence was then followed by the insertion of a self-cleaving autocatalytic hammerhead ribozyme A (HHRbzA) sequence (GGGAGATTGGTCTGATGAGTCCGTGAGGACGAAACGGAGTCTAGACTCCGTC) [36]. This synthesized gene fragment ($T7_{opt}$-HHRbzA) (Genscript; NJ, USA) was enzymatically inserted to precede the CedV 3′ Leader (3′ Le) sequence in the pOLTV5-rCedV plasmid to yield pOLTV5$_{opt}$-rCedV (Figure 1A).

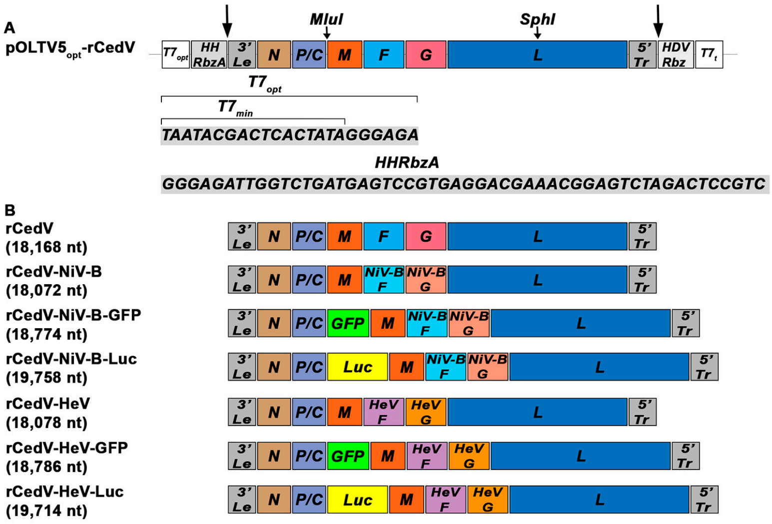

Figure 1. Schematic representation of the optimized rCedV plasmid and the genomes of the generated rCedV chimeric viruses. (**A**) The pOLTV5$_{opt}$-rCedV plasmid illustrates the location and sequences of the T7 optimal promoter ($T7_{opt}$) and the Hammerhead Ribozyme A (HHRbzA). The long arrows indicate regions of self-cleavage. Unique restriction sites MluI and SphI used to construct the rCedV chimeric plasmids are shown. (**B**) The genomes and the lengths of the generated chimeras are schematically diagrammed as rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, and rCedV-HeV-Luc. pOLTV5$_{opt}$-rCedV, optimized pOLTV5-rCedV plasmid; $T7_{min}$, T7 minimal promoter; $T7_{opt}$, T7 optimal promoter; HHRbzA, Hammerhead Ribozyme A; 3′Le, 3′ Leader; 5′Tr, 5′ Trailer; HDVRbz, hepatitis delta virus ribozyme; $T7_t$, T7 terminator.

Large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the respective NiV-B or HeV F and G coding sequences were synthesized (Genscript). The NiV-B F and G coding sequences were based on the NiV-B 2010 Faridpur isolate (GenBank: JN808864.1). The HeV F and G protein sequences used here, HeV genome (GenBank: MN062017.1), are identical to that of the HeV 2008 Redlands isolate (GenBank: JN255805.1). The isolates and GenBank accession numbers for each F and G protein are listed in Table 1. Unique restriction enzyme sites facilitated the insertion of the NiV-B or HeV F and G gene cassettes into pOLTV5$_{opt}$-rCedV (Figure 1A) to ultimately generate non-reporter versions, pOLTV5$_{opt}$-rCedV-NiV-B or pOLTV5$_{opt}$-rCedV-HeV. The "rule-of-six" was maintained by removing the last three nucleotides (ACG; amino acid Threonine) from the NiV-B F coding sequence and adding a stop codon (TAA) to the end of the HeV F coding region. The insertion of a modified turbo Green Fluorescent Protein (*GFP*) gene (Lonza Inc., Allendale, NJ, USA) or firefly (*Photinus pyralis*) luciferase (*Luc*) gene (a kind gift from Dr. B Schaefer, USU) between CedV *P* and *M* genes of the newly constructed pOLTV5$_{opt}$-rCedV chimeric plasmids using standard molecular techniques was as previously described [20,37] and yielded pOLTV5$_{opt}$-rCedV chimeric reporter gene encoding versions of the rCedV antigenome clones. All cloning was performed with *Escherichia coli* Stbl2 cells (Invitrogen; Carlsbad, CA, USA). The insertions were sequenced to obtain at least 2-fold coverage.

Table 1. GenBank accession numbers of NiV-B and HeV envelope glycoproteins.

Henipavirus	Isolate	Protein	GenBank Accession Number
NiV-B	2010 Faridpur	F	AEZ01396.1
		G	AEZ01397.1
HeV	2008 Redlands	F	AEQ38070.1
		G	AEQ38071.1

2.2. Cells, Monoclonal Antibodies, Rhesus Macaque, and Rabbit Immune Sera

BSR-T7/5 cells, a BHK-derived cell line stably expressing T7 RNA polymerase [38], HeLa-USU, HeLa (ATCC CCL-2), Vero E6 (ATCC CCL-81), and Vero 76 (ATCC CRL-1587) cell lines were maintained at 37 °C, 5% CO_2 in Dulbecco's modified eagle media (DMEM) (Quality Biological; Gaithersburg, MD, USA) supplemented with 10% cosmic calf serum (CCS) and 1% L-glutamine (Quality Biological) (DMEM-10). HeLa-USU-ephrin-B2 and HeLa-USU-ephrin-B3 stable cell lines were maintained in DMEM-10% CCS, 1% L-glutamine supplemented with 0.4 mg/mL Hygromycin B (Invitrogen).

The neutralizing HeV and NiV cross-reactive human mAb, m102.4, is a G glycoprotein-specific IgG1 subclass antibody [28,39–43]. The humanized 5B3.1 (h5B3.1) mAb [44,45] and the murine mAbs 12B2 and 1F5 [46] are IgG1 mAbs cross-reactive to HeV and NiV F glycoprotein. Anti-NiV G glycoprotein-specific sera were from four rhesus macaques immunized at the University of Texas Medical Branch at Galveston, TX, on days 0, 28, and 56 with an equal mixture of 0.1 mg NiV-B and 0.1 mg NiV-M recombinant soluble G (sG) glycoproteins adjuvanted with aluminum hydroxide suspension (Auro Vaccines, LLC, Pearl River, NY, USA) [47]. Sera were collected on days 42 and 84 post-immunization and stored at −80 °C. Anti-HeV G glycoprotein-specific sera were prepared using the HeV/NiV recombinant soluble HeV G glycoprotein vaccine candidate (HeV-sG) [26,27,48–54] or HeV-sG$_{tet}$ [55], a tetrameric version of the HeV sG glycoprotein which was constructed similarly to other henipavirus sG glycoproteins as described in Cheliout Da Silva et al. [56]. Sera from rabbits immunized on days 0 and 28 with 0.1 mg HeV-sG or HeV-sG$_{tet}$ formulated with complete Freund's adjuvant (initial injection) and boosted with immunogen formulated with incomplete Freund's adjuvant (booster injection) were prepared by Noble Life Sciences; Woodbine, MD. Sera were collected on day 45 post-immunization and stored at −80 °C.

2.3. Rescue of Recombinant CedV Chimeras

BSR-T7/5 cells in a 12-well plate (2.5×10^5 cells/well) were co-transfected with pCMV-CedV helper plasmids pCMV-CedV-N (1.25 µg), pCMV-CedV-P (0.8 µg) and pCMV-CedV-L (0.4 µg) together with one of the pOLTV5$_{\text{opt}}$-rCedV chimera antigenome constructs (3.5 µg) using TransIT-LT1 transfection reagent (Mirus Bio; Madison, WI, USA) according to the manufacturer's recommendations. After 4–5 days, transfected cells were observed for syncytia formation and/or GFP expression. Supernatants from successful rescue wells were collected and passaged onto naïve Vero E6 cells in a T-75 flask to prepare a master stock of each of the rCedV chimeras. When maximal syncytia and/or GFP expression was observed (~2–3 days), viral supernatants were collected and clarified by centrifugation at 948× *g* (2400 rpm) for 10 min to pellet cell debris. The supernatant was transferred to screw-cap tubes as single-use aliquots and stored at −80 °C. All rCedV chimeras were deep sequenced using Illumina short reads, and variants were analyzed. Briefly, sequencing libraries were prepared from total RNA using the TruSeq Stranded Total RNA Sample Prep kit (Illumina, San Diego, CA, USA) and subjected to multiplexed sequencing on either the Illumina MiSeq platform using 600 cycles, V3 chemistry, or the Illumina NextSeq platform using 300 cycles, V2 chemistry. The resulting sequencing reads were analyzed using EDGE Bioinformatics tools [57] and an in-house metagenomics pipeline called MetaDetector (unpublished). EDGE Bioinformatics suite was used for read processing, and the host read subtraction, de novo assembly, taxonomic classification, and variant detection. Sequencing reads were also processed in parallel using MetaDetector, which checked for quality using FASTQC [58], trimmed for quality using BBDuk (Q20) [59], and removed incidental matching human genome reads using BBMAP [59]. The remaining reads were assembled using metaSPAdes and SPAdes [60]; the resulting contigs, along with all the cleaned singleton reads, were BLAST searched using Diamond [61] for taxonomic classification. The final assemblies were examined and constructs were identified to be annotated using BLASTn and BLASTx implemented in CLC Genomics Workbench (QIAGEN Bioinformatics; Redwood City, CA). Variant analysis was performed by mapping the reads to a publicly available reference Cedar virus genome from isolate CG1a (GenBank accession JQ001776) using EDGE Bioinformatics tools and iVar [62].

2.4. Viral Plaque Assay

Viral stocks were titrated by plaque assay as previously described [20,37,63]. Briefly, a ten-fold serial dilution of the virus stock was prepared in DMEM-10, 200 µL of which was applied to pre-seeded Vero E6 cells in duplicate (5×10^5 cells/well) in a 12-well plate and incubated for 1 h at 37 °C, 5% CO_2. A 2 mL overlay of a 1:1 mix of DMEM containing 5% CCS and 1% L-glutamine (DMEM-5) with 2% carboxymethylcellulose sodium salt (medium viscosity) (Sigma-Aldrich; St. Louis, MO, USA) was applied to all wells and incubated for 4 days at 37 °C, 5% CO_2. Cells were fixed with 4% Formaldehyde in 1× PBS for 1 h at room temperature and stained with 0.5% crystal violet in 80% methanol for 15 min at room temperature. The stain was removed and washed with diH_2O, and plaque-forming units (PFU) were counted and expressed as PFU/mL.

2.5. Virus Biosafety Procedures and Regulations

Laboratory manipulation guidelines and standard operating procedures for rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, rCedV-HeV-Luc, rCedV, rCedV-GFP and rCedV-Luc under BSL-2 conditions have been established, reviewed, and approved by the Uniformed Services University (USU), Institutional Biosafety Committee in accordance with NIH guidelines. The rCedV-HeV-GFP and/or rCedV-NiV-B-GFP chimeras have been previously used in mAb neutralization and mAb synergy neutralization studies [47,64,65]. A P2 stock of NiV-B was used in these studies. There were four mutations of sufficient frequency in comparison to the reference sequence GenBank Accession number AY988601.1. Of these, one was non-coding, and the other three led to single amino acid changes: one in the M protein and two in the F protein [66]. The HeV isolate used in these studies (GenBank Accession number NC_001906) was obtained from a patient from the 1994 outbreak in Australia and was provided by Dr. Thomas Ksiazek [45]. All studies with authentic NiV-B and HeV were performed within the BSL-4 facilities of the Galveston National Laboratory, The University of Texas Medical Branch at Galveston, TX, USA.

2.6. Western Blot Analysis

Vero E6 cells in a 6-well plate were infected at a density of 1×10^6 cells/well with rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, rCedV-HeV-Luc, rCedV, rCedV-GFP or rCedV-Luc at a multiplicity of infection (MOI) of 0.01. Simultaneously, the cells were co-transfected with a total of 2 µg of the plasmid to express both F and G glycoproteins from either NiV or HeV. A promoter-modified pcDNA3.1 vector with a hygromycin selection marker [67] encoding either NiV-F (pcDNA3.1-NiV-F) or NiV-G (pcDNA3.1-NiV-G) was used for the NiV-F and NiV-G expression. A promoter-modified pcDNA3.1 encoding either HeV-F (pcDNA3.1-HeV-F) or HeV-G (pcDNA3.1-HeV-G) was used for the HeV-F and HeV-G expression. At 24 h and 48 h post-infection, cells were collected and lysed with 1× RIPA (radioimmunoprecipitation assay) Lysis and Extraction Buffer (ThermoFisher Scientific; Waltham, MA, USA) containing a protein inhibitor cocktail (ThermoFisher Scientific). Total protein (~30 µg) in reducing sample buffer (2× lithium dodecyl sulfate (LDS) NuPage® sample buffer (Invitrogen), 5% β-mercaptoethanol (Sigma-Aldrich, St. Louis, MO, USA) was boiled for 10 min at 100 °C. Proteins were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) on a 4–12% Bis-Tris gel (ThermoFisher Scientific) and then transferred on nitrocellulose membranes (ThermoFisher Scientific). The membranes were blocked in 5% milk in 1× PBS with 0.1% Tween-20 at room temperature. Cross-reactive murine mAbs specific to NiV and HeV F (mAb 5G7) or to NiV and HeV G (mAb 48D3) glycoproteins, polyclonal rabbit sera to CedV-N (CSIRO, Victoria, Australia), and β-actin (ThermoFisher Scientific) were used as primary antibodies and subsequently probed with a corresponding secondary HRP-coupled antibody.

2.7. Virus Replication Kinetics

Vero E6 cells were seeded at a density of 2×10^4 cells/well in a 96-well cell culture plate. The next day, cells were infected at an MOI of 0.01 at 37 °C, 5% CO_2. After 1 h, the viral inoculum was removed, and fresh DMEM-10 was added to all wells. Supernatants were collected at 0, 8, 24, 48, and 72 h post-infection and stored at −80 °C until ready to analyze. Viral titers were determined by plaque assay as described in Section 2.4 and were expressed as plaque-forming units (PFU) per mL (PFU/mL). To determine intracellular luciferase activity, cells infected with either the non-reporter or Luc expressing viral chimeras were lysed with the Steady-Glo® Luciferase Assay System (Promega, Madison, WI, USA) in a 1:1 mixture with DMEM-10. After a 10 min incubation at room temperature, the homogenate was transferred to a white opaque 96-well cell culture plate, Nunc™ F96 MicroWell™ White Polystyrene Plate (ThermoFisher Scientific), and luminescence read using the GloMax®—Multi Detection System (Promega, Madison, WI, USA). Relative light units (RLU) were measured and normalized by subtracting the luminescence values of rCedV-NiV-B or rCedV-HeV infected cells from the luminescence values of rCedV-NiV-B-Luc or rCedV-HeV-Luc infected cells, respectively. Virus titers and luciferase activity levels at 0 h post-infection indicate the lower limit of detection for the plaque assay and the luminometer, respectively.

2.8. Ephrin Entry Receptor Tropism

HeLa-USU, HeLa-USU-ephrin-B2, and HeLa-USU-ephrin-B3 cell lines were seeded at a density of 2.5×10^5 cells/well in a 12-well cell culture plate. When confluent, the cell culture medium was removed, and cells were left uninfected (Mock) or infected at an MOI of 0.5 with either rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP individually diluted in DMEM-10. At 24 h post-infection, rCedV-NiV-B-GFP, rCedV-HeV-GFP, and rCedV-GFP infected cell cultures were monitored for GFP fluorescence and syncytia. Images were captured with a Zeiss Axio Observer A1 inverted microscope using the 5× objective.

2.9. Reverse Transcriptase Quantitative PCR (RT-qPCR) and Type I IFN Response

HeLa-CCL-2 cells were seeded at a density of 1.25×10^5 cells/well in a 24-well plate and incubated overnight. Cells were left intact (Mock), transfected with polyinosinic:polycytidylic acid (Poly I:C) (InvivoGen; San Diego, CA, USA) (10 μg/mL) using Lipofectamine LTX (ThermoFisher Scientific), or infected with rCedV-NiV-B, rCedV-HeV or rCedV at either an MOI of 0.5 or 1.0. At 24 h post-infection, total RNA was extracted using the RNeasy Mini Kit (Qiagen Sciences Inc., Germantown; MD, USA). An amount of 500 ng of DNase I digested RNA was converted to cDNA using the Superscript III First-Strand Synthesis System (ThermoFisher Scientific) with oligo(dT) primers. Quantitative PCR (qPCR) was then performed with the synthesized cDNA using the Power SYBR Green PCR Master Mix (ThermoFisher Scientific) and the Applied Biosystems 7500 Real-Time PCR System. PCR cycling conditions were: 95 °C, 10 min; 40× cycles of 95 °C, 15 s; 60 °C, 1 min; followed by a melt curve analysis at the completion of each experiment. Each sample was analyzed for IFN-α, IFN-β and 18S ribosomal RNA in triplicate, and fold changes were calculated relative to 18S ribosomal RNA and normalized to mock samples using the $2^{(-\Delta\Delta Ct)}$ method. IFN-α forward primer, 5′ TTTCTCCTGCCTGAAGGACAG 3′, IFN-α reverse primer, 5′ ACAGTCTCGTCTTTAGTACTCG 3′ [68]. IFN-β forward primer, 5′ GTCAGAGTGGAAATCCTAAG 3′, IFN-β reverse primer, 5′ ACAGCATCTGCTGGTTGAAG 3′ [69]. An 18S ribosomal RNA forward primer 5′ GGGCATTCGTATTTCATAGTCAGAG 3′, 18S ribosomal RNA reverse primer 5′ CGGTTCTTGATTAATGAAAACATCCT 3′ [70].

2.10. Plaque Reduction Neutralization Test (PRNT)

Vero 76 cells were seeded at a density of 6×10^5 cells/well in a 6-well plate and incubated overnight at 37 °C, 5% CO_2. The mAbs were serially diluted 3-fold in DMEM-10 such that an initial concentration of 10 μg/mL was used for the 9-point dose-response curve. The diluted mAbs were incubated with an equal volume of either rCedV-NiV-B-GFP, rCedV-HeV-GFP, NiV-B, or HeV at an MOI of 0.0001 for 1 h at 37 °C, 5% CO_2. MOI was calculated for a tentative 10^6 cells/well and 0.4 mL virus and antibody mixture per well. Each virus-mAb mixture (400 μL/well) was added to duplicate wells. Following a 1 h incubation at 37 °C, 5% CO_2, the wells were overlaid with a 1:1 mix of 0.8% agarose/DMEM-10 and incubated for 4 days. A neutral red solution was added to each well and incubated for 24 h, at which time plaques were counted. Neutralization percent (%) was calculated by subtracting the PFU_{mAb} for each virus from the respective PFU without the antibody, i.e., $Neutralization(\%) = 100 \times \frac{(PFU_0 - PFU_{mAb})}{PFU_0}$, where the PFU_{mAb} is the PFU at the respective mAb concentration, and PFU_0 is the PFU without the antibody. The 50% inhibitory concentration (IC_{50}) was determined as the antibody concentration at which there was a 50% reduction in plaque counts versus untreated control wells. The IC_{50} values were calculated by non-linear regression curve fitting with a variable slope using GraphPad Prism 9 (GraphPad Software Inc., San Diego, CA, USA). The limit of detection for this assay was 50 PFU.

2.11. Fluorescent Reduction Neutralization Test (FRNT)

Vero 76 cells were seeded at a density of 2×10^4 cells/well in black-walled clear bottom 96-well plates (Corning Life Sciences; Corning, NY, USA) and incubated for 24 h at 37 °C, 5% CO_2. m102.4, h5B3.1, 12B2, and 1F5 mAbs were serially diluted 3-fold such that an initial concentration of 1.1 μg/mL was used for the 7-point dose-response curve. Immunized sera were 3-fold serially diluted in DMEM-10 such that NiV-B and NiV-M sG immunized rhesus macaque sera were at a starting dilution of 1:200, and the HeV-sG and HeV-sG_{tet} rabbit sera were at a starting dilution of 1:400. An equal volume of DMEM-10 containing either rCedV-NiV-B-GFP or rCedV-HeV-GFP was added to each dilution for a final MOI of 0.05 and incubated for 2 h at 37 °C, 5% CO_2. Each of the virus-mAb or virus-sera mixtures (90 μL/well) was added to the pre-seeded Vero 76 cells in triplicate and incubated for an additional 24 h at 37 °C, 5% CO_2. The virus-mAb supernatants were removed, and the plates were fixed with 4% Formaldehyde in 1× PBS for 20 min at room temperature. The plates were then washed 3 times by hand with a slow stream of diH_2O, and the last wash was discarded before the plates were imaged using a CTL S6 analyzer (Cellular Technology Limited; Shaker Heights, OH, USA). Fluorescent foci were counted using the CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) was determined as the antibody concentration or serum dilution at which there was a 50% reduction in fluorescent foci versus untreated control wells. The IC_{50} values were calculated by non-linear regression curve fitting with a variable slope using GraphPad Prism 9 (GraphPad Software Inc., San Diego, CA, USA). The limit of detection for this assay was 50 fluorescent foci.

2.12. Statistical Analysis

Data were analyzed and graphed using GraphPad Prism 9 (GraphPad Software Inc.). Unless otherwise stated, graphs and images are the average of three independent experiments and are expressed as the arithmetic mean. Standard deviations were calculated and represented accordingly. Statistical analyses for viral replication kinetics were performed with two-way ANOVA followed by the Tukey post hoc test ($\alpha = 0.05$). Statistical analyses for qPCR experiments were performed with the unpaired, two-tailed Student *t*-test using GraphPad Prism 9. Correlation analyses were performed using Pearson correlation coefficient analyses.

3. Results

3.1. Construction and Rescue of Recombinant Cedar Virus-Based Chimeras

To generate rCedV chimeric viruses encoding the NiV-B or HeV envelope glycoprotein genes, we first optimized the virus rescue efficiency of the previously described rCedV reverse genetics system [20]. A $pOLTV5_{opt}$-rCedV antigenome plasmid was constructed by inserting a DNA fragment containing sequences for a T7 optimal promoter ($T7_{opt}$) and an autocatalytic Hammerhead Ribozyme A (HHRbzA) sequence upstream of the rCedV 3′ leader antigenome sequence (see Materials and Methods) (Figure 1A). Next, a large fragment of the $pOLTV5_{opt}$-rCedV plasmid flanked by unique restriction enzyme sites MluI and SphI was replaced with synthesized DNA fragments containing the open reading frames of either the NiV-B or HeV F and G glycoproteins in place of the CedV F and G glycoprotein encoding region. Reporter genes containing antigenome plasmids encoding either *GFP* or *Luc* genes for each chimera were also generated (see Materials and Methods). The reverse genetics method was then used to rescue a panel of replication-competent rCedV chimeras as non-reporter gene versions (rCedV-NiV-B and rCedV-HeV) and reporter gene encoding versions expressing GFP (rCedV-NiV-B-GFP and rCedV-HeV-GFP) or Luc (rCedV-NiV-B-Luc and rCedV-HeV-Luc) proteins. A schematic representation of the genomes and genome lengths of all rescued viruses is illustrated in Figure 1B. Successful rescue of the viruses was confirmed by the detection of syncytia formation (cytopathic effect (CPE)) when supernatants from BSR-T7/5 cells transfected with the rCedV chimeric antigenome and CedV helper plasmids were then passaged onto Vero E6 cells. Stock virus preparations were subsequently prepared, and virus genomes were sequenced. When compared to the predicted genome sequences, the following mutations were detected within coding sequences in the chimera genomes (e.g., excluding intergenic regions) (Table S1). There were two mutations in the rCedV-HeV genome: one synonymous single nucleotide variation (SNV) and one SNV that resulted in a single amino acid change in the F protein. Three mutations were detected in the rCedV-HeV-GFP genome: one synonymous SNV and two that resulted in single amino acid changes: one in the N protein and the other in the M protein. There were four mutations in the rCedV-HeV-Luc genome, and all four were synonymous mutations. The rCedV-NiV-B genome contained four mutations, all resulting in single amino acid changes: one in the N protein, one in the M protein, and two in the L protein. There were eight mutations in the rCedV-NiV-B-GFP genome: six were synonymous SNVs, and two resulted in single amino acid changes in the N protein. There were nine mutations detected in the rCedV-NiV-B-Luc genome: five were synonymous SNVs, and four resulted in single amino acid changes: one in the N protein, one in the Luc protein, one in the M protein, and one in the L protein. No apparent loss of rCedV chimera reproductive capacity or reporter gene loss or integrity has been observed to date, probably owing to the requirement of these paramyxoviruses to the 'rule-of-six.'

3.2. Characterization of Recombinant Cedar Virus-Based Chimeric Viruses

We assessed the ability of the rCedV-NiV-B chimeras and the rCedV-HeV chimeras to facilitate membrane fusion and syncytia formation when used to infect cells (Figure 2). Vero E6 cells were either uninfected (Mock) or infected with either rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, or rCedV-HeV-Luc and comparisons then made to Vero E6 cells infected with rCedV, rCedV-GFP or rCedV-Luc. At 24 h post-infection, cells infected with the GFP-expressing viruses were imaged for fluorescence and syncytia (Figure 2A), while cells infected with the non-reporter or Luc expressing rCedV chimeras were imaged following fixation and crystal violet staining (Figure 2B). Fluorescence and/or syncytia (yellow arrows) were observed in all infected Vero E6 cells. The syncytia observed in cells infected with either the rCedV-NiV-B chimeras or the rCedV-HeV chimeras were noticeably larger and contained more nuclei than those syncytia observed in rCedV-infected cells (Figure 2). These data confirmed the functionality of the NiV-B and HeV F and G glycoproteins expressed in the context of rCedV.

We next evaluated the relative expression levels of NiV-B and HeV F and G envelope glycoproteins from cells infected with the rCedV chimeras in comparison to rCedV (comparative control). Vero E6 cells were uninfected (Mock) or infected with either rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, rCedV-HeV-Luc, rCedV, rCedV-GFP or rCedV-Luc. For additional comparative purposes, separate populations of Vero E6 cells were co-transfected with plasmids, pcDNA3.1-NiV-F and pcDNA3.1-NiV-G (pcDNA3.1-NiV F + G), or pcDNA3.1-HeV-F and pcDNA3.1-HeV-G (pcDNA3.1-HeV F + G). Representative western blot images for NiV-B and HeV F and G glycoproteins probed with cross-reactive NiV/HeV F or G specific mAbs are shown in Figure 3. We observed the precursor protein F_0 and the processed F_1 subunit in the lysates of cells infected with the rCedV-NiV-B chimeras (Figure 3A) or the rCedV-HeV chimeras (Figure 3B,C). A distinct band representing the G glycoprotein was detected in all rCedV-NiV-B (Figure 3A) and rCedV-HeV (Figure 3B,C) infected lysates. Furthermore, the NiV-B and HeV F and G glycoprotein SDS-PAGE gel migration profiles were similar to those observed in the pcDNA3.1-NiV F + G (Figure 3A) and pcDNA3.1-HeV F + G (Figure 3B,C) transfected cell lysates, respectively. Whereas, HeV/NiV-B F_0, $F_{1,}$ or G bands were not observed in any of the rCedV infected lysates (Figure 3). The lower levels of F_0, $F_{1,}$ and G observed in the rCedV-HeV-Luc infected lysates in comparison to the other rCedV-HeV chimera infected lysates at 24 h post-infection (Figure 3B) could be attributed to slower virus replication kinetics of rCedV-HeV-Luc (see Figure 4B). To address this, we analyzed lysates of all rCedV-HeV chimeras at 48 h post-infection by western blot. As shown in Figure 3C, the levels of HeV F_0, $F_{1,}$ and G glycoproteins in all rCedV-HeV chimeras were comparable at this later time point. The presence of CedV N protein served as an expressed viral protein control and was observed in all infected cell lysates, while β-actin served as a lysate loading control. These data confirm the expression of NiV-B and HeV F and G glycoproteins in infected cells and indicate functional compatibility between rCedV and NiV-B and HeV envelope glycoproteins in a relevant viral context.

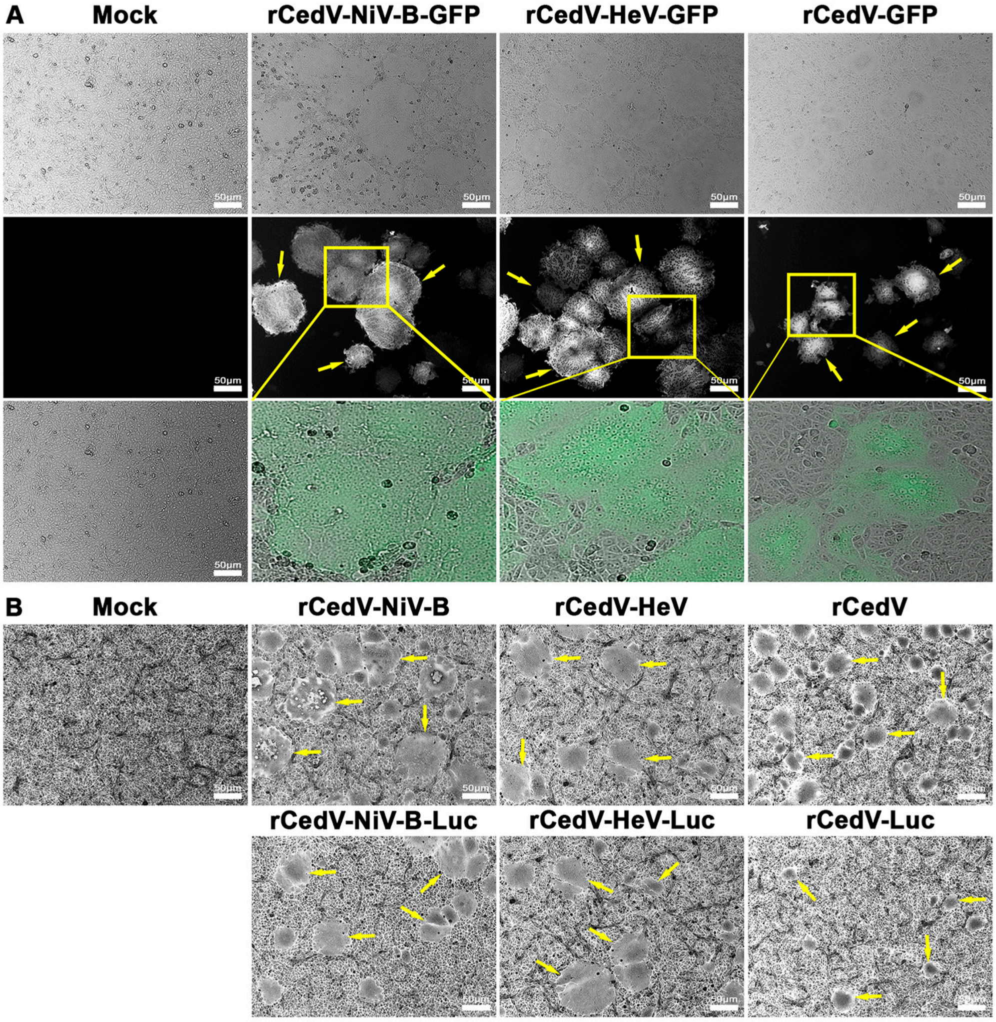

Figure 2. Syncytia induced by rCedV expressing NiV-B or HeV envelope glycoproteins. Vero E6 cells were uninfected (Mock) or infected with either rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc, rCedV-HeV, rCedV-HeV-GFP, rCedV-HeV-Luc, rCedV, rCedV-GFP or rCedV-Luc at a MOI of 0.01. All images were taken 24 h post-infection. (**A**) Cells infected with GFP-expressing viruses. Transmitted light (**top** row), fluorescence (**middle** row), and merged (**bottom** row) images are shown. The respective zoomed-in fluorescence images (3rd row) are regions from the yellow boxes. (**B**) Cells infected with non-reporter or Luc expressing rCedV chimeras were fixed, stained, and then imaged for syncytia. The images taken with transmitted light are shown. Images were captured with a Zeiss Axio Observer A1 inverted microscope using a 5× objective. Arrows indicate giant multinucleated cells (syncytia). Representative images from three independent experiments are shown. Scale bar, 50 µm.

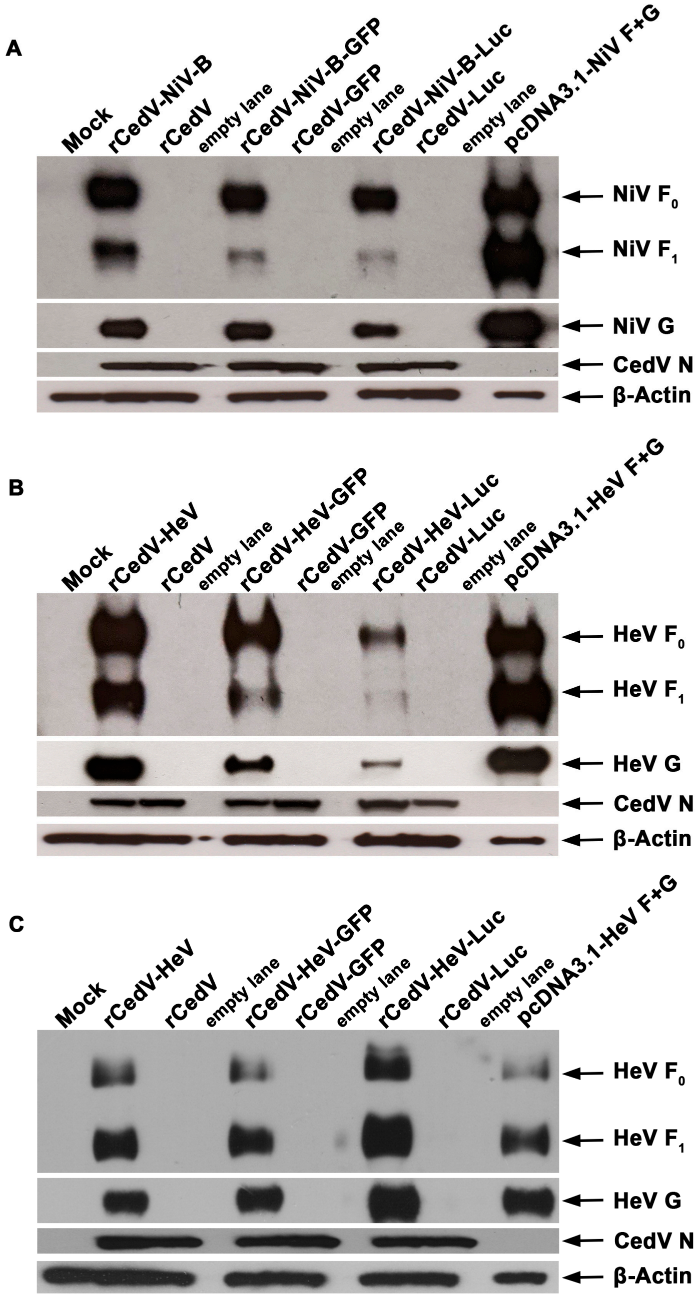

Figure 3. Expression of NiV-B and HeV envelope glycoproteins in infected cells. Vero E6 cells were uninfected (Mock) or infected at a MOI of 0.01 with either rCedV-NiV-B, rCedV-NiV-B-GFP, rCedV-NiV-B-Luc (**A**), rCedV-HeV, rCedV-HeV-GFP, rCedV-HeV-Luc (**B**,**C**), rCedV, rCedV-GFP or rCedV-Luc. As a reference, cells were co-transfected with a total of 2 µg of pcDNA3.1-NiV-F and pcDNA3.1-NiV-G (pcDNA3.1-NiV F + G), or pcDNA3.1-HeV-F and pcDNA3.1-HeV-G (pcDNA3.1-HeV F + G). Cells were harvested at 24 h post-infection (**A**,**B**) (rCedV-NiV-B and rCedV-HeV chimeras) or 48 h post-infection (**C**) (rCedV-HeV chimeras only), lysates were prepared and total protein (~30 µg) resolved by SDS-PAGE followed by western blot assay. The subsequent membrane was probed with HeV and NiV cross-reactive monoclonal antibodies (mAbs) against F glycoprotein (mAb 5G7) and G glycoprotein (mAb 48D3), polyclonal rabbit serum to CedV-N and β-actin. Representative images from two independent experiments are shown.

The replication kinetics of rCedV-NiV-B, rCedV-NiV-B-GFP, and rCedV-NiV-B-Luc (Figure 4A) and rCedV-HeV, rCedV-HeV-GFP, and rCedV-HeV-Luc (Figure 4B) were also compared to rCedV. Plaque assays were performed on harvested viral supernatants, and infectious virus titers were determined. We observed a gradual increase in infectious virus titers of all rCedV chimeric viruses that peaked 48 h post-infection (Figure 4). Specifically, the rCedV-NiV-B chimeras reached maximum virus titers of ~4–7 × 10^5 PFU/mL, while the rCedV-HeV chimeras peaked at ~2–9 × 10^5 PFU/mL. No statistically significant differences in replicated virus titers were observed between any of the rCedV-NiV-B chimeras or the rCedV-HeV chimeras or when compared to rCedV. In parallel, luciferase activity in rCedV-NiV-B-Luc and rCedV-HeV-Luc infected cells was measured. Figure 4 (right *y*-axes, black dashed lines) shows an increase in luminescence signal for both rCedV-NiV-B-Luc (Figure 4A) and rCedV-HeV-Luc (Figure 4B), which corresponded to the increase in infectious virus titers of their respective chimeras. Maximum luminescence signal was measured at 3.5 × 10^7 RLU at 48 h post-infection for rCedV-HeV-Luc and at ~8 × 10^6 RLU at 24 h post-infection for rCedV-NiV-B-Luc. The latter is likely due to extensive syncytia, and CPE observed in rCedV-NiV-B infected cells. These data illustrate that the rCedV chimeric viruses replicated efficiently and were comparable to rCedV and that luciferase activity is an indicator of viral genome expression.

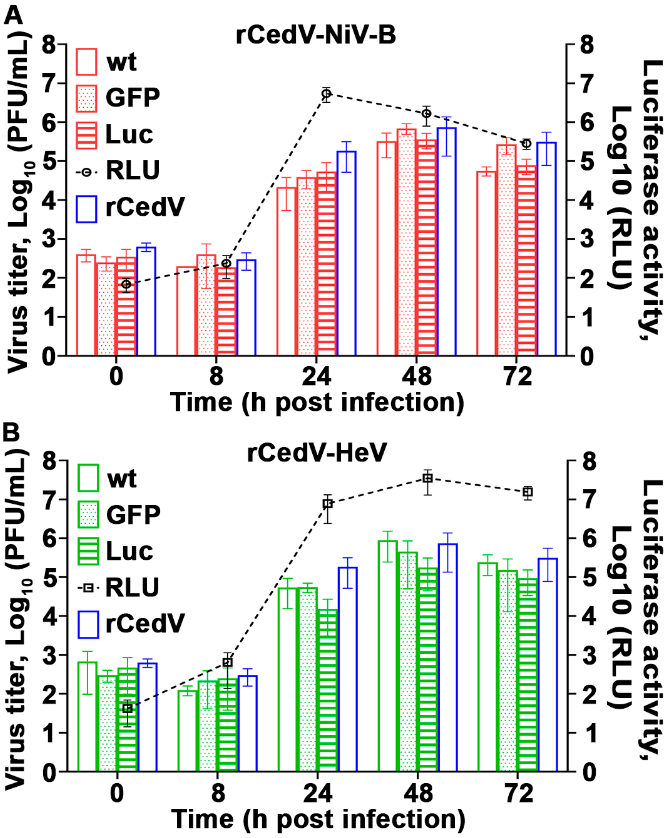

Figure 4. Replication kinetics of rCedV chimeras. Infectious virus titers (PFU/mL) determined from supernatants harvested at the indicated time points from Vero E6 cells infected at a MOI of 0.01 with rCedV-NiV-B (clear red bar), rCedV-NiV-B-GFP (dotted red bar), rCedV-NiV-B-Luc (striped red bar) (**A**), rCedV-HeV (clear green bar), rCedV-HeV-GFP (dotted green bar) or rCedV-HeV-Luc (striped green bar) (**B**). As a reference, separate populations of Vero E6 cells were also infected with rCedV (blue bar) (**A**,**B**). Normalized relative light units (RLU) for CedV-NiV-B-Luc (**A**) and rCedV-HeV-Luc (**B**) infected cells are represented on the right *y*-axes as black dashed lines. These data represent mean ± standard deviation from three independent experiments. Virus titers and luciferase activity levels at 0 h post-infection indicate the lower limit of detection for the plaque assay and the luminometer, respectively. Statistical analysis was performed in GraphPad Prism 9 by two-way ANOVA followed by Tukey's post hoc test ($\alpha = 0.05$).

3.3. Ephrin Entry Receptor Tropism of Recombinant Cedar Virus Chimeras

To define the receptor tropism of the newly generated rCedV chimeras, we used the NiV and HeV non-permissive cell line, HeLa-USU [31] and HeLa-USU cells stably expressing either ephrin-B2 (HeLa-USU-ephrin-B2) or ephrin-B3 (HeLa-USU-ephrin-B3) [20]. Here, all cells were either uninfected (Mock) or infected with rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP and at 24 h post-infection imaged for GFP expression. We observed fluorescence and/or syncytia in rCedV-NiV-B-GFP, and rCedV-HeV-GFP infected HeLa-USU-ephrin-B2 (Figure 5A) and HeLa-USU-ephrin-B3 (Figure 5B) cells, but not in the HeLa-USU infected cells (Figure 5C). In addition, GFP expression was detected in all rCedV-GFP infected cells, although syncytia were only observed in HeLa-USU-ephrin-B2 infected cells and were consistent with prior observations [20].

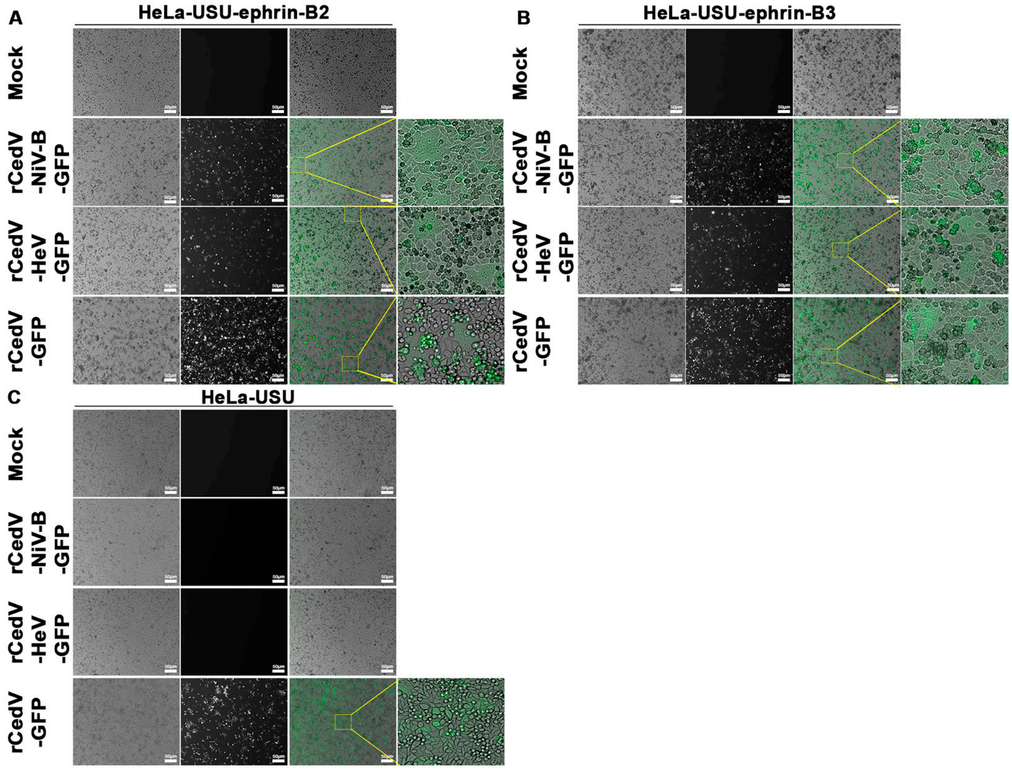

Figure 5. Ephrin-B2 and ephrin-B3 receptors facilitate rCedV-NiV-B-GFP and rCedV-HeV-GFP infection. Confluent HeLa-USU-ephrin-B2 (**A**), HeLa-USU-ephrin-B3 (**B**), and HeLa-USU (**C**) cells were uninfected (Mock) or infected with rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP at a MOI of 0.5. Infected cells were imaged for fluorescence and syncytia at 24 h post-infection. In each panel, transmitted light (1st column), fluorescence (2nd column), and merged (3rd column) images are shown. Zoomed-in regions are from the yellow boxes. Images were captured with a Zeiss Axio Observer A1 inverted microscope using a 5× objective. Representative images from two independent experiments are shown. Scale bar, 50 µm.

3.4. Recombinant Cedar Virus Chimeras Induce an Interferon Response

We next evaluated the induction of a type I IFN response in cells infected with the rCedV chimeras. HeLa-CCL-2 cells were uninfected (Mock) or infected with rCedV-NiV-B, rCedV-HeV, or rCedV. Additional HeLa-CCL-2 cells were transfected with Poly I:C to verify the induction of IFN-β (positive control). At 24 h post-infection, total RNA was extracted from all samples, and IFN-α and IFN-β mRNA levels were quantified by qPCR. As shown in Figure 6, in contrast to the mock samples, we observed a significant dose-dependent increase in IFN-β mRNA expression levels following rCedV-NiV-B, rCedV-HeV, and rCedV infection. A significant increase in the expression levels of IFN-α mRNA was not observed in any of the infected samples. These data demonstrate that rCedV chimeric viruses induced a robust and dose-dependent IFN-β response similar to rCedV [20] and also CedV [2].

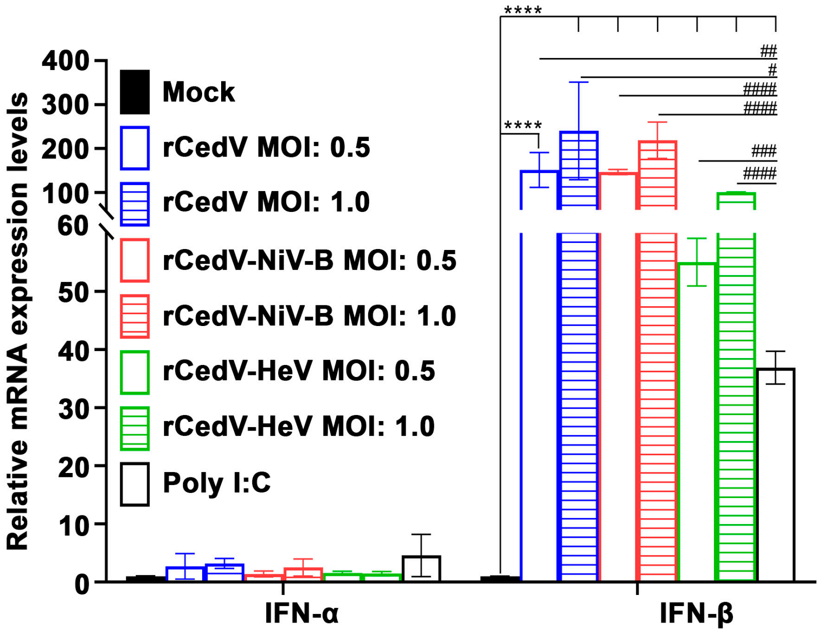

Figure 6. rCedV chimeras induce an IFN-β response. HeLa-CCL-2 cells were uninfected (Mock) or infected with rCedV-NiV-B, rCedV-HeV, or rCedV at a MOI of either 0.5 or 1.0 or transfected with Poly I:C (10 µg/mL) for 24 h. IFN-α and IFN-β mRNA expression were determined by qPCR. Fold changes were calculated relative to 18S ribosomal RNA and normalized to mock samples using the $2^{(-\Delta\Delta Ct)}$ method. These data represent mean ± standard deviation from two independent experiments, each performed in triplicate. Statistical analysis was performed with all samples in GraphPad Prism 9 by performing *t*-tests of each virus against Mock (asterisk *) or each virus against Poly I:C (hash #). **** $p < 0.0001$, # $p = 0.011$, ## $p = 0.012$, ### $p = 0.0001$ and #### $p < 0.0001$.

3.5. Plaque Reduction Neutralization Test (PRNT) of Chimeric Recombinant Cedar Viruses by Cross-Reactive NiV and HeV Specific Monoclonal Antibodies

To determine whether the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras could serve as suitable surrogate viruses for authentic NiV-B and HeV, respectively, the ability of the GFP expressing rCedV chimeras to be neutralized by a panel of well-characterized NiV/HeV cross-reactive neutralizing mAbs was conducted by PRNT. The antibody panel included the human mAb m102.4 specific to the G glycoprotein and the humanized mAb h5B3.1 and murine mAbs 12B2 and 1F5 specific to the F glycoprotein [44–46,71]. Figure 7 illustrates the dose-response neutralization profiles for each mAb against rCedV-NiV-B-GFP and rCedV-HeV-GFP performed at BSL-2 (Figure 7A). In addition, a set of parallel PRNTs using authentic NiV-B and HeV and both rCedV chimeras were also performed simultaneously in BSL-4 containment (Figure 7B,C). Each mAb tested neutralized the infectivity of rCedV-NiV-B-GFP and rCedV-HeV-GFP and NiV-B and HeV (Figure 7) with highly similar dose-response virus neutralization profiles. The mean 50% inhibitory concentrations (IC_{50}) for each of the mAbs against rCedV-NiV-B-GFP, rCedV-HeV-GFP, NiV-B, and HeV are summarized in Table 2. The most potent mAb was m102.4 with average IC_{50} values of ~20 ng/mL against rCedV-NiV-B-GFP and NiV-B, ~101 ng/mL against rCedV-HeV-GFP and ~50 ng/mL against HeV. The IC_{50} values for the mAbs tested here are within comparable ranges when compared to previous in vitro PRNT studies conducted with authentic NiV and HeV with the same set of cross-reactive neutralizing mAbs [43,44,46,66].

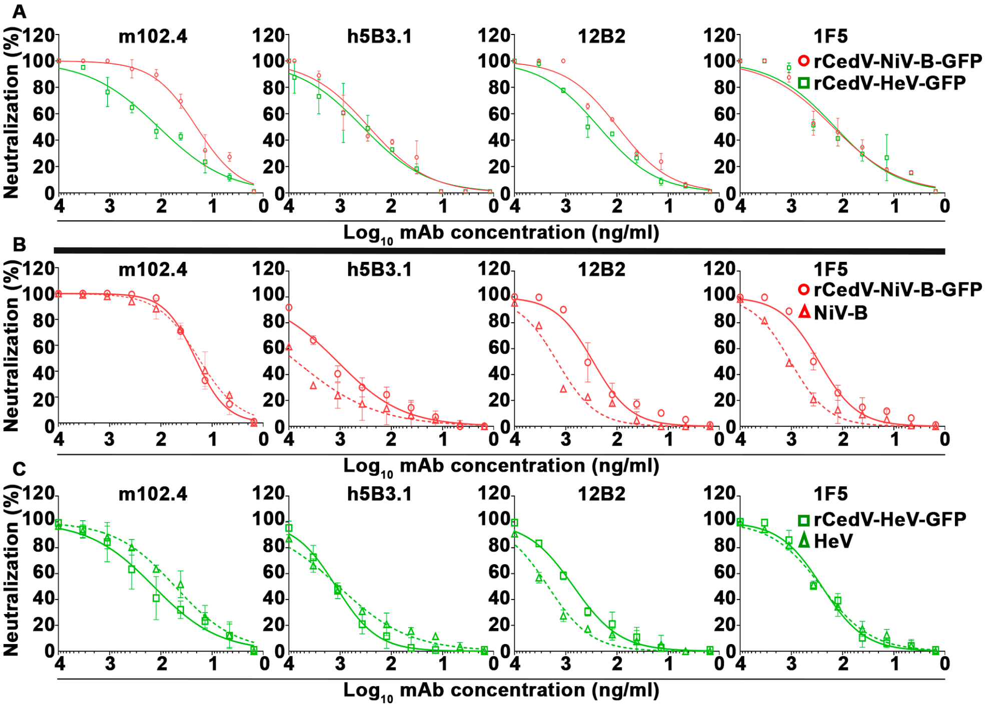

Figure 7. Neutralization of rCedV-NiV-B-GFP and rCedV-HeV-GFP by plaque reduction neutralization test (PRNT). Nine-point dose-response neutralization profiles for mAbs m102.4, h5B3.1, 12B2, and 1F5 against rCedV-NiV-B-GFP and rCedV-HeV-GFP at BSL-2 (**A**), at BSL-4 (**B**,**C**) and authentic NiV-B and HeV at BSL-4 (**B**,**C**). The diluted mAbs were incubated with an equal volume of either rCedV-NiV-B-GFP, rCedV-HeV-GFP, NiV-B, or HeV at an MOI of 0.0001 for 1 h at 37 °C, 5% CO_2. MOI was calculated for a tentative 10^6 cells/well and 0.4 mL virus and antibody mixture per well. Neutralization percent (%) was calculated based on PFU for each virus without mAb. These data represent mean ± standard deviation and are plotted as a non-linear regression curve fit with variable slope. BSL-2 studies are representative of two independent experiments, each performed in duplicate, and BSL-4 studies are from a single experiment performed in duplicate. The limit of detection for this assay was 50 PFU. Red circles and lines represent rCedV-NiV-B-GFP, red triangles and dashed lines represent NiV-B, green squares and lines represent rCedV-HeV-GFP, and green triangles and dashed lines represent HeV. The thick black line divides the BSL-2 PRNT from the BSL-4 PRNT.

Table 2. IC_{50} values of NiV and HeV cross-reactive monoclonal antibodies against henipavirus infection by PRNT.

Monoclonal Antibody (mAb)	IC_{50} (95% CI) (ng/mL)					
	BSL-2	BSL-4		BSL-2	BSL-4	
	rCedV-NiV-B-GFP	rCedV-NiV-B-GFP	NiV-B	rCedV-HeV-GFP	rCedV-HeV-GFP	HeV
m102.4	20.30 (16.58–24.99)	21.20 (18.80–23.89)	18.36 (15.21–22.17)	112.9 (82.82–154.1)	137.0 (89.09–208.8)	52.41 (39.32–70.07)
h5B3.1	274.8 (185.9–403.7)	1122 (813.6–1548)	7101 (4323–15,087)	363.5 (241.6–546.3)	1202 (975.2–1481)	1064 (827.4–1372)
12B2	130.0 (97.10–174.0)	291.9 (219.9–381.5)	1467 (1098–1925)	502.3 (377.4–658.3)	700.1 (570.0–857.0)	2202 (1692–2846)
1F5	153.8 (107.0–219.4)	289.4 (229.9–360.9)	1036 (812.3–1298)	140.6 (83.29–232.0)	253.2 (200.5–318.8)	259.8 (213.2–315.8)

Note: All IC_{50} values are calculated by a nonlinear fit model and are shown with 95% confidence intervals (95% CI). BSL-2 studies are representative of two independent experiments, each performed in duplicate, and BSL-4 studies are from a single experiment performed in duplicate.

3.6. Correlation Analysis of Plaque Reduction Neutralization Tests (PRNT) Using GFP Expressing Recombinant Cedar Virus Chimeras and Authentic NiV-B and HeV

To further evaluate if the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras are suitable surrogate virus platforms for authentic NiV-B and HeV antibody neutralization, a correlation analysis was performed. A Pearson correlation coefficient 'r' for each mAb was calculated by comparing the neutralization values derived from the rCedV chimeras BSL-2 PRNT with those of the NiV-B or HeV BSL-4 PRNT. The analysis indicated strong and statistically significant positive correlations between the two PRNTs (r values ranging from 0.86 to 0.99, *p* values from 0.005 to 0.0001) (Figure 8 and Table 3).

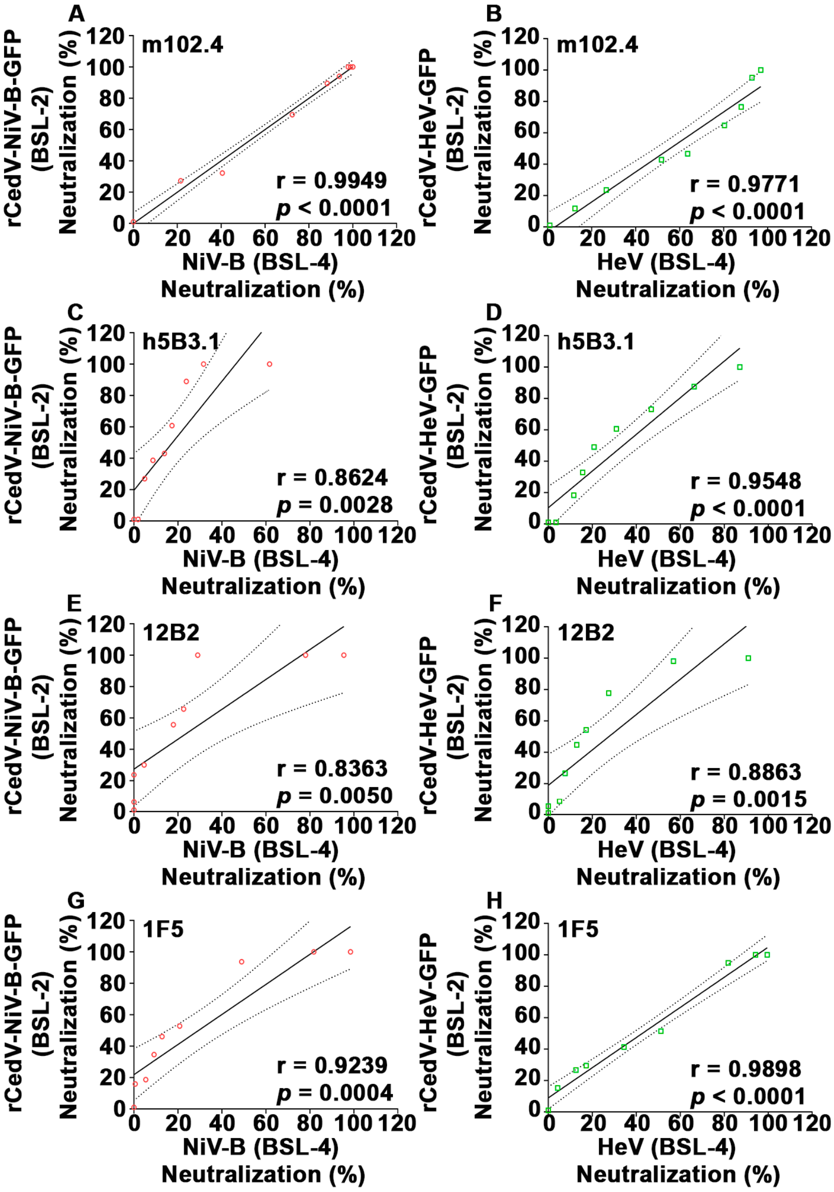

Figure 8. Correlation analysis of plaque reduction neutralization test (PRNT) neutralization values. Pearson correlation analysis of PRNT neutralization (%) values of rCedV-NiV-B-GFP versus NiV-B (**A**,**C**,**E**,**G**) and rCedV-HeV-GFP versus HeV (**B**,**D**,**F**,**H**) with mAbs m102.4, h5B3.1, 12B2 or 1F5. The Pearson correlation coefficient 'r,' *p*-value (two-tailed), linear regression line (solid lines), and 95% confidence intervals (dashed lines) are represented. Pearson's r $\geq$ 0.8 and *p*-value < 0.05 indicate a strong significant positive correlation.

Table 3. Correlation analysis of rCedV chimeric viruses in BSL-2 PRNT versus NiV-B and HeV BSL-4 PRNT assays.

Virus	Monoclonal Antibody (mAb)	Pearson's Correlation Coefficient (r)	Coefficient of Determination (R^2)	Significance (*p*)	95% Confidence Interval (CI)
rCedV-NiV-B-GFP vs. NiV-B	m102.4	0.9949	0.9898	<0.0001	0.9750–0.990
	h5B3.1	0.8624	0.7437	0.0028	0.4640–0.9706
	12B2	0.8363	0.6994	0.0050	0.3873–0.9647
	1F5	0.9239	0.8536	0.0004	0.6722–0.9842
rCedV-HeV-GFP vs. HeV	m102.4	0.9771	0.9547	<0.0001	0.8914–0.9953
	h5B3.1	0.9548	0.9117	<0.0001	0.7945–0.9907
	12B2	0.8863	0.7855	0.0015	0.5400–0.9760
	1F5	0.9898	0.9796	<0.0001	0.9503–0.9979

Note: Correlation analysis was performed with the neutralization values from Figure 7.

3.7. Establishment of a Fluorescence Reduction Neutralization Test (FRNT)

To further develop the utility of rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras as a surrogate platform for authentic NiV-B and HeV neutralization testing, we developed a high-throughput and quantitative assay based on the reduction in GFP fluorescent virus infection foci. Here, the virus neutralization efficacies of the same panel of mAbs used in the PRNT assays (Figure 7) were analyzed against rCedV-NiV-B-GFP and rCedV-HeV-GFP in a FRNT assay. As shown in Figure 9, the dose-response neutralization data were similar to those obtained by a PRNT (Figures 7A and 9). The IC_{50} values for each mAb against rCedV-NiV-B-GFP and rCedV-HeV-GFP are summarized in Table 4. The mAb m102.4 potently neutralized rCedV-NiV-B-GFP at an IC_{50} of 16.91 ng/mL, while rCedV-HeV-GFP was neutralized by m102.4 and 1F5 with similar potencies at IC_{50} values of 58.12 ng/mL and 50.16 ng/mL, respectively. These data reveal that rCedV-NiV-B-GFP and rCedV-HeV-GFP mAb neutralization values in a FRNT are comparable to those obtained in a PRNT (comparisons of Tables 2 and 4).

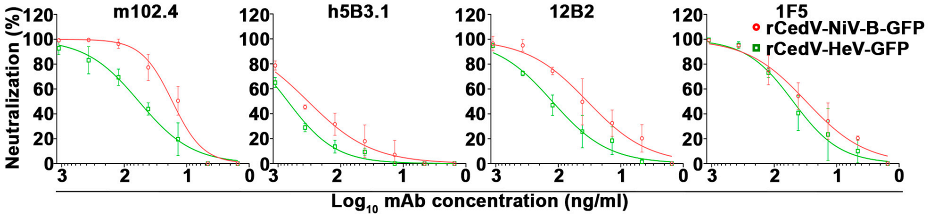

Figure 9. Neutralization profiles of NiV and HeV cross-reactive monoclonal antibodies by fluorescence reduction neutralization test (FRNT). Seven-point dose-response neutralization profiles for mAbs m102.4, h5B3.1, 12B2, and 1F5 against rCedV-NiV-B-GFP and rCedV-HeV-GFP. Neutralization percent (%) was calculated based on fluorescent foci for each virus without mAb. These data represent mean ± standard deviation from three independent experiments, each performed in triplicate. Data are plotted as non-linear regression curve fit with variable slope. The limit of detection for this assay was 50 fluorescent foci. Red circles and lines represent rCedV-NiV-B-GFP, and green squares and lines represent rCedV-HeV-GFP.

Table 4. IC_{50} values of NiV and HeV cross-reactive specific monoclonal antibodies against rCedV-NiV-B-GFP and rCedV-HeV-GFP infection by FRNT.

Monoclonal Antibody (mAb)	IC_{50} (95% CI) (ng/mL)	
	rCedV-NiV-B-GFP	rCedV-HeV-GFP
m102.4	16.91 (14.72–19.45)	58.12 (49.27–68.70)
h5B3.1	333.0 (255.5–439.9)	700.2 (620.0–798.8)
12B2	34.07 (24.88–46.48)	124.5 (98.17–157.2)
1F5	28.97 (22.86–36.65)	50.16 (40.95–61.07)

Note: All IC_{50} values are calculated by a nonlinear fit model from three independent experiments, each performed in triplicate, and are shown with 95% confidence intervals (95% CI).

3.8. Correlation Analysis of the Conventional PRNT and the FRNT Neutralization Assays

To further evaluate the FRNT assay as a suitable alternative virus neutralization assay to the standard PRNT, a correlation analysis was performed. A Pearson correlation analysis using the neutralization values obtained with each mAb against the rCedV-GFP chimeras by PRNT and FRNT assays was conducted (Figure 10 and Table 5), and a strong and significant positive correlation between the neutralization values obtained by PRNT versus the corresponding FRNT assay derived values was observed (r ≥ 0.9 and $p \leq 0.001$). Taken together, these data demonstrate that rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeric viruses are an ideal set of suitable surrogate viruses for authentic NiV-B and HeV for conducting a rapid FRNT-based assay for assessing NiV and HeV antibody neutralization.

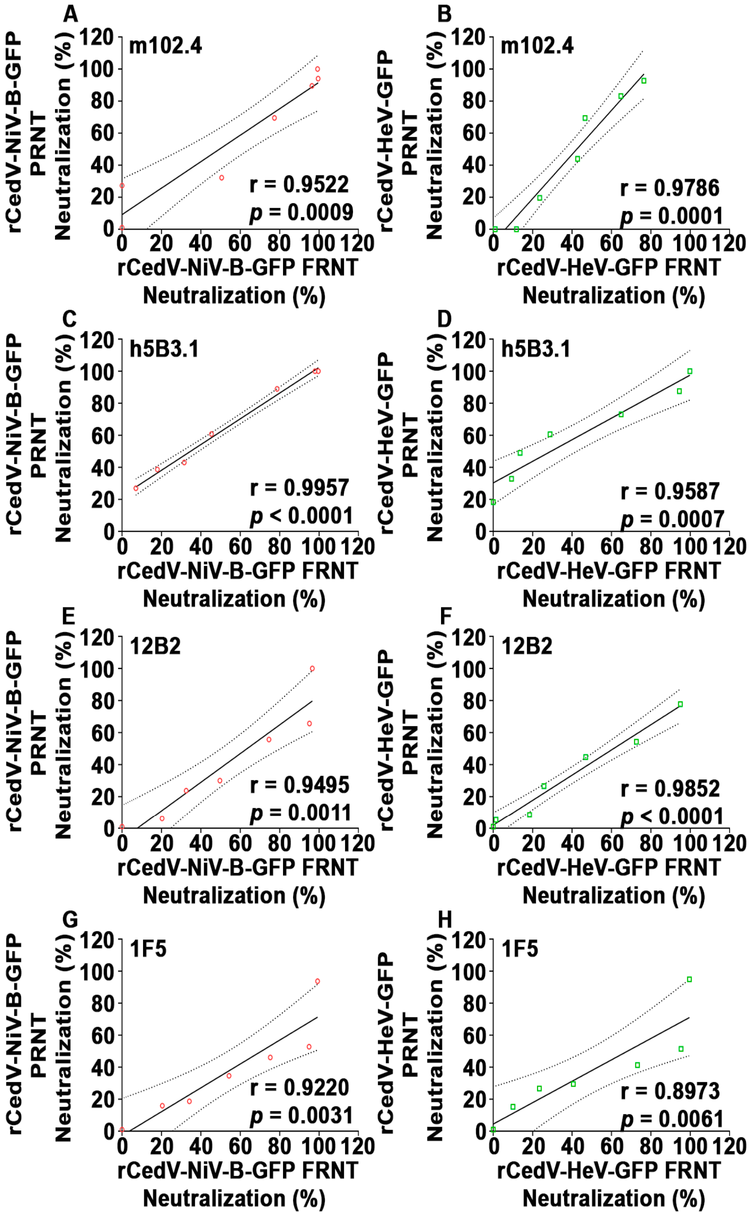

Figure 10. Correlation analysis of neutralization assays using the GFP expressing rCedV chimeric viruses. Pearson correlation analysis of neutralization (%) values from plaque reduction neutralization tests (PRNTs) (y-axes) and fluorescence reduction neutralization tests (FRNTs) (x-axes) performed with rCedV-NiV-B-GFP (**A**,**C**,**E**,**G**) and with rCedV-HeV-GFP (**B**,**D**,**F**,**H**) with mAbs m102.4, h5B3.1, 12B2 or 1F5. The Pearson correlation coefficient 'r,' p-value (two-tailed), linear regression line (solid lines), and 95% confidence intervals (dashed lines) are represented. Pearson's r ≥ 0.8 and p-value < 0.05 indicate a strong significant positive correlation.

Table 5. Correlation analysis of rCedV chimeric viruses in the PRNT versus FRNT assays.

Virus	Monoclonal Antibody (mAb)	Pearson's Correlation Coefficient (r)	Coefficient of Determination (R^2)	Significance (*p*)	95% Confidence Interval
rCedV-NiV-B-GFP	m102.4	0.9522	0.9067	0.0009	0.7038–0.9931
	h5B3.1	0.9957	0.9914	<0.0001	0.9698–0.9994
	12B2	0.9495	0.9016	0.0011	0.6894–0.9927
	1F5	0.9220	0.8501	0.0031	0.5527–0.9886
rCedV-HeV-GFP	m102.4	0.9786	0.9576	0.0001	0.8573–0.9970
	h5B3.1	0.9587	0.9191	0.0007	0.7397–0.9941
	12B2	0.9852	0.9707	<0.0001	0.8997–0.9979
	1F5	0.8973	0.8051	0.0061	0.4448–0.9849

Note: Correlation analysis was performed with the neutralization values from Figures 7A and 9.

3.9. Neutralization of rCedV-NiV-B-GFP and rCedV-HeV-GFP Using Henipavirus sG Immune Antisera

The utility of the rCedV-NiV-B-GFP and rCedV-HeV-GFP viruses in the FRNT assay for measuring immune serum neutralization was examined by testing sera from NiV-sG or HeV-sG immunized nonhuman primates (NHP) (rhesus macaques) and rabbits, respectively. NHP subjects were immunized with an equal mixture of recombinant NiV-M and NiV-B sG glycoproteins (see Section 2) [47]. Figure 11 shows the dose-response neutralization profiles for each NHP sera against the rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeras. The IC_{50} titers for each of the sera against rCedV-NiV-B-GFP and rCedV-HeV-GFP are summarized in Table 6. Sera collected on day 42 from subject 171269 had the highest neutralizing titer against rCedV-NiV-B-GFP (1:32,147) and rCedV-HeV-GFP (1:4157). In addition, we were also able to test sera collected on day 84 from 2 subjects, 171269 and 180227, and the IC_{50} titers are summarized in Table 6. Although still potently neutralizing, the 50% serum neutralization titers for animal 171269 declined 2-fold against rCedV-NiV-B-GFP to 1:16,101 and 4.8-fold against rCedV-HeV-GFP to 1:873.6. As expected, although the NHP sera were cross-neutralizing against rCedV-HeV-GFP the IC_{50} titers were much greater against the homologous immunized subjects (NiV).

Table 6. IC_{50} Anti-NiV G glycoprotein immunized rhesus macaque serum titers against rCedV-NiV-B-GFP and rCedV-HeV-GFP infection.

Animal ID	IC_{50} (95% CI) (Serum Titer)	
	rCedV-NiV-B-GFP	**rCedV-HeV-GFP**
171269 Day 42	1:32,147 (1:29,414–1:35,182)	1:4157 (1:3711–1:4658)
171269 Day 84	1:16,101 (1:12,288–1:21,024)	1:873.6 (1:809.4–1:941.3)
180274 Day 42	1:14,860 (1:14,018–1:15,761)	1:2704 (1:2375–1:3082)
180606 Day 42	1:19,480 (1:18,181–1:20,948)	1:3739 (1:3094–1:4542)
180227 Day 42	1:19,408 (1:17,817–1:21,158)	1:2048 (1:1668–1:2539)
180227 Day 84	1:7283 (1:6079–1:8739)	1:689.0 (1:499.2–1:904.4)

Note: All IC_{50} values are calculated by a nonlinear fit model from two independent experiments, each performed in triplicate, and are shown with 95% confidence intervals (95% CI).

We also analyzed sera from rabbits immunized with either HeV-sG or HeV-sG tetramer (HeV-sG_{tet}) (see Materials and Methods). The sG immune rabbit sera neutralized the infectivity of both rCedV-NiV-B-GFP and rCedV-HeV-GFP, as shown by the dose-response neutralization profiles in Figure 12. The IC_{50} titers for each of the rabbit sera against rCedV-NiV-B-GFP and rCedV-HeV-GFP are summarized in Table 7. The HeV-sG and HeV-sG_{tet} sera had similar and very high neutralizing titers of 1:65,820 and 1:59,457, respectively, against rCedV-HeV-GFP. Here, the HeV-sG-specific rabbit sera had higher cross-neutralizing heterologous titers against rCedV-NiV-B-GFP (HeV-sG: 1:6881 and HeV-sG_{tet}: 1:7367, respectively) with IC_{50} values again greater against the homologous immunized subjects (HeV), consistent with prior authentic NiV and HeV neutralization data derived from NiV-sG versus HeV-sG immunized cats [49].

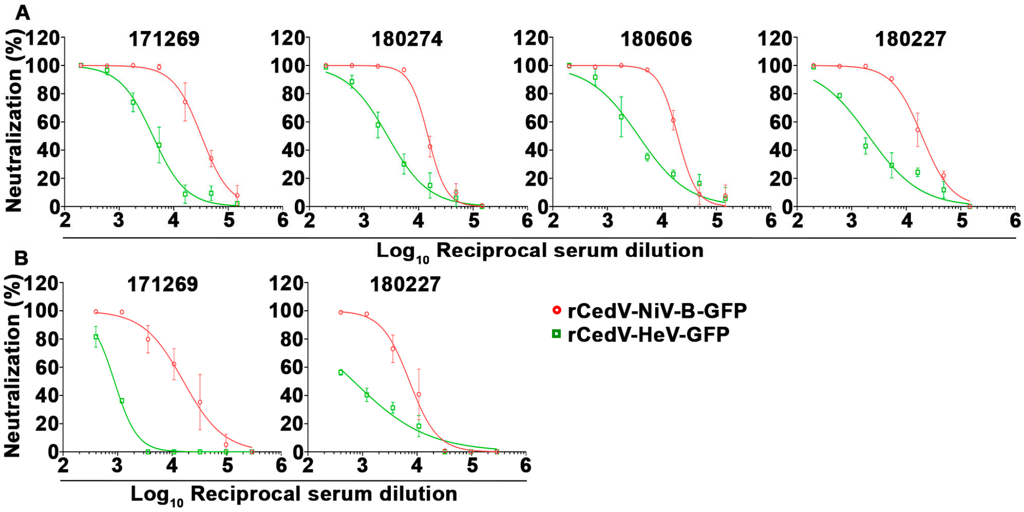

Figure 11. Neutralization profiles of NHP immunized sera against the GFP expressing rCedV chimeras by fluorescence reduction neutralization test (FRNT). Seven-point dose-response neutralization profiles of rhesus macaque sera collected on day 42 (**A**) and day 84 (**B**) post-immunization against rCedV-NiV-B-GFP and rCedV-HeV-GFP are shown. Neutralization percent (%) was calculated based on fluorescent foci for each virus without serum. These data represent mean ± standard deviation from two independent experiments, each performed in triplicate. Data are plotted as non-linear regression curve fit with variable slope. The limit of detection for this assay was 50 fluorescent foci. Animal ID numbers are 171269, 180274, 180606, and 180227. Red circles and lines represent rCedV-NiV-B-GFP, and green squares and lines represent rCedV-HeV-GFP.

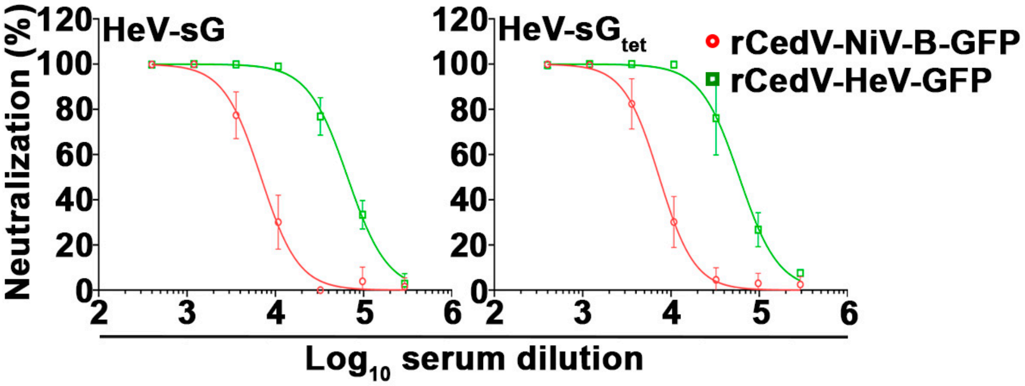

Figure 12. Neutralization profiles of rabbit immunized sera against rCedV chimeras expressing GFP. Seven-point dose-response neutralization profiles of HeV-sG (**left**) and HeV-sG$_{tet}$ (**right**) immunized sera against rCedV-NiV-B-GFP and rCedV-HeV-GFP are shown. Neutralization percent (%) was calculated based on fluorescent foci for each virus without serum. These data represent mean ± standard deviation from two independent experiments, each performed in triplicate. Data are plotted as non-linear regression curve fit with variable slope. The limit of detection for this assay was 50 fluorescent foci. Red circles and lines represent rCedV-NiV-B-GFP, and green squares and lines represent rCedV-HeV-GFP.

Table 7. IC_{50} rabbit serum titers against rCedV-NiV-B-GFP and rCedV-HeV-GFP infection.

Immunogen	**IC_{50} (95% CI) (Serum Titer)**	
	rCedV-NiV-B-GFP	**rCedV-HeV-GFP**
HeV-sG	1:6881 (1:6211–1:7616)	1:65,820 (1:61,407–1:70,409)
HeV-sG_{tet}	1:7367 (1:6642–1:8158)	1:59,457 (1:54,002–1:65,333)

Note: All IC_{50} values are calculated by a nonlinear fit model from two independent experiments, each performed in triplicate, and are shown with 95% confidence intervals (95% CI).

4. Discussion

There has been increased concern regarding respiratory pathogens such as NiV as a consequence of the COVID-19 pandemic [72]. The most recent significant outbreak of NiV-B, which occurred in Kerala, India, in 2018, had a case-fatality rate of 91% and revealed a high incidence of acute respiratory distress syndrome among those infected, correlating with nosocomial respiratory droplet-mediated human-to-human transmission by exposure to patient's coughing [73]. Experimentally, both NiV-M and NiV-B have been shown to cause lethal infection in NHPs when delivered as an aerosol [74,75], also the likely route of infection from deliberate release. Indeed, in 2020 the US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) recommended that NiV be added to the list of Tier 1 Select Agents [76]. NiV-B has several characteristics enhancing its pandemic potential, including its respiratory tissue tropism; human susceptibility to infection; person-to-person transmission capability; and its potential to mutate, and the emergence of a human-adapted strain in South Asia could lead to the rapid spread of infection [77]. NiV and HeV have been important targets for vaccine development for more than 20 years, and these efforts have recently intensified [22,25].

In the present study, the rCedV reverse genetics platform [20,21] was modified by employing an optimized T7 promoter ($T7_{opt}$) and the self-cleaving HHRbzA in the pOLTV5-rCedV antigenome plasmid, which improved the rescue efficiency of rCedVs. A similar strategy was used to rescue a number of other single-stranded, negative-sense RNA viruses, including NiV [36,78–82]. We then expanded the utility of the rCedV platform by replacing the coding sequences of the CedV F and G glycoproteins with their NiV-B or HeV counterparts to generate a panel of non-reporter gene and reporter gene encoding versions of rCedV-NiV-B and rCedV-HeV chimeric viruses. Interestingly, all chimeras appeared more fusogenic than those observed in rCedV-infected cells, and a similar phenotype was observed by Yeo et al., where cell fusion levels of CedV were consistently lower than NiV in transfected HEK293T cells [83]. All rCedV chimeras expressed the heterologous envelope glycoproteins in infected cells, replicated similarly in comparison to rCedV, and infection tropism was specific for ephrin-B2 and ephrin-B3 as entry receptors.

Previous in vitro cell-based assays demonstrated that CedV and rCedV induced a robust IFN-β response [2,20], and CedV infection stimulated the expression of interferon response genes, such as *IFNA7*, *CCL5*, *STAT1*, and *STAT2* in primary hamster endothelial cells [11]. Here, the rCedV chimeric viruses also induced the expression of IFN-β mRNA in an infection dose-dependent manner to comparable levels observed with rCedV infection and Poly I:C treatment.

Several surrogate NiV neutralization assays using recombinant Vesicular Stomatitis Virus (VSV) as a replication-incompetent pseudovirus with a deletion of the VSV G glycoprotein gene have been developed as a tool to measure NiV neutralization at BSL-2 containment [84–86]. The VSV-based pseudotype virus particle system has also been utilized with the HeV and GhV envelope glycoproteins for measuring neutralization [87]. Preparation of VSV pseudoviruses involves the budding progeny virions from cells that are transiently expressing henipavirus F and G glycoproteins which can sometimes be technically challenging to produce large quantities of pseudovirus stocks with reproducible characteristics. We previously found similar challenges in developing a retrovirus-based pseudotyped virus assay system that also required significant optimization [88]. These replication-incompetent pseudovirus assays are sensitive and have a high correlation when samples are scored as either positive or negative for henipavirus neutralizing antibody. However, specific mAb neutralization potencies or the virus-neutralizing titers of sera against NiV using VSV pseudotypes, as examples, are often quite different in comparison to sera titers obtained using authentic NiV [84–86].

Here, we sought to develop an improved surrogate neutralization assay system for NiV and HeV using rCedV as replication-competent chimeric viruses. The rCedV chimeric viruses developed and characterized here can be readily produced and stored in large quantities and are an authentic replication-competent henipavirus platform that can be used to study NiV and HeV F and G glycoprotein-mediated infection and also as surrogate viruses for authentic NiV and HeV in neutralization assays without the requirement for BSL-4 containment. Indeed, similar dose-response neutralization data and comparable IC_{50} concentrations of well-characterized NiV and HeV cross-reactive mAbs were observed between PRNTs using rCedV-NiV-B-GFP and NiV-B or rCedV-HeV-GFP and HeV. A strong and significant correlation between the overall neutralization values of the BSL-2 and BSL-4 PRNTs (Figure 8 and Table 3) validated the utility of the rCedV chimeric platform as suitable surrogate viruses for authentic NiV and HeV by PRNT.

We also expanded the utility of these novel reporter genes encoding rCedV chimeric viruses by developing a rapid and high-throughput fluorescence-based neutralization assay, FRNT. In contrast to the PRNT, which is the current gold standard for determining the presence of neutralizing antibodies and measuring the neutralizing titer in henipavirus-specific antisera, the FRNT (i) is high-throughput and allows for more samples to be assayed with more replicates in a 96-well plate format, (ii) requires smaller sample volumes, (iii) is less time consuming taking less than 36 h from infection to assay completion, and (iv) reduces the requirement for other reagents such as luciferase substrate. The rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeric viruses were used to assess the neutralization potencies of mAbs by FRNT assay, and the neutralization values at each mAb concentration obtained by FRNT were found to be highly correlated with those values obtained by PRNT (Table 5). We further evaluated the utility of the rCedV-NiV-B-GFP and rCedV-HeV-GFP FRNT by measuring the neutralization activities of henipavirus sG immunized NHP sera and rabbit sera. The NiV-sG immunized NHP sera, and the HeV-sG immunized rabbit sera were both cross-neutralizing to rCedV-NiV-B-GFP and rCedV-HeV-GFP, with higher homotypic serum neutralization titers as expected. The rabbit HeV-sG immune sera exhibited greater heterologous neutralization titers in comparison to the NHP NiV-sG immune sera, which was also consistent with neutralization data derived from NiV-sG versus HeV-sG immunized cats against authentic NiV-M and HeV [49].

In summary, a surrogate henipavirus-based system for NiV and HeV using the rCedV platform suitable for use at BSL-2 containment has been developed and well-characterized. These rCedV chimeras can serve as useful tools to study NiV and HeV entry, membrane fusion mechanisms, and F and G glycoprotein interactions and aid in the discovery and development of henipavirus countermeasures. More importantly, the specificity and utility of the rCedV-NiV-B-GFP and rCedV-HeV-GFP viruses as a surrogate neutralization assay for authentic NiV and HeV to evaluate the neutralization potential of mAbs and NiV/HeV specific antisera has also been demonstrated. The rCedV chimeras will reduce the cost and technical challenges of the high-containment environment, particularly when large numbers of serum samples derived from NiV or HeV vaccine development programs will require testing and quantitation.

5. Patents

C.C.B. and M.A. are United States federal employees and co-inventors on US and foreign patents pertaining to Recombinant Cedar Virus Chimeras, whose assignees are the United States as represented by the Henry M Jackson Foundation for the Advancement of Military Medicine, Inc. (Bethesda, MD, USA).

Supplementary Materials: The following supporting information can be downloaded at: https://www.mdpi.com/article/10.3390/v15051077/s1, Table S1: Mutations identified by genome sequencing of recombinant Cedar virus chimeras.

Author Contributions: Conceptualization, M.A. and C.C.B.; Methodology, M.A., C.C.B., R.Y., L.Y., V.B., B.N.A., A.B., F.M., R.Z.C. and K.A.B.-L.; Formal Analysis, M.A., A.S.D., R.W.C., K.A.B.-L., B.N.A., A.B., F.M., R.Z.C., T.W.G. and C.C.B.; Writing—Original Draft Preparation, M.A., A.S.D. and C.C.B.; Writing—Review and Editing, M.A., A.S.D., K.A.B.-L. and C.C.B.; Funding Acquisition, T.W.G. and C.C.B. C.C.B. revised and prepared the final version of the manuscript. All authors have read and agreed to the published version of the manuscript.

Funding: Research support was provided by National Institutes of Health grant U19AI142764 to C.C.B. and CEPI (Coalition for Epidemic Preparedness Innovations (CEPI)) to C.C.B. Operations support of the Galveston National Laboratory was funded by NIAID/NIH grant UC7AI094660 and support by Naval Medical Research Center was funded by Navy WUN A1417.

henipavirus, Hendra virus, Nipah virus, vaccine, subunit vaccine, henipavirus countermeasures

Abstract

Hendra virus (HeV) and Nipah virus (NiV) are bat-borne zoonotic paramyxoviruses identified in the mid- to late 1990s in outbreaks of severe disease in livestock and people in Australia and Malaysia, respectively. HeV repeatedly re-emerges in Australia while NiV continues to cause outbreaks in South Asia (Bangladesh and India), and these viruses have remained transboundary threats. In people and several mammalian species, HeV and NiV infections present as a severe systemic and often fatal neurologic and/or respiratory disease. NiV stands out as a potential pandemic threat because of its associated high case-fatality rates and capacity for human-to-human transmission. The development of effective vaccines, suitable for people and livestock, against HeV and NiV has been a research focus. Here, we review the progress made in NiV and HeV vaccine development, with an emphasis on those approaches that have been tested in established animal challenge models of NiV and HeV infection and disease.

INTRODUCTION

Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid- to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia [NiV-Malaysia (NiV-M)] (1). They are the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae* (2). NiV outbreaks have also been recorded in Bangladesh and India by a closely related strain, NiV-Bangladesh (NiV-B) (3). Three other henipaviruses are also recognized: Cedar virus (CedV) as an isolate and Ghana virus (GhV) and Mojiang virus (MojV) known only from sequence data (4–7). Both NiV and HeV are highly pathogenic in a broad range of mammalian hosts that are capable of infecting and causing severe disease in humans, monkeys, pigs, horses, cats, dogs, ferrets, hamsters, and guinea pigs and that span six mammalian orders including bats, although bats do not exhibit disease when infected (8–21). In contrast, CedV is nonpathogenic in well-characterized models of HeV and NiV disease including ferrets and hamsters (4, 22). The pathogenic potential of GhV and MojV is unknown.

Several species of *Pteropus* fruit bats are the natural reservoir hosts of NiV, HeV, and CedV (4, 23–27). NiV- or HeV-mediated disease has not been reported in wild or experimentally infected bats (13, 28–30). NiV and HeV infections in people and many animals manifest as severe systemic and often fatal neurologic and/or respiratory diseases (31–33). Both NiV and HeV are regarded as transboundary biological threats to both human and animal health and are classified as biosafety level 4 (BSL-4) select agents (34, 35). NiV and henipaviral diseases are included in the World Health Organization (WHO) R&D Blueprint list of priority pathogens with epidemic potential that need research attention (36). This review summarizes the important characteristics of the NiV and HeV pathogens, the modes of virus transmission, and the immunization strategies being developed against them.

Emergence and Outbreaks of Hendra and Nipah Viruses

In 1994 in the Brisbane suburb of Hendra, Australia, an outbreak of severe respiratory disease resulted in the deaths of 14 horses and their trainer, along with the nonfatal infection of 7 other horses and 1 other person. This led to the discovery of a novel paramyxovirus initially termed equine morbillivirus, now known as HeV (37–39). The first known cases of HeV in horses and a human actually occurred a few months prior, where one person became ill after assisting in the necropsies of two horses later shown to have died from HeV (40, 41). This individual experienced a relapsed fatal encephalitis caused by HeV 13 months later (42). HeV has since re-emerged in Australia 62 times with a total of 104 horse deaths (fatal or euthanized), along with 4 human fatalities of 7 cases (43). Every recorded occurrence of HeV in Australia has involved horses, all resulting in a severe or fatal disease, and all cases of human infection were acquired from virus-shedding horses (31, 44).

In 1998, an outbreak of encephalitis among pig farmers in Peninsular Malaysia occurred and a virus was isolated from samples of cerebrospinal fluid (CSF) of two patients who had died; cells infected with this virus cross-reacted with antibodies against HeV (45). Genetic studies revealed a new paramyxovirus that was closely related to HeV, and it was named Nipah after the village in Malaysia where one of the patients had lived (45). There were 265 cases of human infection with 105 fatalities in Malaysia and 11 cases and 1 fatality among abattoir workers in Singapore (46, 47). This outbreak was controlled through the culling of more than 1 million pigs, resulting in significant economic impacts to the region (48, 49).

A genetically similar but distinct strain of NiV was identified as the causative agent of fatal encephalitis in people in Bangladesh (NiV-B) (3, 50). Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and there have been three outbreaks in

India (51–54). The recent 2018 NiV outbreak in Kerala, India, was significant, having occurred in a new geographic region far from locations in Bangladesh and India where all prior outbreaks had occurred and with a case fatality rate of 91% (51). In 2014, an outbreak of NiV-M encephalitis occurred in the Philippines with 9 fatalities of 11 human cases of acute encephalitis and influenza-like illness or meningitis in another 6 individuals (55). Altogether, there have been over 650 cases of human NiV infection (combined ~60% fatality rate) in South Asia and Southeast Asia in five countries (54, 56).

Transmission of Hendra and Nipah Viruses

The routes of transmission of virus infection to humans from animals are different for HeV and NiV, with horses the only spillover host of HeV in Australia, while for NiV it was pigs in Malaysia and horses in the Philippines (**Figure 1**). However, human NiV infections in Bangladesh, India, and the Philippines also include bat-to-human and human-to-human transmission (57–60). Transmission routes of HeV and NiV to animals are likely urine from infected bats contaminating pastures or pigsties and/or virus-contaminated fruit spat from bats that is ingested (61, 62) (**Figure 1**). Recoverable virus is shed in the urine of experimentally infected bats and can also be detected in throat and rectal swabs (13, 28–30). Pooled urine samples from flying foxes are also routinely used to detect and isolate henipaviruses (4, 13, 23, 27, 63–65).

It was previously suggested that infected horses could transmit HeV to people during the feeding of ill animals (38). Also, the majority of all HeV-infected horse cases have involved a single animal, suggesting that HeV is not readily transmitted between horses, and multiple horse outbreaks are likely via contamination of fomites (43, 66). The transmission risk of HeV from infected horses to humans appears to be virus-contaminated fluids or tissues during examination procedures and/or the necropsy of horses (31, 67) (**Figure 1**). Indeed, all cases of human HeV infection have been associated with postmortem examination of horses or close contact with ill horses (31, 38, 42, 68). In Malaysia, it was contact with infected pigs or fresh infected pig products that was required for transmission of virus to humans (45, 69, 70) (**Figure 1**). NiV shedding in respiratory fluids of infected pigs suggested that it probably spread among farmed animals by aerosol droplets or direct contact (16, 71, 72). In Bangladesh, the transmission of NiV from bats to people has been linked to the consumption of virus-contaminated fresh date palm sap, and bats will consume sap during its collection (57, 73, 74). Domestic animals have also been linked to NiV infection in people in Bangladesh from unwell animals (cows and goats) and pigs (50, 59). Human-to-human transmission of NiV has been well documented in Bangladesh and India (52, 58–60, 75) (**Figure 1**). A study of human NiV-B cases in Bangladesh spanning 14 years reported that of 248 cases studied, one-third were caused by human-to-human transmission (56). Human-to-human transmission of NiV-M was not apparent in Malaysia (76, 77), whereas in the Philippines' NiV-M outbreak, human cases were linked to horse slaughtering and horse meat consumption or exposure to other human patients, indicating both horse-to-human and human-to-human transmission (55) (**Figure 1**). The NiV-B outbreak in Kerala had a very high rate of human-to-human transmission (22 of 23 cases) at three different hospital locations (51).

Naturally acquired NiV infections were also recorded in cats, dogs, and horses in the initial Malaysian outbreak (**Figure 1**), and serological evidence of natural NiV infection in dogs was linked to outbreak farms (11, 61, 78). In the Philippines, both dogs and cats were linked to NiV-M infection, with cats dying after eating horse meat and dogs having NiV-neutralizing antibodies (55) (**Figure 1**). In Australia, a dog was found to be seropositive for HeV and later euthanized but showed no signs of disease, and a second HeV-positive dog was identified in 2013 following exposure to blood from an infected horse (79) (**Figure 1**). Dogs are susceptible to experimental HeV infection and shed virus but show little evidence of clinical illness (80).

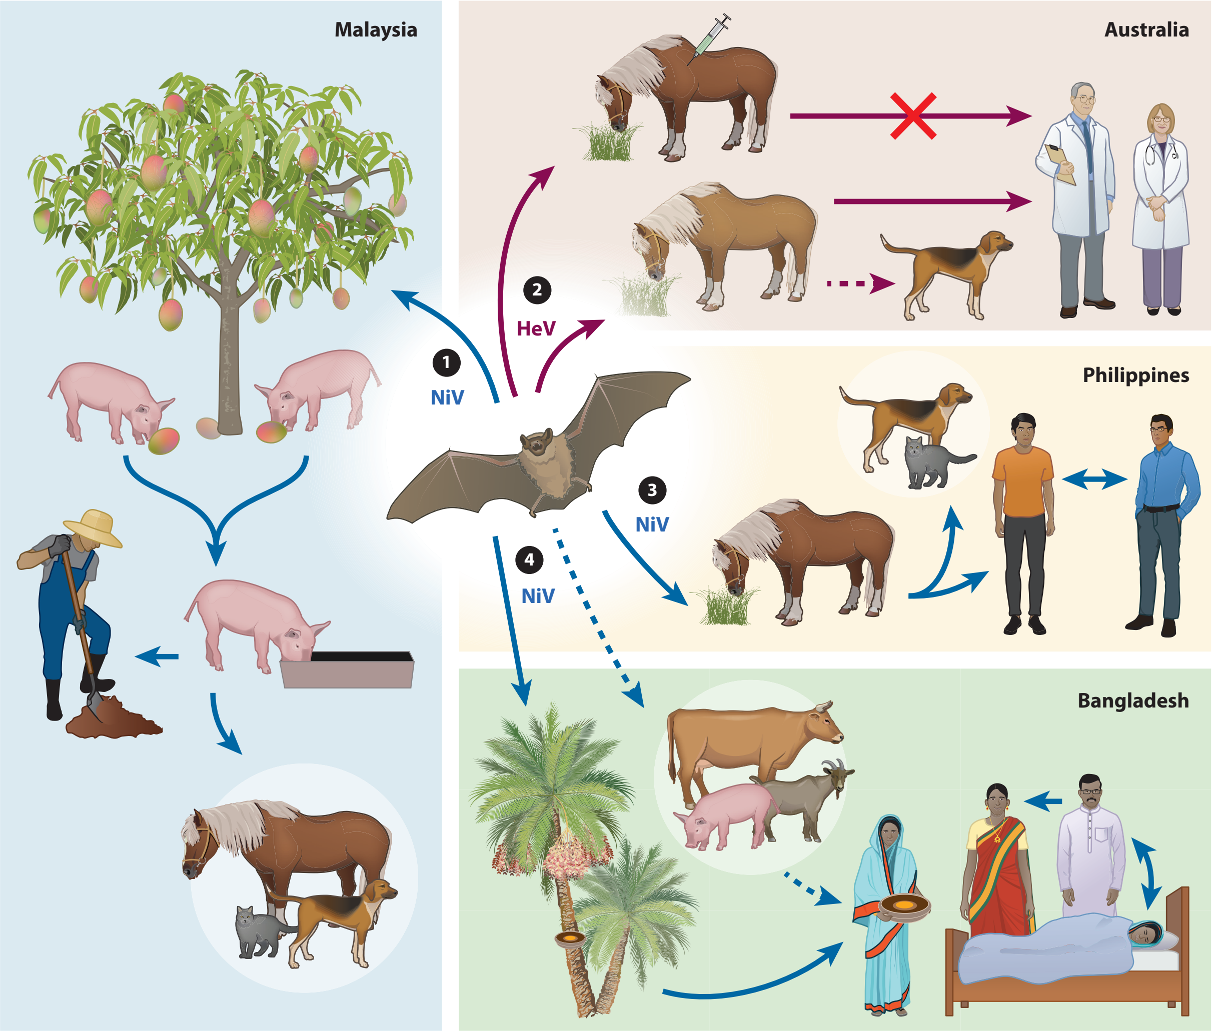

Figure 1

Nipah virus (NiV) and Hendra virus (HeV) modes of transmission in different countries. The transmission routes of NiV in Malaysia (*left*), Philippines (*middle right*), Bangladesh (*bottom right*), and HeV (*top right*) are depicted. Solid lines represent transmission that has been observed and documented, and dashed lines represent suspected transmission in natural conditions. Fruit bats are the natural reservoirs of NiV and HeV. (①) Pigs are infected by consuming partially eaten or contaminated fruit from infected bats (urine, saliva) and transmit NiV to other pigs, pig farmers, or other animals (dogs, cats, and horses) through close or direct contact. (②) Horses can be infected from grazing in contaminated pastures and transmit HeV to humans and on occasion domestic dogs through close contact. A One Health vaccine approach was developed for vaccination of horses in Australia with the dual purpose of saving horses from lethal HeV infection and preventing HeV transmission from horses to humans. (③) NiV is transmitted to humans through close contact with infected horses. NiV transmission to humans, cats, and dogs appears to have occurred following close contact with or consumption of infected horse meat. Human-to-human NiV transmission can occur through close contact. (④) Bat-to-human NiV transmission occurs through consumption of contaminated date palm sap. Human-to-human transmission can occur through close contact with infected patients. Humans may also become infected through contact with infected animals. Figure adapted with permission from Reference 171.

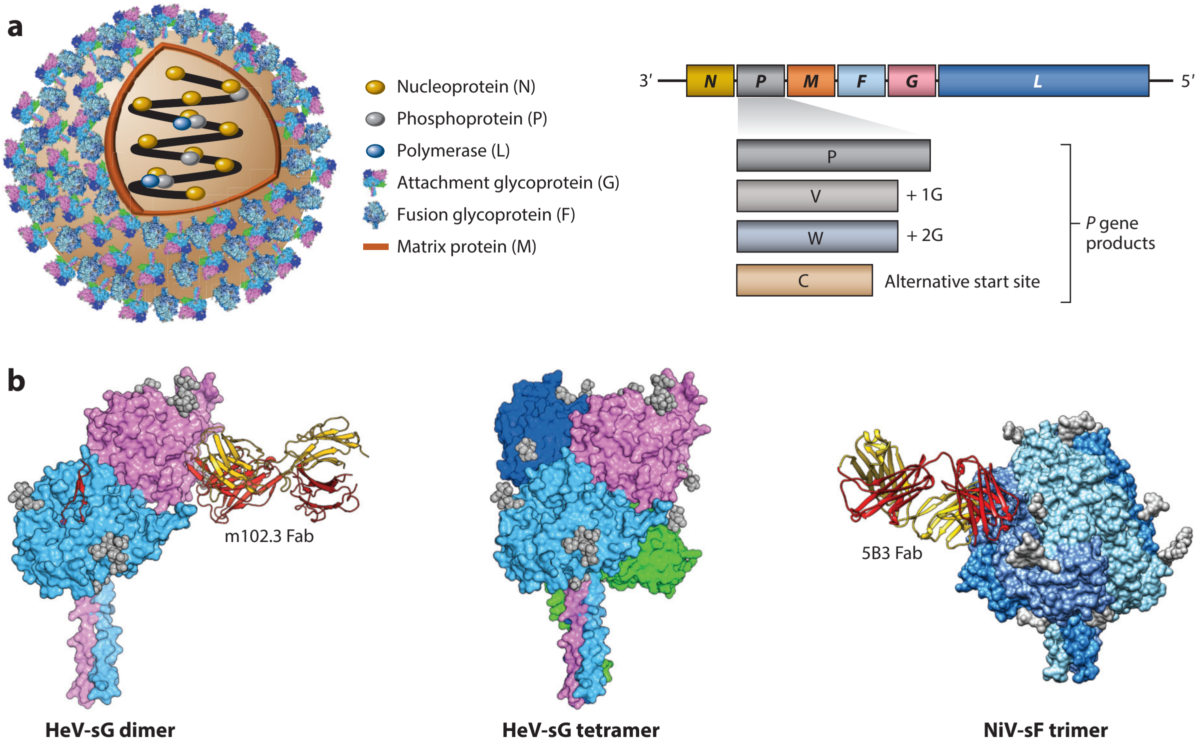

Figure 2

Henipavirus structure and genome organization and models of the G and F glycoprotein soluble ectodomains, Hendra virus (HeV-sG) and Nipah virus (NiV-sF), respectively, and their complexes with respective NiV and HeV cross-reactive neutralizing monoclonal antibodies m102.3 (anti-G) and 5B3 (anti-F). (*a*) Schematic representation of a henipavirus particle with the structural proteins depicted in different colors (*left*) and the henipavirus genome (*right*). HeV and NiV *P* genes encode 3 nonstructural proteins: The C protein is expressed from an alternative start site, and the V and W proteins are expressed following the addition of one or two G residues at the messenger RNA editing site, respectively (*right*). (*b*, *left*) HeV-sG shown as a dimer solvent-accessible surface view with one monomer (*cyan*) overlaid with the monoclonal antibody m102.3 CDR-H3 loop (*red*) at the receptor binding site, and the other monomer (*magenta*) in complex with m102.3 Fab, which has an identical heavy chain and a similar light chain, that was used in place of the m102.4 monoclonal antibody (mAb) in the structural solution of the complex (109). The HeV-sG consists of amino acids 76–604, and the structures of the two globular head domains of HeV-sG are derived from the crystal structure (103, 172). The stalk regions of each G monomer (residues 77–136) are modeled (173). The light chain of m102.3 Fab is colored in yellow, and the heavy chain is colored in red. (*b*, *middle*) The HeV-sG tetramer surface view is modeled with one dimer (*cyan* and *magenta*) in front and the other dimer (*blue* and *green*) in back. *N*-linked glycans are gray spheres. (*b*, *right*) Structural model of the NiV-sF trimer in complex with the 5B3 Fab derived from the cryo–electron microscopy structure (110). The NiV-sF consists of amino acid residues 1–494 with a FLAG tag (DYKDDDK) introduced between residues L104-V105 and a C-terminal GCN4 motif. Each monomer of NiV-sF is in a different shade of blue, 5B3 heavy chain is in red, and light chain is in gold. *N*-linked glycans are illustrated in gray.

Entry and Tropism of Nipah and Hendra Viruses

NiV and HeV are enveloped viruses containing an unsegmented, single-stranded, negative-sense RNA genome (2). **Figure 2*a*** is an illustration of the viral particle and the associated viral proteins. The genomes of HeV and NiV, and also CedV, GhV, and MojV, are considerably longer than the genomes of other paramyxoviruses, at greater than 18 kb. Henipavirus genomes encode 6 structural proteins: nucleoprotein (N), phosphoprotein (P), matrix protein (M), fusion glycoprotein (F), attachment glycoprotein (G), and the polymerase protein (L) (**Figure 2*a***). The N, P, and L proteins comprise the replication complex. The *P* gene undergoes RNA editing to produce 2 additional nonstructural proteins, V and W, that are interferon (IFN) antagonists (81–84). The C protein is transcribed from a second open reading frame in the *P* gene (**Figure 2*a***). NiV has been central to understanding the V, W, P, and C protein roles in antagonizing the innate immune responses via a diverse set of mechanisms (85, 86). Recent in vivo studies with recombinant NiV variants have further defined the varying importance of these nonstructural proteins in pathogenesis, but only a lack of the V protein results in a nonlethal infection (87–89).

The henipavirus virion bears surface projections composed of the F and G glycoproteins that are anchored in the viral membrane and together mediate infection of host cells, and they are the major antigens of vaccine strategies (1) (**Figure 2*a***). The F glycoprotein facilitates membrane fusion between the virus and host cell. The G glycoprotein consists of a characteristic stalk with a globular head that engages entry receptors on host cells, leading to the fusion activation of F and virus infection. The native structure of G is a tetramer while F is a trimer, and together they are the key determinants of infection and tropism (90–92). Models of the soluble ectodomain of the HeV G (HeV-sG) as a dimer and tetramer and the soluble ectodomain of the NiV F (NiV-sF) as a trimer are shown in **Figure 2*b***. NiV and HeV utilize the host cell proteins ephrin-B2 and ephrin-B3 for entry (93–96). Ephrin-B2 and ephrin-B3 are members of a large family of ligands that bind to Eph receptors and are highly sequence conserved among mammals (97, 98). Ephrin-B2 expression is prominent in the vasculature of multiple organs, whereas ephrin-B3 is found predominantly in the nervous system (99–101). The ability of HeV and NiV to use these ephrins as receptors provided explanations of their broad host and tissue tropism (32, 33, 102). The NiV and HeV G head domain structures alone and in complex with ephrin-B2 and ephrin-B3 receptors have been determined (103–106). The structures of both the NiV and HeV F in their prefusion conformation have also been determined (107, 108). These studies have provided insights into understanding the virus entry receptors and host tropism features of the viruses on the molecular level and also facilitated further structural studies of henipavirus G and F glycoproteins in complexes with specific virus-neutralizing antibodies, providing valuable information that has aided vaccine design and choice (109, 110).

Nipah Virus and Hendra Virus Infection in Humans and Animals

Human NiV and HeV infections are generally accepted to occur via the oronasal route, and the incubation periods for both have been estimated to be 1 to 2 weeks (31, 51, 111). Acute infection in people is a systemic infection likely via hematogenous spread of the virus from the respiratory system (112). In general, HeV and NiV disease onset is characterized by fever, myalgia, shortness of breath, and cough (38, 111). Human HeV infections have resulted in both fatal respiratory or encephalitic disease and also recovery from infection (31, 38, 42, 68). The predominant clinical feature in the NiV-M outbreak in Malaysia was encephalitis, but respiratory symptoms were also common with fever, cough, and headache (47, 111, 112). The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease. In the 2018 NiV-B outbreak in Kerala, 83% of cases presented with acute respiratory distress syndrome (ARDS) (51, 113). Central findings of human NiV and HeV infection are a widespread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected (45, 112, 114). Human NiV and HeV infections can also take a protracted course following apparent recovery, and some patients can experience late-onset encephalitis or relapsed encephalitis can occur in patients who previously recovered (42, 115). Relapsed encephalitis caused by NiV appears to result from a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later (116–118). Recrudescence of virus has important implications for vaccine development.

The development of animal models of NiV and HeV infection and pathogenesis has been a major focus since the late 1990s and an essential component of vaccine development and testing. Also, the approval process of countermeasures for NiV and HeV would fall under the animal rule requirement set forth by the US Food and Drug Administration (FDA) in 2002 as an alternative licensing pathway for countermeasures against highly pathogenic agents when human efficacy studies are not feasible or ethical (119, 120). Several animal models of NiV and HeV infection have emerged that well reflect the pathogenesis seen in infected people, which includes a systemic vasculitis with both respiratory and neurological diseases. Detailed reviews of NiV and HeV infections of a variety of mammalian species have recently been published (33, 121–123). It is generally accepted that the pathogenic processes of NiV and HeV infection in the hamster, ferret, and African green monkey (AGM) best reflect the pathogenesis observed in humans, whereas the most appropriate models for livestock are the horse and pig themselves.

VACCINATION

The attachment and fusion glycoproteins of paramyxoviruses such as measles, mumps, and parainfluenza viruses are the viral antigens to which virtually all neutralizing antibodies are directed (124–126). Likewise, immunization strategies for NiV and HeV have largely targeted their G and F glycoproteins.

Passive Immunization Strategies

Early passive immunization studies in the hamster model demonstrated that polyclonal antiserums or mouse monoclonal antibodies (mAbs) to NiV F or G could provide complete protection against NiV-M or HeV when administered before and immediately after virus infection (10, 127, 128). These studies demonstrated a major role of a viral glycoprotein-specific antibody in protection.

Recombinant human antibody technology was used to generate a potent cross-neutralizing mAb against NiV and HeV (m102.4) (129, 130). The m102.4 mAb epitope maps to the ephrin receptor binding site of G and blocks virus infection (see the left side of **Figure 2*b***), and it can neutralize NiV-M, NiV-B, and HeV (8, 109). The m102.4 mAb provided complete protection from NiV-M-mediated disease in ferrets as a single 50 mg dose administered 10 h post-challenge (8). In the AGM model, m102.4 administered as two 20 mg/kg doses, intravenously, at 10 h and again on day 3, on days 1 and 3 (days 1/3), or on days 3/5, after HeV challenge [4×10^5 50% tissue culture infectious dose ($TCID_{50}$)] by intratracheal (i.t.) administration, protected 100% of treated subjects (131). All treated subjects seroconverted against HeV F glycoprotein with a rise in antibody titer over time, indicating all animals had become infected with HeV and recovered, whereas untreated control subjects succumbed to HeV disease and failed to mount a protective immune response. No clinical signs were evident at any time in the early treatment groups; although neurological symptoms were observed in subjects in the late treatment group (days 3/5), all later recovered from infection. There was no HeV antigen or virus-specific histopathology detected in the lung or brain at the conclusion of the study in any treated subject, and infectious virus could not be recovered from any tissue. A similar study evaluated m102.4 against NiV-M disease in the AGM model at several time points following virus challenge (5×10^5 PFU), including a late cohort where treatment was initiated at the onset of clinical illness (day 5) (132). All subjects became infected after challenge, and all subjects that received m102.4 survived infection and all controls succumbed to disease. Subjects in the late day 5/7 treatment group exhibited disease, but all recovered. A comparative study in AGMs using NiV-M and NiV-B [5×10^5 PFU divided by i.t. and intranasal (i.n.) administration] revealed that NiV-B caused a more aggressive disease, with a shortened time to death and higher virus loads in tissues and fluids (133). When m102.4 was tested in this model, all subjects in the days 1/3 and days 3/5 post-infection treatment groups survived NiV-B challenge, but subjects in the days 5/7 treatment group succumbed, indicating a shorter therapeutic window in treating NiV-B infection (133). Another well-characterized, humanized mouse mAb, 5B3 (h5B3.1), that is cross-reactive to the F glycoprotein of NiV and HeV and binds a prefusion conformation epitope on F, preventing membrane fusion, was recently tested (110, 134) (**Figure 2*b***). The h5B3.1 mAb was given to ferrets in 20 mg/kg doses by intraperitoneal (i.p.) injection, at 1 to several days post-challenge, with either NiV or HeV ($\sim 5 \times 10^3$ PFU) delivered i.n. (135). All subjects that received h5B3.1 after infection were protected from disease and had increasing neutralizing antibody titers, whereas all controls died. No pathology was observed, and no infectious virus could be isolated at the study endpoint. Altogether, these studies demonstrate that passive immunization with mAbs can provide therapeutic benefit and allow the infected host an extended period to mount a protective immune response. The findings from these experiments were also important because they suggest that vaccine approaches designed to induce adequate neutralizing antibody responses to NiV and HeV should be effective.

The m102.4 mAb producing cell line was provided to the Queensland Government, Australia, to produce the mAb for compassionate use in future cases of high-risk human HeV infection. To date, 14 individuals exposed to either HeV in Australia ($n = 13$) or NiV in the United States ($n = 1$) have been given high-dose m102.4 therapy (15–20 mg/kg) by emergency use protocols, and all have remained well. In Australia, m102.4 was used in a randomized, controlled phase I study in healthy adults (136). The study included four single and one repeat dosing groups, and the m102.4 mAb was found to be safe and well tolerated, with a half-life ranging between ~16.5 and 27 days, and no observed immunogenicity was reported. Two doses of 20 mg/kg (days 1/3) were as well tolerated as a single dose. This study's findings will aid in the design of future dosing regimens of mAbs for evaluating their ability to prevent and/or treat HeV and NiV human infections.

Active Immunization Strategies

A variety of immunization strategies have been developed to prevent NiV and HeV infection including several live-recombinant virus vectors, protein subunit, and virus-like particle (VLP) approaches, and all target the virus attachment and entry steps of infection by employing the G and/or F glycoprotein antigens. Here we summarize these various vaccination countermeasure approaches to NiV and HeV infection (**Tables 1** and **2**).

Poxvirus vectored. Poxviruses have a long history as a platform for the expression of heterologous genes to study protein function and serve as vaccine candidates as a live-attenuated viral vaccine platform capable of inducing both cell-mediated and humoral immune responses (137). The F and G glycoproteins of NiV and HeV were functionally characterized using recombinant vaccinia viruses in the early 2000s (138, 139). The first NiV vaccine tested used a highly attenuated vaccinia virus strain (NYVAC) encoding either the F or G glycoproteins from NiV-M (127). Hamsters were vaccinated by subcutaneous (s.c.) injection in a prime-boost strategy with NYVAC-NiV-F or NYVAC-NiV-G, individually and in combination, and then 3 months later challenged i.p. with NiV-M. Vaccination yielded complete protection from NiV-M with no detection of viral RNA, and control subjects succumbed 7–10 days after challenge (127) (**Table 1**). Another poxvirus-based approach was examined as a vaccine for pigs using canarypox (ALVAC) vaccine vectors encoding either NiV-M F or G glycoprotein (140). A prime-boost strategy with ALVAC-NiV-F or ALVAC-NiV-G vectors was tested alone or in combination in pigs. The animals were then challenged 28 days later with NiV-M via i.n. administration. All vaccinated animals survived NiV-M challenge

Table 1 Virus vectored vaccine strategies for NiV and HeV

Approach	Name(s)	Animal model	Vaccination dose, route, schedule	Adjuvant	Challenge	Challenge dose, route, schedule	Survival	Correlate(s) of immunity/ protection	Reference
Poxvirus	NYVAC-NiV-F and/or -G	Hamster	2 doses at 1×10^7 PFU, s.c., 1 month apart	None	NiV-M	1×10^3 PFU, i.p., 3 months later	100%	NAb response, viral RNA	127
	ALVAC-NiV-F and/or -G	Pigs	2 doses at 1×10^8 PFU, i.m., 2 weeks apart	None	NiV-M	2.5×10^5 PFU, i.n., 28 days later	100%	NAb response, viral RNA, infectious virus, viral shedding, cytokine production	140
	ALVAC-HeV-F and/or -G	Hamster	2 doses at 7.4 or 5.4 log10 $CCID_{50}$, s.c., 3 weeks apart	None	HeV	1×10^3 LD_{50}, i.p., 21 days later	89% and 63%	NAb response, viral RNA, viral antigen, viral shedding	141
		Ponies	2 doses at 6 log10 $CCID_{50}$, i.m., 3 weeks apart	None	NT	NA	NA	High NAb titers	
	MVA-NiV-sG and/or MVA-NiV-G	IFNAR−/− mice	1 or 2 doses at 1×10^8 PFU, i.m., 3 weeks apart	None	NT	NA	NA	High serum IgG titers, NiV-G-specific CD8 and CD4 T cells	142

Table 2 ***(Continued)***

Approach	Name	Animal model	Immunization dose, route, schedule	Adjuvant	Challenge	Challenge dose, route, schedule	Survival	Immune correlate(s) of survival	Reference
		AGM	2 doses at 100, 50, or 10 μg, i.m., 3 weeks apart	CpG/Alhydrogel	NiV-M	1×10^5 TCID$_{50}$, i.t., 3 weeks later	100%	Serum IgG, NAb response, viral RNA, viral antigen, infectious virus	165
			2 doses at 100 μg, i.m., 3 weeks apart	Alhydrogel or CpG/Alhydrogel	HeV	5×10^5 PFU, i.t., 21 days later	100%	NAb response, viral RNA	166
		Horse	2 doses at 100 or 50 μg, i.m., 3 weeks apart	Zoetis	HeV	2×10^6 TCID$_{50}$, o.n., 28 or 194 days later	100%	NAb response, viral RNA, viral antigen, infectious virus	167
		Pig	2 doses of 2 mL preformulation, i.m., 3 weeks apart	Zoetis	HeV	5×10^5 PFU, i.n., 35 days later	Partial	NAb response, viral RNA, infectious virus, viral shedding	168
					NiV-M		0%		
Nucleic acid–based vaccine	HeV-sG mRNA LNP	Hamster	10 or 30 μg, i.m.	None	NiV-M	1×10^5 TCID$_{50}$, i.p., 30 days later	30% or 70%	Serum IgG, NAb response	169

All NiV glycoprotein vaccines employ the NiV-M strain.

Abbreviations: AGM, African green monkey; CSIRO, Commonwealth Scientific and Industrial Research Organisation; F, fusion glycoprotein; G, attachment glycoprotein; HeV, Hendra virus; i.m., intramuscular; i.n., intranasal; i.p., intraperitoneal; i.t., intratracheal; IgG, immunoglobulin G; LNP, lipid nanoparticle; M, matrix protein; MPLA, monophosphoryl lipid A; mRNA, messenger RNA; NA, not applicable; NAb, neutralizing antibody; NiV, Nipah virus; NiV-B, Nipah virus Bangladesh; NiV-M, Nipah virus Malaysia; NT, not tested; o.n., oronasal; PFU, plaque forming unit; s.c., subcutaneous; sG, G glycoprotein soluble ectodomain; TCID$_{50}$, 50% tissue culture infectious dose; VLP, virus-like particle.

as determined by the lack of NiV RNA and infectious virus from nasal washes, pharyngeal swabs, and a variety of sampled organs (140).

ALVAC-vectored vaccines encoding HeV F or G glycoprotein for potential use in horses were also examined (141). ALVAC-HeV-F or ALVAC-HeV-G vectors were combined and first used to vaccinate hamsters at a high or low dose of each vector, by s.c. injection, and then challenged with HeV by i.p. administration. Vaccination did not result in complete protection, with 8 out of 9 subjects in the high-dose group and 5 out of 8 subjects in the low-dose group surviving challenge. No signs of disease were noted, and viral antigen or viral RNA could not be detected in survivors. Nine ponies vaccinated using the same prime-boost regimen were able to develop high cross-neutralizing antibody titers to HeV and NiV-M at day 28 after vaccination. Although ponies were not challenged, most animals yielded titers of at least 1:32 and were considered likely protective (141).

More recently, a modified vaccinia virus Ankara (MVA) vector encoding NiV-M G glycoprotein and a soluble version of G (NiV-sG) were examined in interferon receptor α and β (IFNAR−/−) knockout mice (142) (**Table 1**). IFNAR−/− mice were immunized once with MVA-NiV-G or MVA-NiV-sG or prime-boosted. IFNAR−/− mice developed high serum immunoglobulin G (IgG) titers to NiV-G and also generated NiV-G-specific CD8 and CD4 T cells following vaccination. MVA-NiV-sG vaccination induced rapid and significantly higher amounts of NiV-G epitope-specific CD8 T cells compared with the MVA-NiV-G candidate vaccine, suggesting superior immunogenicity. Together, these immunization studies with poxvirus vectors highlight that both T cell and B cell responses play a role in an adaptive immune response to NiV and HeV. However, detailed studies on the adaptive immune responses in animal experiments with henipaviruses have been limited. Future studies evaluating the role of NiV-specific T cells will be important because two human survivors of NiV-B infection in the 2018 outbreak in Kerala showed marked elevation of activated $CD8^+$ T cells, which coincided with virus clearance (143).

Vesicular stomatitis virus vectored. Recombinant vesicular stomatitis virus (rVSV) vectors as a vaccine platform suitable for single immunization strategies to potentially meet emergency use requirements have been tested by several groups (**Table 1**). A method of using two defective VSVΔG vectors each expressing only the NiV G or F glycoprotein was devised using VSV G glycoprotein complementation that can generate replication-defective VSV vectors that could elicit NiV-neutralizing antibodies (144). Using this technique, researchers tested rVSV vaccines expressing either NiV-M F or G glycoproteins (VSV-ΔG-NiVG, VSV-ΔG-NiVF) in hamsters by intramuscular (i.m.) vaccination (145). Hamsters were then challenged 32 days later with NiV-M by i.p. administration. All vaccinated animals survived lethal infection with no clinical signs of disease. No viral RNA or viral antigen could be detected in the sampled tissues when compared with controls, and there was a lack of an anamnestic immune response in vaccinated subjects following challenge, suggesting the induction of sterilizing immunity.

Another study used rVSV-ΔG vectors expressing NiV-B F or G glycoprotein and also tested them as single-injection vaccinations in NiV-M-challenged ferrets (146). Ferrets were vaccinated i.m. with rVSV-NiV-B F or rVSV-NiV-B G complemented with VSV G or a mix of both vectors, rVSV-NiV-B F/G, that was generated as a complementing pair in the absence of VSV G and then challenged at 28 days with NiV-M by i.n. administration. All vaccinated ferrets were completely protected against NiV-M challenge. Although viral RNA was detected in blood at day 6 post-challenge in 2 of 5 animals in each group, those levels were 100 times lower than in the unvaccinated controls, and by day 21 no viral RNA was detected (146). In a second study, rVSV-NiV-B F and rVSV-NiV-B G were assessed separately and in combination in AGMs (147). Cohorts were vaccinated with the rVSVs by i.m. injection and challenged 28 days later with NiV-B divided between the i.t. and i.n. routes (147). Complete protection was recorded from NiV-B disease with no gross pathology and no detectable NiV antigen in lung or spleen tissues. Viral RNA was detected in nasal and oral swabs of the vaccinated groups, but no viral RNA could be detected in blood samples.

Replication-competent rVSV-NiV-M F or G vectors, generated by the retention of the envelope glycoprotein from *Zaire ebolavirus* (ZEBOV-GP), which allowed virus stocks to be propagated (rVSV-ZEBOV-GP-NiVF, rVSV-ZEBOV-GP-NiVG, and rVSV-ZEBOV-GP-NiVN), have also been tested (148). These rVSVs were used to immunize hamsters by i.p. administration and were challenged 28 days later with NiV-M. All subjects vaccinated with either the NiV F or G glycoprotein encoding rVSV vectors were completely protected with no clinical disease or pathology, whereas those vaccinated with the NiV N protein were only partially protected (2 of 6 animals) with no clinical signs of disease and the other subjects succumbed to infection. The protective efficacy of the rVSV-ZEBOV-GP-NiVG was also tested in AGMs, where vaccinated subjects were challenged with NiV-M by i.t. administration 29 days later (149). All vaccinated subjects were protected from lethal challenge and showed no signs of clinical disease, no viral RNA was detected in the blood or oral and nasal swabs, and no infectious virus could be recovered. Another study using a rVSV vector expressing a codon-optimized HeV *G* gene together with an inactivated counterpart was evaluated in mice for humoral immune responses only as a comparator to a recombinant rabies virus vaccine encoding HeV G as a HeV vaccine candidate (150). Here, the live rVSV vectors induced greater levels of HeV G-specific antibodies and higher levels of HeV-neutralizing antibodies than did the recombinant rabies virus vectors (see the section titled Rabies Virus Vectored).

Adeno-associated virus and adenovirus vectored. Adeno-associated virus (AAV) vectors as a vaccine platform against infectious diseases, particularly viral pathogens, have been explored. AAV is a small, single-stranded DNA virus in the family *Parvoviridae*. Immunization of hamsters with an AAV vector expressing NiV-M G glycoprotein (AAV8 NiV.G) by i.m. injection demonstrated complete protection from a challenge of NiV-M by i.p. administration, and no signs of clinical disease were recorded (151) (**Table 1**). Neutralizing antibodies to NiV were induced, no viral RNA or viral antigen was detected in any of the sampled tissues, and there was only a moderate anamnestic response observed in a single subject, suggestive of potential sterilizing immunity. However, in a cross-protection study, AAV8 NiV.G protected only 50% of hamsters challenged with HeV.

Chimpanzee adenoviral (ChAd) vectors circumvent issues of the preexisting immunity observed with human adenovirus vectors (152). Adenoviruses are double-stranded DNA viruses in the family *Adenoviridae*. An engineered replication-deficient ChAd vector, Oxford 1 (ChAdOx1), was tested as a NiV/HeV vaccine (153). Here, ChAdOx1 encoding NiV-B (ChAdOx1 NiV-B) G glycoprotein was used to vaccinate hamsters by i.m. injection, either as a single dose or as a prime-boost protocol. Hamsters were challenged by i.p. administration with NiV-B 42 days following the booster or the single vaccination. Neutralizing antibodies were detectable, and all vaccinated hamsters were protected against lethal disease with no lung pathology, suggesting that a single dose of ChAdOx1 NiV-B was sufficient to completely protect against NiV-B. No viral RNA in the lung tissue and no viral shedding in oropharyngeal swabs could be detected, and no infectious virus could be isolated. A second cohort using a single dose of ChAdOx1 NiV-B to vaccinate hamsters was trialed, and these animals were challenged 28 days later with NiV-M or HeV. All vaccinated animals were protected from lethal NiV-M challenge, but 4 out of 6 hamsters succumbed to HeV disease between days 5 and 7 post-challenge. Neither virus shedding in oropharyngeal swabs nor infectious virus was detected in the lung or brain tissues of NiV-M-challenged vaccinated hamsters. In contrast, infectious virus was detected in the lung tissues of 75% of the HeV-challenged vaccinated animals. The lower cross-protection observation using NiV G vaccination followed by HeV challenge was not unexpected, as it was previously shown that when the G glycoprotein (as a recombinant soluble subunit immunogen) of either HeV or NiV was used to vaccinate cats, both could completely protect against lethal NiV-M challenge, and that the HeV-sG elicited greater heterologous neutralizing antibody responses in comparison to NiV-sG (14).

Measles virus vectored. Recombinant measles virus vectors based on the HL (rMV-HL) and Edmonston (rMV-Ed) measles virus strains have also been explored in which they encoded the NiV-M G glycoprotein (rMV-HL-G and rMV-Ed-G) (154) (**Table 1**). Hamsters were immunized twice by i.p. administration of rMV-HL-G or rMV-Ed-G. All vaccinated animals produced NiV G-specific antibody titers after the booster immunization. Animals were challenged 1 week after the second immunization with NiV-M by i.p. administration. All immunized hamsters exhibited no clinical symptoms and survived challenge. The study was extended to non-human primates (NHPs), where 2 AGMs were immunized twice by s.c. injection with rMV-Ed-G. Subjects were challenged 2 weeks after the second immunization with NiV-M by i.p. administration. Here, immunization completely protected the AGMs with no observed clinical disease and no detectable pathological changes, and no viral RNA could be detected in sampled tissues. Although this was a small study, the safety profile and success of the live-attenuated measles virus vaccine suggests that a recombinant platform encoding the NiV G glycoprotein as a NiV vaccine candidate is promising and should induce a balanced and long-lasting immune response against NiV.

Rabies virus vectored. A rabies virus (RABV) SAD B19 vaccine strain, BNSP333, expressing HeV or NiV G glycoproteins has been evaluated (150, 155). Recombinant BNSP333 encoding either the wild-type or a codon-optimized HeV *G* gene, together with their inactivated counterparts, was used in mice (150) (**Table 1**). Mice were immunized by i.m. injection with a single dose of the RABV-based vectors or with 3 doses of their inactivated versions. The inactivated RABV-based vectors induced higher and more rapid HeV G-specific antibody responses and higher neutralizing antibody titers than their live counterparts. The inactivated RABV-coHeV-G induced cross-neutralizing antibodies against NiV. A similar study used the BNSP333 vector expressing NiV-B G glycoprotein (RABV-NiV-BG) (**Table 1**) and elicited NiV G-specific neutralizing antibodies (155).

Recently, the recombinant RABV Evelyn-Rokitnicki-Abelseth (ERA) strain ($\text{rERAG}_{333\text{E}}$) expressing either NiV-M F or G glycoproteins was evaluated in mice and pigs (156) (**Table 1**). This vector, $\text{rERAG}_{333\text{E}}$, serves as an oral vaccine in dogs. Here, mice were orally immunized with RABV-NiV-F or RABV-NiV-G either individually or in combination. Pigs were also immunized in a similar manner but with 2 doses of each vector either alone or in combination. RABV-NiV-F and/or RABV-NiV-G immunization induced NiV F- and G-specific IgG antibody responses and neutralizing antibodies in both mice and pigs with the combination vaccine inducing higher titers. Although not suitable for human use, the live-attenuated $\text{rERAG}_{333\text{E}}$ vector is of interest as a potential veterinary vaccine for NiV because it is already approved for use in some animals and could be adapted for emergency use to protect against NiV infection in livestock, particularly swine.

Many of these virus-vectored vaccines for NiV are promising candidates because of their established safety profiles and ease of genetic modification. Several of these virus-vectored vaccines also require no adjuvants, and some are clearly efficacious as a single immunization strategy, suitable features for emergency use circumstances. In addition, several of these platforms are able to induce both cell-mediated and humoral immune responses, which may also be desirable but as yet are not fully explored in the development of vaccines for NiV and HeV. Although animals immunized with viral vectors encoding the NiV G glycoprotein and challenged with the homologous virus were completely protected, cross-protection studies with some of these vaccines against a HeV challenge were less effective. For example, only 50% of AAV8 NiV.G-immunized hamsters or 33% of ChAdOx1 NiV-B G glycoprotein–immunized hamsters were protected from a lethal HeV challenge (151, 153). In addition, the ALVAC-HeV-F and ALVAC-HeV-G vaccination studies showed that these vectors did not provide 100% protection in hamsters challenged with HeV, perhaps due to either a suboptimal immunization dose or the immunization route (141).

Virus-like particles. VLPs have been explored as a vaccine platform because of the resemblance of their surface structure, dimensions, and compositions to authentic virus yet are of high safety because of the lack of viral genetic material. Earlier studies revealed that the M protein of NiV was capable of orchestrating the formation and budding of NiV VLPs when expressed in cells that appeared structurally similar to authentic NiV virions, and these VLPs could also incorporate other viral proteins such as the F and G glycoproteins (157, 158). VLPs composed of NiV M, F, and G were used to vaccinate mice s.c. at weeks 0, 2, and 4 and demonstrated they could induce high neutralizing antibody titers by day 35 (159) (**Table 2**). NiV VLPs were later used in NiV-M challenge studies either alone or in combination with adjuvant, monophosphoryl lipid A (MPLA) and Alhydrogel^{TM} (15 μg/50 μg) or CpG and Alhydrogel (40 μg/50 μg) (160). Hamsters were vaccinated i.m. either as a single dose or as a 3-dose regimen and then challenged via i.p. administration of NiV-M at 28 days or 58 days, respectively. In all cohorts, 100% of the vaccinated animals survived with no clinical signs of disease and no detection of viral RNA in any of the sampled tissues, regardless of the presence of adjuvant. VLPs are thus an alternative means, with inherent safety, of producing an inactivated whole virus vaccine from an otherwise highly pathogenic virus.

Subunit vaccine. The HeV-sG subunit vaccine has been extensively evaluated in several studies. Here, a brief summary of earlier reports is made, but the focus is on studies in NHPs and livestock. Recombinant HeV-sG and NiV-sG can elicit a potent neutralizing antibody response and were first tested as vaccine immunogens in the feline model (14, 161) (**Table 2**). Both HeV-sG and NiV-sG vaccination of cats completely protected against lethal NiV-M challenge, and HeV-sG elicited greater heterologous neutralizing titers than did NiV-sG, demonstrating that a single subunit vaccine may be effective against both NiV and HeV (14). Other studies using lower doses of HeV-sG (**Table 2**) demonstrated that a pre-challenge neutralizing titer of 1:32 could protect against NiV-M (162). Additional studies in ferrets showed that low doses of HeV-sG could protect against HeV and NiV-B (163, 164) (**Table 2**). Also, a longevity study showed that vaccinated ferrets challenged with NiV-B at 14 months post-immunization, with pre-challenge neutralizing titers of 1:16 to 1:128, were also protected (164).

The HeV-sG vaccine has been extensively evaluated in AGMs (**Table 2**). In a cross-protection study, 100 μg, 50 μg, or 10 μg doses of HeV-sG in combination with Alhydrogel and CpG were administered i.m. as a prime-boost, on days 0 and 21. Pre-challenge 50% neutralization titers ranged from 1:28 to 1:379. All subjects were challenged with NiV-M by i.t. administration on day 42. All vaccinated subjects were completely protected, displaying no clinical signs of disease, and no viral RNA could be detected in blood and tissues and no infectious virus was isolated (165). Similarly, HeV-sG vaccination HeV challenge in AGMs has also been performed. Using a prime-boost regimen, AGMs were vaccinated twice, 3 weeks apart, by i.m. injection with 100 μg HeV-sG with Alhydrogel or HeV-sG with Alhydrogel and CpG, and then challenged 3 weeks later with HeV by i.t. administration (166). All vaccinated animals were completely protected from clinical disease, and no HeV RNA or viral antigen could be detected in swabs, blood, or tissues, and notably HeV-sG formulated in only Alhydrogel protected (166).

The efficacy and inherent safety of the HeV-sG subunit led to its development as an equine vaccine to prevent HeV infection of horses and also reduce the risk of HeV transmission to people, as a One Health concept (**Figure 1**). HeV-sG, formulated in an approved equine adjuvant (Zoetis, Inc.), was evaluated in two efficacy studies; the first tested 50 μg and 100 μg doses of the same HeV-sG used in prior animal studies to vaccinate horses, and the second used 100 μg doses of HeV-sG produced in Chinese hamster ovary cells (Zoetis, Inc.). Two vaccinations were given by i.m. administration 3 weeks apart. All horses in these efficacy studies were challenged by oronasal inoculation with HeV (**Table 2**). Seven horses were challenged at 28 days and 3 horses were challenged at 194 days after the second immunization. All vaccinated horses remained clinically healthy following challenge; pre-challenge neutralization titers ranged from 1:128 to more than 4,096 in horses challenged 21 days after vaccination and only from 1:16 to 1:32 in horses challenged at 6 months. There was no gross or histologic evidence of infection in any of the vaccinated horses at study completion, and all tissues examined were negative for viral antigen, with no viral genome detected in any tissue. In 9 of 10 vaccinated horses, HeV nucleic acid was not detected in daily nasal, oral, or rectal swab samples or from blood, urine, or fecal samples collected before euthanasia, no recoverable virus was present, and no rise in antibody titer was detected in any vaccinated horse following challenge (167). The HeV-sG horse vaccine (Equivac® HeV) was launched by Zoetis, Inc., in November 2012 on a minor use permit by the regulatory authority, the Australian Pesticides and Veterinary Medicines Authority (APVMA), and is the first commercially developed and deployed vaccine against a BSL-4 agent. All vaccinated horses are microchipped, and a database is maintained. Equivac HeV received full registration by the APVMA in 2015. To date, more than 765,000 doses of Equivac HeV vaccine have been administered to more than 179,000 unique horses, and laboratory-confirmed HeV infections in horses have since occurred only in unvaccinated animals.

Studies showed HeV-sG as a NiV vaccine in the pig model (which is a non-lethal challenge model) was much less effective in comparison to results observed in the cat, ferret, NHP, and horse, and HeV-sG was only partially protective against HeV challenge and unprotective against NiV-M in the pig (168). These experiments also indicated that both humoral and cellular immune responses were required for protection of swine against NiV and HeV. Here, pigs were immunized with HeV-sG in a proprietary adjuvant (Zoetis, Inc.), and subjects were challenged with HeV or NiV via i.n. administration (**Table 2**). HeV-sG-vaccinated pigs developed neutralizing titers ranging from 1:160 to 1:320 to HeV, but only partial protection was achieved with reduced viral RNA in tissues and no recoverable virus, and there was no reduction of viral shedding in nasal washes. These HeV-sG-vaccinated pigs did not develop neutralizing antibodies to NiV-M that were considered protective (low), nor did they have measurable activation of cellular immune memory. Only a comparative group of pigs that were first orally infected (vaccinated) with NiV (and recovered) were subsequently protected against an i.n. rechallenge with NiV. This group of pigs developed protective antibody levels and cell-mediated immune memory responses (168).

Single-dose lipid nanoparticle mRNA, HeV-sG vaccine. More recently, messenger RNA (mRNA)-based vaccines have emerged as an attractive vaccine strategy because of safety, efficacy, and rapid implementation features. In a recent study, the efficacy of an mRNA vaccine approach was assessed in a NiV-M animal challenge model (169). mRNA transcripts encoding HeV-sG were complexed with lipid nanoparticles (LNPs) to generate HeV-sG mRNA LNP. Two groups of 10 hamsters were vaccinated with a single dose of HeV-sG mRNA LNP at either 10 μg or 30 μg by i.m. injection. Subjects were challenged with NiV-M by i.p. administration 30 days post-vaccination (**Table 2**). The HeV-sG mRNA LNP was only partially protective, with 3 hamsters from the low-dose group and 7 hamsters from the high-dose group surviving challenge. Of the surviving animals, signs of clinical disease were observed in 2 low-dose group and 6 high-dose group hamsters; however, disease symptoms were gone by study termination. NiV *N* gene RNA levels in the blood and a variety of tissues in surviving hamsters were lower compared with nonsurvivors, but NiV RNA copy levels were not different compared with controls. No anti-NiV IgG or virus-neutralizing activity was detected in vaccinated animals prior to challenge; however, all post-challenge survivors were positive for anti-NiV IgG antibodies, and all survivors (in both groups) had similar neutralizing titers ranging from 1:160 to 1:640. Euthanized animals had little to undetectable neutralizing activity, highlighting the correlation of this immune response to protection. Although promising, the partial efficacy of HeV-sG mRNA LNP observed in this study suggests that further optimization of vaccination route, addition of an adjuvant, and/or a prime-boost regimen is needed.

SUMMARY AND FUTURE PERSPECTIVES

The frequency of henipavirus outbreaks and human infections is a significant global health concern. A promising passive immunization strategy has been developed using a human mAb, m102.4, shown effective in the NHP challenge model, which has also been administered numerous times to people by compassionate use protocol and has successfully completed a phase I safety trial in Australia. In addition, the Equivac HeV vaccine is available, targeting the protection of horses and also people by breaking the chain of HeV transmission to people, and is an example of a One Health approach to counter an infectious disease threat. Over the past 15 years, nearly a dozen NiV and HeV vaccine approaches have been trialed in animal challenge models, and many show promise as effective human-use vaccines. Recently, the formation of the Coalition for Epidemic Preparedness Innovations (CEPI), a global partnership between public and private organizations, was undertaken with the goals of developing vaccines against emerging infectious diseases and offering equitable access to those vaccines (170). Indeed, without the support of CEPI, the prospects of having a NiV or HeV vaccine suitable for use in people, at a deployable stage in the event of a significant outbreak, would have remained academic. Research teams can now capitalize on the large body of basic and preclinical vaccine development data on a half-dozen important emerging viral threats including NiV and, with the support of CEPI, can develop vaccine candidates for clinical use and future licensure. Several of the NiV human vaccine candidates described in this review are now supported by CEPI.

DISCLOSURE STATEMENT

C.C.B. is a US federal employee and co-inventor on US and foreign patents pertaining to soluble forms of HeV and NiV G and F glycoproteins and monoclonal antibodies against HeV and NiV whose assignee is the United States as represented by the Henry M. Jackson Foundation for the Advancement of Military Medicine (Bethesda, Maryland). The soluble forms of the HeV and NiV G glycoproteins are licensed to Zoetis, Inc., and Aurobindo Pharma USA Inc. M.A. declares no competing interests.

---

hi Chris,

great to meet you today.

attached is Cedar chimera paper.
also a recent Nipah/Hendra review

A good plan for Nipah/Hendra as the prototypes in **VSVdeltaG**
Could be
NiV G(bangladesh)
NiV sG(bangladesh)
HeV sG(redlands)

We could also consider a comparison of these vaccines to recombinant Cedar virus encoding HeV sG ?

AAV and adenovirus platforms with NiV G did not work well against Hendra challenge

Mouse sera could be sent to us for testing. against NiV/HeV
and any prechallenge sera (if animals are not yet moved to bsl4)

Or we could simply collaborate on the project and MTA/Supply
virus stocks to your Cores
v/r
Chris

Other Support – Project/Proposal

ACTIVE

Title: Collaborative Development and Evaluation of a Human Subunit Vaccine (HeV-sG) to Protect Against Nipah and Hendra Viruses

Major Goals: This project will develop, characterize and test chimeric, luciferase encoding henipaviruses using CedV along with the fusion and attachment glycoproteins of Nipah virus and Hendra virus

Overlap: None. This Project supported the development of the chimeric recombinant CedV serum neutralization test platform to be supplied to AuroVaccines LLC.

Status of Support: Active
Project Number: N/A
Name of PD/PI: Hamm, Stefan.
Source of Support: Subward from Profectus (Now AuroVaccines LLC) / CEPI CRADA
Primary Place of Performance: USUHS, Bethesda, MD
Project/Proposal Start and End Date: (MM/YYYY): 01/30/2019 – 01/29/2024
Total Award Amount (including Indirect Costs): $796,308
Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)

Title: Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia

Major Goals: The overarching goal is to characterize the distribution and detect the spillover of henipaviruses and filoviruses among indigenous farming and hunting communities in Peninsular Malaysia.

Status of Support: Active
Project Number: 07-103-7096
Name of PD/PI: Daszak, P.
Source of Support: Subward from EcoHealth Alliance / DTRA
Primary Place of Performance: USUHS, Bethesda, MD
Project/Proposal Start and End Date: (MM/YYYY) 05/01/2017-04/30/2023
Total Award Amount (including Indirect Costs): $1,339,017
Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
7. 2023	0.3 calendar

Name of Individual: **Broder, Christopher**
Commons ID: (b) (6)

Title: Advancement of Vaccines and Therapies for Henipaviruses

Major Goals: The primary objective of the Center is to perform pivotal studies that will facilitate the development of products used for the prevention and treatment of Nipah and Hendra infections. All three RPs, and Center Cores: Administrative; human monoclonal antibody; and Biosafety Level (BSL)-4 work together to provide broadly effective countermeasures.

Overlap: None. This program is focused on vaccine and antiviral monoclonal antibody countermeasure development. It uses recombinant CedV and recombinant CedV chimeras to measure virus neutralizing potencies of antibodies and to develop novel vaccine platforms and small animal models. Not antiviral drug discovery.

Status of Support: Active

Project Number: U19AI142764

Name of PD/PI: Broder, C.

Source of Support: NIAID/NIH (CETR)

Primary Place of Performance: USUHS, Bethesda, MD

Project/Proposal Start and End Date: (MM/YYYY): 03/01/19 – 02/28/24

Total Award Amount (including Indirect Costs): $24,587,556

Person Months (Calendar/Academic/Summer) per budget period.

Title: Biosurveillance for Spillover of Henipaviruses and Filoviruses in Rural Communities in India

Major Goals: The major goals of this project are to enhance early detection and surveillance capacity in India.

Status of Support: Active

Project Number: HDTRA12010026

Name of PD/PI: Epstein, Jonathan

Source of Support: Subaward from EcoHealth Alliance / DTRA

Primary Place of Performance: USUHS, Bethesda, MD

Project/Proposal Start and End Date: (MM/YYYY): 10/01/2020-9/30/2023

Total Award Amount (including Indirect Costs): $175,000

Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
3. 2023	0.6 calendar

Name of Individual: **Broder, Christopher**
Commons ID: (b) (6)

Title: Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

Major Goals: The major goals of this project is to develop multidisciplinary teams of investigators in the program will conduct pathogen/host surveillance, study pathogen transmission, pathogenesis and immunologic responses in the host, and will develop reagents and diagnostic assays for improved detection for important emerging pathogens and their vectors.

Status of Support: Active

Project Number: U01AI151797 NIH/NIAID/CREID 07-049-7012-52338

Name of PD/PI: Daszak, P.

Source of Support: Subaward from EcoHealth Alliance / CREID, NIAID, NIH

Primary Place of Performance: USUHS, Bethesda, MD

Project/Proposal Start and End Date: (MM/YYYY): 06/17/2020-05/31/2024

Total Award Amount (including Indirect Costs): $136,903

Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)

Commons ID: (b) (6)

Title: Establishment of a Bat Resource for Infectious Disease Research

Major Goals: The major goals of this proposal is to contribute significant insight into the viral determinants that confer henipaviral pathogenesis. The construction and generation of recombinant henipavirus chimeric viruses will be the primary means for determining how virus receptor usage and the expression of virulence factors act individually or in conjunction to cause limited or severe disease. The recombinant constructs generated from the proposed studies will also be used to determine host determinants of immunity in Jamaican fruit bats and animal models.

Status of Support: Pending

ALL PERSONNEL REPORT

Place this form at the end of the signed original copy of the application. Do not duplicate.

GRANT NUMBER
U19AI171413

Always list the PD/PI(s). In addition, list all other personnel who participated in the project during the current budget period for at least one person month or more, regardless of the source of compensation (a person month equals approximately 160 hours or 8.3% of annualized effort). Use the following abbreviated categories for describing Role on Project:

- **PD/PI**
- **Co-Investigator**
- **Faculty**
- **Postdoctoral (scholar, fellow, or other postdoctoral position)**
- **Technician**
- **Staff Scientist (doctoral level)**
- **Statistician**
- **Graduate Student (research assistant)**
- **Non-student Research Assistant**
- **Undergraduate Student**
- **High School Student**
- **Consultant**
- **Other (please specify)**

If personnel are supported by a Reentry or Diversity Supplement please indicate such after the Role on Project, using the following abbreviations: RS - Reentry Supplement; DS - Diversity Supplement.

Use Cal (calendar), Acad, or Summer to enter months devoted to project.

Commons ID	Name	Degree(s)	SSN (last 4 digits)	Role on Project	DoB (MM /YY)	Cal	Acad	Summer

Subject: URGENT: Revised Format for the Annual Progress Report for 1U19AI171413-01
Importance: High

Dear Dr. Shi and Authorized Institutional Official,

NIH has identified issues with the submission of Multi-Year Funded Research Performance Progress Reports (RPPRs) using the eRA Commons, consequently **all AViDD awardees must now use the PHS 2590 format** instead of the eRA Commons to prepare and submit the Annual Progress Report for Year 1. **Please disregard the instructions previously transmitted via the email sent in November 2022**.

Please see the attached instructions for the PHS 2590 format and the Revised AViDD Progress Report Guidelines. The additional information being requested in the Revised AViDD Progress Report Guidelines is the same as the previous version, however, for the PHS 2590 format you will now provide this information using Form page 5 instead of sections noted in the previous version.

The PHS 2590 forms can be downloaded from: https://grants.nih.gov/grants/funding/2590/2590.htm

The Annual Progress Report will contain separate reports for each component of your AViDD. You will create a separate PHS 2590 report for the AViDD Overall progress, each Research Project, and each Core, and these will be combined to generate the Annual Progress Report.

The separate reports for each component will contain:

Form Page 1: Face Page – leave Items 8a and 8b blank

Form Page 1-continued: Additional form if Multiple PIs are involved

Project/Performance Site Format Page - use only if additional space is needed

Biographical Sketch: Complete a Biographical Sketch for all new senior/key personnel since the previous submission. Use form available from https://grants.nih.gov/grants/forms/biosketch.htm

Other Support: Include other active support for all senior/key personnel whose support has changed during the past year and indicate what the change has occurred. Use form available from https://grants.nih.gov/grants/forms/othersupport.htm

Form Page 5: Progress Report Summary - this form will be used to provide both the additional information required for AViDD awards as well as the standard information required for a Progress Report. Please refer to the Revised AViDD Progress Report Guidelines for the additional information required to be included in the Progress Summary for the AViDD Overall, Research Project and Core reports.

Use the Continuation page after Form page 5 is full for this section and any other sections that require additional pages after the initial form.

Form Page 6: Checklist

Form Page 7: All Personnel Report

If Human Subjects Research is being conducted - include the PHS Inclusion Enrollment Report

Please refer to the attached Revised AViDD Progress Report Guidelines and the phs2590 General Instructions found on pages 5 through 17 for guidance about the information required for each section.

Because your AViDD award is a Multi-Year Funded award you are not required to submit Detailed Budget for Next Budget Period or Budget Justification pages as part of the Annual Progress Report. In addition, carry forward requests are not required during the remaining time of the Multi-Year Funded project period. However, if the situation arises, please note, prior approval is still required for compliance with the significant rebudgeting policy as stated in the NIH Grants Policy Statement https://grants.nih.gov/policy/nihgps/index.htm:

Significant rebudgeting, whether or not the particular expenditure(s) require prior approval: Significant rebudgeting occurs when expenditures in a single direct cost budget category deviate (increase or decrease) from the categorical commitment level established for the budget period by 25 percent or more of the total direct costs awarded. For example, if the award budget for total direct costs is $200,000, any rebudgeting that would result in an increase or decrease of more than $50,000 in a budget category is considered significant rebudgeting

To submit the report, your Authorized Institutional Official will email the entire Annual Progress Report to Regina Kitsoulis, who is the NIAID Grants Management Official for this award, and me.

These reports are due by the project anniversary date (05/16/2023) for your award and can be submitted anytime between now and then. As noted above, please read through the Revised AViDD Report Guidelines and the PHS 2590 instructions. If questions remain, then please have your business official contact Regina Kitsoulis and me.

We apologize for the inconvenience.

Sincerely yours,

Ping

Funding Opportunity Purpose

This Funding Opportunity Announcement (FOA) solicits applications to participate in the Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Network. The purpose of this FOA is to establish comprehensive, cooperative basic and translational research Centers to carry out in-depth research on prototype members of select virus families that have the potential to emerge as pandemic pathogens. The goal of these Centers will be to develop vaccine and monoclonal antibody strategies for prototype pathogen(s) that can be applied to closely related family members based on shared functional and structural properties. This FOA solicits for centers proposing research on virus families from Bunyavirales, Paramyxoviridae and Picornaviridae to be part of the ReVAMPP Network.

Required Application Instructions

It is critical that applicants follow the Multi-Project (M) Instructions in the SF424 (R&R) Application Guide (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82400), except where instructed to do otherwise (in this FOA or in a Notice from the *NIH Guide for Grants and Contracts* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11164)). Conformance to all requirements (both in the Application Guide and the FOA) is required and strictly enforced. Applicants must read and follow all application instructions in the Application Guide as well as any program-specific instructions noted in Section IV. When the program-specific instructions deviate from those in the Application Guide, follow the program-specific instructions. **Applications that do not comply with these instructions may be delayed or not accepted for review.**

There are several options available to submit your application through Grants.gov to NIH and Department of Health and Human Services partners. You **must** use one of these submission options to access the application forms for this opportunity.

1. Use the NIH ASSIST system to prepare, submit and track your application online.

   Apply Online Using ASSIST

2. Use an institutional system-to-system (S2S) solution to prepare and submit your application to Grants.gov and eRA Commons (https://public.era.nih.gov/commons/) to track your application. Check with your institutional officials regarding availability.

Part 2. Full Text of Announcement

Section I. Funding Opportunity Description

The National Institute of Allergy and Infectious Diseases (NIAID) supports complementary research programs to understand, control and prevent viral diseases and related pandemics. As part of pandemic preparedness planning, this Funding Opportunity Announcement (FOA) solicits applications to establish comprehensive, cooperative basic and translational research centers to 1) advance scientific knowledge needed to develop vaccines and monoclonal antibodies (mAbs) for prototype viral pathogens within virus families that have pandemic potential; and 2) leverage this information to develop and evaluate generalizable approaches for vaccines and mAbs for the prototype pathogens and other related family members based on shared functional and structural properties. Centers proposing research on select virus families from Bunyavirales, Paramyxoviridae and Picornaviridae are included in this FOA.

The ReVAMPP Network is comprised of ReVAMPP Centers from both this RFA (Bunyavirales, Paramyxoviridae and Picornaviridae) and its companion FOAs soliciting for ReVAMPP Centers focusing on Flaviviridae and Togaviridae (see RFA-AI-23-019 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-019.html)) and the ReVAMPP Coordinating and Data Sharing Center (CDSC) (see RFA-AI-23-021 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-021.html)). ReVAMPP Centers will conduct independent research project(s) and are expected to share information and collaborate within the Network under the direction of the ReVAMPP CDSC which is responsible for establishing and maintaining a collaborative ReVAMPP Network platform for data sharing and overall collaboration among the ReVAMPP Centers.

In the event of an outbreak, the ReVAMPP Centers will be poised to leverage the expertise and resources within the network to assist in a coordinated research response. This new NIAID Network will align with the goals of the American Pandemic Preparedness Plan: Transforming Our Capabilities (AP3) (https://www.whitehouse.gov/wp-content/uploads/2021/09/American-Pandemic-Preparedness-Transforming-Our-Capabilities-Final-For-Web.pdf), which was announced in September 2021, and recognizes the need for a trans-government investment and response to combat future pandemics and NIAID's Pandemic Preparedness Plan (https://www.niaid.nih.gov/sites/default/files/pandemic-preparedness-plan.pdf).

Background

The emergence and re-emergence of infectious diseases continues to threaten the health of Americans and people worldwide. Over the past two decades, the public health community has responded to emerging infectious diseases including those caused by Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV-1), the 2009 H1N1 influenza virus, Middle East Respiratory Syndrome Coronavirus (MERS-CoV), Ebola virus, Zika virus, and most recently, SARS-CoV-2. The global pandemic caused by SARS-CoV-2 further underscores the continual threat of newly emerging and re-emerging pathogens and the critical value of basic and translational research for pandemic preparedness. The unprecedented rapid development of vaccines and mAbs for SARS-CoV-2 was enabled by decades of foundational research on related coronaviruses which allowed scientists to quickly and effectively respond once SARS-CoV-2 emerged. In recent years, considerable resources have been invested in vaccine and mAb development for coronavirus and influenza viruses to prepare for the next pandemic from these families. However, viruses from other families also propose substantial risk of causing a pandemic. Thus, continuing to build a robust basic research portfolio and advancing translational science for other viral families with pandemic potential is essential for biomedical countermeasure preparedness. In addition to known threats, effective preparedness must also account for unexpected emerging disease threats. To mitigate risks associated with these yet-unknown pathogens, NIAID's intent for the ReVAMPP Network is to promote focused research needed to develop vaccines and mAbs for prototype-pathogens from viral families known to infect humans (Graham BS and Corbett KS J Clin Invest. 2020; 130(7):3348-3349 (https://www.jci.org/articles/view/139601), Cassetti MC, et al., JID. D022; jiac296). (https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiac296/6649664?login=true) As defined in this FOA, a prototype pathogen is a representative virus from which research on the virology, pathology and immunology of the prototype will generate generalizable knowledge, and in turn vaccine and mAb strategies, which can be applied to other members of the viral family. As the prototype pathogen approach proposes, viruses are organized into families based upon shared functional and structural similarities and thus candidate vaccine strategies developed against a prototype pathogen may similarly work against other members in the same family. Through targeted basic and applied research on these prototype pathogens, a solid foundation of knowledge will enable a rapid response when a previously unknown (or known but understudied) pathogen emerges or spreads from any of the known high-risk viral families. This anticipatory approach will increase the knowledge base needed for preparedness and enable rapid development and translation of candidate vaccines and mAbs into clinical trials and large-scale production.

Research Objectives and Scope

The objective of this FOA is to establish multidisciplinary research Centers to be part of the highly collaborative ReVAMPP Network focused on in-depth basic and translational research on prototype members of certain virus families that have the potential to emerge as pandemic pathogens, namely Paramyxoviridae, Picornaviridae and Bunyavirales including Arenaviridae, Hantaviridae, Nairoviridae, Phenuiviridae, and Peribunyaviridae. The major goal of these Centers will be to develop vaccine strategies for prototype pathogens that can be applied to other closely related family members based on shared functional and structural properties. Additionally, these Centers may perform basic research to expand foundational knowledge of virology, pathology, and immunology, or perform early development activities for mAbs for prototype viruses. Towards these goals, each Center will encompass a multi-project multidisciplinary research program that employs innovative virology, structural biology, and immunology to identify strategies for vaccine design. Each Center will collaborate across the ReVAMPP Network through the sharing of data, reagents, protocols, and animal models to facilitate advancement toward pandemic preparedness for all virus families.

Priority Viral Families for Pandemic Preparedness

A prototype pathogen is a representative virus from which research on the virology, pathology and immunology of the prototype will generate generalizable knowledge, and in turn vaccine and mAb strategies, which can be applied to other members of the virus family. For this FOA, each ReVAMPP Center will support a multi-project research program directed towards enabling basic and translational research and development of vaccines, and optionally early development of mAbs, against prototype viruses from one or more of the following selected virus families of pandemic potential, and Centers are encouraged to work on more than one virus family (listed alphabetically, all of equivalent priority):

- Bunyavirales
    - Arenaviridae (e.g., Lassa virus, Junin virus)
    - Hantaviridae (e.g., Andes virus, Sin Nombre virus, Hantaan orthohantavirus virus)
    - Nairoviridae (e.g., Crimean-Congo Hemorrhagic Fever virus (CCHF), Hazara virus)
    - Phenuiviridae (e.g., Rift Valley Fever virus, Severe Fever with thrombocytopenia syndrome virus, Punta Toro virus)
    - Peribunyaviridae (e.g., LaCrosse virus (LAC), Cache Valley virus)
- Paramyxoviridae (e.g., Menangle virus, HPIV1, HPIV3, Canine Distemper virus, Cedar virus)
- Picornaviridae (e.g., Enterovirus A71, Enterovirus D68, Echovirus B29, Rhinovirus C)

Centers are encouraged to include research projects focused on multiple virus families and may include a single prototype or multiple prototypes from a family. The investigators will determine which virus should serve as a prototype for a given family, but prototype selection must be justified. Considerations may include, but are not limited to, how well the prototype reflects properties shared by other members of the family, whether a single prototype is sufficient or whether multiple prototypes are needed to address differences amongst family members, the ease of working with the prototype virus, and whether vaccines against the prototype would have potential value for current public health needs.

These selected priority virus families of pandemic potential were identified by NIAID based on the ability to infect humans, the potential to cause a pandemic, and the current resources invested. The Coronaviridae and Orthomyxovirdae virus families were not included in this list as vaccine development and preparedness research for these families is supported through other mechanisms such as NOT-AI-21-002: Emergency Awards: Notice of Special Interest (NOSI) on Pan-Coronavirus Vaccine Development Program Projects (https://grants.nih.gov/grants/guide/notice-files/NOT-AI-21-002.html) and NIAID Centers of Excellence for Influenza Research and Surveillance (https://www.niaidceirs.org/), among others. In November 2021, NIAID convened a workshop titled "NIAID Workshop on Pandemic Preparedness: The Prototype Pathogen Approach to Accelerate Medical Countermeasures - Vaccines and Monoclonal Antibodies" where experts summarized current knowledge of the basic and translational research landscape, described research and intervention gaps, and proposed suitable prototype pathogens for further study and medical countermeasure development (Graham BS and Corbett KS J Clin Invest. 2020; 130(7):3348-3349 (https://www.jci.org/articles/view/139601), Cassetti MC, et al. JID. 2022;jiac296. (https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiac296/6649664)) This workshop highlighted the critical need to continue to expand basic research efforts and advance translational science for nine of the selected virus families. NIAID's intent for the ReVAMPP Network is to promote focused and coordinated research needed for the development of vaccines, and optionally early development of mAbs, for prototype-pathogens from virus families known to infect humans.

Research Areas

This FOA will support basic research such as virology studies to better understand cell tropism and receptor/entry requirements and to determine replication mechanisms, pathogenesis, and capacity for antigenic diversity. It will also support structural biology research to define the atomic-level details of surface proteins likely to be antigenic/immunologic targets. It will support research to assess the immune response in humans to natural infections and existing vaccines as well as determine correlates of immune protection, establish robust animal models, and develop reagents and new immunological assays.

This FOA will also support early and Investigational New Drug Application (IND)-enabling translational research for vaccines. Translational activities may include antigen/immunogen design and evaluation, screening technology platforms or adjuvants for immunogenicity and efficacy in animal models, development of assays and reagents, identification of correlates or surrogate markers of protection, lead optimization, stability, and manufacturability testing, and/or early process development. Once lead vaccine candidates/strategies have been identified, the same generalizable approach will be applied to other viruses within in the same family to validate the overall strategy for the virus family. Given the need to respond rapidly to emerging threats, the vaccine strategies should incorporate technologies that are amendable to antigen interchange and rapid manufacturing such as "plug and play" platforms.

The development of prototype vaccine strategies and structure-function characterization of the immune response to infection and vaccination is likely to result in the identification of mAbs with therapeutic potential. Thus, this FOA will support functional characterization of candidate mAbs and early translational activities for mAb development for prototype viruses. These activities may include discovery, *in vitro* characterization including epitope identification, neutralization potency, effector function analysis and structural studies, mAb optimization, determination of mechanism of action, *in vivo* evaluation including efficacy, dose titration, and route of administration studies in animal models, and candidate down-selection. If early mAb development is included, following the identification of lead mAb candidates for the prototype virus, it should be determined if antibodies with similar epitopes and/or properties are effective against other viruses within the same family.

Milestones

This FOA will utilize a bi-phasic, milestone-driven cooperative agreement award mechanism with Phase I consisting of the first 3 years, and Phase II consisting of years 4 and 5. Although applicants will apply for five years of funding, near the end of year 3 grantees will submit a transition package which will be evaluated by NIAID program staff for progress of research towards development of a generalizable vaccine strategy for the proposed viral family(ies), and if applicable early mAb development, and contribution to the ReVAMPP Network through data sharing and collaboration. The administrative review for funding of years 4 and 5 will be based on successful achievement of milestones included in the application and negotiated with the recipient prior to award, overall feasibility of program advancement,compliance with the ReVAMPP Network data sharing and CDSC requests, evidence of collaboration with other ReVAMPP Centers, programmatic priorities, and the availability of funding.

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required. For the purpose of this FOA, "industry" is defined as a large or small, domestic, or foreign, pharmaceutical, biotechnology, or bioengineering company, or a related non-profit entity. The establishment of these public-private-partnerships is expected to extend the reach of the Center's comprehensive translational efforts, helping to ensure a focused, critical path through early-phase clinical trials for the most promising candidates. Centers will be encouraged to create partnerships/in-licensing opportunities and intellectual property strategies in compliance with NIH Intellectual Property Policy (https://grants.nih.gov/policy/intell-property.htm) to support advancing promising vaccine, and if applicable mAb, candidates into the clinic and to allow for hand-off to industry for advanced development. Centers are encouraged to develop and use intellectual property strategies that promote accessibility, similar to efforts from the World Health Organization (WHO), NIAID, and Bill & Melinda Gates Foundation (BMGF) to make COVID-19 vaccine and mAbs technologies accessible for the developing world (COVID-19 technology access pool (https://www.who.int/initiatives/covid-19-technology-access-pool)).

NIAID Resources

Each ReVAMPP Center is expected to provide lead candidates for comparative studies using NIAID's preclinical services or other gap filling mechanisms. It is anticipated that after award NIAID's comprehensive suite of preclinical services (Resources for Researchers | NIH: National Institute of Allergy and Infectious Diseases (https://www.niaid.nih.gov/research/resources)), NIAID's Division of Allergy, Immunology, and Transplantation (DAIT) programs (Adjuvant Discovery Program (https://www.niaid.nih.gov/research/adjuvant-discovery-program), B cell and T cell Epitope Discovery program, etc.) and repositories could be leveraged as needed to support ReVAMPP objectives including reagent storage/development, assay and animal model harmonization and evaluation, and development of lead vaccine and mAb candidates developed under this Network. NIAID program officials will connect ReVAMPP investigators to these services.

ReVAMPP Network interactions

Collaboration and data sharing among ReVAMPP Centers and with external partners is key to successful achievement of the ReVAMPP network goals. Therefore, each ReVAMPP Center must adopt FAIR data principles (https://www.go-fair.org/fair-principles/) as per the NIH Data Management Sharing Plan (DMSP (https://sharing.nih.gov/data-management-and-sharing-policy)) and manage and rapidly share data within the Network of ReVAMPP Centers under the direction of the ReVAMPP CDSC. This data will be shared confidentially within the Network to harmonize reagents, assays, and animal models and exchange knowledge on structure/function-based vaccine solutions and antigen/immunogen designs as well as assess the utility of vaccine technology platforms for virus families. To assist in the administration and management of information exchange, a separate ReVAMPP CDSC will be directing these efforts for the Network. The ReVAMPP CDSC will facilitate collaboration within and outside the Network, and each ReVAMPP Center will be expected to comply in accordance with network-wide timelines. As such, the CDSC will develop network-wide data sharing platforms and templates for all types of data generated by the ReVAMPP Centers. This may include information/data related to reagents, tools, assays, models, vaccine technology platforms, immune epitope design and/or correlates of protection. The CDSC will also develop, in conjunction with the Centers, a network wide ReVAMPP governance structure, provide guidance as to engagement with stakeholders within and outside the research centers, and collate information and facilitate exchange with other NIAID Programs, U.S. Government partners and other key stakeholders, including the WHO, BMGF, and Coalition for Epidemic Preparedness Innovations (CEPI), among others as appropriate.

ReVAMPP Center Structure

Each Center in the ReVAMPP Network will be organized around a multidisciplinary research program with interrelated projects focused on the prototype member(s) of virus families that have the potential to emerge as pandemic pathogens to inform a strategy for development of vaccines for the prototype pathogen and other closely related family members based on shared functional and structural properties, with the objective of translating research results to product development. Each Center is expected to include the following components:

Administrative Core

An Administrative Core will manage, coordinate, and supervise all Center activities under the direction of the Program Director(s)/Principal Investigator(s) (PD(s)/PI(s). The Administrative Core will also ensure seamless communication across the projects through regular meetings of Center participants and the ReVAMPP network as directed by the ReVAMPP CDSC. In addition, the Administrative Core will coordinate detailed communication of Center efforts and progress with NIAID program staff, including organizing annual ReVAMPP Center progress meetings with NIAID, and participating and assisting with ReVAMPP Network meetings as necessary virtually and/or at NIAID. The Administrative Core will also be responsible for leading coordination and collaboration efforts with the CDSC and other Centers within the Network and ensuring the Center program complies with requests from the CDSC and NIAID program staff.

Scientific Advisory Board

Each Center will include a Scientific Advisory Board (SAB) that will act as an independent, external advisory body for the PD(s)/PI(s) but will not be involved in the day-to-day activities of the Center. The SAB will facilitate Go/No-Go decision making and recommend new research directions as appropriate. The SAB will participate in annual ReVAMPP Center progress meetings at NIAID to review Center activities and evaluate progress, adherence to milestones and timelines, and the continued relevance of each Research Project, including those within industry partnerships, to the overall Center objective(s). If requested by the PD(s)/PI(s) and NIAID Project Scientist, the SAB will provide a summary written evaluation of the group's activities and recommendations following the annual ReVAMPP Center progress meeting. The SAB will include at least 5 non-conflicted external advisors. Centers must have at least 2 of the external advisors who have demonstrated and relevant industry-level expertise. SAB membership will be established in consultation with NIAID program staff. *Potential external SAB members MUST NOT be named in the application or contacted prior to completion of review activities.*

Data Management Core

A Data Management Core will be responsible for housing data generated by the Center and managing the transfer of data within the Center and to the ReVAMPP Network as directed by the ReVAMPP CDSC, including the upload of data to the ReVAMPP Network data sharing platforms. The Data Management Core will also be responsible for collating and collecting information from the Center as requested by the ReVAMPP CDSC or NIAID program staff in accordance with network-wide timelines, and ensuring the Center complies with network data sharing policies.

Scientific Cores

A Center may include up to three Scientific Cores to support resources and/or facilities that are essential for the activities of two or more Research Projects, but inclusion of Scientific Cores is not required. Scientific Cores are intended to only serve the needs of Center project researchers and they may not conduct research independent of the Research Projects. In lieu of a Scientific Core, use of existing institutional core facilities may be included in specific Research Projects.

Research Projects

Each Center must include at least 2 and no more than 5 interdependent Research Projects focused on prototype members of the priority virus families of pandemic potential listed above. At least one Research Project must focus on development of vaccines, and other Research Projects may focus on additional vaccine development, early mAb development or foundational research in virology, immunology, pathology, and structural biology necessary for such development. Each Research Project must clearly and directly contribute to the Center's approach and objective(s). The Center PD(s)/PI(s) will monitor all Research Projects and actively promote efforts that foster integration, collaboration, and synergy across the program. Research Project Leaders may be affiliated with either an academic organization or industry.

Research Projects are expected to incorporate state-of-the-art technology and approaches and may include consortium arrangements for required activities. Applicants are encouraged to carefully consider the scope and range of research proposed and develop a Center that is coherent overall and consistent with available resources and personnel.

Example ReVAMPP Centers:

Center programs and objectives may range from research and development of single or multiple prototype vaccines targeting one or more of the priority virus families, and activities may range from early basic research aimed at gaining the foundational knowledge needed to design a generalizable vaccine strategy, to mAb discovery and characterization to late-stage preclinical vaccine development with industry participation. Examples of hypothetical ReVAMPP Centers follow:

Example 1:

Center for Countermeasure Discovery for Bunyaviruses

Administrative Core

Data Management Core

Scientific Core: Virology, Reagents, and Assays

Scientific Core: Structural Biology of Viral Proteins, Vaccines, and Monoclonal Antibodies

Research Project 1: Viral receptor discovery and characterization for Nairoviruses and Peribunyaviruses

Research Project 2: Characterization of the human immune response and antibody discovery

Research Project 3: Antigen design and immunogenicity evaluation of Nairovirus vaccines

Research Project 4: Animal model development and determination of CCHF and LAC pathogenesis

Research Project 5: Antigen design and immunogenicity evaluation of Peribunyavirus vaccines

Example 2:

Paramyxovirus and Arenavirus Vaccine and Monoclonal Antibody Development Center

Administrative Core

Data Management Core

Scientific Core: Animal model development and candidate vaccine and monoclonal antibody evaluation

Research Project 1: Antigen design and immunogenicity testing of Paramyxovirus vaccine candidates

Research Project 2: Antigen design and immunogenicity testing of Arenavirus vaccine candidates

Research Project 3: Determination of correlates of protection for different vaccine platforms

Research Project 4: Preclinical evaluation of monoclonal antibodies targeting paramyxoviruses and arenaviruses

Applications including the following types of studies will be considered non-responsive and will not be reviewed:

- Clinical trials: Clinical research may be supported but not clinical trials, as defined by the NIH (https://grants.nih.gov/policy/clinical-trials/definition.htm (https://grants.nih.gov/policy/clinical-trials/definition.htm)).
- Centers proposing only monoclonal antibody discovery and development without vaccine development.
- Projects proposing toxicology studies or GMP manufacturing for vaccines.
- Projects proposing later-stage development of monoclonal antibodies including process development, tissue cross-reactivity studies, toxicology studies, or GMP manufacturing.
- Centers proposing research on Coronaviridae, Orthomyxoviridae or other virus families not listed under *Priority Viral Families for Pandemic Preparedness*.
- Centers proposing research on Flaviviridae or Togaviridae families which are covered in the companion RFA-AI-22-019 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-22-019.html)

- Applications that do not include a clear section on Milestones with Go/No-Go criteria for the Overall Program and each individual project.

This FOA supports research on virus families from Bunyavirales, Paramyxoviridae and Picornaviridae. For ReVAMPP Center programs proposing research on virus families from Flaviviridae and Togaviridae see the companion FOA, RFA-AI-23-019 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-019.html). The ReVAMPP Coordinating and Data Sharing Center (CDSC) will oversee data coordination and sharing for the ReVAMPP Centers in the ReVAMPP Network (companion FOA, RFA-AI-23-021 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-021.html)).

For additional information about the Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers), see the "Frequently Asked Questions (FAQ)" link here: https://www.niaid.nih.gov/grants-contracts/questions-and-answers-revampp-funding-opportunities (https://www.niaid.nih.gov/grants-contracts/questions-and-answers-revampp-funding-opportunities).

Webinar Announcement

NIAID plans to hold a pre-application informational webinar for this FOA. Details about webinar registration will be available at this same FAQ link shortly after FOA publication. Participation in the webinar is not required to submit an application in response to this FOA.
See Section VIII. Other Information for award authorities and regulations.

Section II. Award Information

Funding Instrument

Cooperative Agreement: A support mechanism used when there will be substantial Federal scientific or programmatic involvement. Substantial involvement means that, after award, NIH scientific or program staff will assist, guide, coordinate, or participate in project activities. See Section VI.2 for additional information about the substantial involvement for this FOA.

Application Types Allowed

New

The OER Glossary (//grants.nih.gov/grants/guide/url_redirect.htm?id=11116) and the SF424 (R&R) Application Guide provide details on these application types. Only those application types listed here are allowed for this FOA.

Clinical Trial?

Not Allowed: Only accepting applications that do not propose clinical trials.

Need help determining whether you are doing a clinical trial? (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82370)

Funds Available and Anticipated Number of Awards

NIAID intends to commit ~$70-85M in FY2024 to fund 5-6 awards. Funding in subsequent years is subject to the availability of funds.

Award Budget

Application budgets are not expected to exceed $10M direct costs/year and need to reflect the actual needs of the proposed project.

Award Project Period

The scope of the proposed project should determine the project period. The maximum period is 5 years.

NIH grants policies as described in the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120) will apply to the applications submitted and awards made from this FOA.

Section III. Eligibility Information

1. Eligible Applicants

Eligible Organizations

Higher Education Institutions

- Public/State Controlled Institutions of Higher Education
- Private Institutions of Higher Education

The following types of Higher Education Institutions are always encouraged to apply for NIH support as Public or Private Institutions of Higher Education:

- Hispanic-serving Institutions
- Historically Black Colleges and Universities (HBCUs)
- Tribally Controlled Colleges and Universities (TCCUs)
- Alaska Native and Native Hawaiian Serving Institutions
- Asian American Native American Pacific Islander Serving Institutions (AANAPISIs)

Nonprofits Other Than Institutions of Higher Education

- Nonprofits with 501(c)(3) IRS Status (Other than Institutions of Higher Education)
- Nonprofits without 501(c)(3) IRS Status (Other than Institutions of Higher Education)

For-Profit Organizations

- Small Businesses
- For-Profit Organizations (Other than Small Businesses)

Local Governments

- State Governments
- County Governments
- City or Township Governments
- Special District Governments
- Indian/Native American Tribal Governments (Federally Recognized)
- Indian/Native American Tribal Governments (Other than Federally Recognized)

Federal Governments

- Eligible Agencies of the Federal Government
- U.S. Territory or Possession

Foreign Institutions

Non-domestic (non-U.S.) Entities (Foreign Institutions) **are** eligible to apply.

Non-domestic (non-U.S.) components of U.S. Organizations **are** eligible to apply.

Foreign components, as defined in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11118), **are** allowed.

Required Registrations

Applicant organizations

Applicant organizations must complete and maintain the following registrations as described in the SF 424 (R&R) Application Guide to be eligible to apply for or receive an award. All registrations must be completed prior to the application being submitted. Registration can take 6 weeks or more, so applicants should begin the registration process as soon as possible. The NIH Policy on Late Submission of Grant Applications (//grants.nih.gov/grants/guide/notice-files/NOT-OD-15-039.html) states that failure to complete registrations in advance of a due date is not a valid reason for a late submission.

- System for Award Management (SAM) (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82390) – Applicants must complete and maintain an active registration, **which requires renewal at least annually**. The renewal process may require as much time as the initial registration. SAM registration includes the assignment of a Commercial and Government Entity (CAGE) Code for domestic organizations which have not already been assigned a CAGE Code.
    - NATO Commercial and Government Entity (NCAGE) Code (//grants.nih.gov/grants/guide/url_redirect.htm?id=11176) – Foreign organizations must obtain an NCAGE code (in lieu of a CAGE code) in order to register in SAM.
    - Unique Entity Identifier (UEI) - A UEI is issued as part of the SAM.gov registration process. The same UEI must be used for all registrations, as well as on the grant application.
- eRA Commons (https://era.nih.gov/) - Once the unique organization identifier is established, organizations can register with eRA Commons in tandem with completing their Grants.gov registration; all registrations must be in place by time of submission. eRA Commons requires organizations to identify at least one Signing Official (SO) and at least one Program Director/Principal Investigator (PD/PI) account in order to submit an application.
- Grants.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=82300) – Applicants must have an active SAM registration in order to complete the Grants.gov registration.

Program Directors/Principal Investigators (PD(s)/PI(s))

All PD(s)/PI(s) must have an eRA Commons account. PD(s)/PI(s) should work with their organizational officials to either create a new account or to affiliate their existing account with the applicant organization in eRA Commons. If the PD/PI is also the organizational Signing Official, they must have two distinct eRA Commons accounts, one for each role. Obtaining an eRA Commons account can take up to 2 weeks.

Eligible Individuals (Program Director/Principal Investigator)

Any individual(s) with the skills, knowledge, and resources necessary to carry out the proposed research as the Program Director(s)/Principal Investigator(s) (PD(s)/PI(s)) is invited to work with his/her organization to develop an application for support. Individuals from diverse backgrounds, including underrepresented racial and ethnic groups, individuals with disabilities, and women are always encouraged to apply for NIH support. See, Reminder: Notice of NIH's Encouragement of Applications Supporting Individuals from Underrepresented Ethnic and Racial Groups as well as Individuals with Disabilities, NOT-OD-22-019 (https://grants.nih.gov/grants/guide/notice-files/NOT-OD-22-019.html).

For institutions/organizations proposing multiple PDs/PIs, visit the Multiple Program Director/Principal Investigator Policy and submission details in the Senior/Key Person Profile (Expanded) Component of the SF424 (R&R) Application Guide.

Applicants listed as a PD(s)/PI(s) for this FOA will not be eligible to be listed as PD(s)/PI(s) on applications submitted to the companion FOA (RFA-AI-23-019) (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-019.html) ReVAMPP Centers for Flaviviridae and Togaviridae but can participate as collaborators on subcomponents of those Centers. Applicants to this FOA will not be eligible to submit to or participate in the companion ReVAMPP CDSC FOA (RFA-AI-23-021 (https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-021.html)) due to the centralized role of the CDSC in the Network coordination and communication.

2. Cost Sharing

This FOA does not require cost sharing as defined in the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11126).

3. Additional Information on Eligibility

Number of Applications

Applicant organizations may submit more than one application, provided that each application is scientifically distinct.

The NIH will not accept duplicate or highly overlapping applications under review at the same time, per 2.3.7.4 Submission of Resubmission Application (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_2/2.3.7_policies_affecting_applications.htm#Submissi). This means that the NIH will not accept:

- A new (A0) application that is submitted before issuance of the summary statement from the review of an overlapping new (A0) or resubmission (A1) application.
- A resubmission (A1) application that is submitted before issuance of the summary statement from the review of the previous new (A0) application.
- An application that has substantial overlap with another application pending appeal of initial peer review (see 2.3.9.4 Similar, Essentially Identical, or Identical Applications (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_2/2.3.9_application_receipt_information_and_deadlines.htm#Similar,)).

Section IV. Application and Submission Information

1. Requesting an Application Package

The application forms package specific to this opportunity must be accessed through ASSIST or an institutional system-to-system solution. A button to apply using ASSIST is available in Part 1 of this FOA. See your administrative office for instructions if you plan to use an institutional system-to-system solution.

2. Content and Form of Application Submission

It is critical that applicants follow the Multi-Project (M) Instructions in the SF424 (R&R) Application Guide (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82400), except where instructed in this funding opportunity announcement to do otherwise and where instructions in the Application Guide are directly related to the Grants.gov downloadable forms currently used with most NIH opportunities. Conformance to the requirements in the Application Guide is required and strictly enforced. Applications that are out of compliance with these instructions may be delayed or not accepted for review.

Letter of Intent

Although a letter of intent is not required, is not binding, and does not enter into the review of a subsequent application, the information that it contains allows IC staff to estimate the potential review workload and plan the review.

By the date listed in Part 1. Overview Information, prospective applicants are asked to submit a letter of intent that includes the following information:

- Descriptive title of proposed activity
- Name(s), address(es), and telephone number(s) of the PD(s)/PI(s)
- Names of other key personnel
- Participating institution(s)
- Number and title of this funding opportunity

The letter of intent should be sent to:

Frank De Silva, Ph.D.
Telephone: 240-669-5023
Email: fdesilva@niaid.nih.gov (mailto:fdesilva@niaid.nih.gov)

Page Limitations

All page limitations described in the SF424 Application Guide and the Table of Page Limits (//grants.nih.gov/grants/guide/url_redirect.htm?id=11133) must be followed.

Component	Component Type for Submission	Page Limit	Required/Optional	Minimum	Maximum
Overall	Overall	12	Required	1	1
Admin Core	Admin Core	12	Required	1	1
Data Management Core	Data Management Core	6	Required	1	1
Core	Core	6	Optional	0	3
Project	Project	12	Required	2	5

Instructions for the Submission of Multi-Component Applications

The following section supplements the instructions found in the SF424 (R&R) Application Guide and should be used for preparing a multi-component application.

The application should consist of the following components:

Overall: required

Administrative Core: required

Data Management Core: required

Scientific Cores: optional, maximum 3, each Scientific Core must support at least two Research Projects

Projects: required, minimum 2, maximum 5

Overall Component

When preparing your application, use Component Type ‘Overall’.

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions, as noted.

SF424(R&R) Cover (Overall)

Complete entire form.

PHS 398 Cover Page Supplement (Overall)

Note: Human Embryonic Stem Cell lines from other components should be repeated in cell line table in Overall component.

Research & Related Other Project Information (Overall)

Follow standard instructions.

Facilities & Other Resources

Describe any unique features in the environment and/or resources that make this a strong research program.

In the " Facilities & Other Resources" attachment include a clearly marked section titled “BSL3/4 facilities” detailing availability of adequate access to BSL3/4 biocontainment facilities to support the proposed Center program, if applicable. Applicants must identify all Research Projects within the application that will require BSL3/4 containment facilities and provide a description of facilities including that are available currently or planned at either the applicant institution or though consortium institutions. A table format may be used to list each activity that requires BSL3/4 access and the likely facilities to be used. All information on BSL3/4 facilities should be contained in the Overall and not within individual Research Projects.

If institutional core facilities will be utilized, in a clearly marked section titled "Institutional Core Facilities" describe how institutional core facilities will be used to support the Research Projects.

Project/Performance Site Locations (Overall)

Enter primary site only.

A summary of Project/Performance Sites in the Overall section of the assembled application image in eRA Commons compiled from data collected in the other components will be generated upon submission.

Research and Related Senior/Key Person Profile (Overall)

Include only the Project Director/Principal Investigator (PD/PI) and any multi-PDs/PIs (if applicable to this FOA) for the entire application.

A summary of Senior/Key Persons followed by their Biographical Sketches in the Overall section of the assembled application image in eRA Commons will be generated upon submission.

Budget (Overall)

The only budget information included in the Overall component is the Estimated Project Funding section of the SF424 (R&R) Cover.

A budget summary in the Overall section of the assembled application image in eRA Commons compiled from detailed budget data collected in the other components will be generated upon submission.

PHS 398 Research Plan (Overall)

Specific Aims: List in priority order, the broad, long-range objectives, and goals of the proposed Center. Concisely describe the Center objectives.

Research Strategy: This narrative section summarizes the overall research plan for the multi-project application. The multi-project application should be viewed as a confederation of interrelated research projects, each capable of standing on its own scientific merit, but complementary to one another. This is an important section for it provides the group of investigators an opportunity to give conceptual wholeness to the overall program – by giving a statement of the general problem area and by laying out a broad strategy for attacking the problems.

Applicants should clearly define the Center program and its significance regarding the scientific approach in terms of discovery and development of vaccines, and if applicable early development of mAbs, against prototype viruses from families with high pandemic potential. Discuss the rationale behind the overall approach and prototype selected for research and development including the public health need and benefit of a successful effort, and the range of activities being pursued. For the prototype selection justification, considerations may include, but are not limited to, how well the prototype reflects properties shared by other members of the family, whether a single prototype is sufficient or whether multiple prototypes are needed to address differences amongst family members, the ease of working with the prototype virus, and whether vaccines against the prototype would have potential value for current public health needs. Include a discussion of the current state of foundational knowledge and maturity of product development for the proposed virus families, and how this Center program will advance vaccine development, and if applicable, early development of mAbs, and enhance the ability to respond rapidly to an emerging virus from the prototype virus's family. Additionally, each application must detail how each Research Project and Core contributes to the Center program, objectives, and project interdependence. Applications should outline expected synergies provided by the proposed Center structure and any other special features that make this application strong or unique.

Milestone Plan: In a clearly labeled section titled "Program Milestones and Timelines", applicants should describe specific quantifiable milestones for the overall program, including detailed quantitative and qualitative criteria for Go/No-Go decisions by annum and include annual timelines for the overall research program and for tracking progress from individual research projects and Cores. This plan must include Go/No-Go criteria to be met by the end of Year 3 of the award for continuation to Phase II. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include major milestones from the individual research projects and Cores. Include any milestones that are integrated from independent research projects or Cores. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research Center.

Resource Sharing Plan:
Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide.

Other Plan(s):

Note: Effective for due dates on or after January 25, 2023, the Data Management and Sharing Plan will be attached in the Other Plan(s) attachment in FORMS-H application forms packages. If required, the Data Management and Sharing (DMS) Plan must be provided in the Overall component.

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions:

- All applicants planning research (funded or conducted in whole or in part by NIH) that results in the generation of scientific data are required to comply with the instructions for the Data Management and Sharing Plan. All applications, regardless of the amount of direct costs requested for any one year, must address a Data Management and Sharing Plan.
- Investigators must develop data structures that are FAIR (FAIR Principles - GO FAIR (go-fair.org) (https://gcc02.safelinks.protection.outlook.com/?url=https%3A%2F%2Fwww.go-fair.org%2Ffair-principles%2F&data=05%7C01%7Cchelsea.boyd%40nih.gov%7C8247f78a75c04c5ea99208db1b643066%7C14b77578977342d58507251ca2dc2b06%7C0%7C0%7C638133
This will produce data sets that are harmonized and facilitate progressive data sharing models. Applications must provide a well-thought-out plan for how data will be shared using the FAIR principles.

Appendix:

Only limited items are allowed in the Appendix. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide; any instructions provided here are in addition to the SF424 (R&R) Application Guide instructions.

PHS Human Subjects and Clinical Trials Information (Overall)

When involving human subjects research, clinical research, and/or NIH-defined clinical trials follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered "Yes" to the question "Are Human Subjects Involved?" on the R&R Other Project Information form, there must be at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information** form or a **Delayed Onset Study** record within the application. The study record(s) must be included in the component(s) where the work is being done, unless the same study spans multiple components. To avoid the creation of duplicate study records, a single study record with sufficient information for all involved components must be included in the Overall component when the same study spans multiple components.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed.

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start).All instructions in the SF424 (R&R) Application Guide must be followed.

PHS Assignment Request Form (Overall)

All instructions in the SF424 (R&R) Application Guide must be followed.

Administrative Core

When preparing your application, use Component Type ‘Admin Core.’

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions, as noted.

Note: Effective for due dates on or after January 25, 2023, the Data Management and Sharing Plan will be attached in the Other Plan(s) attachment in FORMS-H application forms packages. If required, the Data Management and Sharing (DMS) Plan must be provided in the Overall component.

SF424 (R&R) Cover (Administrative Core)

Complete only the following fields:

- Applicant Information
- Type of Applicant (optional)
- Descriptive Title of Applicant’s Project
- Proposed Project Start/Ending Dates

PHS 398 Cover Page Supplement (Administrative Core)

Enter Human Embryonic Stem Cells in each relevant component.

Research & Related Other Project Information (Administrative Core)

Human Subjects: Answer only the ‘Are Human Subjects Involved?’ and 'Is the Project Exempt from Federal regulations?’ questions.

Vertebrate Animals: Answer only the ‘Are Vertebrate Animals Used?’ question.

Project Narrative: Do not complete. Note: ASSIST screens will show an asterisk for this attachment indicating it is required. However, eRA systems only enforce this requirement in the Overall component and applications will not receive an error if omitted in other components.

Project /Performance Site Location(s) (Administrative Core)

List all performance sites that apply to the specific component.

Note: The Project Performance Site form allows up to 300 sites, prior to using additional attachment for additional entries.

Research & Related Senior/Key Person Profile (Administrative Core)

- In the Project Director/Principal Investigator section of the form, use Project Role of ‘Other’ with Category of ‘Project Lead’ and provide a valid eRA Commons ID in the Credential field.
- In the additional Senior/Key Profiles section, list Senior/Key persons that are working in the component.
- Include a single Biographical Sketch for each Senior/Key person listed in the application regardless of the number of components in which they participate. When a Senior/Key person is listed in multiple components, the Biographical Sketch can be included in any one component.
- If more than 100 Senior/Key persons are included in a component, the Additional Senior Key Person attachments should be used.

Budget (Administrative Core)

Budget forms appropriate for the specific component will be included in the application package.

- The Core Lead must commit at least 0.6 person months effort per year to these responsibilities.
- Include funds for the overall administrative effort, collaborative activities, communications, and publications.
- Include costs related to Regulatory expertise as defined effort or periodic consultation.
- Include funds for the PD(s)/PI(s), Project Leaders, additional Center Key Personnel and postdocs/researchers/students (at the discretion of the PD(s)/PI(s)), to travel and attend annual ReVAMPP Network-wide review meetings to be held over an approximately 1-3 full days in the Rockville, MD area or other NIAID-approved site for data presentation, progress evaluation and related activities.
- Include funds for the PD(s)/PI(s), Project Leaders, external SAB members, and additional Center Key Personnel (at the discretion of the PD/PI) to travel and attend annual mandatory ReVAMPP Center progress meetings at NIAID in Years 1-4 of the project period.

Note: The R&R Budget form included in many of the component types allows for up to 100 Senior/Key Persons in section A and 100 Equipment Items in section C prior to using attachments for additional entries. All other SF424 (R&R) instructions apply.

PHS 398 Research Plan (Administrative Core)

Specific Aims: List in priority order, the broad, long-range objectives, and goals of the proposed Core. In addition, state the Core's relationship to the Center’s program and how it relates to the individual Research Projects or other Cores in the application.

Research Strategy: The Administrative Core must include a Management Plan that identifies and discusses: The Administrative Core organizational structure, the roles of Administrative Core personnel, the facilitation of communications throughout the Center, including with industry partners and how a strong collaborative environment will be established within the Center. The plan should specifically address continual evaluation of research and development progress, communications, group meetings and teleconferences, the identification and proposed resolution of problems and engagement of the NIAID staff as appropriate. A description of how consortia (subcontracts) will be managed should be provided and should include how communications such as periodic meetings and conference calls will be organized, managed, and documented. The plan should also detail how Center and research-related travel will be managed.

Describe how the Center will coordinate communication and collaborations with the CDSC, NIAID Staff, and other Centers within the Network. Describe how the Administrative Core will ensure the Center program complies in a timely manner with requests from the CDSC and NIAID program staff.

Each Administrative Core must include the following:

Scientific Advisory Board: Describe the composition and duties of the Scientific Advisory Board (SAB), including the categories of expertise to be represented on the SAB and how the SAB will be utilized to guide Center activities. The description should include a discussion of how the proposed expertise of the SAB will be integrated into the operations of the Center. Describe the procedures and approaches for obtaining SAB input via teleconferences, ad hoc and annual meetings, review of written materials/data, etc. The SAB must include at least two members with relevant industry-level experience and procedures for identification and selection of the SAB should be included. *Candidates for the SAB MUST NOT be named in the application or contacted prior to completion of review activities.*

Resource Sharing Plan: Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide.

Appendix:

Only limited items are allowed in the Appendix. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide; any instructions provided here are in addition to the SF424 (R&R) Application Guide instructions.

PHS Human Subjects and Clinical Trials Information (Administrative Core)

When involving human subjects research, clinical research, and/or NIH-defined clinical trials follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered "Yes" to the question "Are Human Subjects Involved?" on the R&R Other Project Information form, you must include at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information form** or a **Delayed Onset Study** record.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetHumanSubjectStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start). All instructions in the SF424 (R&R) Application Guide must be followed.

Data Management Core

When preparing your application, use Component Type 'Data Management Core.'

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions, as noted.

Note: Effective for due dates on or after January 25, 2023, the Data Management and Sharing Plan will be attached in the Other Plan(s) attachment in FORMS-H application forms packages. If required, the Data Management and Sharing (DMS) Plan must be provided in the Overall component.

SF424 (R&R) Cover (Data Management Core)

Complete only the following fields:

- Applicant Information
- Type of Applicant (optional)
- Descriptive Title of Applicant's Project
- Proposed Project Start/Ending Dates

PHS 398 Cover Page Supplement (Data Management Core)

Enter Human Embryonic Stem Cells in each relevant component.

Research & Related Other Project Information (Data Management Core)

Human Subjects: Answer only the 'Are Human Subjects Involved?' and 'Is the Project Exempt from Federal regulations?' questions.

Vertebrate Animals: Answer only the 'Are Vertebrate Animals Used?' question.

Project Narrative: Do not complete. Note: ASSIST screens will show an asterisk for this attachment indicating it is required. However, eRA systems only enforce this requirement in the Overall component and applications will not receive an error if omitted in other components.

Project /Performance Site Location(s) (Data Management Core)

List all performance sites that apply to the specific component.

Note: The Project Performance Site form allows up to 300 sites, prior to using additional attachment for additional entries.

Research & Related Senior/Key Person Profile (Data Management Core)

- In the Project Director/Principal Investigator section of the form, use Project Role of 'Other' with Category of 'Core Lead' and provide a valid eRA Commons ID in the Credential field.
- In the additional Senior/Key Profiles section, list Senior/Key persons that are working in the component.
- Include a single Biographical Sketch for each Senior/Key person listed in the application regardless of the number of components in which they participate. When a Senior/Key person is listed in multiple components, the Biographical Sketch can be included in any one component.
- If more than 100 Senior/Key persons are included in a component, the Additional Senior Key Person attachments should be used.

Budget (Data Management Core)

Budget forms appropriate for the specific component will be included in the application package.

The Core Leader should commit to the Core at least 1.2 person months of effort.

Note: The R&R Budget form included in many of the component types allows for up to 100 Senior/Key Persons in section A and 100 Equipment Items in section C prior to using attachments for additional entries. All other SF424 (R&R) instructions apply.

PHS 398 Research Plan (Data Management Core)

Specific Aims: List in priority order, the broad, long-range objectives, and goals of the proposed Core. In addition, state the Core's relationship to the Center program and how it relates to the individual Research Projects or other Cores in the application.

Research Strategy: Describe the organizational structure and role of the Data Management Core in the overall Center research activities and include a Strategy for Management of Data Activities Plan that describes internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the Center to the ReVAMPP CDSC. Describe the quality control procedures for the data, and how to identify and resolve issues with quality control that maintains data integrity. Describe how the Data Management Core will ensure compliance with the ReVAMPP network-wide data sharing.

Resource Sharing Plan: Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide.

Appendix:

Only limited items are allowed in the Appendix. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide; any instructions provided here are in addition to the SF424 (R&R) Application Guide instructions.

PHS Human Subjects and Clinical Trials Information (Data Management Core)

When involving human subjects research, clinical research, and/or NIH-defined clinical trials follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered “Yes” to the question “Are Human Subjects Involved?” on the R&R Other Project Information form, you must include at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information** form or a **Delayed Onset Study** record.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start). All instructions in the SF424 (R&R) Application Guide must be followed.

Scientific Core

When preparing your application, use Component Type ‘Core.’

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions, as noted.

Note: Effective for due dates on or after January 25, 2023, the Data Management and Sharing Plan will be attached in the Other Plan(s) attachment in FORMS-H application forms packages. If required, the Data Management and Sharing (DMS) Plan must be provided in the Overall component.

SF424 (R&R) Cover (Scientific Core)

Complete only the following fields:

- Applicant Information
- Type of Applicant (optional)
- Descriptive Title of Applicant’s Project
- Proposed Project Start/Ending Dates

PHS 398 Cover Page Supplement (Scientific Core)

Enter Human Embryonic Stem Cells in each relevant component.

Research & Related Other Project Information (Scientific Core)

Human Subjects: Answer only the ‘Are Human Subjects Involved?’ and 'Is the Project Exempt from Federal regulations?’ questions.

Vertebrate Animals: Answer only the ‘Are Vertebrate Animals Used?’ question.

Project Narrative: Do not complete. Note: ASSIST screens will show an asterisk for this attachment indicating it is required. However, eRA systems only enforce this requirement in the Overall component and applications will not receive an error if omitted in other components.

Project /Performance Site Location(s) (Scientific Core)

List all performance sites that apply to the specific component.

Note: The Project Performance Site form allows up to 300 sites, prior to using additional attachment for additional entries.

Research & Related Senior/Key Person Profile (Scientific Core)

- In the Project Director/Principal Investigator section of the form, use Project Role of ‘Other’ with Category of ‘Core Lead’ and provide a valid eRA Commons ID in the Credential field.
- In the additional Senior/Key Profiles section, list Senior/Key persons that are working in the component.
- Include a single Biographical Sketch for each Senior/Key person listed in the application regardless of the number of components in which they participate. When a Senior/Key person is listed in multiple components, the Biographical Sketch can be included in any one component.
- If more than 100 Senior/Key persons are included in a component, the Additional Senior Key Person attachments should be used.

Budget (Scientific Core)

Budget forms appropriate for the specific component will be included in the application package.

The Core Leader should commit to the Core at least 1.2 person months of effort.

Note: The R&R Budget form included in many of the component types allows for up to 100 Senior/Key Persons in section A and 100 Equipment Items in section C prior to using attachments for additional entries. All other SF424 (R&R) instructions apply.

PHS 398 Research Plan (Scientific Core)

Specific Aims: List in priority order, the broad, long-range objectives, and goals of the proposed Core. In addition, state the Core's relationship to the Center program and how it relates to the individual Research Projects or other Cores in the application.

Research Strategy: Describe and justify the role of the Core in the overall Center research activities, describe how the proposed Core activities will contribute to meeting the Center's goals and objectives, specify how a proposed scientific Core provides a unique service that cannot be obtained through institutional or commercial means, and explain the rationale for selection of the general methods and approaches proposed to accomplish the specific aims. Describe the facilities or services that will be provided by the Core including procedures, techniques, and quality control to ensure high quality outputs. In addition, this section should indicate the relevance of the Core to the primary objectives of the application. Provide details of the services or resources provided by the optional Cores to at least two Research Projects and clarify how the optional Cores are not duplicative of other services or facilities. Additionally, plans for staffing, managing, and prioritizing use of the Cores must be provided, as well as plans for determining fees to users if charging fees is necessary.

Resource Sharing Plan: Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide.

Appendix:

Only limited items are allowed in the Appendix. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide; any instructions provided here are in addition to the SF424 (R&R) Application Guide instructions.

PHS Human Subjects and Clinical Trials Information (Scientific Core)

When involving human subjects research, clinical research, and/or NIH-defined clinical trials follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered “Yes” to the question “Are Human Subjects Involved?” on the R&R Other Project Information form, you must include at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information** form or a **Delayed Onset Study** record.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start). All instructions in the SF424 (R&R) Application Guide must be followed.

Research Project

When preparing your application, use Component Type ‘Project.’

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions, as noted.

Note: Effective for due dates on or after January 25, 2023, the Data Management and Sharing Plan will be attached in the Other Plan(s) attachment in FORMS-H application forms packages. If required, the Data Management and Sharing (DMS) Plan must be provided in the Overall component.

SF424 (R&R) Cover (Research Project)

Complete only the following fields:

- Applicant Information
- Type of Applicant (optional)
- Descriptive Title of Applicant’s Project
- Proposed Project Start/Ending Dates

PHS 398 Cover Page Supplement (Research Project)

Enter Human Embryonic Stem Cells in each relevant component.

Research & Related Other Project Information (Research Project)

Human Subjects: Answer only the ‘Are Human Subjects Involved?’ and 'Is the Project Exempt from Federal regulations? questions.

Vertebrate Animals: Answer only the ‘Are Vertebrate Animals Used?’ question.

Project Narrative: Do not complete. Note: ASSIST screens will show an asterisk for this attachment indicating it is required. However, eRA systems only enforce this requirement in the Overall component and applications will not receive an error if omitted in other components.

Project /Performance Site Location(s) (Research Project)

List all performance sites that apply to the specific component.

Note: The Project Performance Site form allows up to 300 sites, prior to using additional attachment for additional entries.

Research & Related Senior/Key Person Profile (Research Project)

- In the Project Director/Principal Investigator section of the form, use Project Role of ‘Other’ with Category of ‘Project Lead’ and provide a valid eRA Commons ID in the Credential field.
- In the additional Senior/Key Profiles section, list Senior/Key persons that are working in the component.
- Include a single Biographical Sketch for each Senior/Key person listed in the application regardless of the number of components in which they participate. When a Senior/Key person is listed in multiple components, the Biographical Sketch can be included in any one component.
- If more than 100 Senior/Key persons are included in a component, the Additional Senior Key Person attachments should be used.

Budget (Research Project)

Budget forms appropriate for the specific component will be included in the application package.

Each project leader must commit at least 1.2 person months effort to their project per year.

Note: The R&R Budget form included in many of the component types allows for up to 100 Senior/Key Persons in section A and 100 Equipment Items in section C prior to using attachments for additional entries. All other SF424 (R&R) instructions apply.

PHS 398 Research Plan (Research Project)

Specific Aims: List, in priority order, the broad long-range objectives and goals of the proposed project. Concisely describe the research activities to be performed. In addition, concisely state the individual Research Project's relationship to the Center program and how it relates to other projects or cores.

Research Strategy: Use this section to describe how the proposed research will contribute to meeting the Center objectives and explain the rationale for selecting the methods to accomplish the specific aims, and the biological significance of the research.

At least one Research Project must focus on development of vaccines, and other Research Projects may focus on additional vaccine development, early mAb development or foundational research in virology, immunology, pathology, and structural biology necessary for such development.

Describe the research design, conceptual procedures, and analyses to be used to accomplish the specific aims of the project. Describe any new methodology and its advantage over existing methodologies. Describe any novel concepts, approaches, techniques, methodologies, tools, or technologies for the proposed studies that will fundamentally advance how vaccines, and if applicable mAbs, will be developed. Discuss whether traditional approaches will be used in a new, novel way and how reliable, validated methods that mitigate risk will be balanced with innovative new approaches to expand foundational knowledge and advance product development. Describe plans for how the vaccine strategies and other research findings from the prototype virus research will be applied broadly to other viruses within the family to assess the breadth of the approach within and outside of the virus family to validate the generalizability of the approach. Discuss how the vaccine technologies or platforms used can be rapidly adapted for response to known or novel emerging viruses within the same family. If proposing early mAb development, describe plans for the assessment of whether antibodies with similar epitopes and/or properties of identified lead mAb candidates for the prototype virus are effective against other viruses within the same family. Discuss the potential difficulties and limitations of the proposed procedures and alternative approaches to achieve the aims.

Milestone Plan: In a clearly labeled section titled "Project Milestones and Timelines" include a clear delineation of goals with measurable milestones, including detailed quantitative and qualitative criteria for Go/No-Go decision-making, and a timeline for the attainment of each goal and milestone and should be reflected in the Milestone Plan for the overall Program. This plan must include Go/No-Go criteria to be met by the end of Year 3 of the award for continuation to Phase II. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, for example, identification of protective epitopes, animal model development, vaccine or mAb candidate down-selection, identification of correlates of protection, validation of vaccine or mAb strategies for other family members, and analysis, sharing and publication of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research Center.

Industry Expertise and Regulatory Considerations: For projects proposing early vaccine development, describe how industry partners will be identified and incorporated into the proposed project including a timeline for inclusion. For projects proposing IND-enabling later stage vaccine development, NIAID requires Centers to include active participation of an industry partner to ensure access to vaccine technology platforms, expertise in manufacturing, clinical development, and regulatory pathways. Applicants should describe the role of this partner in the proposed project and/or team to facilitate discovery, candidate evaluation and/or product development. For the purpose of this FOA, "industry" is defined as a large or small, domestic or foreign, pharmaceutical, biotechnology, bioengineering, or chemical company, or a related non-profit entity.

Additionally, each Center is expected to consider anticipated regulatory barriers for the targeted vaccine technology, particularly for new technology platforms for which there are no precedents for FDA approval. Describe anticipated regulatory barriers and propose research and/or strategies to resolve or overcome these barriers. For a project where multiple and/or complementary expertise is required, discuss plans for coordination among investigators and other collaborators including industry partners and the process to overcome obstacles to achieve the Center aims.

Letter of Support: For projects proposing later stage vaccine development where an industry partner is required, provide a Letter of Support from the Industry partner(s). For projects without later stage vaccine development, a Letter of Support from Industry partners may be included. Provide any additional letters of support that are specific to this project.

Resource Sharing Plan: Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide.

Appendix:

Only limited items are allowed in the Appendix. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide; any instructions provided here are in addition to the SF424 (R&R) Application Guide instructions.

PHS Human Subjects and Clinical Trials Information (Research Project)

When involving human subjects research, clinical research, and/or NIH-defined clinical trials follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered "Yes" to the question "Are Human Subjects Involved?" on the R&R Other Project Information form, you must include at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information** form or a **Delayed Onset Study** record.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start). All instructions in the SF424 (R&R) Application Guide must be followed.

Foreign Institutions

Foreign (non-U.S.) institutions must follow policies described in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11137), and procedures for foreign institutions described throughout the SF424 (R&R) Application Guide.

3. Unique Entity Identifier and System for Award Management (SAM)

See Part 1. Section III.1 for information regarding the requirement for obtaining a unique entity identifier and for completing and maintaining active registrations in System for Award Management (SAM), NATO Commercial and Government Entity (NCAGE) Code (if applicable), eRA Commons, and Grants.gov

4. Submission Dates and Times

Part I. Overview Information contains information about Key Dates and times. Applicants are encouraged to submit applications before the due date to ensure they have time to make any application corrections that might be necessary for successful submission. When a submission date falls on a weekend or Federal holiday (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82380), the application deadline is automatically extended to the next business day.

Organizations must submit applications to Grants.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=11128) (the online portal to find and apply for grants across all Federal agencies) using ASSIST or other electronic submission systems. Applicants must then complete the submission process by tracking the status of the application in the eRA Commons (//grants.nih.gov/grants/guide/url_redirect.htm?id=11123), NIH's electronic system for grants administration. NIH and Grants.gov systems check the application against many of the application instructions upon submission. Errors must be corrected and a changed/corrected application must be submitted to Grants.gov on or before the application due date and time. If a Changed/Corrected application is submitted after the deadline, the application will be considered late. Applications that miss the due date and time are subjected to the NIH Policy on Late Application Submission.

Applicants are responsible for viewing their application before the due date in the eRA Commons to ensure accurate and successful submission.

Information on the submission process and a definition of on-time submission are provided in the SF424 (R&R) Application Guide.

5. Intergovernmental Review (E.O. 12372)

This initiative is not subject to intergovernmental review (https://grants.nih.gov/grants/policy/nihgps/html5/section_10/10.10.1_executive_orders.htm).

6. Funding Restrictions

All NIH awards are subject to the terms and conditions, cost principles, and other considerations described in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120).

Pre-award costs are allowable only as described in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11143).

7. Other Submission Requirements and Information

Applications must be submitted electronically following the instructions described in the SF424 (R&R) Application Guide. Paper applications will not be accepted.

For information on how your application will be automatically assembled for review and funding consideration after submission go to: http://grants.nih.gov/grants/ElectronicReceipt/files/Electronic_Multi-project_Application_Image_Assembly.pdf (//grants.nih.gov/grants/ElectronicReceipt/files/Electronic_Multi-project_Application_Image_Assembly.pdf).

Applicants must complete all required registrations before the application due date. Section III. Eligibility Information contains information about registration.

For assistance with your electronic application or for more information on the electronic submission process, visit How to Apply – Application Guide (https://grants.nih.gov/grants/how-to-apply-application-guide.html). If you encounter a system issue beyond your control that threatens your ability to complete the submission process on-time, you must follow the Dealing with System Issues (https://grants.nih.gov/grants/how-to-apply-application-guide/due-dates-and-submission-policies/dealing-with-system-issues.htm) guidance. For assistance with application submission, contact the Application Submission Contacts in Section VII.

> **Important reminders:**
>
> All PD(s)/PI(s) and component Project Leads must include their eRA Commons ID in the Credential field of the Senior/Key Person Profile form**.** Failure to register in the Commons and to include a valid PD/PI Commons ID in the credential field will prevent the successful submission of an electronic application to NIH.
>
> The applicant organization must ensure that the unique entity identifier provided on the application is the same identifier used in the organization's profile in the eRA Commons and for the System for Award Management. Additional information may be found in the SF424 (R&R) Application Guide (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82400).
>
> See more tips (//grants.nih.gov/grants/guide/url_redirect.htm?id=11146) for avoiding common errors.

Upon receipt, applications will be evaluated for completeness and compliance with application instructions by the Center for Scientific Review and responsiveness by NIAID, NIH. Applications that are incomplete, non-compliant and/or nonresponsive will not be reviewed.

Post Submission Materials

Applicants are required to follow the instructions for post-submission materials, as described in the policy (//grants.nih.gov/grants/guide/url_redirect.htm?id=82299).

Section V. Application Review Information

1. Criteria

Only the review criteria described below will be considered in the review process. Applications submitted to the NIH in support of the NIH mission (//grants.nih.gov/grants/guide/url_redirect.htm?id=11149) are evaluated for scientific and technical merit through the NIH peer review system.

Overall Impact - Overall

Reviewers will provide an overall impact score to reflect their assessment of the likelihood for the Program to exert a sustained, powerful influence on the research field(s) involved, in consideration of the following review criteria and additional review criteria (as applicable for the Program proposed).

Scored Review Criteria - Overall

Reviewers will consider each of the review criteria below in the determination of scientific merit and give a separate score for each. An application does not need to be strong in all categories to be judged likely to have major scientific impact. For example, a project that by its nature is not innovative may be essential to advance a field.

Significance

Does the project address an important problem or a critical barrier to progress in the field? Is the prior research that serves as the key support for the proposed project rigorous? If the aims of the project are achieved, how will scientific knowledge, technical capability, and/or clinical practice be improved? How will successful completion of the aims change the concepts, methods, technologies, treatments, services, or preventative interventions that drive this field?

Specific to this FOA:

How well does the application describe a single clearly defined and scientifically justified program that supports the development of vaccine strategies for prototype pathogens that can be applied to other family members? Understanding that the different virus families have different levels of existing foundational knowledge and different states of maturity for product development, how appropriate is the research to increase knowledge to advance vaccine, and if applicable mAb, development for the proposed virus family? If successful, how likely will the proposed Center program enhance the ability to rapidly respond to an emerging known or currently unknown virus from the prototype virus's family?

How well does the Center as a whole leverage scientific gains and synergy by combining the component projects into a multi-project program beyond the gains achievable if each project were pursued independently? To what extent is the program cohesive and do the Research Projects and Cores relate to a common objective demonstrating cohesion, multidisciplinary interactions, and coordination? How well are the scientific cores justified relative to the Overall?

Investigator(s)

Are the PD(s)/PI(s), collaborators, and other researchers well suited to the project? If Early Stage Investigators or those in the early stages of independent careers, do they have appropriate experience and training? If established, have they demonstrated an ongoing record of accomplishments that have advanced their field(s)? If the project is collaborative or multi-PD/PI, do the investigators have complementary and integrated expertise; are their leadership approach, governance and organizational structure appropriate for the project?

Specific to this FOA:

To what extent is there an appropriate balance between investigators with expertise studying the virus families and investigators with product development experience? To what extent is there appropriate and adequate representation of investigators with the necessary vaccine discovery and development experience and expertise? For projects involving IND-enabling later stage activities, how appropriate are industry partnerships proposed to support this effort? For early development projects, how appropriate is the plan and timeline for identification and incorporation of industry partnership to facilitate rapid transition of vaccines into clinical development? How sufficiently are the academic and industry partners coordinated to facilitate discovery, candidate evaluation and/or product development? How adequate is the level of commitment of the PD(s)/PI(s) and key personnel to manage the overall Program?

Innovation

Does the application challenge and seek to shift current research or clinical practice paradigms by utilizing novel theoretical concepts, approaches or methodologies, instrumentation, or interventions? Are the concepts, approaches or methodologies, instrumentation, or interventions novel to one field of research or novel in a broad sense? Is a refinement, improvement, or new application of theoretical concepts, approaches or methodologies, instrumentation, or interventions proposed?

Specific to this FOA:

To what extent is there an effective balance between reliable, validated methods that mitigate risk with innovative, new approaches that could expand the field? How well have the investigators used traditional approaches in new, novel ways? To what extent are there techniques, methodologies, concepts, or processes which fundamentally advance how vaccines, and if applicable mAbs, are developed?

Approach

Are the overall strategy, methodology, and analyses well-reasoned and appropriate to accomplish the specific aims of the project? Have the investigators included plans to address weaknesses in the rigor of prior research that serves as the key support for the proposed project? Have the investigators presented strategies to ensure a robust and unbiased approach, as appropriate for the work proposed? Are potential problems, alternative strategies, and benchmarks for success presented? If the project is in the early stages of development, will the strategy establish feasibility and will particularly risky aspects be managed? Have the investigators presented adequate plans to address relevant biological variables, such as sex, for studies in vertebrate animals or human subjects?

If the project involves human subjects and/or NIH-defined clinical research, are the plans to address:

1) the protection of human subjects from research risks, and
2) inclusion (or exclusion) of individuals on the basis of sex/gender, race, and ethnicity, as well as the inclusion or exclusion of individuals of all ages (including children and older adults), justified in terms of the scientific goals and research strategy proposed?

Specific to this FOA:

How well is the selection of the prototype(s) justified, and likely to generate generalizable knowledge that can be applied to develop vaccines for related viruses? To what extent do the investigators propose a well-reasoned plan to evaluate their vaccine approach broadly to other viruses within a given family to validate the generalizability of the approach? If proposing early mAb development, to what extent do the investigators propose a well-reasoned plan to validate the generalizability of the approach by assessing whether mAbs with similar epitopes and/or properties of lead candidate mAbs against the prototype virus are effective against other viruses within a given family?

To what extent does the approach use technologies and platforms that could be rapidly adapted for response to known or novel emerging viruses within the same family? How appropriate is the proposed project given the current level of knowledge and vaccine development landscape for the virus family? For programs that include IND-enabling translational research, how well does the approach take into consideration the anticipated regulatory process and any anticipated regulatory barriers and resolutions?

How well are the overall Timelines and proposed Milestones defined with quantifiable measures and criteria that are appropriate for enabling clear Go/No-Go decisions and assessing the success of the overall program? How well do the overall milestones support the goal of advancing generalizable vaccine, and if applicable, mAb solutions? How realistic are the timelines proposed for achieving these overall milestones?

How well do the individual projects contribute, either directly or through generation of essential resources or foundational knowledge, to the identification of generalizable vaccine, and if applicable mAb, approaches for a given virus family? How well are the Research Project milestones defined with quantifiable measures and appropriate for enabling clear Go/No-Go decisions and assessing the success of the individual Research Projects? How well do the investigators provide a clear plan for achieving defined Research Project milestones and timelines? To what extent are the timelines proposed for achieving these Research Project milestones realistic or inclusive of necessary steps?

Environment

Will the scientific environment in which the work will be done contribute to the probability of success? Are the institutional support, equipment and other physical resources available to the investigators adequate for the project proposed? Will the project benefit from unique features of the scientific environment, subject populations, or collaborative arrangements?

Specific to this FOA: To what extent do the investigators have access to facilities with the appropriate biocontainment and capacity and resources for the proposed research?

Additional Review Criteria - Overall, Administrative Core, Data Management Core, Scientific Core, and Research Projects

As applicable for the project proposed, reviewers will evaluate the following additional items while determining scientific and technical merit, and in providing an overall impact score, but will not give separate scores for these items.

Administrative Core

How appropriate is the administrative and organizational structure and adequate to achieve the goals of the proposed program? How appropriate is the Management Plan for fiscal accountability and communication within the program? How appropriate are the plans for coordination and the establishment of a strong collaborative environment for the program? How adequate are the plans for communication among the Centers and with the CDSC to facilitate collaborative activities? How appropriate is the plan for collaboration with industry partners clear given the state of the program? How sufficient is the time and effort committed by the PD/PI and Key Personnel to adequately manage the Program? To what extent do the investigators provide a well-thought-out plan for coordination, communication, and collaborations with the CDSC, NIAID Staff, and other Centers within the Network? How well have the applicants developed a plan for ensuring timely communication and collaboration with the CDSC, NIAID Staff, and other Centers within the Network?

Data Management Core

How appropriate and adequate is the organizational structure to achieve the goals of the proposed program? How appropriate is the Strategy for Management of Data Activities Plan for the type of data generated by the research program? How sufficient are the described data management activities sufficient? To what extent do the investigators provide a well-thought-out plan for network-wide sharing of the data generated by the Center?

Scientific Core

How sufficiently is the Core justified? To what extent does it support at least two Research Projects? How well is the core connected to the central focus of the overall program? To what extent are the facilities or services provided by the core (including procedures, techniques, and quality control) high quality and well-justified? How effectively will the services be used? To what extent are the core leader and key personnel well qualified and is there an adequate commitment of time?

Protections for Human Subjects

For research that involves human subjects but does not involve one of the categories of research that are exempt under 45 CFR Part 46, the committee will evaluate the justification for involvement of human subjects and the proposed protections from research risk relating to their participation according to the following five review criteria: 1) risk to subjects, 2) adequacy of protection against risks, 3) potential benefits to the subjects and others, 4) importance of the knowledge to be gained, and 5) data and safety monitoring for clinical trials.

For research that involves human subjects and meets the criteria for one or more of the categories of research that are exempt under 45 CFR Part 46, the committee will evaluate: 1) the justification for the exemption, 2) human subjects involvement and characteristics, and 3) sources of materials. For additional information on review of the Human Subjects section, please refer to the Guidelines for the Review of Human Subjects (//grants.nih.gov/grants/guide/url_redirect.htm?id=11175).

Inclusion of Women, Minorities, and Individuals Across the Lifespan

When the proposed project involves human subjects and/or NIH-defined clinical research, the committee will evaluate the proposed plans for the inclusion (or exclusion) of individuals on the basis of sex/gender, race, and ethnicity, as well as the inclusion (or exclusion) of individuals of all ages (including children and older adults) to determine if it is justified in terms of the scientific goals and research strategy proposed. For additional information on review of the Inclusion section, please refer to the Guidelines for the Review of Inclusion in Clinical Research (//grants.nih.gov/grants/guide/url_redirect.htm?id=11174).

Vertebrate Animals

The committee will evaluate the involvement of live vertebrate animals as part of the scientific assessment according to the following criteria: (1) description of proposed procedures involving animals, including species, strains, ages, sex, and total number to be used; (2) justifications for the use of animals versus alternative models and for the appropriateness of the species proposed; (3) interventions to minimize discomfort, distress, pain and injury; and (4) justification for euthanasia method if NOT consistent with the AVMA Guidelines for the Euthanasia of Animals. Reviewers will assess the use of chimpanzees as they would any other application proposing the use of vertebrate animals. For additional information on review of the Vertebrate Animals section, please refer to the Worksheet for Review of the Vertebrate Animals Section (//grants.nih.gov/grants/guide/url_redirect.htm?id=11150).

Biohazards

Reviewers will assess whether materials or procedures proposed are potentially hazardous to research personnel and/or the environment, and if needed, determine whether adequate protection is proposed.

Resubmissions

Not Applicable

Renewals

Not Applicable

Revisions

Not Applicable

Additional Review Considerations - Overall, Administrative Core, Data Management Core, Scientific Core, and Research Projects

As applicable for the project proposed, reviewers will consider each of the following items, but will not give scores for these items, and should not consider them in providing an overall impact score.

Applications from Foreign Organizations

Reviewers will assess whether the project presents special opportunities for furthering research programs through the use of unusual talent, resources, populations, or environmental conditions that exist in other countries and either are not readily available in the United States or augment existing U.S. resources.

Select Agent Research

Reviewers will assess the information provided in this section of the application, including 1) the Select Agent(s) to be used in the proposed research, 2) the registration status of all entities where Select Agent(s) will be used, 3) the procedures that will be used to monitor possession use and transfer of Select Agent(s), and 4) plans for appropriate biosafety, biocontainment, and security of the Select Agent(s).

Resource Sharing Plans

Reviewers will comment on whether the Resource Sharing Plan(s) (e.g., Sharing Model Organisms (https://sharing.nih.gov/other-sharing-policies/model-organism-sharing-policy#policy-overview)) or the rationale for not sharing the resources, is reasonable.

Authentication of Key Biological and/or Chemical Resources:

For projects involving key biological and/or chemical resources, reviewers will comment on the brief plans proposed for identifying and ensuring the validity of those resources.

Budget and Period of Support

Reviewers will consider whether the budget and the requested period of support are fully justified and reasonable in relation to the proposed research.

2. Review and Selection Process

Applications will be evaluated for scientific and technical merit by (an) appropriate Scientific Review Group(s) convened by the National Institute of Allergy and Infectious Diseases, in accordance with NIH peer review policy and procedures (//grants.nih.gov/grants/guide/url_redirect.htm?id=11154), using the stated review criteria. Assignment to a Scientific Review Group will be shown in the eRA Commons.

As part of the scientific peer review, all applications will receive a written critique.

Applications may undergo a selection process in which only those applications deemed to have the highest scientific and technical merit (generally the top half of applications under review) will be discussed and assigned an overall impact score.

Appeals (https://grants.nih.gov/grants/policy/nihgps/html5/section_2/2.4.2_appeals_of_initial_scientific_review.htm) of initial peer review will not be accepted for applications submitted in response to this FOA

Applications will be assigned to the appropriate NIH Institute or Center. Applications will compete for available funds with all other recommended applications submitted in response to this FOA. Following initial peer review, recommended applications will receive a second level of review by the National Advisory Allergy and Infectious Diseases Council. The following will be considered in making funding decisions:

- Scientific and technical merit of the proposed project as determined by scientific peer review.
- Availability of funds.
- Relevance of the proposed project to program priorities.

3. Anticipated Announcement and Award Dates

After the peer review of the application is completed, the PD/PI will be able to access his or her Summary Statement (written critique) via the eRA Commons (//grants.nih.gov/grants/guide/url_redirect.htm?id=11123). Refer to Part 1 for dates for peer review, advisory council review, and earliest start date.

Information regarding the disposition of applications is available in the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120).

Section VI. Award Administration Information

1. Award Notices

If the application is under consideration for funding, NIH will request "just-in-time" information from the applicant as described in the NIH Grants Policy Statement (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_2/2.5.1_just-in-time_procedures.htm).

A formal notification in the form of a Notice of Award (NoA) will be provided to the applicant organization for successful applications. The NoA signed by the grants management officer is the authorizing document and will be sent via email to the recipient's business official.

Recipients must comply with any funding restrictions described in Section IV.6. Funding Restrictions. Selection of an application for award is not an authorization to begin performance. Any costs incurred before receipt of the NoA are at the recipient's risk. These costs may be reimbursed only to the extent considered allowable pre-award costs.

Any application awarded in response to this FOA will be subject to terms and conditions found on the Award Conditions and Information for NIH Grants (https://grants.nih.gov/grants/policy/nihgps/HTML5/part_ii_subpart_b.htm) website. This includes any recent legislation and policy applicable to awards that is highlighted on this website.

Institutional Review Board or Independent Ethics Committee Approval: Grantee institutions must ensure that protocols are reviewed by their IRB or IEC. To help ensure the safety of participants enrolled in NIH-funded studies, the recipient must provide NIH copies of documents related to all major changes in the status of ongoing protocols.

2. Administrative and National Policy Requirements

All NIH grant and cooperative agreement awards include the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120) as part of the NoA. For these terms of award, see the NIH Grants Policy Statement Part II: Terms and Conditions of NIH Grant Awards, Subpart A: General (//grants.nih.gov/grants/guide/url_redirect.htm?id=11157) and Part II: Terms and Conditions of NIH Grant Awards, Subpart B: Terms and Conditions for Specific Types of Grants, Recipients, and Activities (//grants.nih.gov/grants/guide/url_redirect.htm?id=11159), including of note, but not limited to:

- Federal wide Research Terms and Conditions (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_3/3.1_federalwide_standard_terms_and_conditions_for_research_grants.htm)
- Prohibition on Certain Telecommunications and Video Surveillance Services or Equipment (https://grants.nih.gov/grants/guide/notice-files/NOT-OD-21-041.html)
- Acknowledgment of Federal Funding (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_4/4.2.1_acknowledgement_of_federal_funding.htm)

If a recipient is successful and receives a Notice of Award, in accepting the award, the recipient agrees that any activities under the award are subject to all provisions currently in effect or implemented during the period of the award, other Department regulations and policies in effect at the time of the award, and applicable statutory provisions.

Should the applicant organization successfully compete for an award, recipients of federal financial assistance (FFA) from HHS will be required to complete an HHS Assurance of Compliance form (HHS 690) (https://ocrportal.hhs.gov/ocr/aoc/instruction.jsf) in which the recipient agrees, as a term and condition of receiving the grant, to administer their programs in compliance with federal civil rights laws that prohibit discrimination on the basis of race, color, national origin, age, sex and disability, and agreeing to comply with federal conscience laws, where applicable. This includes ensuring that entities take meaningful steps to provide meaningful access to persons with limited English proficiency; and ensuring effective communication with persons with disabilities. Where applicable, Title XI and Section 1557 prohibit discrimination on the basis of sexual orientation, and gender identity. The HHS Office for Civil Rights provides guidance on complying with civil rights laws enforced by HHS. Please see https://www.hhs.gov/civil-rights/for-providers/provider-obligations/index.html (https://www.hhs.gov/civil-rights/for-providers/provider-obligations/index.html) and https://www.hhs.gov/civil-rights/for-individuals/nondiscrimination/index.html (https://www.hhs.gov/civil-rights/for-individuals/nondiscrimination/index.html)

HHS recognizes that research projects are often limited in scope for many reasons that are nondiscriminatory, such as the principal investigator’s scientific interest, funding limitations, recruitment requirements, and other considerations. Thus, criteria in research protocols that target or exclude certain populations are warranted where nondiscriminatory justifications establish that such criteria are appropriate with respect to the health or safety of the subjects, the scientific study design, or the purpose of the research. For additional guidance regarding how the provisions apply to NIH grant programs, please contact the Scientific/Research Contact that is identified in Section VII under Agency Contacts of this FOA.

- Recipients of FFA must ensure that their programs are accessible to persons with limited English proficiency. For guidance on meeting the legal obligation to take reasonable steps to ensure meaningful access to programs or activities by limited English proficient individuals see https://www.hhs.gov/civil-rights/for-individuals/special-topics/limited-english-proficiency/fact-sheet-guidance/index.html (https://www.hhs.gov/civil-rights/for-individuals/special-topics/limited-english-proficiency/fact-sheet-guidance/index.html)andhttps://www.lep.gov (https://www.lep.gov/).

- For information on an institution’s specific legal obligations for serving qualified individuals with disabilities, including providing program access, reasonable modifications, and to provide effective communication, see https://www.hhs.gov/civil-rights/for-individuals/disability/index.html (https://www.hhs.gov/civil-rights/for-individuals/disability/index.html).

- HHS funded health and education programs must be administered in an environment free of sexual harassment, see https://www.hhs.gov/civil-rights/for-individuals/sex-discrimination/index.html (https://www.hhs.gov/civil-rights/for-individuals/sex-discrimination/index.html). For information about NIH's commitment to supporting a safe and respectful work environment, who to contact with questions or concerns, and what NIH's expectations are for institutions and the individuals supported on NIH-funded awards, please see https://grants.nih.gov/grants/policy/harassment.htm (https://grants.nih.gov/grants/policy/harassment.htm).

- For guidance on administering programs in compliance with applicable federal religious nondiscrimination laws and applicable federal conscience protection and associated anti-discrimination laws see https://www.hhs.gov/conscience/conscience-protections/index.html (https://www.hhs.gov/conscience/conscience-protections/index.html) and https://www.hhs.gov/conscience/religious-freedom/index.html (https://www.hhs.gov/conscience/religious-freedom/index.html).

Please contact the HHS Office for Civil Rights for more information about obligations and prohibitions under federal civil rights laws at https://www.hhs.gov/ocr/about-us/contact-us/index.html (https://www.hhs.gov/ocr/about-us/contact-us/index.html) or call 1-800-368-1019 or TDD 1-800-537-7697.

In accordance with the statutory provisions contained in Section 872 of the Duncan Hunter National Defense Authorization Act of Fiscal Year 2009 (Public Law 110-417), NIH awards will be subject to the Federal Awardee Performance and Integrity Information System (FAPIIS) requirements. FAPIIS requires Federal award making officials to review and consider information about an applicant in the designated integrity and performance system (currently FAPIIS) prior to making an award. An applicant, at its option, may review information in the designated integrity and performance systems accessible through FAPIIS and comment on any information about itself that a federal agency previously entered and is currently in FAPIIS. The Federal awarding agency will consider any comments by the applicant, in addition to other information in FAPIIS, in making a judgement about the applicant’s integrity, business ethics, and record of performance under Federal awards when completing the review of risk posed by applicants as described in 45 CFR Part 75.205 and 2 CFR Part 200.206 “Federal awarding agency review of risk posed by applicants.” This provision will apply to all NIH grants and cooperative agreements except fellowships.”

Cooperative Agreement Terms and Conditions of Award

The following special terms of award are in addition to, and not in lieu of, otherwise applicable U.S. Office of Management and Budget (OMB) administrative guidelines, U.S. Department of Health and Human Services (DHHS) grant administration regulations at 45 CFR Part 75 and 2 CFR Part 200, and other HHS, PHS, and NIH grant administration policies.

The administrative and funding instrument used for this program will be the cooperative agreement, an "assistance" mechanism (rather than an "acquisition" mechanism), in which substantial NIH programmatic involvement with the recipients is anticipated during the performance of the activities. Under the cooperative agreement, the NIH purpose is to support and stimulate the recipients' activities by involvement in and otherwise working jointly with the recipients in a partnership role; it is not to assume direction, prime responsibility, or a dominant role in the activities. Consistent with this concept, the dominant role and prime responsibility resides with the recipients for the project as a whole, although specific tasks and activities may be shared among the recipients and the NIH as defined below.

The PD(s)/PI(s) will have the primary responsibility for:

PD(s)/PI(s) will have the primary responsibility for coordinating the Projects and Cores within the overall Program. Specifically, the PD(s)/PI(s) have primary responsibility as described below.

- The PD(s)/PI(s) will be responsible for defining the research objectives, approaches, and details of the projects within the guidelines of the FOA and retains primary responsibility for the planning, directing, and executing the proposed scientific activities
- The PD(s)/PI(s) will monitor all Research Projects and actively promote efforts that foster integration, collaboration, and synergy across the projects.
- The PD(s)/PI(s) will be responsible for ensuring timely compliance with ReVAMPP Network policies for template usage, data sharing, and collaboration.
- The PD(s)/PI(s) are responsible for ensuring that appropriate systems are in place to provide for biosafety and security of materials, data, facilities and resources, including compliance with regard to Select Agent Regulations, Biosafety in Microbiology and Biomedical Laboratories (BMBL) Guidelines, Centers for Disease Control and Prevention and the National Institutes of Health, sixth Edition; U.S. Code of Federal Regulations 42 C.F.R. Part 73, 7 C.F.R. Part 331, and 9 C.F.R. Part 121.

In addition, the PD(s)/PI(s) will be responsible for:

- Organizing and chairing annual ReVAMPP Center Progress meeting activities. The annual ReVAMPP Center progress meetings are anticipated to be held at a location at/near Rockville, MD or at another NIAID-approved site and will last up to 2 days.
- Advertising the availability of the Program generated resources through outreach activities.

Recipients will retain custody of and have primary rights to the data and software developed under these awards, subject to Government rights of access consistent with current HHS, PHS, and NIH policies.

NIH staff have substantial programmatic involvement that is above and beyond the normal stewardship role in awards, as described below:

The role of the NIAID Project Scientist is to support and encourage the recipient's activities by substantial involvement as partners and facilitators in the process without assuming responsibilities that remain with the PDs/PIs.

- The NIAID Project Scientist will work closely with the PD(s)/PI(s) and other Program member scientists to facilitate collaborations and to leverage the resources available to the ReVAMPP Network.
- The NIAID Project Scientist will monitor the progress of the Center, help coordinate research approaches among all Centers funded through the FOA and contribute to the shaping of research projects or approaches as warranted. The NIAID Project Scientist will support and facilitate this process but will not direct it.
- Near the end of year 3 of the award, Program Staff will assess the progress towards development of generalizable approaches for vaccine, and if applicable early development of mAbs, for virus families of pandemic concern through the accomplishment of the milestones and overall feasibility of program advancement. The assessment will be based on the first three annual reports, the milestones included in the application and negotiated with the recipient prior to award, any additional information that the PD/PI elects to submit, evidence of collaboration with other ReVAMPP Centers, compliance with the ReVAMPP Network data sharing and CDSC requests, programmatic priorities, and the availability of funding.
- The NIAID Project Scientist will keep the ReVAMPP Centers informed about other ongoing studies supported by NIAID to avoid duplication of effort and encourage sharing/collaboration in infectious diseases research.
- The NIAID Project Scientist will coordinate access for the recipients to other NIAID resources, as well as assist the research efforts of the Program by facilitating access to fiscal and intellectual resources provided by industry, private foundations, NIH intramural scientists and other federal government agencies as appropriate.

In addition to the NIAID Project Scientist, an agency program official or IC program director will be responsible for the normal scientific and programmatic stewardship of the award and will be named in the award notice.

Areas of Joint Responsibility include:

- The NIAID Project Scientist and the PD(s)/PI(s) will hold regular program-wide discussions to facilitate the achievement of program goals.
- The PD(s)/PI(S) and the NIAID Project Scientist will collaborate in the establishment of the Scientific Advisory Board
- The NIAID Project Scientist and the PD/PI will collaborate during the course of the award to revise and/or update project milestones as appropriate.

Dispute Resolution

Any disagreements that may arise in scientific or programmatic matters (within the scope of the award) between award recipients and the NIH may be brought to Dispute Resolution. A Dispute Resolution Panel composed of three members will be convened. It will have three members: a designee of the Steering Committee chosen without NIH staff voting, one NIH designee, and a third designee with expertise in the relevant area who is chosen by the other two; in the case of individual disagreement, the first member may be chosen by the individual recipient. This special dispute resolution procedure does not alter the recipient's right to appeal an adverse action that is otherwise appealable in accordance with PHS regulation 42 CFR Part 50, Subpart D and DHHS regulation 45 CFR Part 16.

3. Data Management and Sharing

Note: The NIH Policy for Data Management and Sharing is effective for due dates on or after January 25, 2023.

Consistent with the NIH Policy for Data Management and Sharing, when data management and sharing is applicable to the award, recipients will be required to adhere to the Data Management and Sharing requirements as outlined in the NIH Grants Policy Statement (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_8/8.2.3_sharing_research_resources.htm). Upon the approval of a Data Management and Sharing Plan, it is required for recipients to implement the plan as described.

Recipients will be required to adhere to the FAIR Principles (FAIR Principles - GO FAIR (go-fair.org) (https://gcc02.safelinks.protection.outlook.com/?url=https%3A%2F%2Fwww.go-fair.org%2Ffair-principles%2F&data=05%7C01%7Cchelsea.boyd%40nih.gov%7C8247f78a75c04c5ea99208db1b643066%7C14b77578977342d58507251ca2dc2b06%7C0%7C0%7C63813388934
for data management and sharing.

4. Reporting

When multiple years are involved, recipients will be required to submit the Research Performance Progress Report (RPPR) (//grants.nih.gov/grants/rppr/index.htm) annually and financial statements as required in the NIH Grants Policy Statement. (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_8/8.4.1_reporting.htm)

A final RPPR, invention statement, and the expenditure data portion of the Federal Financial Report are required for closeout of an award, as described in the NIH Grants Policy Statement (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_8/8.6_closeout.htm). NIH FOAs outline intended research goals and objectives. Post award, NIH will review and measure performance based on the details and outcomes that are shared within the RPPR, as described at 45 CFR Part 75.301 and 2 CFR Part 200.301.

The Federal Funding Accountability and Transparency Act of 2006 (Transparency Act), includes a requirement for recipients of Federal grants to report information about first-tier subawards and executive compensation under Federal assistance awards issued in FY2011 or later. All recipients of applicable NIH grants and cooperative agreements are required to report to the Federal Subaward Reporting System (FSRS) available at www.fsrs.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=11170) on all subawards over the threshold. See the NIH Grants Policy Statement (https://grants.nih.gov/grants/policy/nihgps/HTML5/section_4/4.1.8_federal_funding_accountability_and_transparency_act__ffata_.htm) for additional information on this reporting requirement.

In accordance with the regulatory requirements provided at 45 CFR 75.113and 2 CFR Part 200.113 and Appendix XII to 45 CFR Part 75 and 2 CFR Part 200, recipients that have currently active Federal grants, cooperative agreements, and procurement contracts from all Federal awarding agencies with a cumulative total value greater than $10,000,000 for any period of time during the period of performance of a Federal award, must report and maintain the currency of information reported in the System for Award Management (SAM)about civil, criminal, and administrative proceedings in connection with the award or performance of a Federal award that reached final disposition within the most recent five-year period. The recipient must also make semiannual disclosures regarding such proceedings. Proceedings information will be made publicly available in the designated integrity and performance system (currently FAPIIS). This is a statutory requirement under section 872 of Public Law 110-417, as amended (41 U.S.C. 2313). As required by section 3010 of Public Law 111-212, all information posted in the designated integrity and performance system on or after April 15, 2011, except past performance reviews required for Federal procurement contracts, will be publicly available. Full reporting requirements and procedures are found in Appendix XII to 45 CFR Part 75and 2 CFR Part 200 – Award Term and Condition for Recipient Integrity and Performance Matters.

Section VII. Agency Contacts

We encourage inquiries concerning this funding opportunity and welcome the opportunity to answer questions from potential applicants.

Application Submission Contacts

eRA Service Desk (Questions regarding ASSIST, eRA Commons, application errors and warnings, documenting system problems that threaten submission by the due date, and post-submission issues)

Finding Help Online: https://www.era.nih.gov/need-help (https://www.era.nih.gov/need-help) (preferred method of contact)
Telephone: 301-402-7469 or 866-504-9552 (Toll Free)

General Grants Information (Questions regarding application instructions, application processes, and NIH grant resources)
Email: GrantsInfo@nih.gov (mailto:GrantsInfo@nih.gov) (preferred method of contact)

Section VIII. Other Information

Recently issued trans-NIH policy notices (//grants.nih.gov/grants/guide/url_redirect.htm?id=11163) may affect your application submission. A full list of policy notices published by NIH is provided in the NIH Guide for Grants and Contracts (//grants.nih.gov/grants/guide/url_redirect.htm?id=11164). All awards are subject to the terms and conditions, cost principles, and other considerations described in the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120).

Authority and Regulations

Awards are made under the authorization of Sections 301 and 405 of the Public Health Service Act as amended (42 USC 241 and 284) and under Federal Regulations 42 CFR Part 52 and 45 CFR Part 75 and 2 CFR Part 200.

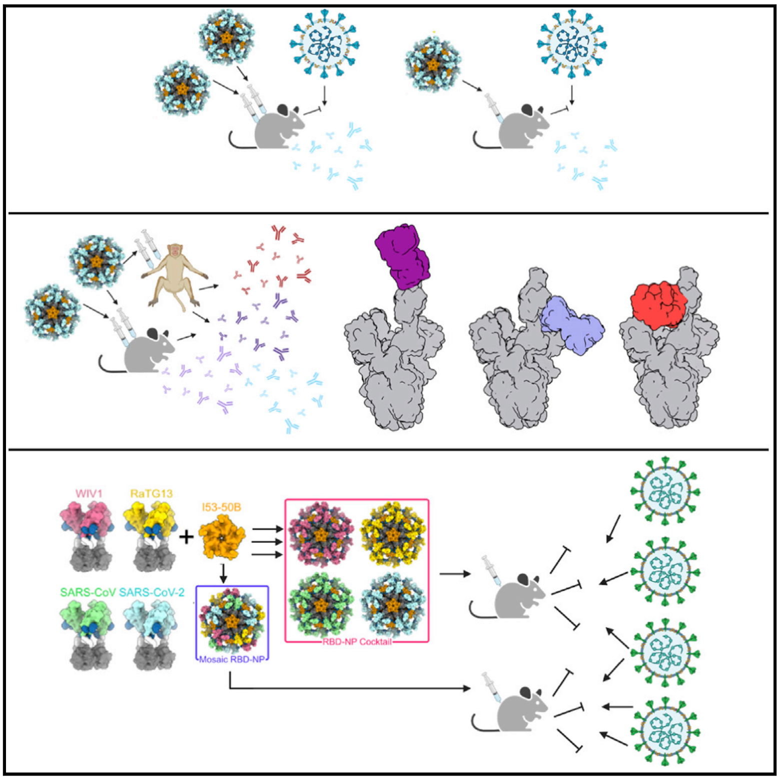
Article

Elicitation of broadly protective sarbecovirus immunity by receptor-binding domain nanoparticle vaccines

Graphical abstract



Highlights

- RBD-NP enables dose-sparing and protects mice after only one dose
- RBD-NP elicits diverse polyclonal antibody responses in non-human primates
- RBD-NP and HexaPro confer similar resilience to antigenic drift
- Mosaic and cocktail RBD-NPs protect against heterotypic SARS-CoV challenge

dveesler@uw.edu (D.V.)

In brief

A clinical stage multivalent SARS-CoV-2 spike receptor-binding domain nanoparticle (RBD-NP) vaccine is protective in mice after a single immunization and elicits strong antibody responses across circulating mutants and some sarbecoviruses. Multivalent sarbecovirus RBD-NP vaccines elicit heterotypic protection against sarbecoviruses.

SUMMARY

Understanding vaccine-elicited protection against SARS-CoV-2 variants and other sarbecoviruses is key for guiding public health policies. We show that a clinical stage multivalent SARS-CoV-2 spike receptor-binding domain nanoparticle (RBD-NP) vaccine protects mice from SARS-CoV-2 challenge after a single immunization, indicating a potential dose-sparing strategy. We benchmarked serum neutralizing activity elicited by RBD-NPs in non-human primates against a lead prefusion-stabilized SARS-CoV-2 spike (HexaPro) using a panel of circulating mutants. Polyclonal antibodies elicited by both vaccines are similarly resilient to many RBD residue substitutions tested, although mutations at and surrounding position 484 have negative consequences for neutralization. Mosaic and cocktail nanoparticle immunogens displaying multiple sarbecovirus RBDs elicit broad neutralizing activity in mice and protect mice against SARS-CoV challenge even in the absence of SARS-CoV RBD in the vaccine. This study provides proof of principle that multivalent sarbecovirus RBD-NPs induce heterotypic protection and motivates advancing such broadly protective sarbecovirus vaccines to the clinic.

INTRODUCTION

The emergence of SARS-CoV-2 in late 2019 resulted in the COVID-19 pandemic that brought the world to a standstill. Moreover, the recurrent spillovers of coronaviruses in humans along with detection of SARS-CoV-2-, SARS-CoV-, and MERS-CoV-related coronaviruses in bats suggest that future zoonotic transmission events may continue to occur (Menachery et al., 2015, 2016; Zhou et al., 2020a). SARS-CoV-2 infects host cells through the attachment of the viral transmembrane spike (S) glycoprotein to angiotensin-converting enzyme 2 (ACE2), followed by fusion of the viral and host membranes (Hoffmann et al., 2020; Lan et al., 2020; Letko et al., 2020; Shang et al., 2020; Walls et al., 2020a; Wang et al., 2020; Wrapp et al., 2020; Yan et al., 2020; Zhou et al., 2020b). The SARS-CoV-2 S protein is the primary target of neutralizing antibodies (Abs), and the immunodominant receptor-binding domain (RBD) accounts for more than 90% of the neutralizing activity in COVID-19 convalescent sera and vaccinated individuals (Greaney et al., 2021a, 2021b; Piccoli et al., 2020). Numerous monoclonal Abs (mAbs) recognizing distinct antigenic sites on the RBD were isolated and shown to neutralize viral entry and protect small animals and non-human primates (NHPs) from SARS-CoV-2 challenge (Barnes et al., 2020; Baum et al., 2020a; Brouwer et al., 2020; Piccoli et al., 2020; Pinto et al., 2020; Rogers et al., 2020; Starr et al., 2021; Tortorici et al., 2020; Wec et al., 2020; Zost et al., 2020). As a result, SARS-CoV-2 S is the focus of nucleic acid, vectored, and protein subunit vaccines currently being developed and deployed (Corbett et al., 2020a, 2020b; Jackson et al., 2020; Mercado et al., 2020; Polack et al., 2020; Tostanoski et al., 2020; Yu et al., 2020).

Worldwide sequencing of SARS-CoV-2 clinical isolates has led to the identification of numerous mutations in the >1,500,000 genome sequences available to date (https://www.gisaid.org/). The SARS-CoV-2 S D614G mutation has become globally dominant and is associated with enhanced viral transmission and replication but does not significantly affect Ab-mediated neutralization (Hou et al., 2020; Korber et al., 2020; Plante et al., 2020; Yurkovetskiy et al., 2020). Conversely, some mutations found in circulating SARS-CoV-2 isolates were shown to promote escape from mAbs and to reduce neutralization by immune sera (Baum et al., 2020b; Collier et al., 2021; Li et al., 2020; McCallum et al., 2021a, 2021b; Wang et al., 2021a; Weisblum et al., 2020; Wibmer et al., 2021). As a result, formulation of mAb cocktails or the use of mAbs targeting conserved epitopes and neutralizing a broader spectrum of circulating SARS-CoV-2 variants emerged as a promising strategy to overcome this issue (Baum et al., 2020b; Cathcart et al., 2021; Dong et al., 2021; Greaney et al., 2020; Jette et al., 2021; Martinez et al., 2021a; Pinto et al., 2020; Tortorici et al., 2020, 2021). The recent emergence of several variants and variants of concern (VOCs) with numerous S mutations is especially worrisome, including B.1.1.7 (alpha), B.1.351 (beta), B.1.427/B.1.429 (epsilon), P.1 (gamma), and B.1.617.2 (delta) that originated in the UK, South Africa, the USA, Brazil, and India, respectively (Davies et al., 2020; Deng et al., 2021; Faria et al., 2021; McCallum et al., 2021b; Tegally et al., 2020). Some of these mutations lead to significant reductions in the neutralization potency of N-terminal domain (NTD)- and RBD-specific mAbs, convalescent sera, and Pfizer/BioNTech BNT162b2- or Moderna mRNA-1273-elicited sera (Collier et al., 2021; McCallum et al., 2021a, 2021b; Wang et al., 2021a).

We recently described a multivalent subunit vaccine displaying the SARS-CoV-2 RBD nanoparticle (RBD-NP) in a highly immunogenic array using a computationally designed self-assembling protein nanoparticle (Bale et al., 2016; Walls et al., 2020b). Vaccination with RBD-NP resulted in 10-fold higher neutralizing Ab titers in mice than the prefusion-stabilized S2P trimer (which is used in most current vaccines) despite a 5-fold lower dose and protected mice against mouse-adapted SARS-CoV-2 (SARS-CoV-2-MA) challenge (Dinnon et al., 2020; Walls et al., 2020b). We demonstrated that the RBD-NP vaccine elicited robust neutralizing Ab and CD4 T cell responses in NHPs when formulated with several clinic-ready adjuvants and conferred protection against SARS-CoV-2 infection in the nose, pharynges, and bronchioles (Arunachalam et al., 2021). The RBD-NP vaccine is currently being evaluated in two phase I/II clinical trials (ClinicalTrials.gov: NCT04742738 and NCT04750343) and recently received funding from the coalition for epidemic preparedness innovations for phase III clinical trials.

Although the S fusion machinery (S_2 subunit) has higher sequence conservation than the RBD (Pinto et al., 2021; Sauer et al., 2021; Tortorici and Veesler, 2019; Walls et al., 2016, 2020a), the breadth of neutralization and protection provided by RBD-based vaccines remains unknown. The isolation of RBD-specific cross-reactive mAbs neutralizing SARS-CoV-2 and SARS-CoV suggests that RBD-based vaccines could, in principle, elicit Abs that neutralize distantly related sarbecoviruses, which have future pandemic potential (Cathcart et al., 2021; Jette et al., 2021; Martinez et al., 2021a; Pinto et al., 2020; Rappazzo et al., 2021; Starr et al., 2021; Tortorici et al., 2021; Wec et al., 2020). RBD-based vaccines are also unaffected by S mutations outside of the RBD, especially in the highly variable NTD that is heavily mutated in many VOCs (Andreano et al., 2020; Avanzato et al., 2020; Choi et al., 2020; Collier et al., 2021; Wang et al., 2021a; McCallum et al., 2021a, 2021b; McCarthy et al., 2021). Here, we explored dose-sparing strategies for the RBD-NP vaccine and evaluated the impact of genetic diversity among SARS-CoV-2 clinical isolates and sarbecoviruses on vaccine-elicited Abs. We further designed mosaic and cocktail sarbecovirus RBD-NPs that elicit broad and protective Ab responses against heterologous sarbecovirus challenge, which could represent the next generation of pan-sarbecovirus vaccines.

RESULTS

Dose-sparing RBD-NP vaccination protects mice against SARS-CoV-2 challenge

Considering the unprecedented need for rapid global distribution of SARS-CoV-2 vaccines, we investigated the ability of RBD-NP to induce neutralizing and protective Ab titers at lower doses than previously evaluated. Specifically, we set out to test whether vaccine-elicited neutralizing Ab titers are altered by lowering the immunogen dose 10-fold (two 0.1 μg immunizations, RBD antigen dose) or reducing the number of doses

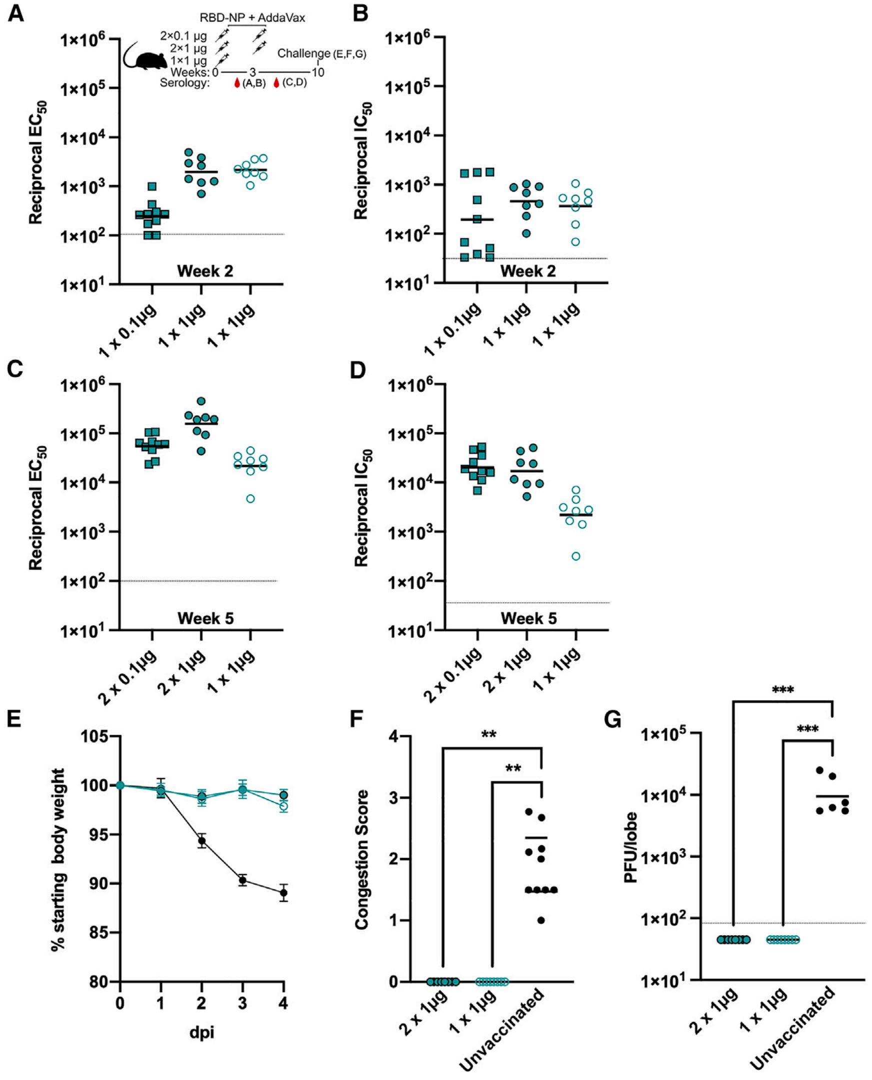

Figure 1. A single immunization with RBD-NP protects BALB/c cByJ mice from SARS-CoV-2 MA10 challenge

(A and C) S2P-binding Abs were measured 2 (A) or 5 (C) weeks post-prime; teal squares: 2 doses of 0.1 µg (n = 10); filled teal circles: 2 doses of 1 µg (n = 8); open teal circles: one dose of 1 µg (n = 8) with a limit of detection (LOD) of 1 × $10^{2\cdot}$

(B and D) Serum neutralizing Ab titers at 2 (B) or 5 (D) weeks post-prime determined using an MLV pseudotyping system with an LOD of 3.3 × 10^1.

(E) Weight loss following SARS-CoV-2 MA10 challenge up to 4 days post infection (n = 8 vaccinated; n = 6 naive mice shown as black filled circles).

(F) Congestion score following SARS-CoV-2 MA10 challenge with a score of 0 indicating unchanged lung color and 4 indicating a darkened and diseased lung.

(G) Viral titers in the mice lungs (expressed in plaque forming units [PFUs] per lobe) following challenge with an LOD of 9 × 10^1. Statistical significance was determined by Kruskal-Wallis test and shown only when significant. $^{**}p < 0.01$. LODs are shown as gray horizontal dotted lines.

Raw data curves shown in Data S1.

(a single 1 µg immunization, RBD antigen dose) compared to our initial work (Walls et al., 2020b). To test this, BALB/c cByJ mice were immunized intramuscularly at week 0 with either 0.1 µg (ten mice) or 1 µg (two groups of eight mice or sixteen mice total) of AddaVax-adjuvanted RBD-NP. Two weeks post-prime, serum binding and neutralizing Ab titers were roughly comparable for the two vaccine doses (neutralization geometric mean titer [GMT] ~2–4 × 10^2) measured using a mouse leukemia virus (MLV) pseudotyping system (Millet and Whittaker, 2016; Walls et al., 2020a) (Figures 1A and 1B; Data S1). Three weeks post prime, we boosted the mice that were immunized with 0.1 µg of the vaccine and eight of the sixteen mice immunized with 1 µg of the vaccine with the same respective dose. Two weeks post-boost, serum binding and neutralizing Ab titers were comparable for the 0.1 µg and 1 µg groups (neutralization GMT ~2 × 10^4) (Figures 1C and 1D; Data S1), suggesting that a 10-fold reduction in the RBD-NP dose does not affect serum neutralizing responses. Furthermore, we observed that the magnitude of binding and neutralizing Ab titers increased over time for the mice that received a single immunization (neutralization GMT 2 × 10^3). These results suggest that lowering the vaccine dose or reducing the number of immunizations represent possible dose-sparing strategies that did not compromise elicitation of high levels of neutralizing Ab titers using RBD-NPs.

To further evaluate vaccine efficacy, eight mice that received one dose and eight mice that received two doses of the 1-µg RBD-NP vaccine along with six unvaccinated mice were challenged ten weeks post-prime with 10^5 plaque-forming units (PFUs) of mouse-adapted SARS-CoV-2 MA10 (Leist et al., 2020). The SARS-CoV-2 MA10 model causes weight loss and lung pathology when 10^5 PFUs (the highest titer tested [Leist et al., 2020]) are used in young BALB/c mice. The mice were followed for four days to assess protection from disease. All mice in the RBD-NP-vaccinated groups were protected from weight loss throughout the duration of the experiment regardless of the number of doses, whereas control mice lost ~10% of their weight by day four (Figure 1E). Analysis of lung pathology and viral titers in lung tissues indicated that the vaccinated mice were not affected by SARS-CoV-2 MA10 challenge, whereas the control mice showed lung discoloration four days post-infection and a high viral load (~1 × 10^4 PFUs) (Figures 1F and 1G). These results indicate that one or two immunizations with 1 µg RBD-NPs results in protection against SARS-CoV-2 MA10-induced disease. Furthermore, mice vaccinated twice with a 10-fold lower dose of RBD-antigen (0.1 µg) had higher serum neutralizing Ab titers than mice receiving a single 1-µg dose, suggesting that they would likely also be protected since neutralizing Ab titers are a correlate of protection against SARS-CoV-2 (Arunachalam et al., 2021; McMahan et al., 2021). These data suggest that multiple RBD-NP dose-sparing regimens may be possible.

RBD-NP vaccination induces Abs targeting diverse antigenic sites in NHPs

To characterize the epitopes targeted by RBD-NP-elicited polyclonal Abs, we used deep mutational scanning (DMS) with sera obtained 56 days post-prime from one of two pigtail macaques immunized at days 0 and 28 with a dose of AddaVax-adjuvanted RBD-NP containing 88 µg of the SARS-CoV-2 RBD (with a linker of twelve glycine/serine (GS) residues between the RBD and the NP) (Walls et al., 2020b) (Figures 2A and 2B). These experiments rely on yeast surface display of RBD libraries covering nearly all possible amino acid mutations coupled with fluorescence-activated cell sorting (FACS) to identify RBD mutants with attenuated Ab binding compared to the wild-type (Wuhan-Hu-1) SARS-CoV-2 RBD (Greaney et al., 2020; Starr et al., 2020a). No single mutation had more than a marginal effect on serum Ab (IgG/IgM/IgA) binding, indicating broad targeting of distinct RBD epitopes, whereas several previously described COVID-19 human convalescent plasmas (HCPs) analyzed by DMS displayed greater sensitivity to individual mutations and are shown for comparison (Greaney et al., 2021b) (Figures 2B and S1; Table S1). These results show that RBD-NP vaccination elicits highly diverse polyclonal Ab responses that target multiple distinct antigenic sites and are more resilient to escape mutations reducing polyclonal Ab binding than HCP (Barnes et al., 2020; Greaney et al., 2021b; Piccoli et al., 2020; Starr et al., 2021).

To measure the magnitude of vaccine-elicited Abs against distinct RBD antigenic sites, we used quantitative competition ELISAs with human ACE2-Fc (hACE2-Fc), which binds to the receptor-binding motif (RBM) corresponding to antigenic sites Ia and Ib, as well as with structurally characterized mAbs recognizing antigenic sites II (CR3022) and IV (S309) (Huo et al., 2020; Piccoli et al., 2020; Pinto et al., 2020; Yuan et al., 2020) (Figures 2C–2E; Data S1). These experiments

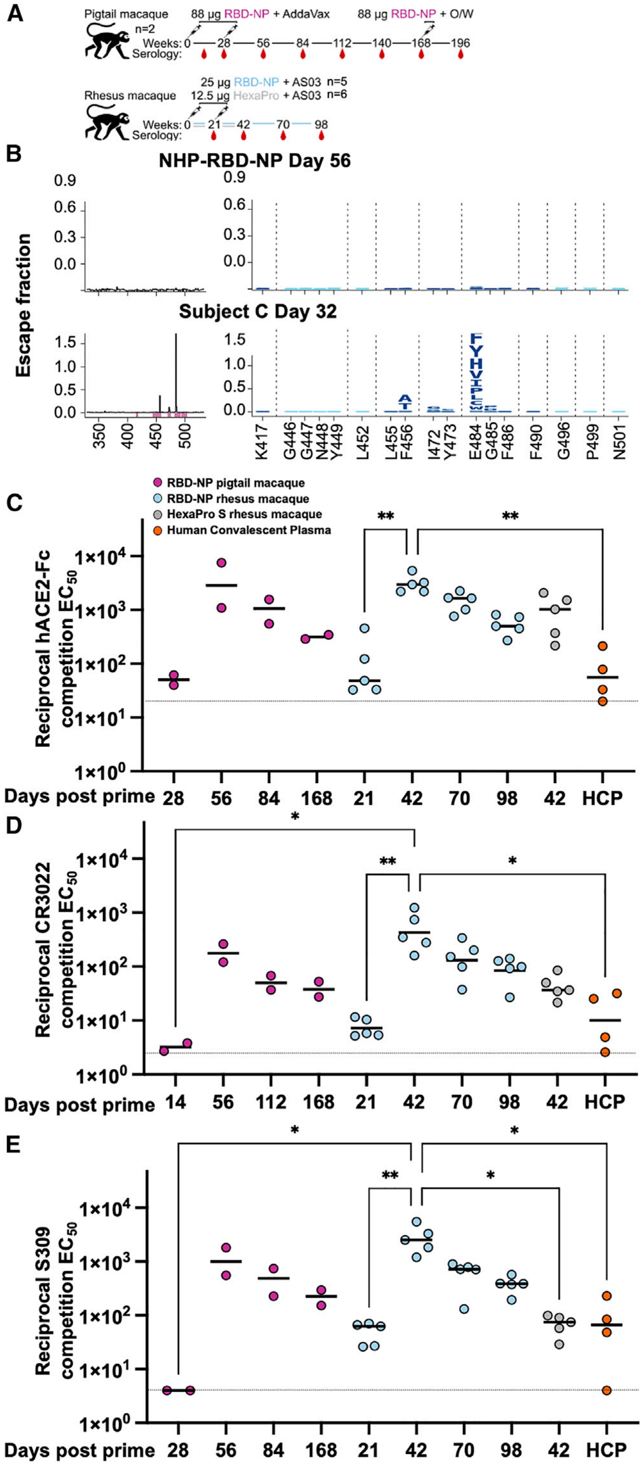

Figure 2. RBD-NP vaccination elicits high titers of Abs targeting diverse RBD antigenic sites in NHPs

(A) NHP study designs.

(B) Effect of RBD mutations on polyclonal Ab binding measured by DMS analysis of serum obtained 8 weeks post-prime from an immunized pigtail macaque (n = 1) compared to a previously reported DMS measurement from a representative COVID-19 HCP sample (reproduced here for comparison; Greaney et al., 2021b). The line plots on the left show the summed effect of all mutations at a site in the RBD on serum or plasma binding, with RBD residues on the x axis and Ab escape on the y axis (Table S1). Due to the use of sample-specific FACS gates (Figure S1), the y axes are scaled independently. Sites in the logo plots are colored dark blue if located in the receptor-binding ridge or cyan if located in the RBD 443–450 loop. Larger values indicate more Ab escape.

(C–E) Competition ELISA between 0.2-nM hACE2-Fc (LOD of 2×10^1) (C), 2-nM CR3022 mAb (LOD of 2×10^0) (D), or 0.01-nM S309 mAb (LOD of 4×10^0) (E), and RBD-NP-elicited sera in pigtail macaques (n = 2), RBD-NP-elicited sera in rhesus macaques (n = 5), or HexaPro S-elicited sera in rhesus macaques (n = 5) at various time points following vaccination, benchmarked against HCP (n = 4) (Table S2). Each plot shows the magnitude of inhibition of hACE2/mAb binding to immobilized SARS-CoV-2 S2P, expressed as reciprocal serum dilution blocking 50% of the maximum binding response. Statistical significance was determined by Kruskal-Wallis test and shown only when significant. **p < 0.01. LODs are shown as gray horizontal dotted lines.

Raw data curves shown in Data S1.

used sera from the aforementioned pigtail macaques (RBD GMT EC_{50} 5 × 10^4) followed for 168 days and sera from 5 rhesus macaques immunized twice on days 0 and 21 with AS03-adjuvanted RBD-NPs containing 25 μg of the SARS-CoV-2 RBD (with a 16-GS linker between the RBD and the NP; RBD GMT EC_{50} 1 × 10^4) and followed for 98 days (Arunachalam et al., 2021; Walls et al., 2020b; Figures 2A and S2A). These two sets of RBD-NP sera were compared to sera from 5 rhesus macaques immunized twice on days 0 and 21 with 12.5 μg of AS03-adjuvanted prefusion-stabilized HexaPro S trimer (RBD EC_{50} 1 × 10^4) and followed for 42 days (Arunachalam et al., 2021; Hsieh et al., 2020), as well as a panel of COVID-19 HCP (Table S2) (RBD EC_{50} 2 × 10^4) (Figures 2A and S2A). All NHP sera post boost had high titers of Abs targeting sites Ia and Ib in the immunodominant RBM (day 42 hACE2 competition RBD-NP GMT 3 × 10^3 and HexaPro GMT 7 × 10^2) (Figure 2C; Data S1), a correlate of neutralization potency (Piccoli et al., 2020), in agreement with the potent immunogenicity and protective efficacy of RBD-NP and HexaPro S in NHPs (Arunachalam et al., 2021). We also observed strong Ab responses against antigenic sites II (RBD-NP day 42 GMT 4 × 10^2 and HexaPro GMT 4 × 10^1) with CR3022 competition and IV (RBD-NP day 42 GMT 2.5 × 10^3 and HexaPro GMT 6.5 × 10^1) (Figures 2D and 2E; Data S1), which comprise conserved sarbecovirus epitopes recognized by broadly neutralizing sarbecovirus mAbs such as S2X259 (site II) and S309 (site IV) (Piccoli et al., 2020; Pinto et al., 2020; Tortorici et al., 2021). Ab responses were durable against all 3 antigenic sites regardless of dose or adjuvant, with a decrease of competition titers by roughly half an order to one order of magnitude 168 days (pigtail macaque) or 98 days (rhesus macaque) post-prime. RBD-NP elicited much higher peak binding titers toward all RBD antigenic sites evaluated compared to HexaPro S and HCP, showcasing the potency, durability, and multi-specificity of Ab responses induced by multivalent display of the RBD, possibly as a result of enhanced accessibility of the antigen.

RBD-NP vaccine elicits potent neutralizing Ab responses in NHPs against a panel of SARS-CoV-2 S variants

To assess the neutralization breadth of RBD-NP- and HexaPro S-elicited Abs in NHPs at peak titer (42 days post-prime), we evaluated serum neutralizing activity against a panel of pseudotyped viruses comprising wild-type (D614G) SARS-CoV-2 S and twelve single-residue SARS-CoV-2 RBD mutants detected in clinical isolates (N439K, L452R, Y453F, L455F, S477N, E484A/K/Q, F486L, S494P, N501Y, and G504D) as well as the B.1.1.7 (H69-V70 deletion, Y144 deletion, N501Y, A570D, D614G, P681H, T716I, S982A, D1118H); B.1.1.7 + E484K (H69-V70 deletion, Y144 deletion, E484K, N501Y, A570D, D614G, P681H, T716I, S982A, D1118H); B.1.351 (L18F, D80A, D215G, L242-L244 deletion, R246I, K417N, E484K, N501Y, D614G, A701V); and P.1 (L18F, T20N, P26S, D138Y, R190S, K417T, E484K, N501Y, D614G, H655Y, T1027I). Several single-residue RBD mutations did not affect neutralizing titers compared to wild-type D614G SARS-CoV-2 S, for which GMTs of 1.8 × 10^3 and 2.4 × 10^3 were determined with RBD-NP- and HexaPro S-elicited sera, respectively, using a vesicular stomatitis virus (VSV) pseudotyped virus (Figure 3A; Data S1). For example, the N439K- (GMT 2.5 × 10^3 for RBD-NP and 2.7 × 10^3 for HexaPro S) and mink-associated Y453F (GMT 4 × 10^3 for RBD-NP and 5 × 10^3 for HexaPro S) mutation did not dampen the neutralization potency of either RBD-NP- or HexaPro S-elicited sera (Figure 3A; Data S1). However, the N501Y substitution (present in the B.1.1.7, P.1, and B.1.351 lineages) reduced the neutralization potency of RBD-NP- (GMT 5 × 10^2) and HexaPro S (GMT 8 × 10^2)-elicited sera 3-to-4-fold and the L452R mutation (present in the B.1.427/B.1.429, B.1.617.1, and B.1.617.22 variant) led to a 3.4-to-4.4-fold drop in neutralization potency (GMT 4 × 10^2 for RBD-NP and 7 × 10^2 for HexaPro S). These substitutions have been associated with the loss of binding and neutralization for vaccine-elicited Abs and mAbs (Collier et al., 2021; McCallum et al., 2021b; Wang et al., 2021b; Thomson et al., 2021; Wang et al., 2021c). The E484A mutation reduced serum neutralization activity up to 2-fold (GMT 1.1x10^3 for RBD-NP and 1.1x10^3 for HexaPro S) whereas E484K, present in B.1.351 and P1 (GMT 2 × 10^2 for RBD-NP and 2 × 10^2 for HexaPro S), and E484Q, found in B.1.617.1 (GMT 5 × 10^2 for RBD-NP and 3.6 × 10^2 for HexaPro S), decreased it 9-fold (E484K) and 4-fold (E484Q) for RBD-NP and 12-fold (484K) and 7-fold (484Q) for HexaPro S compared to D614G SARS-CoV-2 S. These experiments suggest that a substantial fraction of the neutralizing activity elicited by both RBD-NP and HexaPro S is focused on the RBM, especially near position 484, as further supported by the ~5-fold decrease in neutralization resulting from the F486L (GMT 3.7 × 10^2 for RBD-NP and 5 × 10^2 for HexaPro S) substitution.

To understand the impact of the full constellation of mutations present in the S proteins of the aforementioned VOCs, we evaluated RBD-NP- and HexaPro S-elicited serum neutralizing activity against corresponding HIV and VSV pseudotyped variants (D614G GMT RBD-NP HIV 5 × 10^3 and VSV RBD-NP 6 × 10^2, respectively, and D614G GMT HexaPro S HIV 3.5 × 10^3 and VSV 1.2 × 10^3) (Figures 3B and 3C). Although we did not observe major reductions in neutralization titers (up to to 2-fold) toward the B.1.1.7 VOC (GMT RBD-NP HIV 2.5 × 10^3, VSV 4.7 × 10^2 and HexaPro S HIV 1.8 × 10^3, VSV 8.8 × 10^2) (Figures 3B and 3C), addition of the E484K mutation to the B.1.1.7 background reduced neutralization 4-to-6-fold for RBD-NP- (GMT HIV 8.8 × 10^2) and HexaPro S-elicited sera (GMT HIV 8.6 × 10^2), confirming the importance of the 484 position (Figure 3B). Neutralization of B.1.351 was 10-fold lower using HIV pseudovirus (GMT RBD-NP 5 × 10^2 and HexaPro S 3.6x10^2) (Figure 3B) and ~3-fold lower using VSV pseudovirus (GMT RBD-NP 2 × 10^2 and HexaPro S 4x10^2) (Figure 3C) for both RBD-NP- and HexaPro-elicited sera, in agreement with authentic virus neutralization data (Arunachalam et al., 2021). Interestingly, RBD-specific binding Ab titers did not differ significantly between the B.1.351 RBD (GMT RBD-NP 6.5 × 10^3 and HexaPro S 3 × 10^3) and Wuhan-Hu-1 RBD (GMT RBD-NP 1.4 × 10^4 and HexaPro S 1.7 × 10^4) (Figure S2A), indicating that neutralizing activity is accounted for by a portion of total binding Abs. Reductions in neutralizing Ab titers were also observed against P.1 S VSV pseudoviruses, with a 6-fold drop for RBD-NP (GMT 1 × 10^2) and 8-fold dampening for HexaPro S (GMT 1.5 × 10^2) (Figure 3C). Furthermore, we observed a 10-fold reduction in plasma

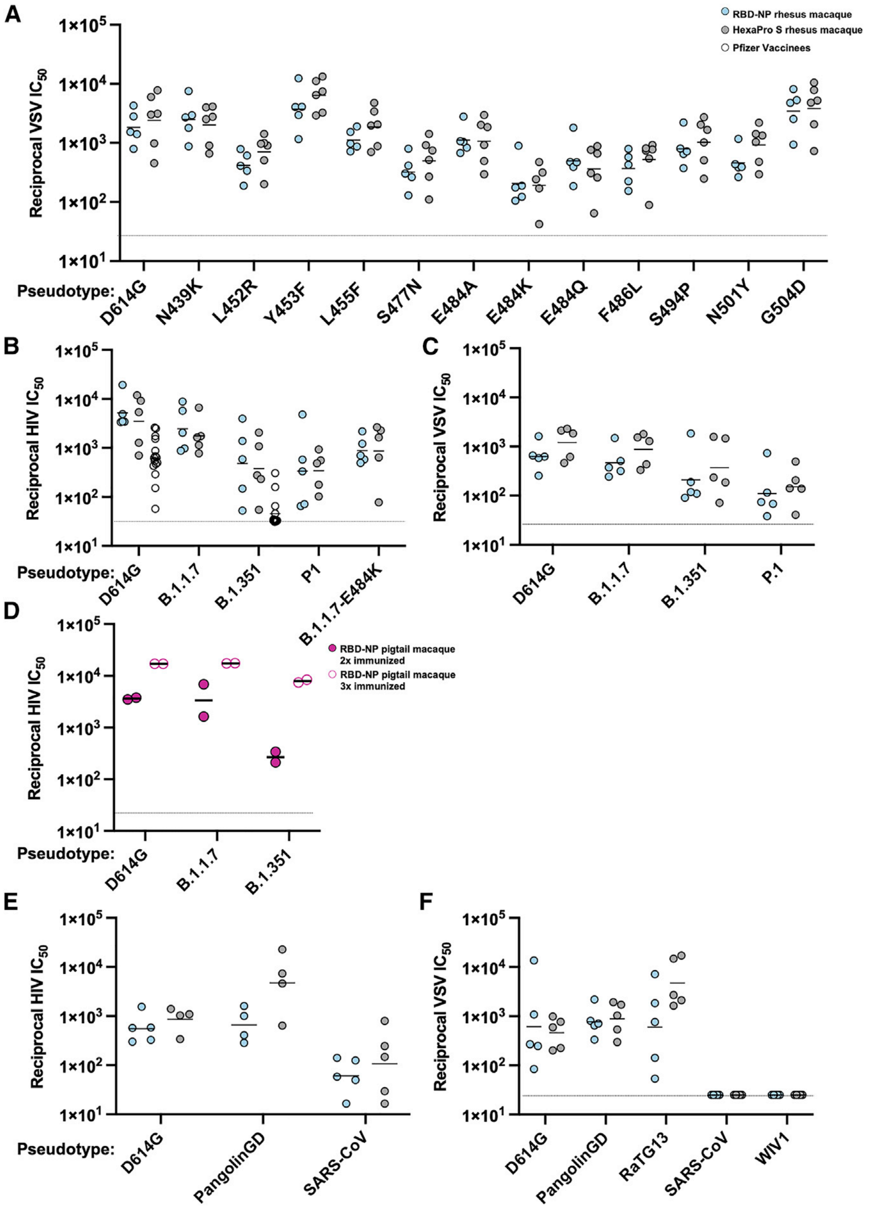

Figure 3. RBD-NP and HexaPro S elicit Abs with similar neutralization breadth toward SARS-CoV-2 variants

(A) Neutralizing Ab titers against wild-type (D614G) SARS-CoV-2 S and RBD point mutants determined using RBD-NP-elicited sera in rhesus macaques (blue, n = 5) and HexaPro S-elicited sera in rhesus macaques (gray, n = 6) with an VSV pseudotyping system with an LOD of 3.3 × 10^1. Neutralization performed once.

(B) Neutralizing Ab titers against HIV pseudotyped viruses harboring wild-type (D614G) SARS-CoV-2 S, B.1.1.7 S, B.1.1.7-E484K S, B.1.351 S, or P.1 S, determined using RBD-NP-elicited sera in rhesus macaques (blue), HexaPro S-elicited sera in rhesus macaques (gray), or plasma from individuals who received two doses of Pfizer mRNA vaccine (open circles) with an LOD of 3.3 × 10^1. Neutralization performed twice and a representative shown.

(C) Neutralizing Ab titers against VSV pseudotyped viruses harboring wild-type (D614G) SARS-CoV-2 S, B.1.1.7 S, B.1.351 S, or P.1 S, determined using RBD-NP-elicited sera in rhesus macaques (blue) or HexaPro S-elicited sera in rhesus macaques (gray) with an LOD of 2.5 × 10^1. Neutralization performed twice and a representative shown.

(D) Neutralizing Ab titers against D614G SARS-CoV-2 S, B.1.1.7, and B.1.351 S HIV pseudoviruses in pigtail macaque sera collected 28 days after a second (filled symbols, n = 2) or third (open symbols, n = 2) immunization with 88-μg RBD-NP (RBD antigen dose) with an LOD of 1 × 10^2. Neutralization performed twice and a representative shown.

(E) Neutralizing Ab titers against HIV pseudotyped viruses harboring wild-type (D614G) SARS-CoV-2 S, Pangolin-GD S, or SARS-CoV S, determined using RBD-NP-elicited sera in in rhesus macaques (blue) or HexaPro S-elicited sera in rhesus macaques (gray) with an LOD of 1 × 10^1. Neutralization performed twice and a representative shown.

(F) Neutralizing Ab titers against VSV pseudotyped viruses harboring wild-type (D614G) SARS-CoV-2 S, Pangolin-GD S, RaTG13 S, SARS-CoV S, or WIV1 S determined using SARS-CoV-2 RBD-NP-elicited sera in rhesus macaques (blue) or HexaPro S-elicited sera in rhesus macaques (gray) with an LOD of 2.5 × 10^1. Neutralization performed twice and a representative shown. Statistical significance was determined by Kruskal-Wallis test and shown in Table S3. LODs are shown as gray horizontal dotted lines. Raw data curves shown in Data S1 and GMTs in Table S4. The various pseudovirus backbones were benchmarked against NIBSC standard and are shown in Table S5.

neutralizing potency for individuals who received two doses of the Pfizer-BioNTech BNT162b2 mRNA vaccine against B.1.351 S pseudotyped virus (GMT 6 × 10^1) relative to the wild-type (D614G) SARS-CoV-2 S (GMT 6 × 10^2) pseudotyped virus (Figure 3B; Data S1). These findings show that, as is the case for many convalescent individuals (Greaney et al., 2021b; Liu et al., 2021; Piccoli et al., 2020), an important fraction of vaccine-elicited neutralizing Abs in NHPs and humans is focused on the RBM (specifically around position 484), independently of the immunogen (RBD-NP, HexaPro S, or 2P-stabilized S [Pallesen et al., 2017]) or the vaccine modality (protein subunit or mRNA). However, we note that neutralization assays may underestimate the contribution of NTD-specific or non-RBM RBD-targeted neutralizing Abs (Lempp et al., 2021; McCallum et al., 2021a; Suryadevara et al., 2021), and protection from challenge will be the ultimate readout.

To further investigate the relationships between neutralizing Ab titers and emerging SARS-CoV-2 variants, we immunized the two pigtail macaques a third time with RBD-NP, formulated with an oil-in-water (O/W) emulsion-based adjuvant, 168 days after the primary immunization (Figure 2A). This boost induced potent serum neutralizing activity against wild-type (D614G)

SARS-CoV-2 (GMT 2 × 10^4) (Figure 3D) as well as the B.1.1.7 (GMT 2 × 10^4) and B.1.351 (GMT 8 × 10^3) VOC pseudoviruses, suggesting that an overall increase in neutralizing Ab titers may be a suitable strategy to cope with emerging variants. These results are consistent with recent studies demonstrating that boosting COVID-19 convalescent individuals with a single mRNA vaccination elicited high (neutralizing) Ab titers, including against the B.1.351 variant (Abu Jabal et al., 2021; Krammer et al., 2021; Stamatatos et al., 2021), and suggest that a third vaccination of naive individuals could be a suitable strategy to limit the impact of emerging variants. This strategy is currently being evaluated for immunocompromised patients in several countries.

RBD-NP vaccine elicits cross-reactive sarbecovirus polyclonal Abs in NHPs

As RBD-NP- and HexaPro S-elicited polyclonal Abs exhibited similar resilience to a range of mutations, we next investigated cross-reactivity with a panel of sarbecovirus RBDs. RBD-NP-elicited polyclonal Abs purified from pigtail macaque serum obtained 70 days post-prime strongly cross-reacted with the SARS-CoV-2-related Pangolin-GD and RaTG13 RBDs and bound more weakly to distantly related RmYN02, SARS-CoV, WIV16, and ZXC21 RBDs (Figures S2B and S2C). Measurement of Ab binding titers using the SARS-CoV and SARS-CoV-2 S2P ectodomain trimers by ELISA showed that RBD-NPs and HexaPro S induced similar levels of cross-reactive Abs against each antigen, with responses roughly two orders of magnitude higher against SARS-CoV-2 S2P (detection antigen matching immunogen) compared to SARS-CoV S2P (Figure S2D; Data S1). The two immunogens also elicited similar peak levels of SARS-CoV S ACE2-competing Abs (GMT 2 × 10^2 RBD-NP and 5 × 10^1 HexaPro) suggesting that cross-neutralizing Abs might have been induced to similar extents between the two vaccines (Figure S2E).

Motivated by the cross-reactivity of RBD-NP-elicited polyclonal Abs with various sarbecovirus RBDs and the correlation between ACE2 competition and serum neutralization titers (Piccoli et al., 2020), we evaluated neutralization of a panel of HIV (D614G GMT 5.5 × 10^2) and VSV (D614G GMT 6 × 10^2) pseudoviruses harboring sarbecovirus S glycoproteins. RBD-NP-elicited sera efficiently neutralized pseudotyped viruses harboring the S glycoprotein of the Pangolin-GD isolate (GMT 6.6 × 10^2 and 7.7 × 10^2 VSV) and RaTG13 (GMT VSV 6 × 10^2) (Figures 3E and 3F) (Lam et al., 2020; Zhou et al., 2020b), in agreement with the close phylogenetic relationship of their RBDs with that of SARS-CoV-2 S (Figure S2B). HexaPro S-elicited NHP sera also efficiently neutralized Pangolin-GD S (GMT HIV 4.7 × 10^3 and VSV 9 × 10^2) and RaTG13 S pseudotypes (GMT VSV 4.7 × 10^3) (Figures 3E and 3F). Furthermore, we observed that both RBD-NP- and HexaPro S-induced polyclonal Abs that weakly neutralized HIV pseudovirus carrying SARS-CoV S (RBD-NP GMT 6 × 10^1 and HexaPro GMT 1 × 10^2) (Figures 3E and 3F). Collectively, these data demonstrate that both immunogens elicited comparable neutralization breadth and potency against the pseudoviruses tested, reinforcing the notion that most sarbecovirus S-directed neutralizing Abs target the RBD (Greaney et al., 2021a, 2021b; Piccoli et al., 2020).

Design, assembly, and characterization of mosaic and cocktail sarbecovirus RBD-NPs

We and others have recently evaluated nanoparticle immunogens that display multiple antigenic variants of viral glycoproteins as a potential route toward broadly protective vaccines (Boyoglu-Barnum et al., 2021; Cohen et al., 2021a, 2021b; Kanekiyo et al., 2019). Given the large number of coronaviruses circulating in zoonotic reservoirs, such vaccines could be important for understanding vaccine-induced neutralization/protection breadth and preventing future pandemics (Menachery et al., 2015, 2016). We expressed and purified four RBDs from the S proteins of SARS-CoV-2, SARS-CoV, and the bat coronaviruses WIV1 and RaTG13 genetically fused to the I53-50A trimer. An equimolar mixture of these four proteins was added to the I53-50B pentamer to assemble a mosaic RBD-NP (mRBD-NP) co-displaying the four RBDs on the same nanoparticle (Figure 4A and S3A). We also assembled a trivalent mosaic RBD-NP designated “drop out” lacking the SARS-CoV RBD (mRBD-NP-DO), as well as cocktail immunogens with three (cRBD-NP-DO; lacking the SARS-CoV RBD) or four (cRBD-NP) independently assembled nanoparticles, each displaying a single type of the aforementioned RBDs, mixed after independent assembly. Finally, we made a bivalent mosaic RBD-NP co-displaying the SARS-CoV and SARS-CoV-2 RBDs (Figure S3A) to directly confirm co-display on the nanoparticles using a sandwich binding assay. All of the nanoparticle immunogens formed the intended icosahedral architecture and retained native antigenicity, as shown by SDS-PAGE, dynamic light scattering, negative staining electron microscopy, and binding to hACE2-Fc (Figures S3B–S3E). We found that the vaccine candidates were stable for at least 4 weeks at several temperatures except the highest temperature evaluated (37°C), at which we observed a decrease in hACE2 recognition over time beginning after 7 to 14 days, presumably due to aggregation (Figures 4B–4E). Following immobilization using the SARS-CoV-2-specific mAb S2H14 (Piccoli et al., 2020), the quadrivalent, trivalent, and bivalent mRBD-NPs all bound the Fab of the SARS-CoV-specific Ab S230 (Piccoli et al., 2020; Rockx et al., 2008; Walls et al., 2019), confirming co-display, whereas the monovalent SARS-CoV-2 RBD-NP did not (Figure S3G). We determined that the reactivity of the trivalent mRBD-NP derived from the inclusion of the WIV1 RBD in this vaccine, as the monovalent WIV1 RBD-NP also bound the S230 Fab after immobilization with hACE2 (as expected [Menachery et al., 2016]), whereas the monovalent SARS-CoV-2 and RaTG13 RBD-NPs did not (Figure S3H). Collectively, these data demonstrate that all of the nanoparticles were stable and (co-)displayed the various RBDs as intended.

Cocktail and mosaic RBD-NP vaccines elicit cross-reactive and broadly neutralizing sarbecovirus Abs

The mosaic and cocktail nanoparticle immunogens were compared to monovalent RBD-NP vaccines and a non-assembling control vaccine comprising all four RBD-I53-50A trimeric components and a non-assembling I53-50B pentamer (Figure S3F) in an immunization study in BALB/c cByJ mice (Figures 4A and S3A). All immunizations comprised 1 μg of total RBD antigen, such that ~0.25 μg of each RBD was given in each administration of the quadrivalent vaccines

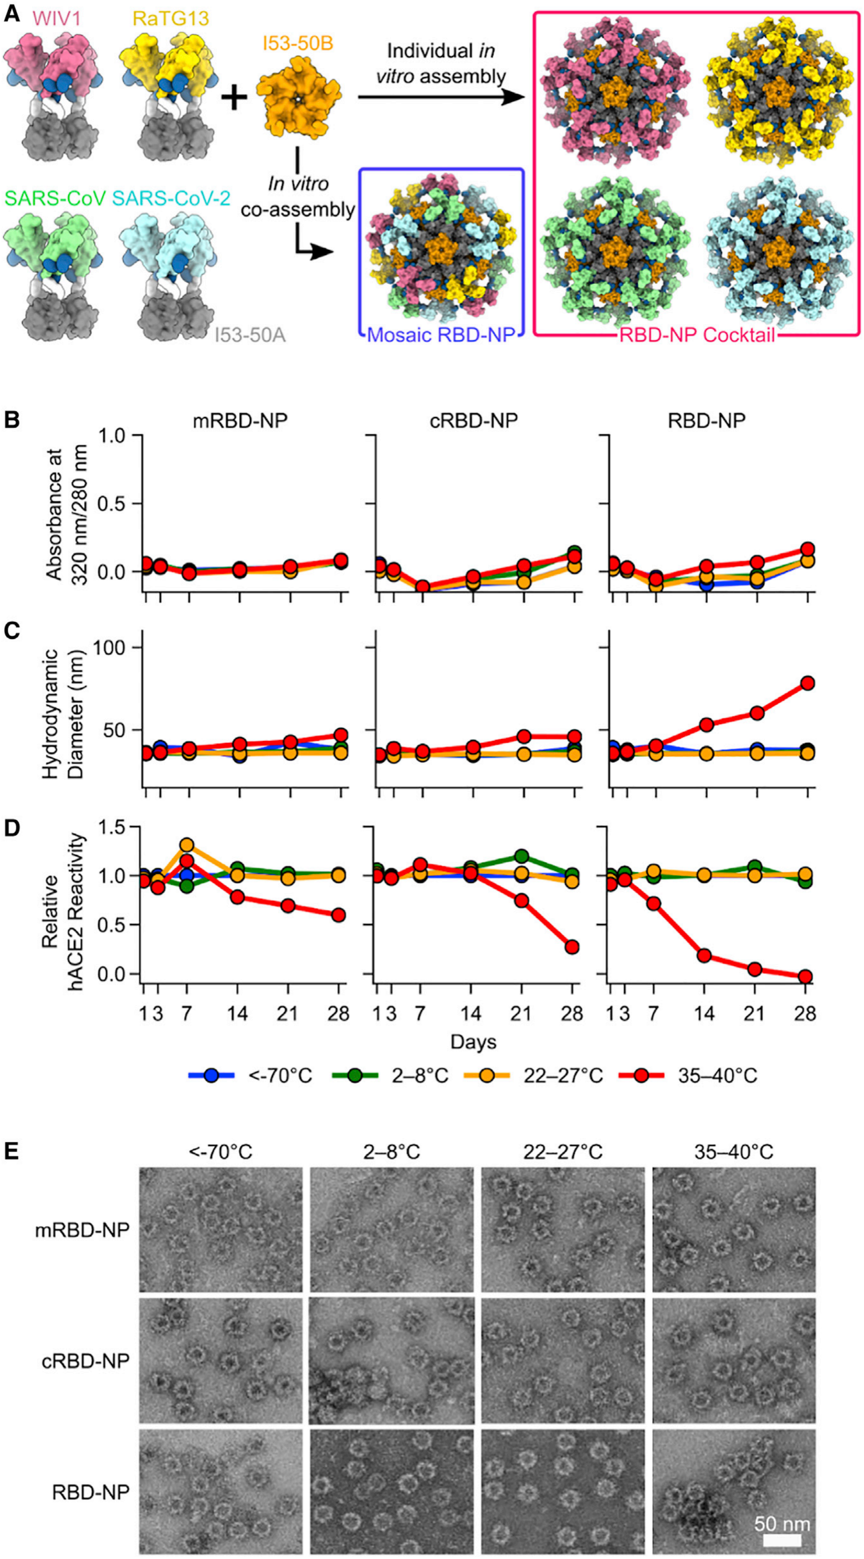

Figure 4. *In vitro* assembly and accelerated stability studies of mosaic and cocktail nanoparticle immunogens

(C) Hydrodynamic diameter of the nanoparticles measured using dynamic light scattering.

(D) hACE2-Fc binding measured by comparing the peak amplitude of hACE2-Fc binding for each sample to a reference sample stored at $< -70^\circ C$ using biolayer interferometry.

(E) Electron micrographs of negatively stained samples after incubation for 28 days at the indicated temperatures. Scale bar, 50 nm.

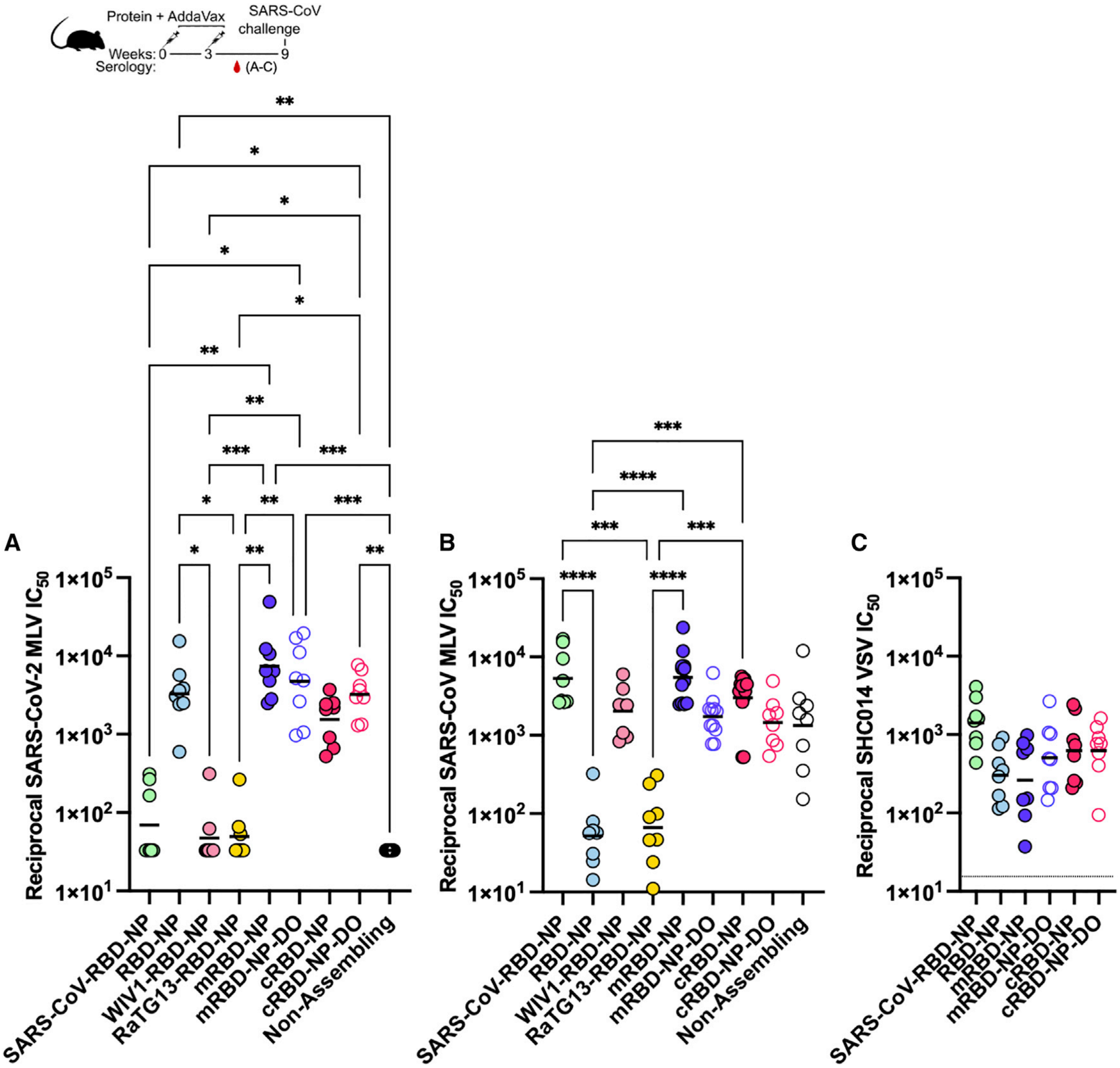

Figure 5. Mosaic and cocktail RBD-NP vaccines elicit neutralizing Abs against multiple sarbecoviruses

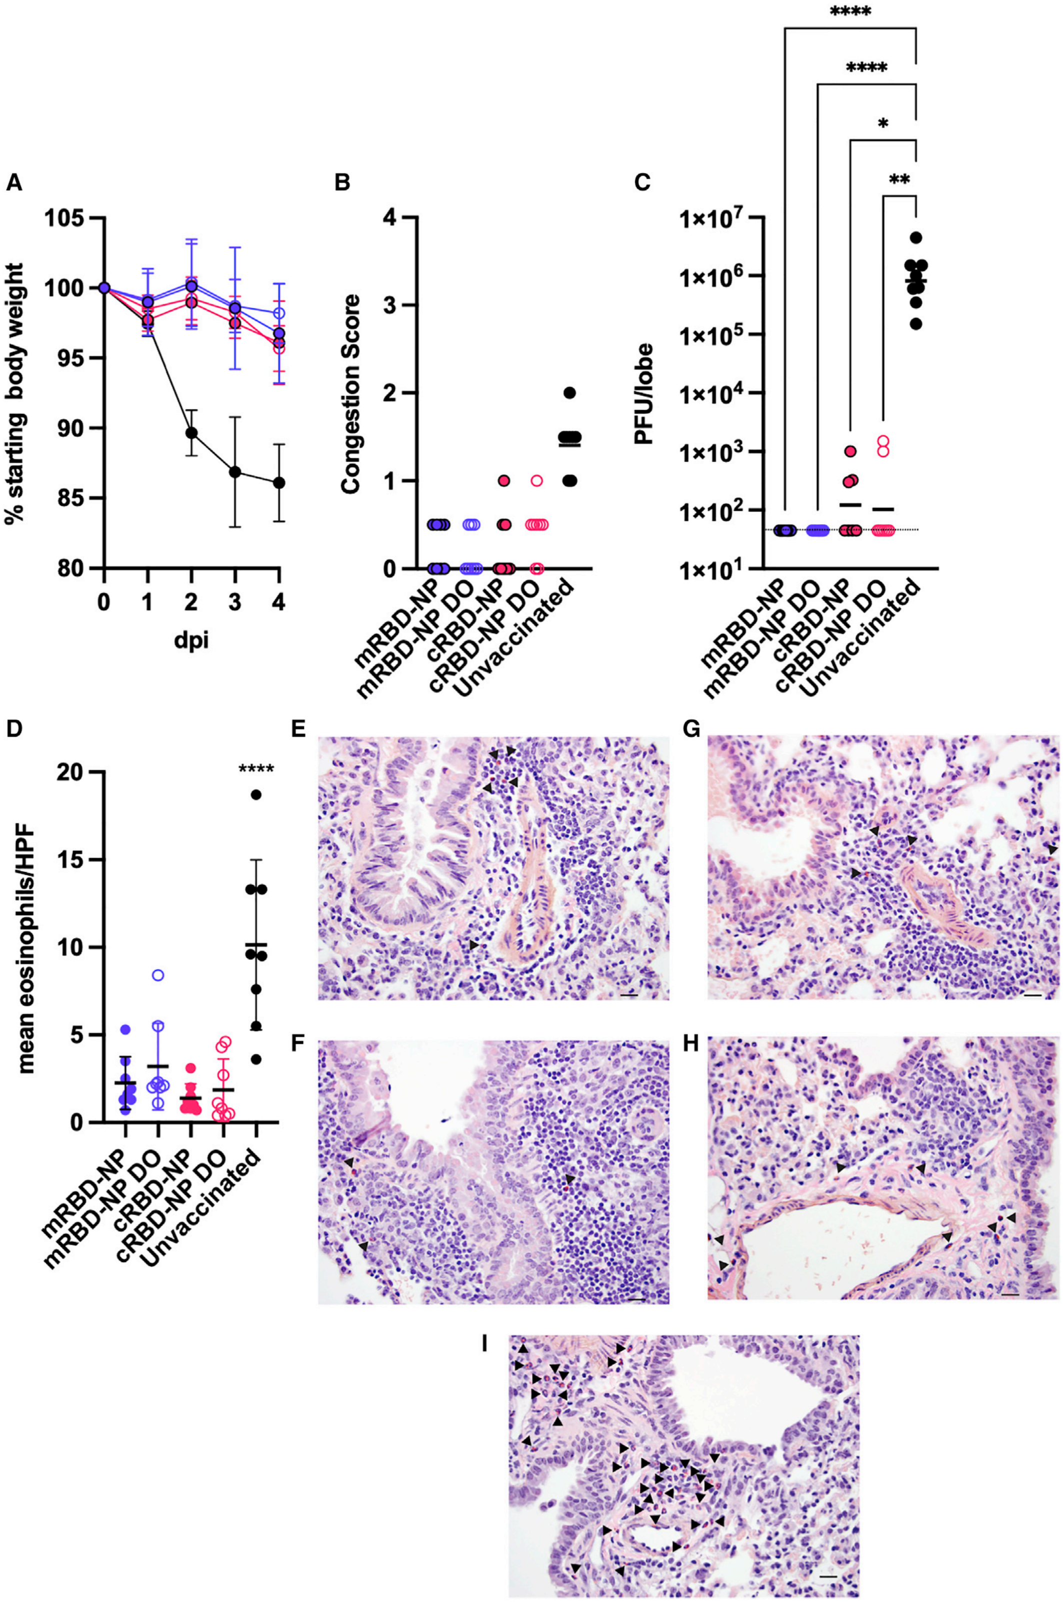
(A) Neutralizing Ab titers in mice (n = 8) against wild-type (D614G) SARS-CoV-2 S MLV pseudovirus five weeks post-prime elicited by monovalent, mosaic, and cocktail RBD-NPs with an LOD of 1 × 10^1.

(B) Neutralizing Ab titers in mice against SARS-CoV S MLV pseudovirus five weeks post-prime elicited by monovalent, mosaic, and cocktail RBD-NPs with an LOD of 1 × 10^1.

(C) Neutralizing Ab titers in mice against SHC014 VSV pseudovirus five weeks post-prime elicited by monovalent, mosaic, and cocktail RBD-NPs with an LOD of 1.7 × 10^1.

Raw data curves shown in Data S1. Statistical significance was determined by Kruskal-Wallis test and shown only when significant. $^{**}p<0.01$. LOD is shown as a gray horizontal dotted line in (C).

and ~0.33 μg of each RBD in the trivalent vaccines. After two immunizations, all four mosaic or cocktail RBD-NP vaccines elicited strong binding (GMT ~1–5 × 10^4) (Figure S4A; Data S1) and potent serum neutralizing (GMT 2–8 × 10^3; Figure 5A; Data S1) Ab titers against wild-type (D614G) SARS-CoV-2 S pseudovirus. Competition ELISAs using hACE2, CR3022, S309, and S2X259 demonstrated that all mosaic and cocktail vaccine candidates elicited robust Ab titers targeting all antigenic sites tested, showcasing the diversity of RBD-specific Abs elicited (Figures S4B–S4E; Data S1). The neutralizing SARS-CoV-2 S (D614G) Ab responses were slightly higher for mRBD-NPs and slightly lower for cRBD-NPs than that of the monovalent RBD-NP (GMT 3 × 10^3) (Figure 5A), similar to the aforementioned low-dose RBD-NP immunization study (Figure 1D) and suggesting that the dose of strain-matched antigen in the multivalent vaccines is not a limiting factor of the magnitude of neutralizing Ab responses. The neutralizing activity against SARS-CoV-2 elicited by the other monovalent RBD-NPs and the non-assembling control were ~2 orders of magnitude lower (GMT < 5 × 10^1) than for the monovalent RBD-NP, indicating poor elicitation of cross-neutralizing Abs by these heterologous monovalent RBD-NPs.



(legend on next page)

Although ELISA binding titers were comparable across mosaic and cocktail groups against SARS-CoV S2P (GMT 3–10 × 10^3), the corresponding pseudovirus neutralization titers showed more nuanced patterns (Figures 5B and S4F; Data S1). Tetravalent mosaic and cocktail RBD-NPs elicited potent neutralizing activity (GMT 3–5.5 × 10^3) with magnitudes roughly comparable to that of the monovalent SARS-CoV-RBD-NP (GMT 5 × 10^3) (Figure 5B). Strikingly, the trivalent nanoparticle immunogens (mRBD-NP-DO and cRBD-NP-DO)—which did not contain the SARS-CoV RBD—also elicited potent neutralization (GMT ~1–2 × 10^3). This cross-neutralization likely arose from the inclusion of the WIV1 RBD (Figure S4G; Data S1) in the trivalent immunogens, as WIV1 cross-reacts with a SARS-CoV-specific mAb (Figure S3H) (Menachery et al., 2016), and the monovalent WIV1-RBD-NP induced similar levels of pseudovirus neutralization (GMT 2 × 10^3) (Figure 5B; Data S1). The non-assembling control immunogen, which contains all four RBD-I53-50A trimeric components, also elicited substantial neutralizing activity against SARS-CoV (GMT 1 × 10^3) but not against SARS-CoV-2. Furthermore, we show that sera elicited by the monovalent, mRBD-NPs, and cRBD-NPs neutralize SHC014 pseudotyped virus, a distantly related sarbecovirus sharing 76%, 76%, 82%, and 84% amino acid sequence identity with the SARS-CoV-2, RaTG13, SARS-CoV, and WIV1 RBDs, respectively (Figure 5C; Data S1). These data show that both mRBD-NPs and cRBD-NPs are promising vaccine candidates for eliciting broad sarbecovirus immunity, in agreement with previous findings using a different nanoparticle platform (Cohen et al., 2021a) or chimeric sarbecovirus S glycoproteins (Martinez et al., 2021b) and recent results obtained with influenza virus hemagglutinin nanoparticle vaccines (Boyoglu-Barnum et al., 2021).

Mosaic RBD-NPs protect mice against heterotypic SARS-CoV challenge

To gauge the ability of the multivalent RBD-NPs to confer protection against vaccine-matched and heterotypic sarbecoviruses, we challenged groups of eight mice with a high dose (10^5 PFUs) of the mouse-adapted SARS-CoV MA15 virus (Roberts et al., 2007). In agreement with the pseudovirus neutralization data, animals immunized with mRBD-NP, mRBD-NP-DO, cRBD-NP, and cRBD-NP-DO were protected from weight loss (ranging between 1% and 5%) and serious lung pathology throughout the four days of the experiment (Figures 6A and 6B). Unvaccinated mice exhibited up to 15% average weight loss and signs of lung pathology (congestion score ~1.5) that were only minorly seen in all other vaccinated groups (Figures 6A and 6B). mRBD-NP- and mRBD-NP-DO-vaccinated mice were completely protected from viral replication in the lungs (Figure 6C). Overall, the trivalent mRBD-NP-DO provided protection that was indistinguishable from the tetravalent mRBD-NP, despite lacking the SARS-CoV RBD. Five out of eight and six out of eight cRBD-NP- and cRBD-NP-DO-vaccinated mice were completely protected from viral replication in the lungs, respectively, with viral burden ranging between 10^2 and 10^3 PFUs/lobe for the remaining animals (compared to unvaccinated mice with ~10^6 PFUs/lobe, Figure 6C). To assess whether the RBD-NP platform causes vaccine-induced immune pathology, which was previously described with double-inactivated SARS-CoV vaccines (Bolles et al., 2011), we investigated eosinophil infiltration and inflammation in the lungs following SARS-CoV MA15 challenge. Although infection induced inflammation and infiltration of eosinophils in the lungs of unvaccinated mice (Figures 6D, 6I, and S5A), no signs of eosinophilia were detected for any animals in the vaccinated groups using histological analysis of stained lung sections (Figures 6D–6I and S5A). These data show that mRBD-NP, mRBD-NP-DO, cRBD-NP, and cRBD-NP-DO protect against weight loss, lung injury, and viral replication following challenge, with no detectable vaccine-induced immune pathology.

To identify the gain in protective breadth provided by multivalent display of sarbecovirus RBD-NP, relative to monovalent RBD-NPs, we performed a second SARS-CoV MA15 challenge experiment including monovalent RBD-NP and SARS-CoV-RBD-NP (Figure S5B). In agreement with the pseudovirus neutralization data and first challenge (Figures 4B–4D and 6A–6C), animals immunized with the SARS-CoV-RBD-NP, mosaic, and cocktail RBD-NP formulations, as well as the non-assembling control immunogen, were protected from weight loss and serious lung pathology throughout the four days of the experiment. The animals receiving the monovalent RBD-NP vaccine experienced up to 12% average weight loss, whereas the unvaccinated mice exhibited further (up to 15%) average weight loss and signs of lung pathology (congestion score ~2) that were only minorly seen in all other vaccinated groups (Figures S5B and S5C). All mice vaccinated with SARS-CoV-RBD-NP, RBD-NP, and mRBD-NP were protected from viral replication in the lungs, whereas we detected ~$10^{2.5}$ and 10^6 PFUs/lobe for half of the mice receiving the non-assembling control immunogen and unvaccinated mice, respectively (Figure S5D). These results provide proof-of-principle that mosaic and cocktail RBD nanoparticle vaccines elicit broad protection against heterotypic sarbecovirus challenge and could represent the next generation of vaccines developed in anticipation of future spillovers.

Figure 6. Mosaic and cocktail RBD-NP vaccines protect against heterotypic SARS-CoV-MA15 challenge in 15-week-old BALB/c cByJ mice

(A) Weight loss following SARS-CoV MA15 challenge up to 4 days post infection (n = 8). Unvaccinated animals are shown as black circles.

(B) Congestion score following SARS-CoV MA15 infection with a score of 0 indicating unchanged lung color and 4 indicating a darkened and diseased lung (n = 8).

(C) Viral titers in mice lungs (expressed in PFUs per lobe) following challenge (n = 8) with an LOD of 9 × 10^1. LOD is shown as a gray horizontal dotted line. Statistical significance was determined by Kruskal-Wallis and shown when significant. **p < 0.01.

(D) Mean eosinophils per high power field (HPF) per sample run over 10 HPF per lung stained with congo red. Significance was determined using one-way ANOVA and shown where significant.

(E–I) Histological analysis of stained lung sections for mRBD-NP (E), mRBD-NP-DO (F), cRBD-NP (G), cRBD-NP-DO (H), and unvaccinated mice (I). Arrowheads indicate eosinophils. Scale bar, 20 μm.

DISCUSSION

The data presented here show that two ultra-low dose immunizations or a single immunization with RBD-NP produces potent neutralizing Ab responses in mice. The latter strategy confers protection against SARS-CoV-2 MA10 challenge, suggesting that the nanoparticle platform could enable dose-sparing regimens to achieve global vaccination, especially given the high shelf stability of this vaccine (Walls et al., 2020b). NHP vaccination with RBD-NP was concurrently shown to also elicit CD4 T cell responses and to protect from viral replication (Arunachalam et al., 2021). Moreover, RBD-NP vaccination, which is currently under phase I/II evaluation in the clinic, elicits diverse Ab responses neutralizing a broad spectrum of SARS-CoV-2 variants detected in clinical isolates with similar potency to those elicited by HexaPro S vaccination. Several RBM mutations, including at position E484, however, lead to reductions in neutralizing activity elicited by either RBD-NP or HexaPro S in NHPs. Although both RBD-NP- and HexaPro S-elicited sera robustly neutralize the B.1.1.7 S variant, which does not contain the E484 substitution, neutralization of the B.1.351, P.1, and B.1.1.7/E484K variants was dampened similarly to sera from individuals vaccinated twice with the Pfizer-BioNTech BNT162b2 mRNA. These findings are in agreement with reports showing that the serum neutralizing activity against the B.1.351 variant from mRNA-1273-vaccinated individuals was comparably reduced (Wu et al., 2021), as was also the case for neutralization of authentic SARS-CoV-2 B.1.351 by HCP (Wibmer et al., 2021). Collectively, these data indicate that a significant fraction of vaccine-elicited neutralizing activity is directed to the RBM, which is the target of potent neutralizing Abs, irrespective of the antigen design strategy (RBD- or S-based), the vaccine modality (protein subunit or mRNA), or species (NHPs or humans). We show that receiving a third immunization, even of an unaltered vaccine, improves the neutralizing Ab responses to VOCs, which is reminiscent of what has been shown in vaccinated humans previously infected with SARS-CoV-2 (Abu Jabal et al., 2021; Krammer et al., 2021; Stamatatos et al., 2021), suggesting that further booster immunizations may limit the impact of VOCs without vaccine update.

The ongoing global spread of SARS-CoV-2 and the circulation of a large number of sarbecoviruses in bats (Menachery et al., 2015, 2016) and other animal reservoirs strongly motivate the development of vaccines that protect against a broad spectrum of coronaviruses. We observed that vaccination of NHPs with RBD-NPs or HexaPro S induced comparable but moderate neutralization breadth against genetically distinct sarbecoviruses. We demonstrate here that co-display (mRBD-NP) and co-immunization (cRBD-NP) of multivalently arrayed sarbecovirus RBDs elicit robust neutralizing Ab responses against SARS-CoV-2, SARS-CoV, and SHC014 pseudotyped viruses and outperform their monovalent vaccine counterparts. The observation that mosaic and cocktail RBD-NPs elicit greater titers of Abs competing with the broadly neutralizing sarbecovirus mAb S2X259 than monovalent vaccines suggest that this vaccine design strategy could enhance neutralization breadth. Accordingly, mice vaccinated with multivalent vaccines were protected from disease upon SARS-CoV MA15 challenge, including with formulations that did not include the SARS-CoV RBD, whereas RBD-NP-vaccinated mice experienced weight loss. Previous studies showed that double-inactivated SARS-CoV vaccines could lead to eosinophil infiltration in the lungs and subsequent immune pathology (Bolles et al., 2011). Our data show that none of the multivalent vaccine candidates evaluated here induced eosinophilia whereas SARS-CoV MA15 challenge did, pointing to the safety and efficacy of these immunogens. Our data highlight the potential of this approach to achieve broad sarbecovirus immunity, overcoming both the emergence of SARS-CoV-2 variants and putative future zoonosis of genetically distinct sarbecoviruses not included in the vaccine. Based on the RBD-centric nature of neutralizing Ab responses resulting from infection and vaccination (Dejnirattisai et al., 2021; Greaney et al., 2021a, 2021b; Piccoli et al., 2020), irrespective of immunogen format or vaccine modality, and the enhanced elicitation of Abs targeting all RBD antigenic sites for multivalent RBD-NPs compared to S-based vaccines, this study paves the way for advancing RBD pan-sarbecovirus subunit vaccines to the clinic.

Limitations of study

Due to the cost of challenge and BSL-3 vivarium limitations, the mice vaccinated with a low dose of RBD-NP were not challenged, and therefore we can only infer the likelihood of protection from their sera's ability to neutralize SARS-CoV-2 pseudovirus better than other mice (i.e., those given a single vaccine dose) that were challenged. Neutralization is a correlate of protection in NHPs (Arunachalam et al., 2021), but we recognize that neutralization assays using HEK-ACE2 cell lines may underestimate the effects of non-RBM targeting Abs (Lempp et al., 2021; McCallum et al., 2021a; Suryadevara et al., 2021). Due to the limitations of the number of animals and the cost of challenge, we cannot challenge with all desired point mutant or variant strains and must use neutralization as the best correlate for interpreting the expected challenge outcome.

STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- RESOURCE AVAILABILITY
  - ○ Lead contact
  - ○ Materials availability
  - ○ Data and code availability
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
  - ○ Cell lines
  - ○ Mice
  - ○ Pigtail macaques
  - ○ Rhesus macaques
  - ○ Convalescent human sera
  - ○ Pfizer vaccinated human sera
- METHOD DETAILS
  - ○ Plasmid construction
  - ○ Transient transfection
  - ○ Microbial protein expression and purification

  - ○ Protein purification
  - ○ *In vitro* nanoparticle assembly and purification
  - ○ Endotoxin measurements
  - ○ Pigtail macaque immunization
  - ○ Rhesus macaque immunization
  - ○ Deep mutational scanning
  - ○ ELISA
  - ○ Competition ELISA of NHP sera with hACE2, CR3022 IgG, and S309 IgG for immobilized SARS-CoV-2 S2P
  - ○ Competition ELISA of mouse sera and immobilized hACE2 or mAbs with SARS-CoV-2 or SARS-CoV S2P
  - ○ Pseudovirus production
  - ○ Pseudovirus neutralization
  - ○ Sarbecovirus biolayer interferometry binding analysis
  - ○ Cocktail and mosaic bio-layer interferometry (antigenicity)
  - ○ Sandwich bio-layer interferometry (mosaic display antigenicity)
  - ○ Cocktail and mosaic negative stain electron microscopy
  - ○ Cocktail and mosaic dynamic light scattering
  - ○ Mouse immunizations and challenge
  - ○ Histopathology of post challenge mouse lungs
- ● QUANTIFICATION AND STATISTICAL ANALYSIS

RESOURCE AVAILABILITY

Lead contact

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, David Veesler (dveesler@uw.edu).

Materials availability

All reagents will be made available on request after completion of a Materials Transfer Agreement.

Data and code availability

All data supporting the findings of this study are found within the paper and its Supplemental information, and are available from the Lead Contact author upon request. Additional supplemental items are available from Mendeley Data at https://doi.org/10.17632/5k989kb8t7.1.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Cell lines

Expi293F (derived from 293 cells which are female) cells are derived from the HEK293F cell line (Life Technologies). Expi293F cells were grown in Expi293 Expression Medium (Life Technologies), cultured at 36.5°C with 8% CO_2 and shaking at 150 rpm. HEK293T/17 is a female human embryonic kidney cell line (ATCC). The HEK-ACE2 (derived from HEK293T cells which are female) adherent cell line was obtained through BEI Resources, NIAID, NIH: Human Embryonic Kidney Cells (HEK293T) Expressing Human Angiotensin-Converting Enzyme 2, HEK293T-hACE2 Cell Line, NR-52511. All adherent cells were cultured at 37°C with 8% CO_2 in flasks with DMEM + 10% FBS (Hyclone) + 1% penicillin-streptomycin. Cell lines other than Expi293F were not tested for mycoplasma contamination nor authenticated.

Mice

Female BALB/c mice (Stock # 000651, BALB/c cByJ mice) four weeks old were obtained from Jackson Laboratory, Bar Harbor, Maine, and maintained at the Comparative Medicine Facility at the University of Washington, Seattle, WA, accredited by the American Association for the Accreditation of Laboratory Animal Care International (AAALAC). Animal procedures were performed under the approvals of the Institutional Animal Care and Use Committee (IACUC) of University of Washington, Seattle, WA, and University of North Carolina, Chapel Hill, NC.

Pigtail macaques

Two adult male Pigtail macaques (*Macaca nemestrina*) were immunized in this study. All animals were housed at the Washington National Primate Research Center (WaNPRC), an AAALAC International accredited institution. All experiments were approved by The University of Washington's IACUC. Animals were singly housed in comfortable, clean, adequately-sized cages with ambient temperatures between 72–82°F. Animals received environmental enrichment for the duration of the study including grooming contact, perches, toys, foraging experiences and access to additional environment enrichment devices. Water was available through automatic watering devices and animals were fed a commercial monkey chow, supplemented daily with fruits and vegetables. Throughout the study, animals were checked twice daily by husbandry staff.

Rhesus macaques

Male Rhesus macaques (Macaca mulatta) of Indian origin, aged 3–7 years were assigned to the study (Arunachalam et al., 2021). Animals were distributed between the groups such that the age and weight distribution were comparable across the groups. Animals were housed and maintained at the New Iberia Research Center (NIRC) of the University of Louisiana at Lafayette, an AAALAC International accredited institution, in accordance with the rules and regulations of the Guide for the Care and Use of Laboratory Animal Resources. The entire study (protocol 2020-8808-15) was reviewed and approved by the University of Louisiana at Lafayette IACUC. All animals were negative for SIV, simian T cell leukemia virus, and simian retrovirus.

Convalescent human sera

Samples collected between 1–60 days post infection from individuals who tested positive for SARS-CoV-2 by PCR were profiled for anti-SARS-CoV-2 S antibody responses and those with anti-S Ab responses were maintained in the cohort (Walls et al., 2020b). Individuals were enrolled as part of the HAARVI study at the University of Washington in Seattle, WA. Baseline sociodemographic and clinical data for these individuals are summarized in Table S1. This study was approved by the University of Washington Human Subjects Division Institutional Review Board (STUDY00000959 and STUDY00003376). All experiments were performed in at least two replicates. One sample is the 20/130 COVID-19 plasma from NIBSC (https://www.nibsc.org/documents/ifu/20-130.pdf).

Pfizer vaccinated human sera

Blood samples were collected from participants who had received both doses of the Pfizer mRNA vaccine and were 7–30 days post second vaccine dose. Clinical data for these individuals are summarized in Table S1. Individuals were enrolled in the UWARN: COVID-19 in WA study at the University of Washington in Seattle, WA. This study was approved by the University of Washington Human Subjects Division Institutional Review Board (STUDY00010350).

METHOD DETAILS

Plasmid construction

The SARS-CoV-2-RBD-Avi construct was synthesized by GenScript into pcDNA3.1- with an N-terminal mu-phosphatase signal peptide and a C-terminal octa-histidine tag, flexible linker, and avi tag (GHHHHHHHHGGSSGLNDIFEAQKIEWHE). The boundaries of the construct are N-$_{328}$RFPN$_{331}$ and $_{528}$KKST$_{531}$-C (Walls et al., 2020a). The GD-Pangolin (326-527), WIV1 (316-518), RaTG13 (359-562), RmYN02 (307-492), and ZXC21 (323-507) were synthesized by GenScript into vector pcDNA3.1- or CMVR with a preceding mu-phosphatase signal peptide and a C-terminal octahistidine tag. SARS-CoV-1 (306-575) was subcloned from a GenArt synthesized SARS-CoV-1 Spike ectodomain. The SARS-CoV S2P ((Pallesen et al., 2017)) was synthesized by GeneArt and placed into a modified pOPING vector with its original N-terminal mu-phosphatase signal peptide, and an engineered C-terminal extension: SG-RENLYFQG (TEV protease site), GGGSG-YIPEAPRDGQAYVRKDGEWVLLSTFL (foldon trimerization motif), G-HHHHHH (hexa-histidine tag), just upstream of the predicted transmembrane region (YIK). The SARS-CoV-2 S2P ectodomain trimer (GenBank: YP_009724390.1, BEI NR-52420) was synthesized by GenScript into pCMV with an N-terminal mu-phosphatase signal peptide and a C-terminal TEV cleavage site (GSGRENLYPQG), T4 fibritin foldon (GGGSGYIPEAPRDGQAYVRKDGEWVLLSTPL), and octa-histidine tag (GHHHHHHHH) (Walls et al., 2020a). The construct contains the 2P mutations (proline substitutions at residues 986 and 987; and an $_{682}$SGAG$_{685}$ substitution at the furin cleavage site. The SARS-CoV-2 RBD was genetically fused to the N terminus of the trimeric I53-50A nanoparticle component using 12 or 16 glycine and serine residues. RBD-12GS-I53-50A fusions were synthesized and cloned by Genscript into pCMV. The RBD-16GS-I53-50A fusion was cloned into pCMV/R using the Xba1 and AvrII restriction sites and Gibson assembly (Gibson et al., 2009). All RBD-bearing components contained an N-terminal mu-phosphatase signal peptide and a C-terminal octa-histidine tag. Human ACE2 ectodomain was genetically fused to a sequence encoding a thrombin cleavage site and a human Fc fragment at the C-terminal end. hACE2-Fc was synthesized and cloned by GenScript with a BM40 signal peptide. Genes encoding CR3022 heavy and light chains were ordered from GenScript and cloned into pCMV/R. S309 construct as previously described (Pinto et al., 2020). SARS-CoV-2 HexaPro construct is as previously described (Hsieh et al., 2020) and placed into CMVR with an octa-his tag.

Transient transfection

Proteins were produced using endotoxin free DNA in Expi293F cells grown in suspension using Expi293F expression medium (Life Technologies) at 33°C, 70% humidity, 8% CO_2 rotating at 150 rpm. The cultures were transfected using PEI-MAX (Polyscience) with cells grown to a density of 3.0 million cells per mL and cultivated for 3 days. Supernatants were clarified by centrifugation (5 min at 4000 *rcf.*), addition of PDADMAC solution to a final concentration of 0.0375% (Sigma Aldrich, #409014), and a second spin (5 min at 4000 *rcf.*).

Microbial protein expression and purification

The I53-50A and I53-50B.4.PT1 proteins (Bale et al., 2016) were expressed in Lemo21(DE3) (NEB) in LB (10 g Tryptone, 5 g Yeast Extract, 10 g NaCl) grown in 2 L baffled shake flasks or a 10 L BioFlo 320 Fermenter (Eppendorf). Cells were grown at 37°C to an OD600 ~0.8, and then induced with 1 mM IPTG. Expression temperature was reduced to 18°C and the cells shaken for ~16 h. The cells were harvested and lysed by microfluidization using a Microfluidics M110P at 18,000 psi in 50 mM Tris, 500 mM NaCl, 30 mM imidazole, 1 mM PMSF, 0.75% CHAPS. Lysates were clarified by centrifugation at 24,000 g for 30 min and applied to a 2.6 × 10 cm Ni Sepharose 6 FF column (Cytiva) for purification by IMAC on an AKTA Avant150 FPLC system (Cytiva). Protein of interest was eluted over a linear gradient of 30 mM to 500 mM imidazole in a background of 50 mM Tris pH 8, 500 mM NaCl, 0.75% CHAPS buffer. Peak fractions were pooled, concentrated in 10K MWCO centrifugal filters (Millipore), sterile filtered (0.22 μm) and applied to either a Superdex 200 Increase 10/300, or HiLoad S200 pg GL SEC column (Cytiva) using 50 mM Tris pH 8, 500 mM NaCl, 0.75% CHAPS buffer. I53-50A elutes at ~0.6 column volume (CV). I53-50B.4PT1 elutes at ~0.45 CV. After sizing, bacterial-derived components were tested to confirm low levels of endotoxin before using for nanoparticle assembly.

Protein purification

Proteins containing His tags were purified from clarified supernatants via a batch bind method where each clarified supernatant was supplemented with 1 M Tris-HCl pH 8.0 to a final concentration of 45 mM and 5 M NaCl to a final concentration of ~310 mM. Talon cobalt affinity resin (Takara) was added to the treated supernatants and allowed to incubate for 15 min with gentle shaking. Resin was collected using vacuum filtration with a 0.2 μm filter and transferred to a gravity column. The resin was washed with 20 mM Tris pH 8.0, 300 mM NaCl, and the protein was eluted with 3 column volumes of 20 mM Tris pH 8.0, 300 mM NaCl, 300 mM imidazole. The batch bind process was then repeated and the first and second elutions combined. SDS-PAGE was used to assess purity. RBD-I53-50A fusion protein IMAC elutions were concentrated to > 1 mg/mL and subjected to three rounds of dialysis into 50 mM Tris pH 7.4, 185 mM NaCl, 100 mM Arginine, 4.5% glycerol, and 0.75% w/v 3-[(3-cholamidopropyl)dimethylammonio]-1-propanesulfonate (CHAPS) in a hydrated 10K molecular weight cutoff dialysis cassette (Thermo Scientific). S2P and HexaPro IMAC elution fractions were concentrated to ~1 mg/mL and dialyzed three times into 50 mM Tris pH 8, 150 mM NaCl, 0.25% L-Histidine in a hydrated 10K molecular weight cutoff dialysis cassette (Thermo Scientific).

Clarified supernatants of cells expressing monoclonal antibodies and human ACE2-Fc were purified using a MabSelect PrismA 2.6 × 5 cm column (Cytiva) on an AKTA Avant150 FPLC (Cytiva). Bound antibodies were washed with five column volumes of 20 mM $NaPO_4$, 150 mM NaCl pH 7.2, then five column volumes of 20 mM $NaPO_4$, 1 M NaCl pH 7.4 and eluted with three column volumes of 100 mM glycine at pH 3.0. The eluate was neutralized with 2 M Trizma base to 50 mM final concentration. SDS-PAGE was used to assess purity.

Recombinant S309 was expressed as a Fab in expiCHO cells transiently co-transfected with plasmids expressing the heavy and light chain, as described above (see Transient transfection) (Pinto et al., 2020). The protein was affinity-purified using a HiTrap Protein A Mab select Xtra column (Cytiva) followed by desalting against 20 mM $NaPO_4$, 150 mM NaCl pH 7.2 using a HiTrap Fast desalting column (Cytiva). The protein was sterilized with a 0.22 μm filter and stored at 4°C until use.

In vitro nanoparticle assembly and purification

Total protein concentration of purified individual nanoparticle components was determined by measuring absorbance at 280 nm using a UV/vis spectrophotometer (Agilent Cary 8454) and calculated extinction coefficients. The assembly steps were performed at room temperature with addition in the following order: RBD-I53-50A trimeric fusion protein, followed by additional buffer (50 mM Tris pH 7.4, 185 mM NaCl, 100 mM Arginine, 4.5% glycerol, and 0.75% w/v CHAPS) as needed to achieve desired final concentration, and finally I53-50B.4PT1 pentameric component (in 50 mM Tris pH 8, 500 mM NaCl, 0.75% w/v CHAPS), with a molar ratio of RBD-I53-50A:I53-50B.4PT1 of 1.1:1. All RBD-I53-50 *in vitro* assemblies were incubated at 2-8°C with gentle rocking for at least 30 min before subsequent purification by SEC in order to remove residual unassembled component. Different columns were utilized depending on purpose: Superose 6 Increase 10/300 GL column was used analytically for nanoparticle size estimation, a Superdex 200 Increase 10/300 GL column used for small-scale pilot assemblies, and a HiLoad 26/600 Superdex 200 pg column used for nanoparticle production. Assembled particles were purified in 50 mM Tris pH 7.4, 185 mM NaCl, 100 mM Arginine, 4.5% glycerol, and 0.75% w/v CHAPS, and elute at ~11 mL on the Superose 6 column and in the void volume of Superdex 200 columns. Assembled nanoparticles were sterile filtered (0.22 μm) immediately prior to column application and following pooling of fractions.

Endotoxin measurements

Endotoxin levels in protein samples were measured using the EndoSafe Nexgen-MCS System (Charles River). Samples were diluted 1:50 or 1:100 in Endotoxin-free LAL reagent water, and applied into wells of an EndoSafe LAL reagent cartridge. Charles River Endo-Scan-V software was used to analyze endotoxin content, automatically back-calculating for the dilution factor. Endotoxin values were reported as EU/mL which were then converted to EU/mg based on UV/vis measurements. Our threshold for samples suitable for immunization was < 50 EU/mg.

Pigtail macaque immunization

Two Pigtail macaques were immunized with 250 μg of RBD-12GS-I53-50 nanoparticle (88 μg RBD antigen) with AddaVax at day 0, day 28, and O/W at day 168. Blood was collected every 14 days post-prime. Blood was collected in serum collection tubes and allowed to clot at room temperature. Serum was isolated after a 15 min spin at 1455 x g for 15 min and stored at −80C until use. Prior to vaccination or blood collection, animals were sedated with an intramuscular injection (10 mg/kg) of ketamine (Ketaset®; Henry Schein). Prior to inoculation, immunogen suspensions were gently mixed 1:1 vol/vol with AddaVax adjuvant for immunizations 1 and 2 and O/W for immunization 3 (VFI) to reach a final concentration of 0.250 mg/mL antigen. The vaccine was delivered intramuscularly into both quadriceps muscles with 1 mL per injection site on days 0, 28, and 168. All injection sites were shaved prior to injection. Animals were observed daily for general health (activity and appetite, urine/feces output) and for evidence of reactogenicity at the vaccine inoculation site (swelling, erythema, and pruritus) for up to 1 week following vaccination. They also received physical exams including temperature and weight measurements at each study time point. None of the animals became severely ill during the course of the study nor required euthanasia.

Rhesus macaque immunization

Adapted from Arunachalam et al. (2021). AS03 was kindly provided by GSK Vaccines. AS03 is an oil-in-water emulsion that contains 11.86 mg a-tocopherol, 10.69 mg squalene, and 4.86 mg polysorbate 80 (Tween-80) in PBS. For each dose, RBD-NP was diluted to 50 μg/ml (RBD component) in 250 μL of Tris-buffered saline (TBS) and mixed with an equal volume of AS03.The dose of AS03 was 50% v/v (equivalent of one human dose). Soluble HexaPro was diluted to 50 μg/ml in 250 μL of Tris-buffered saline (TBS) and mixed with an equal volume of AS03. All immunizations were administered via the intramuscular route in right forelimbs. The volume of each dose was 0.5 ml.

Deep mutational scanning

All mutations that escape serum antibody binding were mapped via a deep mutational scanning approach (Greaney et al., 2020, 2021b). We used previously described yeast-display RBD mutant libraries (Greaney et al., 2020; Starr et al., 2020a). Briefly, duplicate mutant libraries were constructed in the spike receptor binding domain (RBD) from SARS-CoV-2 (isolate Wuhan-Hu-1, GenBank: MN908947, residues N331-T531) and contain 3,804 of the 3,819 possible amino-acid mutations, with > 95% present as single mutants. Each RBD variant was linked to a unique 16-nucleotide barcode sequence to facilitate downstream sequencing. As previously described, libraries were sorted for RBD expression and ACE2 binding to eliminate RBD variants that are completely misfolded or non-functional (i.e., lacking modest ACE2 binding affinity) (Greaney et al., 2020).

Antibody escape mapping experiments were performed in biological duplicate using two independent mutant RBD libraries, with minor modifications from Greaney et al. (2020), and exactly as described in Greaney et al. (2021b). The antibody escape mapping for the vaccinated NHP serum was performed in this study; the antibody escape mapping from convalescent human plasma was performed in Greaney et al. (2021b). Briefly, mutant yeast libraries induced to express RBD were washed and incubated with plasma or serum at a range of dilutions for 1 h at room temperature with gentle agitation. For each sample, we chose a sub-saturating dilution such that the amount of fluorescent signal due to plasma antibody binding to RBD was approximately equal across samples. A 1:1000 dilution was used for the vaccinated NHP serum, and the exact dilutions of human convalescent plasma are reported in Greaney et al. (2021b). After the antibody incubations, the libraries were secondarily labeled with 1:100 FITC-conjugated anti-MYC antibody (Immunology Consultants Lab, CYMC-45F) to label for RBD expression and and 1:200 Alexa-647-conjugated goat anti-human-IgA+IgG+IgM (Jackson ImmunoResearch 109-605-064) to label for bound serum or plasma antibodies. A flow cytometric selection gate was drawn to capture approximately 5% of the RBD mutant libraries with the lowest amount of plasma binding for their degree of RBD expression. For each sample, approximately 10 million RBD+ cells were processed on the cytometer. Antibody-escaped cells were grown overnight in SD-CAA (6.7g/L Yeast Nitrogen Base, 5.0g/L Casamino acids, 1.065 g/L MES acid, and 2% w/v dextrose) to expand cells prior to plasmid extraction.

Plasmid samples were prepared from pre-selection and overnight cultures of antibody-escaped cells (Zymoprep Yeast Plasmid Miniprep II) as previously described (Greaney et al., 2020). The 16-nucleotide barcode sequences identifying each RBD variant were amplified by PCR and sequenced on an Illumina HiSeq 2500 with 50 bp single-end reads as described in Greaney et al. (2020 and Starr et al. (2020a).

Escape fractions were computed as described in Greaney et al. (2020), and exactly as described in Greaney et al. (2021b). We used the dms_variants package (https://jbloomlab.github.io/dms_variants/, version 0.8.2) to process Illumina sequences into counts of each barcoded RBD variant in each pre-sort and antibody-escape population using the barcode/RBD look-up table from Starr et al. (2021).

For each serum selection, we computed the "escape fraction" for each barcoded variant using the deep sequencing counts for each variant in the original and serum-escape populations and the total fraction of the library that escaped antibody binding via the formula provided in Greaney et al. (2020). These escape fractions represent the estimated fraction of cells expressing that specific variant that fall in the antibody escape bin, such that a value of 0 means the variant is always bound by serum and a value of 1 means that it always escapes serum binding. We then applied a computational filter to remove variants with low sequencing counts or highly deleterious mutations that might cause antibody escape simply by leading to poor expression of properly folded RBD on the yeast cell surface (Greaney et al., 2020; Starr et al., 2020a). Specifically, we removed variants that had (or contained mutations with) ACE2 binding scores < -2.35 or expression scores < -1, using the variant- and mutation-level deep mutational scanning scores from Starr et al. (2020a). Note that these filtering criteria are slightly more stringent than those used in Greaney et al. (2020) but are identical to those used in Greaney et al. (2021b) and Starr et al. (2020b).

We next deconvolved variant-level escape scores into escape fraction estimates for single mutations using global epistasis models (Otwinowski et al., 2018) implemented in the dms_variants package, as detailed at (https://jbloomlab.github.io/dms_variants/dms_variants.globalepistasis.html) and described in Greaney et al. (2020). The reported escape fractions throughout the paper are the average across the libraries (correlations shown in Figure S2); these scores are also in Table S1 and at https://github.com/jbloomlab/SARS-CoV-2-RBD_MAP_RBD-nano-vax-NHP1/blob/main/results/supp_data/NHP_HCS_raw_data.csv. Sites of strong escape from each antibody were determined heuristically as sites whose summed mutational escape scores were at least 10 times the median sitewise sum of selection, and within 10-fold of the sitewise sum of the most strongly selected site. Sites shown in Figures 2 and S2A are the sites of strong escape for any of the three human convalescent plasma, plus sites 417, 452, and 501 due to their prevalence in circulating SARS-CoV-2 variants. For each plasma, the y axis is scaled to be the greatest of (a) the maximum site-wise escape metric observed for that plasma, (b) 20x the median site-wise escape fraction observed across all sites for that plasma, or (c) an absolute value of 1.0 (to appropriately scale plasma that are not "noisy" but for which no mutation has a strong effect on plasma binding). Full documentation of the computational analysis is at https://github.com/jbloomlab/SARS-CoV-2-RBD_MAP_RBD-nano-vax-NHP1. These results are also available in a zoomable, interactive form at https://jbloomlab.github.io/SARS-CoV-2-RBD_MAP_RBD-nano-vax-NHP1/.

ELISA

For anti-S2P ELISA, 25 μL of 2 μg/mL S2P was plated onto 384-well Nunc Maxisorp (ThermoFisher) plates in PBS and sealed overnight at RT. The next day plates were washed 4 × in Tris Buffered Saline Tween (TBST) using a plate washer (BioTek) and blocked with SuperBlock (ThermoFisher) for 1 h at 37°C. Plates were washed 4 × in TBST and 1:5 serial dilutions of mouse, NHP, or human sera were made in 25 μL TBST and incubated at 37°C for 1 h. Plates were washed 4 × in TBST, then anti-mouse (Invitrogen), anti-NHP (AlphaDiagnostics), or anti-human (Invitrogen) horseradish peroxidase-conjugated antibodies were diluted 1:5,000 and 25 μL added to each well and incubated at 37°C for 1 h. Plates were washed 4 × in TBST and 25 μL of TMB (SeraCare) was added to every well for

~5 min at room temperature. The reaction was quenched with the addition of 25 μL of 1 N HCl. Plates were immediately read at 450 nm on a BioTek plate reader and data plotted and fit in Prism (GraphPad) using nonlinear regression sigmoidal, 4PL, X is log(concentration) to determine EC_{50} values from curve fits.

Competition ELISA of NHP sera with hACE2, CR3022 IgG, and S309 IgG for immobilized SARS-CoV-2 S2P

384-well Maxisorp plates (Thermo Fisher) were coated overnight at room temperature with 3 μg/mL of SARS-CoV-2 S2P (Pallesen et al., 2017) in 20mM Tris pH 8 and 150mM NaCl. Plates were slapped dry and blocked with Blocker Casein in TBS (Thermo Fisher) for one hour at 37°C. Plates were slapped dry and NHP sera was serially diluted 1:4 in TBST with an initial dilution of 1:4 for hACE2 competition or 1:2 for antibody competition. Random primary amine biotinylated (Thermo Fisher) hACE2-Fc, CR3022 (Yuan et al., 2020), or S309 (Pinto et al., 2020) were added, bringing the concentration of each well to the EC_{50} values of 0.2nM, 2nm, and 0.01nM, respectively. Plates were left for one hour at 37°C, then washed 4x with TBST using a 405 TS Microplate Washer (BioTek) followed by addition of 1:500 streptavidin-HRP (Thermo Fisher) for one hour at 37°C. Plates were washed 4x and TMB Microwell Peroxidase (Seracare) was added. The reaction was quenched after 1-2 minutes with 1 N HCl and the A450 of each well was read using a BioTek plate reader (BioTek). Data plotted and fit in Prism (GraphPad) using nonlinear regression sigmoidal, 4PL, X is log(concentration) to determine EC_{50} values from curve fits with upper and lower constraints determined by uncompeted ELISA per antigen.

Competition ELISA of mouse sera and immobilized hACE2 or mAbs with SARS-CoV-2 or SARS-CoV S2P

384-well Maxisorp plates (Thermo Fisher) were coated overnight at room temperature with 3 μg/mL of hACE2-Fc, CR3022 (Yuan et al., 2020), or S309 (Pinto et al., 2020) in 20mM Tris pH 8 and 150mM NaCl. Plates were slapped dry and blocked with Blocker Casein in TBS (Thermo Fisher) for one hour at 37°C. Plates were slapped dry and a 30-minute pre-incubated 1:5 serial dilution of mouse sera in TBST, with in initial dilution of 1:50 for hACE2-Fc competition or 1:10 for antibody competition, and a constant concentration of biotinylated (Avidity) SARS-CoV-2 S2P or SARS-CoV 2P at their EC_{50} values were added. Spike concentrations were 0.63nM, 5.98nM, and 0.22nM of SARS-CoV-2 S2P or 4.11nM, 2.89nM, and 0.19nM of SARS-CoV S2P for immobilized hACE2, CR3022, and S309, respectively. Plates were left for one hour at 37°C, then washed 4x with TBST using a 405 TS Microplate Washer (BioTek) followed by addition of 1:500 streptavidin-HRP (Thermo Fisher) for one hour at 37°C. Plates were washed 4x and TMB Microwell Peroxidase (Seracare) was added. The reaction was quenched after 1-2 minutes with 1 N HCl and the A450 of each well was read using a BioTek plate reader (BioTek). Data plotted and fit in Prism (GraphPad) using nonlinear regression sigmoidal, 4PL, X is log(concentration) to determine EC_{50} values from curve fits.

Pseudovirus production

MLV-based D614G SARS-CoV-2 S and SARS-CoV S pseudotypes were prepared as previously described (Millet and Whittaker, 2016; Walls et al., 2020a, 2020b). Briefly, HEK293T cells were co-transfected using Lipofectamine 2000 (Life Technologies) with an S-encoding plasmid, an MLV Gag-Pol packaging construct, and the MLV transfer vector encoding a luciferase reporter according to the manufacturer's instructions. Cells were washed 3 × with Opti-MEM and incubated for 5 h at 37°C with transfection medium. DMEM containing 10% FBS was added for 60 h. The supernatants were harvested by spinning at 2,500 g, filtered through a 0.45 μm filter, concentrated with a 100 kDa membrane for 10 min at 2,500 g and then aliquoted and stored at −80°C.

HIV-based pseudotypes were prepared as previously described (Crawford et al., 2020). Briefly, HEK293T cells were cotransfected using Lipofectamine 2000 (Life Technologies) with an S-encoding plasmid (D614G SARS-CoV-2 S (YP 009724390.1), Pangolin-Guangdong S (QLR06867.1), SARS-CoV S (YP 009825051.1), P1, B.1.351 S, B.1.1.7, and B.1.1.7+E484K S) an HIV Gag-Pol, Tat, Rev1B packaging construct, and the HIV transfer vector encoding a luciferase reporter according to the manufacturer's instructions. Cells were washed 3 × with Opti-MEM and incubated for 5 h at 37°C with transfection medium. DMEM containing 10% FBS was added for 60 h. The supernatants were harvested by spinning at 2,500 g, filtered through a 0.45 μm filter, concentrated with a 100 kDa membrane for 10 min at 2,500 g and then aliquoted and stored at −80°C.

D614G SARS-CoV-2 S (YP 009724390.1), D614G SARS-CoV-2 point mutants, SHC014 (AGZ48806.1), RaTG13 S (QHR63300.2), Pangolin-Guangdong S (QLR06867.1), SARS-CoV S (YP 009825051.1), WIV1 S (AGZ48831.1), B.1.351 S, P1, and B.1.1.7 S pseudotyped VSV viruses were prepared as described previously (McCallum et al., 2021a; Sauer et al., 2021). Briefly, 293T cells in DMEM supplemented with 10% FBS, 1% PenStrep seeded in 10-cm dishes were transfected with the plasmid encoding for the corresponding S glycoprotein using lipofectamine 2000 (Life Technologies) following manufacturer's indications. One day post-transfection, cells were infected with VSV(G*ΔG-luciferase) and after 2 h were washed five times with DMEM before adding medium supplemented with anti-VSV-G antibody (I1- mouse hybridoma supernatant, CRL- 2700, ATCC). Virus pseudotypes were harvested 18-24 h post-inoculation, clarified by centrifugation at 2,500 x g for 5 min, filtered through a 0.45 μm cut off membrane, concentrated 10 times with a 30 kDa cut off membrane, aliquoted and stored at −80°C.

Pseudovirus neutralization

HEK293-hACE2 cells (Crawford et al., 2020) were cultured in DMEM with 10% FBS (Hyclone) and 1% PenStrep with 8% CO_2 in a 37°C incubator (ThermoFisher). One day prior to infection, 40 μL of poly-lysine (Sigma) was placed into 96-well plates and incubated with rotation for 5 min. Poly-lysine was removed, plates were dried for 5 min then washed 1 × with water prior to plating with 40,000 cells. The following day, cells were checked to be at 80% confluence. In an empty half-area 96-well plate a 1:3 serial dilution of sera was made in DMEM and diluted pseudovirus was then added to the serial dilution and incubated at room temperature for 30-60 min. After incubation, the sera-virus mixture was added to the cells at 37°C and 2 hours post-infection, 40 μL 20% FBS-2% PenStrep DMEM was added. After 17-20 hours (VSV) or 48 hours (HIV, MLV) 40 μL/well of One-Glo-EX substrate (Promega) was added to the cells and incubated in the dark for 5-10 min prior reading on a BioTek plate reader. Measurements were done in at least duplicate. Relative luciferase units were plotted and normalized in Prism (GraphPad). Nonlinear regression of log(inhibitor) versus normalized response was used to determine IC_{50} values from curve fits. Kruskal Wallis tests were used to compare two groups to determine whether they were statistically different.

Sarbecovirus biolayer interferometry binding analysis

Purification of Fabs from NHP serum was adapted from Boyoglu-Barnum et al. (2021). Briefly, 1 mL of day 70 serum was diluted to 10 mL with PBS and incubated with 1 mL of 3 × PBS-washed protein A beads (GenScript) with agitation overnight at 37°C. The next day beads were thoroughly washed with PBS using a gravity flow column and bound Abs were eluted with 0.1 M glycine pH 3.5 into 1M Tris-HCl (pH 8.0) to a final concentration of 100 mM. Serum and early washes that flowed through were re-bound to beads overnight again for a second, repeat elution. IgGs were concentrated (Amicon 30 kDa) and buffer exchanged into PBS. 2 × digestion buffer (40 mM sodium phosphate pH 6.5, 20 mM EDTA, 40 mM cysteine) was added to concentrated and pooled IgGs. 500 μL of resuspended immobilized papain resin (ThermoFisher Scientific) freshly washed in 1 × digestion buffer (20 mM sodium phosphate, 10 mM EDTA, 20 mM cysteine, pH 6.5) was added to purified IgGs in 2 × digestion buffer and samples were agitated for 5 h at 37°C. The supernatant was separated from resin and resin washes were collected and pooled with the resin flow through. Pooled supernatants were sterile-filtered at 0.22 μm and applied 6 × to PBS-washed protein A beads in a gravity flow column. The column was eluted as described above and the papain procedure repeated overnight with undigested IgGs to increase yield. The protein A flow throughs were pooled, concentrated (using an Amicon 10 kDa), and buffer exchanged into PBS. Purity was checked by SDS-PAGE.

Assays were performed and analyzed using biolayer interferometry on an Octet Red 96 System (Pall Forte Bio/Sartorius) at ambient temperature with shaking at 1000 rpm. Different Sarbeco RBDs were purified like in Walls et al., 2020 and were diluted with different acetate buffers and applied to a black 96-well Greiner Bio-one microplate at 200ul per well. GD-Pangolin RBD was diluted in pH 6 buffer to 5 μg/mL, RmNY02 were diluted in pH 5 to 25 μg/mL, WIV16 was diluted in pH 5 to 10 μg/mL, SARS-CoV-2 was diluted in pH 6 to 5 μg/mL, RaTG13 was diluted in pH 6 to 10 μg/mL, RaTG13 was diluted in pH 6 to 10 μg/mL, SARS-CoV was diluted in pH 6 to 50 μg/mL, and finally ZXC21 was diluted in pH 6 to 10μg/mL. AR2G biosensors (ForteBio/Sartorius) following 600 s hydration were normalized in water for 180 s. Then tips were NHS-EDC activated for 300 s and the different sarbecovirus RBDs were loaded up to a 1.50 nm threshold for up to 600 s. Immobilized RBDs on the tips were quenched for 300 s in ethanolamine and dipped into kinetics buffer for a 60 s baseline. The association step was performed by dipping the mobilized RBDs into diluted purified polyclonal pigtail macaque IgGs for 600 s. Dissociation was measured by inserting the biosensors in kinetics buffer for 600 s. The data were baseline subtracted and the plots fitted using the Pall ForteBio/Sartorius analysis software (version 12.0).

Cocktail and mosaic bio-layer interferometry (antigenicity)

Binding of hACE2-Fc to monovalent RBD-I53-50 nanoparticles, mosaic-RBD-I53-50 nanoparticles, and cocktail of RBD-nanoparticles was analyzed for antigenicity experiments and real-time stability studies using an Octet Red 96 System (Pall FortéBio/Sartorius) at ambient temperature with shaking at 1000 rpm. Protein samples were diluted to 100 nM in Kinetics buffer (1 × HEPES-EP+ (Pall Forté Bio), 0.05% nonfat milk, and 0.02% sodium azide). Buffer, receptor, and analyte were then applied to a black 96-well Greiner Bio-one microplate at 200 μL per well. Protein A biosensors (FortéBio/Sartorius) were first hydrated for 10 minutes in Kinetics buffer, then dipped into hACE2-Fc diluted to 10 μg/mL in Kinetics buffer in the immobilization step. After 150 s, the tips were transferred to kinetics buffer for 60 s to reach a baseline. The association step was performed by dipping the loaded biosensors into the immunogens for 300 s, and subsequent dissociation was performed by dipping the biosensors back into Kinetics buffer for an additional 300 s. The data were baseline subtracted prior for plotting using the FortéBio analysis software (version 12.0). Plots in Figure S3 show the 600 s of association and dissociation.

Sandwich bio-layer interferometry (mosaic display antigenicity)

Binding of hACE2-Fc or S2H14 mAb and S230 Fab to WIV1-RBD-I53-50, RaTG13-RBD-I53-50, SARS-CoV-SARS-CoV2-RBD-I53-50, SARS-CoV2-I53-50, and mosaic-RBD-I53-50 nanoparticles were analyzed for co-display of RBDs using an Octet Red 96 System (Pall FortéBio/Sartorius) at ambient temperature with shaking at 1000 rpm. Nanoparticles were diluted to 100 nM in Kinetics buffer. Kinetics buffer, mAb, nanoparticles and Fab were then applied to a black 96-well Greiner Bio-one microplate at 200 μL per well. Protein A biosensors (FortéBio/Sartorius) were first hydrated for 10 minutes in Kinetics buffer, then dipped into hACE2-Fc or S2H14 mAb diluted to 10 μg/mL in Kinetics buffer in the immobilization step. After 150 s, the tips were transferred to Kinetics buffer for 60 s to reach a baseline. The receptor or mAb was then loaded with nanoparticle by dipping the loaded biosensors into the immunogens for 300 s, and subsequent baseline was performed by dipping the biosensors back into the Kinetics buffer for an additional 60 s. Association of S230 Fab diluted to 100 nM in Kinetics buffer was then measured for 300 s and subsequent dissociation in Kinetics buffer of S230 Fab for 300 s. The data were baseline subtracted prior for plotting using the FortéBio analysis software (version 12.0). Plots in Figure S3 exclude the initial mAb loading and the first baseline.

Cocktail and mosaic negative stain electron microscopy

Monovalent RBD-I53-50 nanoparticles, mosaic-RBD-I53-50 nanoparticles, and cocktail of RBD-nanoparticles were first diluted to 75 μg/mL in 50 mM Tris pH 7.4, 185 mM NaCl, 100 mM Arginine, 4.5% v/v Glycerol, 0.75% w/v CHAPS prior to application of 3 μL of sample onto freshly glow-discharged 300-mesh copper grids. Sample was incubated on the grid for 1 minute before the grid was dipped in a 50 μL droplet of water and excess liquid blotted away with filter paper (Whatman). The grids were then dipped into 6 μL of 0.75% w/v uranyl formate stain. Stain was blotted off with filter paper, then the grids were dipped into another 6 μL of stain and incubated for ~70 s. Finally, the stain was blotted away and the grids were allowed to dry for 1 minute. Prepared grids were imaged in a Talos model L120C electron microscope at 57,000 × (nanoparticles).

Cocktail and mosaic dynamic light scattering

Dynamic Light Scattering (DLS) was used to measure hydrodynamic diameter (Dh) and % Polydispersity (%Pd) of monovalent RBD-I53-50 nanoparticles, mosaic-RBD-I53-50 nanoparticles, and cocktail of RBD-nanoparticles on an UNcle Nano-DSF (UNchained Laboratories). Sample was applied to a 8.8 μL quartz capillary cassette (UNi, UNchained Laboratories) and measured with 10 acquisitions of 5 s each, using auto-attenuation of the laser. Increased viscosity due to 4.5% v/v glycerol in the RBD nanoparticle buffer was accounted for by the UNcle Client software in Dh measurements.

Mouse immunizations and challenge

At six weeks of age, 8 female BALB/c mice per dosing group were vaccinated with a prime immunization, and three weeks later mice were boosted with a second vaccination (IACUC protocol 4470.01). Prior to inoculation, immunogen suspensions were gently mixed 1:1 vol/vol with AddaVax adjuvant (Invivogen, San Diego, CA) to reach a final concentration of 0.01 mg/mL antigen. Mice were injected intramuscularly into the gastrocnemius muscle of each hind leg using a 27-gauge needle (BD, San Diego, CA) with 50 μL per injection site (100 μL total) of immunogen under isoflurane anesthesia. To obtain sera all mice were bled two weeks after prime and boost immunizations. Blood was collected via submental venous puncture and rested in 1.5 mL plastic Eppendorf tubes at room temperature for 30 min to allow for coagulation. Serum was separated from red blood cells via centrifugation at 2,000 g for 10 min. Complement factors and pathogens in isolated serum were heat-inactivated via incubation at 56°C for 60 min. Serum was stored at 4°C or −80°C until use. The study was repeated twice. Five weeks post-boost, mice (aged 14 weeks) were exported from Comparative Medicine Facility at the University of Washington, Seattle, WA to an AAALAC accredited Animal Biosafety Level 3 (ABSL3) Laboratory at the University of North Carolina, Chapel Hill. After a 7-day acclimation time, mice were anesthetized with a mixture of ketamine/xylazine and challenged intranasally with 10^5 plaque-forming units (pfu) of mouse-adapted SARS-CoV-2 MA10 or SARS-CoV MA15 strain for the evaluation of vaccine efficacy (IACUC protocol 20-114.0). After infection, body weight and congestion score were monitored daily until the termination of the study two days post-infection, when lung and nasal turbinate tissues were harvested to evaluate viral load by plaque assay.

Histopathology of post challenge mouse lungs

For each mouse the left lung was incubated in formalin at 4°C for at least 7 days to fix tissue and inactivate virus. The fixed tissue was processed and embedded in paraffin. 5 μm sections were cut and stained with either Congo red or hematoxylin and eosin (H&E). Eosinophils were enumerated by counting the Congo red positive leukocytes in 10 high power fields (400X final magnification) per mouse lung. Representative images were minimally and similarly adjusted with Adobe Photoshop 2020 to enhance contrast. Airway pathology was assessed in H&E stained sections to assess bronchial epithelial cell death (score: 0 = no dead cells, 1 = 1-5 dead cells, 2 = 6-10 dead cells, 3 = 11-20 dead cells and 4 = > 20 dead cells; scored for 10 400X fields per mouse lung), peribronchial inflammation (score 0 = none, 1 = 0%–25% circumference with > 1 leukocyte cell layer, 2 = 26%–50% circumference with > 1 leukocyte cell layer, and 3 = 50%–100% circumference with > 1 leukocyte cell layer; scored for 10 400X fields per mouse lung), and interstitial pneumonitis (score = percentage of pulmonary alveolar parenchyma with septae expanded by leukocyte; scored for 10 100X fields).

QUANTIFICATION AND STATISTICAL ANALYSIS

Statistical details of experiments can be found in the figure legends. For NHP experiments, 2-6 sera samples were used and experiments were done in at least duplicate unless mentioned. For mouse ELISAs, neutralization, and challenge experiments, sera from 6, 8, or 10 BALB/c animals were used and experiments were completed in at least duplicate unless mentioned. Geometric mean titers were calculated. Kruskal Wallis tests were performed to compare two groups to determine whether they were statistically different for ELISA and neutralization experiments. Significance is indicated with stars: *, $p < 0.05$; **** $p < 0.0001$ and non significant groups are not shown.

Supplemental figures

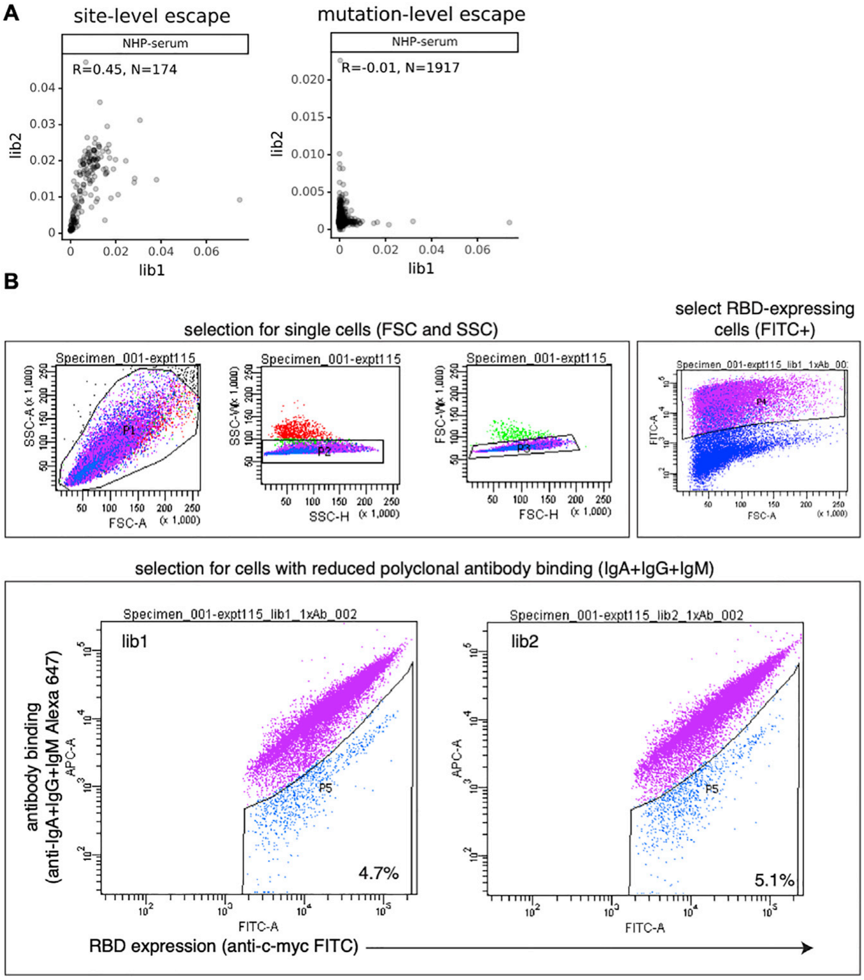

Figure S1. Effects of mutations on binding of HCP Abs to RBD and FACS gating strategy, related to Figure 2

(A) Correlation plots of site- and mutation-level escape for each of the two independent RBD mutant libraries for the Ab-escape map shown in Figure 2B. Site-level escape is the sum of the escape fractions for each mutation at a site. (B) Hierarchical FACS gating strategy used for selecting yeast cells expressing Ab-escape RBD variants. First, gates are selected to enrich for single cells (SSC-A versus FSC-A, and FSC-W versus FSC-H) that also express RBD (FITC-A versus FSC-A, cells in pink). Second, cells expressing RBD mutants with reduced polyclonal Ab binding, detected with an anti-IgA+IgG+IgM secondary Ab, were selected with a gate that captured the ~5% of cells with the lowest Ab binding (cells in blue).

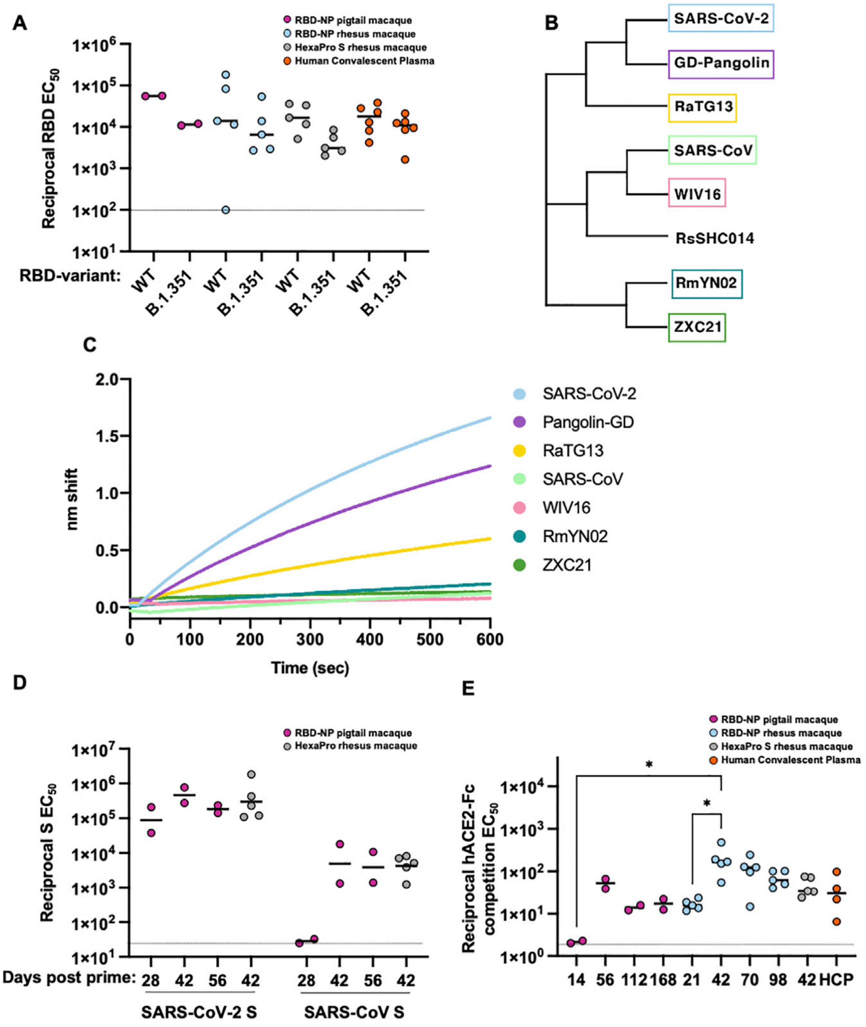

Figure S2. Evaluation of vaccine-elicited binding and neutralizing Ab titers against SARS-CoV-2 variants and sarbecoviruses, related to Figure 3

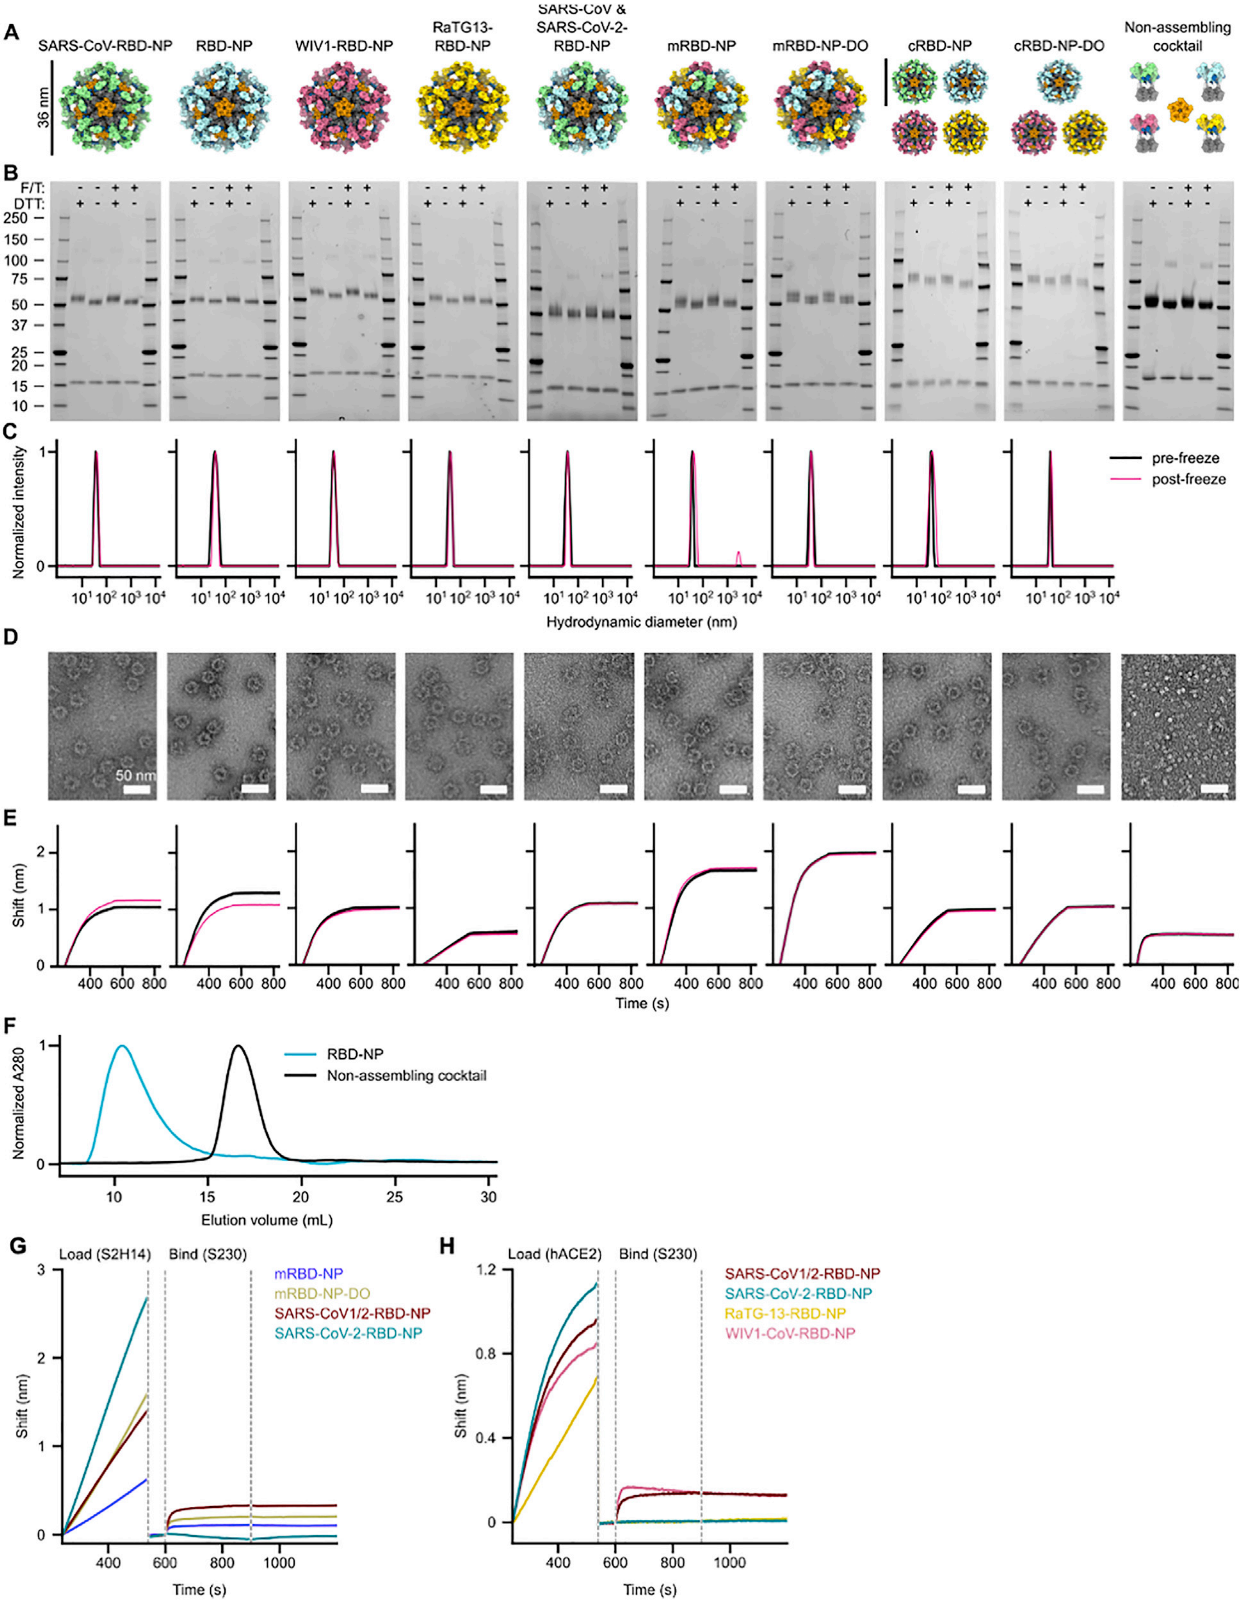
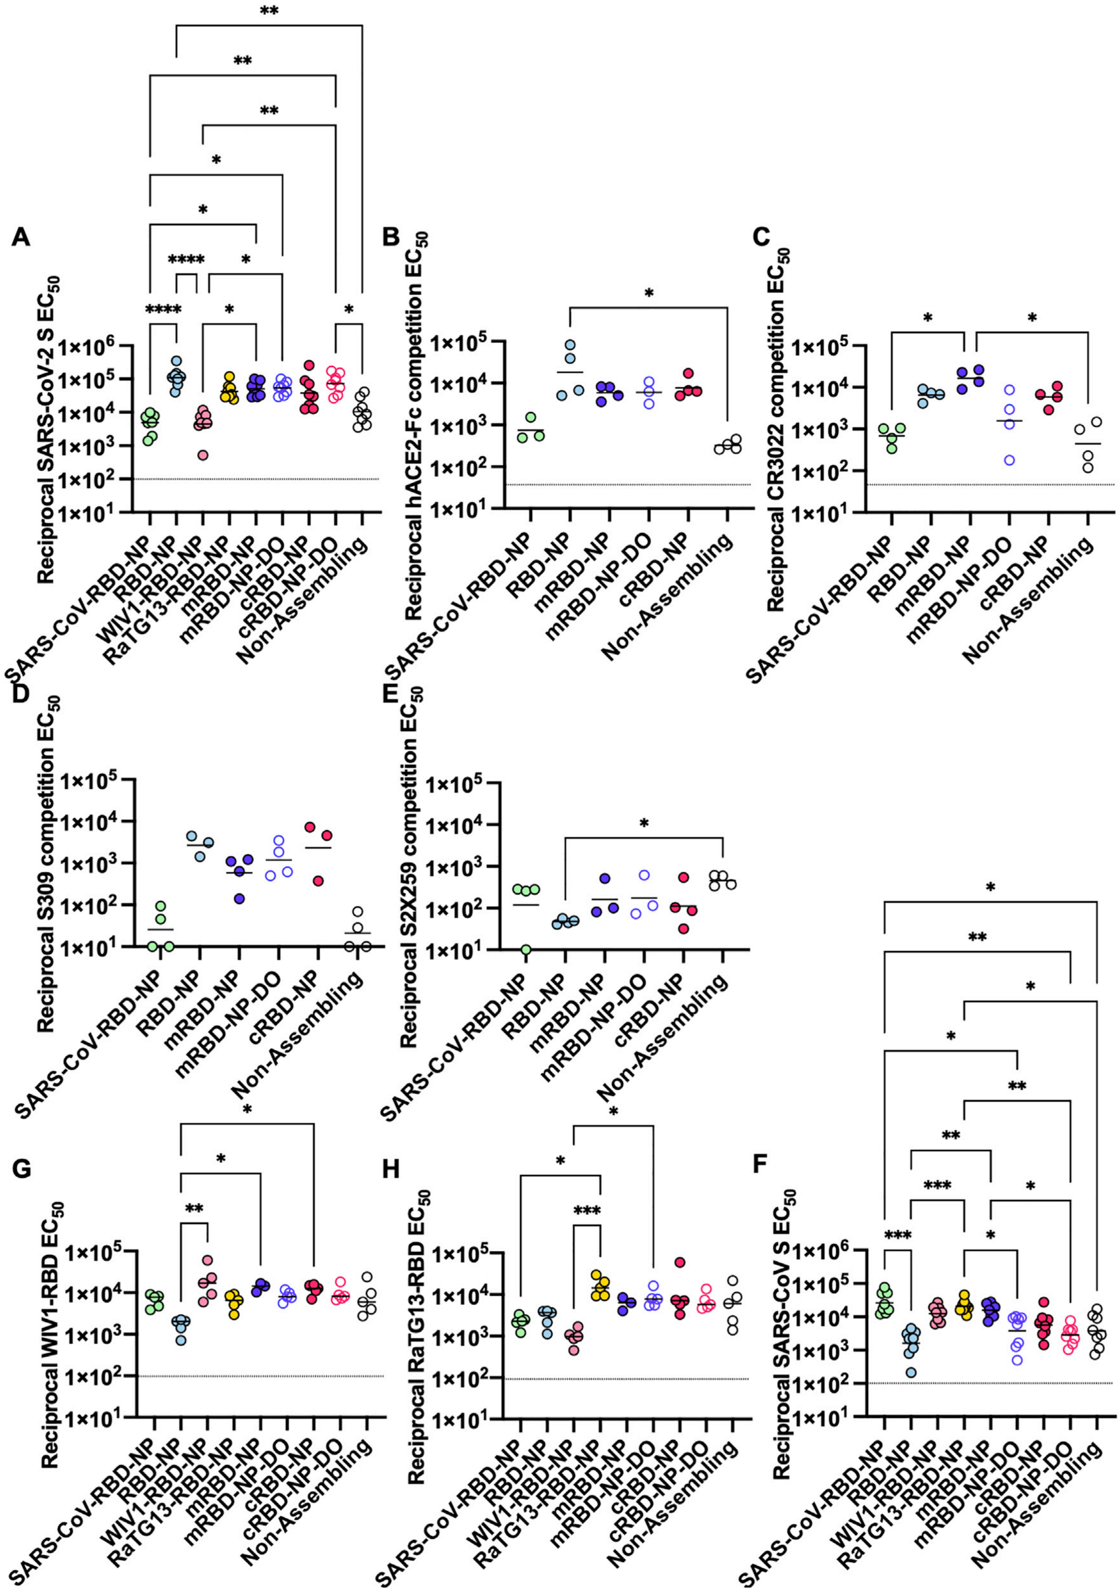
(A) Wild-type (Wuhan-Hu-1) and B.1.351 SARS-CoV-2 RBD-specific Ab binding titers of RBD-NP-elicited sera in pigtail macaques (magenta, n = 2) and rhesus macaques (blue, n = 5), HexaPro S-elicited sera in rhesus macaques (gray, n = 5), or HCP (orange, n = 6, Table S1) analyzed by ELISA with an LOD of 1×10^2. (B) Cladogram based on sarbecovirus RBD amino acid sequences. (C) Biolayer interferometry analysis of binding of 1 μM purified polyclonal pigtail macaque IgGs (obtained 70 days post prime) to sarbecovirus RBDs immobilized at the surface of biosensors. (D) SARS-CoV-2 S2P (left) or SARS-CoV S2P (right) Ab binding titers of RBD-NP-elicited sera in pigtail macaques (magenta) or HexaPro S-elicited sera in rhesus macaques (gray) analyzed by ELISA with an LOD of 2.5×10^1. (E) Competition ELISA between 0.13 nM human ACE2-Fc and RBD-NP-elicited sera in pigtail macaques (magenta) and rhesus macaques (blue), or HexaPro S-elicited sera in rhesus macaques (gray) at various time points following vaccination, benchmarked against COVID-19 HCP with an LOD of 4 × 10°, showing the magnitude of inhibition of ACE2 binding to immobilized SARS-CoV S2P expressed as reciprocal serum dilution blocking 50% of the maximum binding response. Statistical significance was determined by Kruskal-Wallis test and shown when significant. **, $p < 0.01$. All data repeated twice. LODs are shown as gray horizontal dotted lines. Raw data curves shown in Data S1.



(legend on next page)

Figure S3. ***In vitro*** **characterization and confirmation of co-display of sarbecovirus RBD-NP immunogens, related to Figure 4**

(A) Design models of the various vaccine candidates evaluated. Scale bars, 36 nm. (B) SDS-PAGE analysis of purified nanoparticles. DTT, dithiothreitol; F/T, freeze/thaw. (C) Dynamic light scattering. (D) Electron micrographs of negatively stained samples. Scale bars, 50 nm. (E) Binding of 100 nM SEC-purified nanoparticle immunogens and the non-assembling cocktail immunogen (which was not purified with SEC) to immobilized hACE2-Fc. (F) SEC chromatogram overlay of purified RBD-NP and non-assembling cocktail. (G-H) Sandwich biolayer interferometry. The SARS-CoV-2 S-specific mAb S2H14 immobilized on protein A biosensors was used to capture various nanoparticle immunogens from 300-480 s. The captured nanoparticles were subsequently exposed to a Fab derived from the SARS-CoV S-specific mAb S230 from 600-900 s (G). hACE2-Fc immobilized on protein A biosensors was used to capture various nanoparticle immunogens from 300-480 s. The captured nanoparticles were subsequently exposed to a Fab derived from the SARS-CoV S-specific mAb S230 from 600-900 s (H).



(legend on next page)

Figure S4. Serum Ab binding titers elicited by mosaic and cocktail RBD-NPs, related to Figure 5

(A) Ab binding titers to SARS-CoV-2 S2P at five weeks post prime analyzed by ELISA with an LOD of 1x10^{2}. (B–E) Titers of SARS-CoV-2 S-specific Abs competing with ACE2-Fc with an LOD of 5x10^{1} (B), CR3022 with an LOD of 5x10^{1} (C), S309 with an LOD of 1x10^{1} (D), and S2X259 with an LOD of 1x10^{1} (E) in immunized mouse sera analyzed by competition ELISA. (F) Ab binding titers to SARS-CoV S2P at week 5 analyzed by ELISA. (G–H) Ab binding titers to the WIV1 (G), and RaTG13 (H) RBDs analyzed by ELISA with an LOD of 1x10^{2}. Statistical significance was determined by Kruskal Wallis test and shown when significant. **$p < 0.01$. LODs are shown as gray horizontal dotted lines. Raw data curves shown in Data S1.

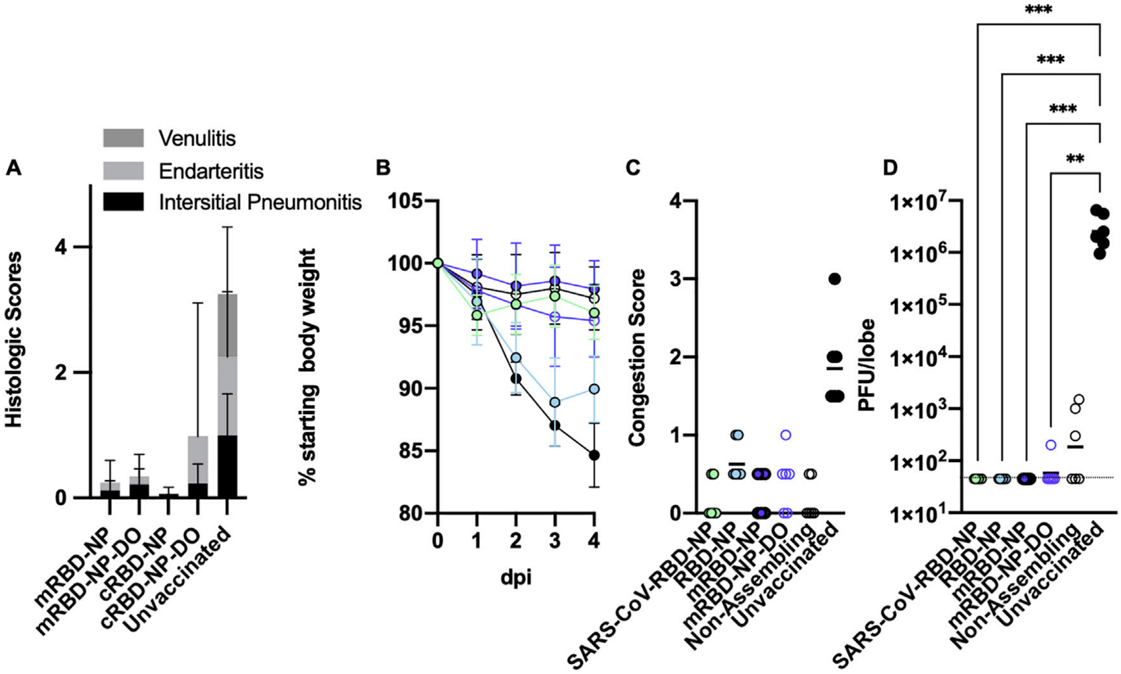


Figure S5. Monovalent, mosaic, and cocktail RBD-NPs protect against heterotypic SARS-CoV-MA15 challenge in 15-week-old BALB/c cByJ mice, related to Figure 6

(A) Normalized active inflammation following SARS-CoV MA 15 challenge shown in Figure 6 with venulitis, endarteritis, and interstitial pneumonitis shown as stacked bar graphs in dark gray, light gray, and black respectively. (B) Weight loss following SARS-CoV MA15 challenge (N = 6). Unvaccinated animals are shown as black circles. (C) Congestion score following SARS-CoV MA15 challenge with a score of 0 indicating unchanged lung color and 4 indicating a darkened and diseased lung (N = 6). (D) Viral titers in mice lungs (expressed in plaque forming units per lobe) following challenge (N = 8) with an LOD of $9x10^{1}$. Statistical significance was determined by Kruskal Wallis test and shown when significant and $^{**}p < 0.01$. LOD is shown as a gray horizontal dotted line.

---

hi all,

thanks for taking the time for the call today on the sG Nipah/Hendra
patch/PCEP vaccine project.
It is looking really terrific.

Attached is the RFA from NIAID on Pandemic Preparedness
that our patch vaccine approaches can be integrated into.

I envision, continuation with NiV/HeV patch,
but the new area is doing Langya virus sG and/or Mojiang virus (both are the other henipaviruses
with different features. Perhaps also Ghana bat virus. All three have human infections, and/or evidence of human infections.
In parallel, we can propose reverse genetics rescue of these viruses for experimental pathogenesis studies.

The other vaccine method to continue, would be with nanoparticles which can also be explored with the patch. (attached)
David Veesler would potentially also be a structural bio Core for the submission. We are now testing
a pilot exp with the nanoparticle method now with David's group.

Bunyavirus (focus on Hantaan virus) can be integrated with either vaccine approach. We have a
pending submission for nanobody generation against these related viruses in collaboration with Tom and Bob at UTMB
with recombinant proteins produced by Genovac. Pete Leland at Genovac, has been able to make Langya Henipavirus soluble
F and G viral glycoproteins which we just received to take a look at. Genovac is also state of the art for
producing human and animal mAbs.

Looking forward to keep our collaborations going.

Chris

BILL & MELINDA GATES foundation

INVESTMENT DOCUMENT – GRANT

Cover Page & Document Guidance

Welcome! The Investment Document is both your proposal shaping document, as well as your reporting document should your project receive funding. Before beginning, discuss the requirements for this document with your foundation contact for guidance and expectations on content, length, and level of detail.

Proposal Sections	Reporting Sections
Section A constitutes the grant proposal narrative. Typically, this section and the budget template (separate Excel document) are considered your proposal package.	**Section B** contains progress narrative questions to be completed for each progress reporting cycle defined in your grant agreement. **Section C** contains final narrative questions to be completed at the end of your grant.

Important Guidance:

- This document is not a commitment by the foundation to fund the work. If a grant agreement is executed, the grant proposal narrative (Section A) and budget will be incorporated therein by reference.
- To better understand the restrictions on foundation funding, please review the foundation's standard grant terms and conditions. This is not an exhaustive list and is subject to change. This list is provided for informational purposes only and does not imply an award, agreement, or offer to contract.
- This document must be submitted in English and as a Microsoft Word file. **PDFs and other file types will not be accepted**.
- **Privacy and Non-Confidentiality Notice:** The Internal Revenue Service (IRS) administers U.S. federal tax laws and requires that the foundation publish a list of its grants. We may also provide a general description of our grants and contracts on our web sites, in press releases, and in other marketing materials. Subject to the foundation's Privacy & Cookies Notice, the foundation may also share information you provide to us (either orally or in writing) with third parties, including external reviewers, key partners and co-funders. This document is subject to the foundation's Terms of Use.

If you have any questions or need support, please reach out to your foundation contact at the email listed on the next page.

SECTION A – GRANT PROPOSAL

Investment Name	HTS for small molecule drug development for henipaviruses		
Investment ID	INV-048917		
Investment Owner	Rob Jordan	**Investment Owner Email**	robert.jordan@gatesfoundation.org
Investment Coordinator	Lisa Galaites	**Investment Coordinator Email**	lisa.galaites@gatesfoundation.org

INVESTMENT DETAILS

Estimated Grant Start Date	01 October 2022	**Grant End Date**	30 September 2025
Requested Grant Amount (USD)	$2,954,167	**Total Project Cost (USD)**	$2,954,167
Organization Legal Name[1]	The Board of Trustees of the University of Illinois		
Organization Doing Business As/Trade Name[2]			
Fiscal Agent[3] (if applicable)		**Fiscal Agent Contact Name** (if applicable)	
Tax Status (if known and applicable) Refer to Tax Status Definitions	509(a)(1) Public Charity	**U.S. Employer Identification Number (EIN)** (if applicable)	37-6000511
Mailing Address		**Primary Contact Name**	Karen McCormack
Street Address 1	MB 502, M/C 551	**Primary Contact Title**	Executive Director, Office of Sponsored Programs
Street Address 2	809 S. Marshfield Avenue	**Primary Contact Email**	Awards@uic.edu
Street Address 3		**Primary Contact Phone**	312-996-2862
City	Chicago	**Additional Contact**	
State / Province	Illinois	**Additional Contact Title**	
Zip / Postal Code	60612-4305	**Additional Contact Email**	

---

[1] Legal Name will be used in the agreement and should match the name on the bank account that receives the grant funds (assuming fully executed agreement).
[2] Trade Name or d/b/a ("doing business as") only required if different from Legal Name.
[3] A fiscal agent is a third-party organization that is not the grantee. The fiscal agent, although not the grantee, signs the grant agreement in addition to the grantee and will receive the grant payments.

Charitable Purpose - completed by the foundation

❖ The following describes the charitable purpose of this project. It is written in a standard format by your foundation contact for publication on the foundation's public website should your project receive funding.

to identify novel agents targeting henipavirus replication for pandemic antiviral preparedness

Strategic Fit - completed by the foundation

❖ The following includes the foundation's 3-5-year strategic goal(s) towards which this project contributes most directly.

The goal of this proposal is to develop fast-acting, orally active small molecule therapeutic agents with an effective mechanism of action that could be stockpiled for any future pandemic. This program will use high throughput screening technologies to identify inhibitor compounds of cedar virus replication and counter screen against other paramyxoviruses to select compounds with broad spectrum antiviral activity. This project is one of several screening programs designed to identify new chemical matter for paramyxovirus antiviral development and is part of the portfolio being developed by the Pandemic Antiviral Discovery (PAD) Initiative to identify antiviral candidates targeting paramyxoviruses that can be deployed in an outbreak setting for pandemic preparedness.

Project Description

Note: this section may be pre-populated with your foundation contact's initial draft, please expand upon and/or continue to refine.

In this section, please describe the proposed work, including a clear outline of the project plan, intended results, time frame, funding considerations and how you and your organization will work to further educational, scientific, or other charitable purposes and impacts for the intended beneficiaries. Please be sure that your project description is sufficiently detailed and includes responses to the below questions:

- What are the primary results (outcomes and outputs) this project will achieve or significantly contribute to? How will you know when the results have been achieved? How will the results be measured?
- How will your management of the project and the intended outcomes align with the Charitable Purpose, Strategic Fit, and the foundation's Global Access requirements?
- Describe potential risks/challenges to the success of this project and how you plan to address them. Include any external factors or critical relationships with other partners/projects that may influence the success of this project (including any anticipated agreements to be entered into for purposes of the project).
- Describe any changes or improvements you plan to make to your organization's capacity to achieve the results of the project.
- Beyond this project's time frame and funding, what factors (financial/economic, organizational, behavioral, etc.) are required to sustain or build on the project's results?

Nipah virus is highly pathogenic human paramyxovirus that is considered a major pandemic threat pathogen. The virus is transmitted to humans through contact with infected bats or domestic animals that serve as amplifying hosts and infection results in both respiratory and neurological symptoms resulting in high mortality. There is documented evidence of person-to-person transmission and long term asymptomatic viral persistence that can lead to lethal disease in those who survive primary infection. Related paramyxoviruses (RSV, PIV, HMPV, measles) cause seasonal infections with low mortality but are highly transmissible via the respiratory route. Evolution of henipavirus to acquire the ability for efficient human-to-human transmission poses a major concern for pandemic preparedness.

A high throughput phenotypic pilot screen of 10K compounds identified two hit series that will be further optimized for potency and drug-like properties. Optimization of hits that target the viral polymerase will be supported by cryoEM studies designed to solve the polymerase-inhibitor complex structure. In addition, an extended HTS of new compound libraries will be conducted using a reporter Cedar virus expressing the luciferase gene (CedV-Luc) to identify additional hit compounds for optimization. Promising hit compounds will undergo a thorough characterization process including initial chemical exploration and antiviral validation in dose response titrations using NiV-B and HeV assays to quantify potency and determine the magnitude of the antiviral effect.

Specific Aims:

Aim 1A: Identify additional chemotypes that inhibit henipavirus replication by high throughput screening. A high throughput screen of a compound library will be conducted using the CedV-Luc construct. Active compounds will be evaluated in dose response experiments and virus yield assays in multiple cell types to determine the potency and magnitude of the antiviral effect.

Aim 1B: Optimize furopyrimidine and 4-aminoquinazoline scaffolds to improve druglike properties. Medicinal chemistry optimization of two series identified from a pilot high throughput screen of 10K compounds will be conducted. Optimization will be facilitated by solving the structure of the henipavirus polymerase in complex with key inhibitors by cryoEM techniques (Aim 2).

Aim 2: Investigate the mechanism of action (MOA) of lead inhibitors. We will use resistance selection assays and an SPR binding assay for target identification. High-resolution structures of the NiV RdRp complex with key inhibitors will be obtained by cryoEM. These structures will provide necessary structural information to facilitate lead optimization.

Aim 3: *In vivo* analysis of lead compounds in animal models of nipah virus replication in BSL-4 containment. Promising candidates with appropriate ADME and PK properties will be evaluated in animal models of Nipah virus replication conducted in BSL-4 containment at UTMB.

Milestones:

1. Complete HTS to identify antivirals active against Cedar virus and validate them against authentic NiV and HeV. (Year 1)
2. Optimize 4-aminoquinazoline and furopyrimidine series to late lead stage (Year 3)
3. Solve structure of henipaivirus polymerase complexes with key inhibitors by cryoEM (Year 2)
4. Evaluate at least nine lead compounds in a hamster model of nipah virus infection (Year 2)
5. Evaluate at least two advanced lead compounds in an African Green monkey model of nipah virus infection (Year 3)

Deliverable:

1. 1-2 small molecule compound series active across the henipavirus subfamily that can be optimized through medicinal chemistry.
2. 1-2 late lead compounds optimized from the 4-aminoquinazoline and furopyrimidine series active in animal models of nipah virus replication advanced for IND-enabling studies.
3. Structure of the henipavirus polymerase complex with key inhibitors.

Risks and Risk Mitigation

1. There is a possibility that the HTS campaign will not yield viable hits that can be advanced into hit-to-lead optimization. While adjustments to the screening assay may yield more hits, the investigators should consider screening additional libraries. (Multiple ready-to-use chemical libraries to facilitate drug discovery and drug target identification are curated at the UIC Research Resource Center (RRC). They are comprised of > 150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional “Antiviral Library” from ChemDiv, composed of 65,937 compounds total, will be purchased by the Rong Lab for this project).

2. Lead optimization of the 4-aminoquinazoline and furopyrimidine may uncover terminal liabilities that can not be fixed by medicinal chemistry. While there is always inherent risk with drug discovery, conducting additional screens for new chemical matter can help mitigate this risk.
   (If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our furopyrimidine scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc., and Pharmaron, Inc. and supervised by Dr. Peet. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim. We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable advanced lead compounds, which will be advanced to *in vivo* studies and will allow for the future

selection of a preclinical candidate.)

3. Optimized compounds do not inhibit nipah virus replication in animal models. While not ideal, a negative result can help inform the field and guide medicinal chemists to improve molecules for this indication.
(A critical aspect of antiviral discovery that is often overlooked is the early-stage testing of lead compounds in well-studied and well-validated in vivo animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM. *In vivo* studies in hamsters will be initiated in Year 1)

4. PI and collaborators are AViDD grant recipients so clear delineation of their roles in these projects is essential to prevent duplication of effort.

Drs. Rong and Gaisina are Co-Is on the National Institutes of Health (U19 AI171954) grant titled: “Midwest Antiviral Drug Discovery Center”(PIs: Reuben Harris and Fang Li); and their specific roles on the Project 1 (“Small molecule viral entry inhibitors”) are to develop small molecule entry inhibitors against Ebolaviruses. The lead series of compounds are not related to the henipavirus lead compounds proposed here. No overlap.

Team: Dr. Lijun Rong (PI) is a Professor in the Department of Microbiology and Immunology at UIC, with expertise in mechanisms of viral entry and antiviral drug discovery. Dr. Rong will be responsible for the overall project and coordinate the assembled team for the proposed experiments. Dr. Irina Gaisina (Co-I) is a Research Associate Professor in the Department of Pharmaceutical Sciences and UICentre at UIC. She has extensive experience in hit-to-lead and lead optimization medicinal chemistry and preclinical drug development. She will assume overall responsibility for the medicinal chemistry work carried out at UIC. Dr. Thomas Geisbert (Co-I), a Professor of Microbiology and Immunology at UTMB, with expertise in highly pathogenic viruses and his group will perform the in vitro and in vivo studies using infectious henipaviruses in a BSL-4 facility. Dr. David Veesler (Co-I), an Associate Professor of Biochemistry at UW and HHMI investigator, is a world leader in structural studies of viral glycoproteins and will carry out cryoEM and X-ray crystallographic studies of the most potent inhibitors in complex with the NiV or HeV polymerase. Dr. Christopher Broder (Collaborator) is a professor and Chairperson of the Department of Microbiology and Immunology, USU, and he is one of the leading experts in the development of therapeutic agents for Nipah virus and Hendra virus. Dr. Norton P. Peet (Consultant), Chief Scientific Officer for Chicago BioSolutions, Inc., is a medicinal chemist who has over 30 years of experience with preclinical development of small molecules as therapeutic agents and their advancement to a clinical setting, working with both multinational pharmaceutical and biotechnology companies. He will oversee the proposed ADME/Tox and PK studies.

A. BACKGROUND AND SIGNIFICANCE

For several decades, the major agents of emerged or newly identified infectious diseases in humans have been viruses of zoonotic origins.[10-12] Among these, two paramyxoviruses of importance are Nipah virus (NiV) and Hendra virus (HeV); the prototype species of the genus *Henipavirus* and are single-stranded, negative sense, enveloped RNA viruses.[13] HeV appeared in 1994, in an outbreak of severe respiratory disease in horses in Australia, with the death of 14 horses and their trainer.[14,15] NiV (Malaysia strain, NiV-M) appeared in an outbreak of encephalitis in pig farmers in Malaysia in 1998.[16,17] NiV outbreaks have since been seen in Bangladesh and India by a related strain NiV-Bangladesh (NiV-B).[18] Pteropid fruit bats are the major reservoir hosts for henipaviruses.[6,19] NiV and HeV have broad host tropism, infecting at least 18 species across 6 orders of mammals. Among these, NiV and HeV will cause a systemic and often fatal respiratory and/or neurological disease in at least 11 species including humans, with human fatality rates ranging from 40-100%.[2,20] A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.[21] However, CedV is not known to be zoonotic and has been shown to be nonpathogenic in HeV and NiV animal models.[21-23] Two additional henipaviruses are also known, Ghana bat virus and Mojiang virus, but only from sequence data.[24-26] Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and 3 outbreaks in India.[27] In 2014, an outbreak of NiV-M occurred in the Philippines with 9 fatalities of 11 human cases, with horse-to-human and human-to-human transmission.[28] The combined NiV case fatality rate is ~60% across a large region of Asia in five countries.[3] The recent 2018 NiV outbreak in Kerala, India was significant, occurring in a new geographic region, with a case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission. Most recently, a fatal case of NiV-B in Kerala occurred in September of 2021 reigniting the outbreak concerns associated with this deadly zoonotic viral agent, underscoring both the transmissibility and the lethal nature of this virus.[4] In the latter and most recent case, an eleven-year-old boy was infected with Nipah virus and he succumbed, along with three health care workers who were in close contact.

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period of 1 to 2 weeks.[4,29] Acute NiV/HeV infection in people is systemic and likely via hematogenous viral spread from the respiratory system.[30] Disease onset is characterized by fever, myalgia, shortness of breath, and cough.[15,31] Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery.[29,32] The predominant clinical feature in the Malaysia outbreak was encephalitis, but respiratory symptoms were also common.[31,33] The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, 83% of cases had acute respiratory distress syndrome (ARDS).[4,34] The key findings of human NiV/HeV infection are wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected.[35,36] Human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset or relapsed encephalitis.[32,37] Relapsed encephalitis caused by NiV appears to be a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later.[38] NiV and HeV are biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents by several US agencies. Also, both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), specifically the African green monkey (AGM), when delivered by small particle aerosol.[39-41] NiV and henipaviral diseases (HeV) are included on the WHO’s Blueprint List of Priority Pathogens.[42] NiV is a potential pandemic threat because of its high case-fatality rates, capacity for human-to-human transmission and potential to mutate, and a human-adapted strain in a region of high population density could lead to rapid spread.[43] *There are presently no approved vaccines or therapeutic modalities for NiV/HeV infections in people.*

The viral RNA-dependent-RNA polymerases of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been hampered by requirements of BSL-4 containment. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications at the BSL-2 containment level (**Figure 1**) and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV.[7] Those leads provide the rationale for the current application. Our ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, that also allows for discovery across the whole replication cycle, not restricted to only the viral polymerase. Another well-exploited stage of virus infection is the attachment and entry process.[44] NiV/HeV possess two membrane anchored glycoproteins required for infection; one for attachment, the G glycoprotein, and the other for membrane fusion of the F glycoprotein.[45] The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and all vaccine strategies.[27]

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of the investigators in this proposal. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may well have activity across related members of the henipavirus genus. *Second,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification. *Third*, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity among small molecules.

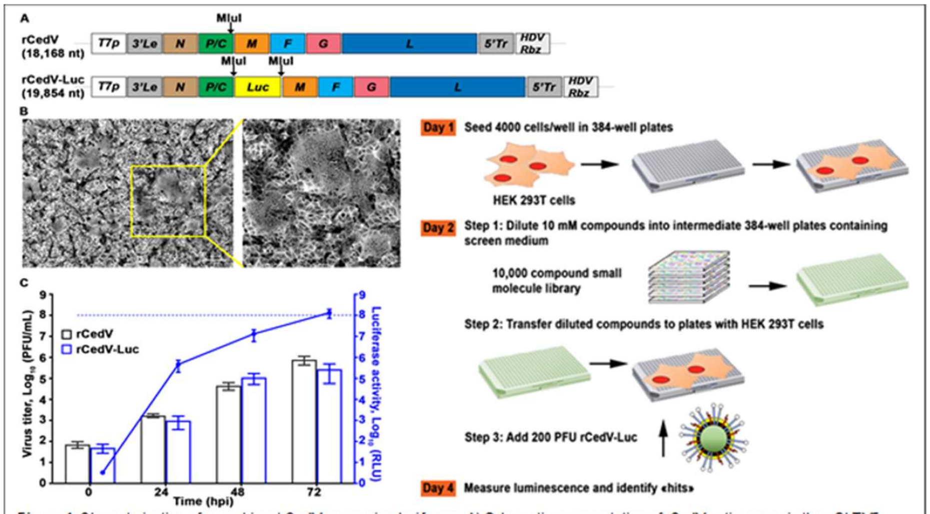

Figure 1. Characterization of recombinant CedV expressing luciferase. A) Schematic representation of rCedV antigenome in the pOLTV5 vector. The firefly luciferase (*Luc*) gene was inserted at the unique MluI restriction site between the *P* and *M* genes to produce rCedV-Luc. To preserve the "rule of six", an additional start codon was added to the 5' terminus of the *Luc* gene. B) At 48 hpi Vero E6 cells infected with rCedV-Luc were fixed with methanol and stained with 0.5% crystal violet solution (80% methanol). Images were captured with a Zeiss Axio Observer A1 inverted microscope using a 5X objective. Yellow box indicates giant cells, and scale bar represents 50 µm. Inset indicates zoomed-in region within the yellow box. C) Vero E6 cells in a 96-well plate were infected with either rCedV or rCedV-Luc at an MOI of 0.01. At 0, 24, 48 and 72 hpi supernatants were collected and viral titers determined by plaque assay and calculated as PFU/ml. Concurrently all infected cells were lysed and relative light units (RLU) were measured and calculated by subtracting the signal of rCedV infected cells from the signal of the rCedV-Luc infected cells and are represented on the right Y-axis in blue. The data represent mean ± standard error from two independent experiments. The blue dashed line represents the upper limit of detection of the luminometer. Viral titers and luciferase activity levels at 0 hpi indicate the lower limit of detection for the plaque assay and the luminometer, respectively. D) HTS workflow. Compounds diluted in medium were added to pre-seeded HEK 293T cells in a 384-well plate, followed by addition of rCedV-Luc (MOI: 0.05). Luminescence was measured 48 h later.

C. PRELIMINARY RESULTS

Identification of small molecule inhibitors of henipaviruses.

C.1. HTS Assay development. We developed a robust (high signal-to-background ratio), safe (BSL-2), cell-based HTS platform to identify small molecule antiviral agents targeting henipavirus replication without the requirement for BSL-4 containment (**Figure 1**).[7] ***rCedV assays and tools.*** We also adapted the rCedV HTS infection platform to create another innovative toolset using novel chimeric viruses, where the viruses are altered only by the substitution of the F and G genes with thoset of NiV or HeV. As with the luciferase-encoding rCedV HTS assay, rCedV chimera using guidelines and procedures at the BSL-2 level were reviewed and approved by the Institutional Biosafety Committee (IBC) in accordance with NIH guidelines.

C.2. Pilot screening of a small molecule library. A library of 10,000 compounds (preselected from a ChemDiv library by UIC medicinal chemists and called "SMART Set") was used for a pilot HTS campaign to identify rCedV-Luc inhibitors. This library (1) is pruned for known frequent hitters (PAINS and alike); (2) is balanced in terms of diversity of chemical scaffolds; and (3) has several representative compounds for each of the scaffolds in the library. From the initial single-dose screen, using 80% inhibition as the cutoff, 151 hits (1.51% hit rate) were selected for further evaluation. To eliminate false positive hits due to cytotoxicity, a validation screen alongside a cellular toxicity assay (compound concentration of 33 µM) was carried out. The antiviral activities of 85 compounds were confirmed at 10 µM, and 47 hits showed only minimal cytotoxicity at 33 µM. Importantly, several small molecule inhibitors (**Figure 2**) have been validated *in vitro* using infectious HeV and NiV in the BSL-4 facility, demonstrating the proof-of-concept feasibility of using this rCedV-based surrogate HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for the current drug discovery project. Particularly, our quinazoline-based hit **Z1** and furopyrimidine-based hit **Z2** were found to have EC_{50} values of 3.3 and 0.5 µM, respectively, against NiV-B (**Table 1**). Note that both HEK293T and Vero cell lines were employed in these assays, and that CC_{50} values were recorded for these two cell lines. Thus, <u>we concluded that our HTS approach was a valid method for defining NiV inhibitors</u>. Next, target specificity was confirmed in a counterscreen assay using a vesicular stomatitis virus G (VSV-G) protein as well as some other unrelated viral proteins, including Lassa glycoprotein, and influenza fusion protein hemagglutinin H1 and H5. These hits showed a lack of detectable inhibition for VSV-G as well as some other unrelated viral proteins (0% inhibition at 12.5 µM). In addition to the high potency and selectivity, **Z2** displays excellent *in vitro* metabolic stability. The percentage of compound remaining after 60 minutes of incubation in both human plasma and liver microsomes is significant (91 and 68%, respectively), indicating good stability in both media. Stability in hamster plasma and liver microsomes will be evaluated by Pharmaron Inc.

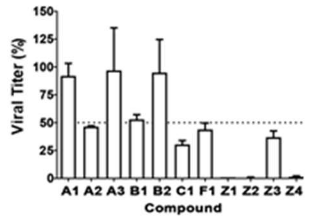

Figure 2. Inhibition of NiV-B replication in Vero 76 cells measured by virus titer reduction assay (% infection relative to the DMSO control).

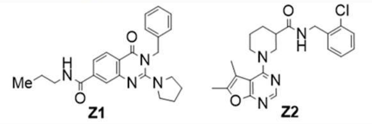
Table 1. Validation of rCedV-based HTS assay hits for inhibition of NiV_B.



Hit	CedV (293T)		CedV (Vero)		NiV_B (Vero)

* Compounds were 3-fold serially diluted in cell culture medium containing 2% DMSO from 200 µM to 0.09 µM. Compounds (50 µL) were added to pre-seeded Vero 76 cells followed by rCedV-Luc (MOI: 0.01) (50 µL) and incubated for 48 hours at 37 °C. Luminescence was measured using the Steady Glo Assay Reagent

In **Table 2** are shown additional inhibitors in the furopyrimidine series that we identified from a focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). We do not yet fully understand the emerging SAR around substituents included on the phenyl ring, the tether length, and substituents on the tether and the pyrimidine ring, but we can make some comments. We do see activity with all three of the tether lengths studied, where n=0, 1 or 2. Replacement of the tether and the phenyl group with large hydrophobes, such as isopropyl or cyclohexyl, is not productive. Comparison of compounds **13** and **6** indicates that a methyl group on the pyrimidine ring is detrimental to activity. A methyl group on the sidechain in the benzyl subset of compounds appears to be tolerated; however, this inclusion adds an asymmetric center to the molecule. Disubstituted compounds **9** (n=0), **11** (n=0) and **12** (n=1) represent a subset of compounds that are of higher affinity, which suggests that we should explore more compounds with two diverse phenyl substituents with all tether lengths.

In the Research Plan we discuss methods for the preparation of new compounds in each series as well as specific plans for developing the SARs. Our recombinant CedV HTS system will be used to support Aim 1.

D. RESEARCH DESIGN AND METHODS

<u>D.1. Aim 1: Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays.</u>

D.1.1. Synthesize diverse analogs of the furopyrimidine and quinazoline hit series to establish structure-activity relationships (SARs) and improve potency and selectivity index. Milestone: Synthesize directed libraries and discrete analogs of hit compounds; using the rCedV-based assay for SAR development define henipavirus replication inhibitors with high potency (EC_{50} <1 µM) and low cytotoxicity (CC_{50} >100 µM).

Chemical optimization and SAR studies. In the initial stages, we will keep the heterocyclic core of the molecules of interest constant while making well-defined changes in substituents. We will initially probe steric and electronic factors of the substituents, but more substantial changes in the scaffold will be investigated as the structure is optimized. By an iterative process of design, synthesis, and assay, we will improve the structure, and ultimately produce a fully optimized structure. We will also assess the cytotoxicity and construct Structure-Toxicity Relationships (STRs). For potent, specific inhibitors, the SAR and the STR will diverge at critical points, and we will synthesize novel inhibitors with maximized activity and minimized cytotoxicity. The SAR plan for optimization of the HTS hit **Z2** is exemplified in **Figure 3**. Substituent changes on the core fused scaffold will involve variation of the alkyl groups on the furan ring, as well as adding alkyl groups at the 2-position of the pyrimidine ring, to explore the optimum overall size for the core. Note that we will be able to use these substituents as “ADME handles” to control the overall hydrophobicity of the molecules and the cLogP values. We will replace the oxygen atom in the furan with a sulfur atom to compare the effect of changing the furan ring to the larger thiophene ring. Importantly, we will explore the biological activities of the *R*- and *S*-stereoisomers of this racemic molecule to determine whether there is differential recognition of these antipodes at the site of interaction in the inhibition assays. In addition to evaluating a variety of mono- and disubstituted aromatic rings, we will also explore length of the tether connecting these aromatic units to the amide nitrogen atom, knowing that both benzyl groups and phenyl groups give rise to active compounds.

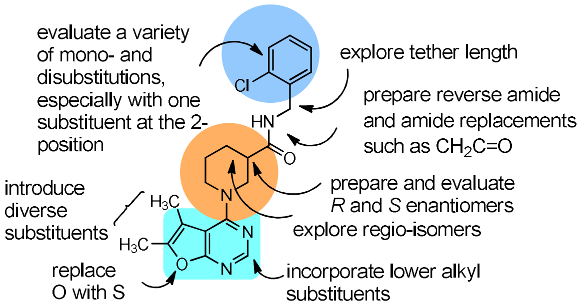

Figure 3. SAR development plan for furopyrimidine **Z2**.

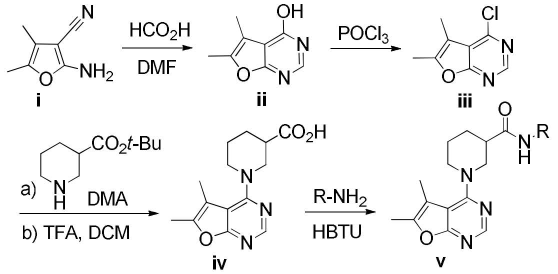
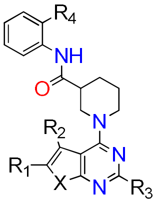
Scheme 1. Preparation of analogs of furopyrimidine **Z2** with optimized amide *N*-substituent.



The synthetic route that we envision for the preparation of the furopyrimidines is shown in **Scheme 1**, as illustrated for the optimization of the amide *N*-substituent for furopyrimidine analogs of compound **Z2**. Starting with the commercially available 2-amino-4,5-dimethyl-3-furancarbonitrile (**i**), treatment with formic acid in dimethylformamide will produce the 5,6-dimethylfuro[2,3-*d*]pyrimidine (**ii**). Conversion of **ii** to the corresponding chloro compound **iii** is accomplished by treatment with phosphoryl chloride. Displacement of the chloro group with piperidine-3-carboxylic acid *t*-butyl ester, followed by removal of the *t*-butyl ester with trifluoroacetic acid, gives key intermediate **iv**, which can then be elaborated to amides **v**.[46] In **Table 3** is shown a set of proposed compounds related to **Z2** (compound **A**) for which we show parameters calculated using Actelion OSIRIS software[47]. All of the proposed compounds (**B** through **H**) show improved druglikeness and drug scores with respect to **Z2**, and therefore represent promising new targets for synthesis and evaluation.

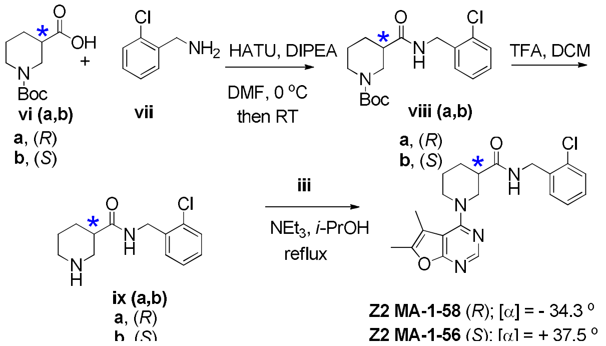
Table 3. Actelion OSIRIS calculated parameters for **Z2** (compound A) and proposed analogs.



ID	R_1	R_2	R_3	R_4	X	cLogP	Sol	MW	Druglikeness	Drug Score
A	Me	Me	H	Cl	O	4.0	-6.7	384	-0.95	0.23
B	Me	Me	H	Cl	S	4.4	-6.8	400	2.01	0.32
C	H	H	H	Cl	O	3.3	-6.0	356	3.04	0.42
D	H	H	H	F	O	2.8	-5.6	340	1.47	0.55
E	H	H	H	Cl	S	3.6	-6.0	372	3.70	0.41
F	H	H	H	F	S	3.1	-5.5	356	2.14	0.54
G	H	H	Me	F	O	3.0	-5.2	354	2.82	0.61
H	H	H	Me	F	S	3.3	-5.2	370	3.48	0.60

We recently synthesized the *R* and *S* enantiomers of compound **Z2** (**MA-1-58** and **MA-1-56,** respectively) using the sequence shown in **Scheme 2**. Thus, starting with the optically active nipecotic acids **vi(a)** (*R*) and **vi(b)** (*S*), coupling with 3-chlorobenzylamine (**vii**) using a standard amide coupling procedure yielded amides **vii(a)** and **viii(b)**, which were then subjected to deprotection conditions to give the free piperidines **ix(a)** and **ix(b)**. Treatment of **ix(a)** and **ix(b)** with chloro compound **iii** in the presence of triethylamine in isopropanol at reflux produced the two final epimeric target compounds **Z2 MA-1-58** and **Z2 MA-1-56**, respectively. As expected, these two epimers rotated the plane of polarized light in opposite directions, to approximately the same degree, as shown in **Scheme 2.** Note that these two epimers have just been prepared and we have not yet tested these most interesting compounds to determine whether there is differentiated recognition of these epimers at their site of action.

Scheme 2. Synthesis of *R*- and *S*-enantiomers of **Z2**.



As cryo-EM structures of polymerase in complex with key inhibitors (i.e., **Z2** and additional derivatives) become available, we will use this model for computational chemistry/docking studies to assist in the design of additional analogs with improved binding properties.

In addition, we have plans to introduce a diversity of substituents in the furan ring, as shown in **Scheme 3**. Using a variety of alpha-bromoketones **x(a-e)** in a condensation rection with malononitrile (**xi**),[48] we will produce furans **xii(a-e)** and use them in our one-pot protocol for preparing furanopyrimidines **xiii(a-e)**. We will then elaborate compounds **xiii(a-e)** to the state of target compounds **xiv(a-e)** as previously described in **Schemes 1-2**. This chemistry will allow us to study the installation of a variety of substituents in the furan ring and to evaluate the consequences of these changes to the biological activity.

Also, the furo[2,3-*d*]pyrimidine moiety will be replaced with the heterocyclic cores showcased in **Figure 4**. Although we will not show the chemistries that we will employ for the preparation of these additional fused ring systems that are bioisosteric with our hit series of furopyrimidines in this document, we have researched methods for the synthesis of these additional cores and are quite confident that we will be able to prepare representatives of these ring systems. Importantly, we will use the knowledge we have gained in developing the SARs with our furopyrimidines, and we will prepare selected derivatives in the additional 5,6-fused systems, based on the biological activities shown with substitutions present on our most active furopyrimidines.

Figure 4. Additional core modifications.

In **Figure 5** is shown the SAR development plan for our quinazolin-4-one scaffold. There are three points of optimization that we envision for this trisubstituted fused core. At the 2-position, we will substitute the pyrrolidinyl substituent with additional cyclic and acyclic amines. The unsubstituted benzyl substituent at the 3-position will be optimized in terms of mono- and disubstitution patterns. The position of the carboxamide substituent located at the 7-position will be optimized, as will the *N*-alkyl group on the carboxamide. We will also replace the amide unit with various amide mimetic units, as indicated in **Figure 5**, since amides are subject to metabolic cleavage. We have also researched and found additional synthetic methods available for the construction of both 2,3,7-trisubstituted quinazolin-4-ones and an additional backup scaffold of 4-aminoquinazolines (**Table 4**).

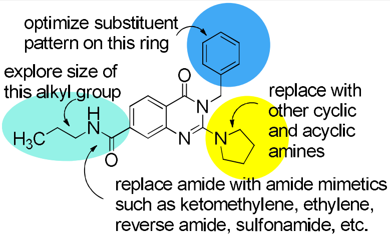


Figure 5. SAR development for **Z1**.

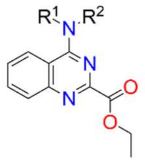
Table 4 shows eight additional inhibitors in the aminoquinazoline series, that we identified from a recent focused screening campaign, which allowed us to develop some initial structure-activity relationships (SARs). Note that these 4-aminoquinazolines all bear substituents on the amino group at the 4-position of the quinazoline ring and a carboethoxy substituent at the 2-position. In terms of SAR to be gleaned from the limited data set in **Table 4**, a few features stand out that are worth mentioning. It is clear that a variety of *N*-phenyl substituents give rise to active compounds, and that H, methyl and *n*-propyl groups as the second *N*-substituent all can produce good activity. However, it is also clear that one of the best compounds is compound **24** (**Table 4**), bearing an unsubstituted cyclohexyl group, which suggests an area for optimization since compound **24** is the only compound where the phenyl ring has been replaced by a completely saturated (cyclohexyl) substituent. Another point worth making is that the *n*-propyl compound **16** and *iso*-propyl-phenyl compound **18** are two of the best inhibitors. There may, in fact, be a rough correlation between cLogP and inhibitory activity, it may be worth exploring with a larger set of derivatives. In **Figure 6** is shown a summary of how we will develop the SAR plan for the 4-aminoquinazoline scaffold, as exemplified by changes to compound **27**. Substituent changes on the core fused scaffold will involve exploration of mono- and di-substituent patterns on the quinazoline core to explore the optimum overall size for the core. Note that we may be able to use these substituents as "ADME handles" to control the overall hydrophobicity of the molecules and the cLogP values. In addition, we will optimize substituents on both aryl rings, as indicated, and optimize the alkyl group on the tertiary amine. We will also optimize the alkyl ester group, and we are very interested in replacing this ester with an amide, which would be chemically and metabolically more stable. If the amide turns out to be an effective replacement, then we will also explore amide replacement units, such as ketomethylene, reduced ketone, retroamide, ethylene, and sulfonamide units, etc. In **Scheme 4** is shown a specific synthesis of one of our best inhibitors in this set. Anthranilamide **xv** is heated with diethyl oxalate in a solution of dimethylformamide to produce 2-carboethoxyquinazoline-4-one (**xvi**) in a condensation/cyclization process. Treatment of **xvi** with

Table 4. Antiviral activity of 4-amino-quinazoline-2-carboxylates **20-27** in the rCedV luciferase reporter virus assay.



N	R1	R2	% inhib at 10 μM

21	H	2,4-difluorophenyl	18
22	H	2-chloro-4-fluorophenyl	58
23	H	3-methoxyphenyl	46
24	Me	cyclohexyl	93
25	H	4-isopropylphenyl	85
26	*n*-propyl	4-fluorophenyl	86
27	Me	2-methylphenyl	94

Compounds (50 μL, 10 μM final concentration) were added to pre-seeded Vero 76 cells followed by rCedV-Luc (MOI: 0.01) (50 μL) and incubated for 48 hours at 37 °C. Luminescence was measured using the Steady Glo Assay Reagent phosphorous oxychloride next provides a reactive intermediate, namely, 2-carboethoxy-4-chloroquinazoline-4-one (**xvii**), which affords the specific inhibitor compound **27** after a displacement reaction with 2-methyl-*N*-methylaniline. A variety of alternate methods are available for accessing these 4-aminoquinazolines, including initial treatment of the anthranilamides with ethyl ethoxycarbonylformimidate in ether[49-50] as well as other methods.[51,52] Likewise, the additional reagents required for these syntheses are mostly commercially available, as well. Thus, it is very realistic that a large library of these potential inhibitors will be quite accessible. In **Figure 7** is shown a set of proposed compounds related to compound **27** for which we show parameters calculated using Actelion OSIRIS software[47]. The proposed compounds (**I** through **M**) generally show improved druglikeness and drug scores (and other parameters) with respect to compound **27**, and therefore represent promising new targets for synthesis and evaluation. Note that a dramatic improvement in all parameters is seen in simply replacing the ester with an amide by substituting NH for O, to provide proposed new compound **I**.

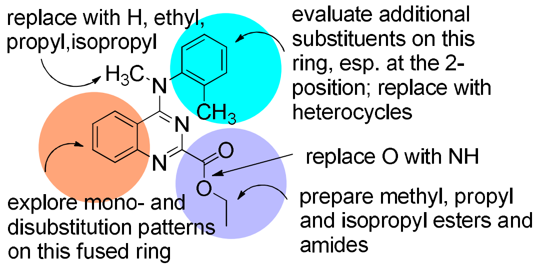

Figure 6. SAR development for 4-aminoquinazolines

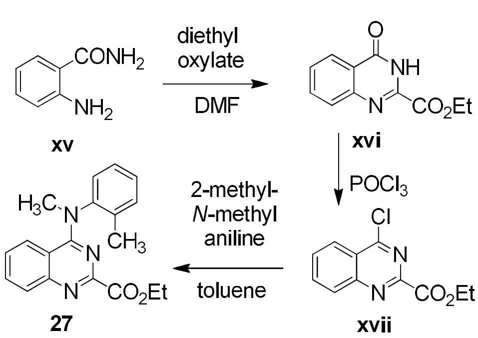
In progressing through the constrained compounds **J** through **M**, improvement of parameters culminates with the indoline derivative **M**, whose druglikeness and druglike scores have very dramatically improved. Advantages of imposed conformational restraints, as seen in tetrahydroquinolines **J** and **K** and indolines **L** and **M**, include a reduction in rotatable bonds, and, importantly, a preorganization of an effective conformation that can mitigate the entropic penalty of binding.

D.1.2. Conduct HTS assays and identify additional hit compounds. *Screening Libraries.* The HTS will be performed in the **Rong Lab**. The libraries will be provided by the UIC Research Resource Center (RRC). They are comprised of >150,000 compounds available in 96- or 384-well plate formats suitable for HTS. Additional libraries from ChemDiv and Enamine, including an Antiviral Library composed of 65,937 novel diverse and targeted compounds with privileged scaffolds from ChemDiv's collection, will be acquired in Year 1.

Scheme 4. Synthesis of compound **27**.



Hit Selection Algorithm. ***Validation:*** A compound which displays more than 90% inhibition (one log decrease in the luciferase activity in the presence of the compound, 10 μM final concentration) will be considered a "hit" compound after the initial round of screening. To further determine the specificity, a secondary screening (counter screen) for the "hit" compounds will be performed, where the VSV-G pseudotyped HIV virions will be used as a specificity control. The third round or "tertiary" screening will focus on a selected group of compounds, and here classical dose-dependent inhibition assays will be carried out to estimate EC_{50} values. Multiple cell lines will also be used in these experiments to avoid cell line bias. The compounds that do not exert effective inhibition (nonpotent) will not be actively pursued, while the more potent compounds (EC_{50} values less than 10 μM) will be analyzed further. It is expected that through multiple rounds of screening, we can select the most potent compounds for optimization and validation studies. ***Cytotoxicity Assessment.*** We will measure the direct toxicity of compounds to human cells to assess the overall cytotoxicity of the potent inhibitors. A variety of human cell lines, including HeLa, Jurkat, HepG2, Huh-7 and Hep3B, will be tested using the "CellTiter 96 aqueous nonradioactive cell proliferation assay" as described previously[97] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI). ***Ranking***: The results from these screening assays will be analyzed and the compounds ranked according to antiviral potency with consideration of SI values.

drug score	0.38	0.23	0.41

Figure 7. Actelion OSIRIS predicted parameters for the proposed quinazoline-based inhibitors.

Hit Quality Control and Identity Assurance. All hits will be analyzed for chemical purity (HPLC), and we will confirm that the compounds have the expected structure (LC-MS, NMR spectroscopy). Compounds found to be <80% pure will be purified and retested. Compounds with incorrect structures assigned will be corrected. We will eliminate compounds that are known PAINS[53] (e.g., rhodanines, aralkyl pyrroles, hydroxyphenylhydrazones), or that have reactive functional groups (e.g., Michael acceptors, alkylating agents).

Synthesis. Lead candidate optimization and SAR development based on established drug design principles will be started as soon as affirmative results from the advanced validation assays are available. Appropriate drug design principles and *in silico* ADMET calculations will be used to direct new compound synthesis, so that analogs will have optimal druglike characteristics while minimizing side effects/toxicity. We will synthesize analogs with altered structures to test the limits of steric, electronic, and configurational factors in the activity and selectivity within the chemotypes. For synthesizing new analogs, we will use our considerable collective knowledge, synthetic search engines and state-of-the-art preparative procedures to prepare specific derivatives, e.g., conformationally constrained versions of the best inhibitors, which will provide the maximum amount of SAR information. When undesirable PK features are present in a hit molecule, we will address structural changes to eliminate these features to improve the molecule. For instance, if the molecule is too flexible due to a high number of rotatable bonds, we will impose conformational restraints that will reduce the number of rotatable bonds and freeze a conformation that might reproduce the conformation required for binding of the inhibitor. Thus, in this process, we may be able to also reduce the energy required to produce this conformation from the unconstrained molecule, and thus reduce the entropic penalty of binding and produce a more potent inhibitor. Moreover, we will use Actelion OSIRIS software to design new derivatives of hit compounds to maximize druglike features of the new compounds and overall drug score. This software allows us to quantify PK parameters and use these numbers as comparators to define improved molecules for synthesis. We expect that we will be able to synthesize between 20 to 50 analogs of each hit compound to ascertain preliminary SARs and structure-toxicity relationships (STRs) for further optimization. From the "Expanded Screening" library screening campaigns, we will ultimately choose a primary scaffold and a backup scaffold for performing extensive lead optimization studies and will produce optimal candidates for further development. The advantage of defining two quality scaffolds is that should a liability arise that is scaffold-associated, e.g., relating to toxicity, we can switch to the alternate scaffold and proceed with optimizing development candidates.

D.1.3. Evaluate efficacy of various derivatives in the furopyrimidine, quinazolin-4-one, and 4-aminoquinazoline and series and additional HTS hits to inhibit viral replication in rCedV-Luc infected cells. We will employ our recently published optimized HTS protocol.[7] Cells preseeded in a 96-well plate at a density of 2.5x10^4 cells per well will be treated with growth medium containing either DMSO or selected compound at a 3-fold serial dilution ranging from 30 nM to 200 µM for 1 h at 37 °C, 5% CO_2. Cells will be infected with rCedV at multiplicity of infection (MOI) of 0.01 and the plate incubated for 48 h. Luciferase activity will be examined by reading the luminescent signal using the ENVISION JANUS automated workstation. The data will be normalized by the average signal of the negative control wells in each plate. The best inhibitors will be evaluated in both HEK293T and Vero 76 cells. EC_{50} and CC_{50} values will be calculated by dose-response curve fitting with GraphPad Prism. These assays will be conducted in the **Rong Lab.**

D.1.4. Evaluation of antiviral activity of advanced candidates. Inhibitors will be tested against authentic NiV and HeV as previously described.[7] Vero cells will be seeded in a 96-well plate at a density of 2 × 10^4 cells per well and incubated at 37 °C overnight. Cells will be incubated with a 3-fold dilution series of the selected compounds diluted in cell culture growth medium (final concentrations ranging from 100 µM to 0.01 µM) with or without NiV and HeV (200 PFU/mL). Infected cells treated with DMSO will serve as controls. At 48 h post infection (hpi), viral supernatant will be collected and titrated by plaque assay to determine infectious viral titer. Compound only cells will be examined microscopically for cytopathic effects (CPE) induced by compound treatment. The percent reduction in PFU/mL titers in the samples containing compounds will be compared to parallel control cultures of virus and DMSO. This work will be performed in the BSL-4 facility at UTMB (**Geisbert Lab)**.

D.1.5. Evaluation of *in vitro* ADME properties and prioritization of the most potent compounds exhibiting optimal profile for whole animal testing. Our goal is to transform the validated hit series into **advanced lead compounds** suitable for further therapeutic development. These *in vitro* ADME-like predictors will not be used as exclusive criteria to select or eliminate inhibitors, but selection will be based upon the combination of all properties determined (e.g., potency, plasma stability, liver microsomal stability, etc.). Up to twelve potent inhibitors with good *in vitro* ADME properties will be chosen for pharmacokinetic/toxicokinetic evaluation in mice.

Cytotoxicity. We will measure the direct toxicity of compounds in human cell lines to assess the overall cytotoxicity of potent inhibitors. A variety of human cell lines, including PTEC, Jurkat, HepG2, Huh-7 and Hep3B, will be examined utilizing the CellTiter 96 aqueous nonradioactive cell proliferation assay (Promega, Madison, WI) as previously described[54] in a 96-well format. The ratio of CC_{50}/EC_{50} is the selectivity index (SI).

Rat/Human Liver Microsome Stability: Rat and human liver microsome preparations will be used to evaluate the metabolic stability of inhibitors using the method described by Kuhnz and Geischen[55]. Inhibitors with >60% recovery (1h) will be considered for further advancement. **CYP450 inhibition:** The CYP450 inhibition assays will be carried out using CYP3A4 and CYP2C9 Human Cytochrome P450 High Throughput Inhibitor Screening Kits (BD Gentest Corp., Woburn, MA). Inhibitors with IC_{50} values ≥30 µM for CYP isoforms will be prioritized for further advancement. **hERG channel blockade:** The ability of inhibitors to block the hERG channel will be assessed in a [^{3}H] dofetilide-binding assay as described by Finlayson *et al*[56] using SHSY5Y cells. Inhibitors with <50% inhibition [^{3}H]dofetilide binding at 5 µM concentration will advance. **Plasma protein binding (PPB):** because PPB affects drug metabolism and PK properties, we will measure the PPB of selected analogs. **Cellular permeability:** We will use the Caco-2 method as described by Gres*et al.*[57] to evaluate the potential for oral bioavailability of the analogs. Inhibitors exhibiting a Caco-2 permeability value (P_{app}) greater than 1 × 10^{-6} cm/sec will be prioritized.

Advanced Lead candidates will be tested in **Bacterial reverse mutation assay (Ames):** Four *Salmonella typhimurium* strains (TA1535, TA1537, TA98, TA100) and one *Escherichia coli* strain (WP2 uvrA) will be used. The bacteria will be exposed to different dose levels and any reverse mutations will be determined. They will also be tested in the Tox-Genotoxicity panel assays, which includes cytotoxicity testing on primary human hepatocytes, cytotoxicity with primarily cultured neuronal model, and nephrotoxicity with HK2 cells (by Pharmaron, Inc.).

Pitfalls and alternative strategies. The proposed synthetic derivatives will be synthesized under the guidance of **Drs. Gaisina and Peet.** If we encounter a synthesis-related problem with our primary scaffold compounds, we will use an alternate strategy using a different reaction sequence. Should we encounter a scaffold-related problem with our furopyrimidine scaffold, we will switch to our backup quinazolin-4-one scaffold or other HTS hits identified using the expanded libraries of compounds. The proposed ADME/Tox and PK studies will be executed through the testing services provided by Eurofins Panlabs, Inc., and Pharmaron, Inc. and supervised by **Dr. Peet**. We do not anticipate any problem obtaining high quality data from the assays. If the compounds fail to meet our benchmarks, then we will synthesize additional groups of compounds, or turn to our backup scaffold to meet the objectives in this aim. We have established rigorous criteria for go-no-go decision-making to ensure the production of suitable **advanced lead compounds (Figure 9)**, which will be advanced to *in vivo* studies (**Aim 3**) and will allow for the future selection of a preclinical candidate.

D.2. Aim 2. Investigate the mechanism of action (MOA) of lead inhibitors. Understanding the mechanism of action of the novel inhibitors of henipaviruses will help us to prioritize the lead compounds. The following experiments will be performed:

D.2.1. Determine the impact of compound treatment on viral protein expression and viral RNA levels in rCedV infected cells. Confluent HEK293T cells in a 6-well plate will be treated in duplicate with medium containing either DMSO or selected inhibitors at a predetermined concentration for 1 h, followed by infection with rCedV at MOI of 0.1. At 4, 8, 16 and 24 hpi cells will be collected to determine viral protein expression by western blot techniques or viral RNA levels by q-RT-PCR. CedV specific antibodies against G F N and P will be utilized. To determine changes in viral protein expression at the different time points, densitometric counts of these bands will be calculated using the ImageJ Software and normalized against β-actin and calculated as a fold change compared to the infected untreated cells (DMSO control). Total RNA will be extracted and 500 ng of total DNase I digested RNA will be used in q-RT-PCR assays with CedV specific TaqMan primer/probe pair targeting the N gene and performed using the ABI 7500 thermocycler. The ABI 7500 software will be used to analyze all q-RT-PCR results. Fold changes will be calculated relative to 18S using the ΔΔCt method and normalized to respective DMSO control samples. We expect to observe a decrease in intracellular viral RNA levels expression with compound treatment when compared to the DMSO control. Results from this data will indicate which viral protein(s) is affected by the compounds and the impact of the compounds on viral RNA levels over time.

D.2.2. Determine the stage(s) of inhibition of furopyrimidines and quinazolin-4-ones in the viral lifecycle. For time of addition studies, HEK293T cells will be infected with rCedV at MOI of 0.1 diluted in cell growth medium for 1 h at 37 °C, at which time the viral inoculum will be removed, and cells washed three times with PBS. This will be considered as 0 hpi. Compounds diluted in cell growth medium will be added to the cells at either 0, 2, 4, 6, 8 or 12 hpi and remain on the cells for the duration of the assay. All supernatants will be collected at 24 hpi and analyzed for infectious viral titers (PFU/mL) by plaque assay.[7,8] Results from this data will indicate at which stage of the viral life cycle the compounds are affecting.

D.2.3. Analyze escape mutants against the advanced lead compounds with Cedar virus. ***Target identification for small molecules.*** The rCedV tools used in **Aim 1** will also be used for antiviral target identification. *In vitro* selection of virus escape mutants that acquire resistant to inhibitors is a routine approach for mapping genetic changes associated with escape. We have successfully used authentic NiV and HeV and also rCedV chimeras to generate neutralizing mAb escape mutants. Here, we will test advanced lead compounds for antiviral resistance using techniques similar for generating mAb escape mutants.[58,59] Briefly, a select compound will be used at the sub-optimal inhibition concentrations determined from the studies in **Aim 1**, and virus will be serial passaged in multiple rounds. Amplified virus stocks obtained after several rounds of passage in the presence of inhibitor will be purified by limiting dilution in the presence of inhibitor, and a "drug resistant" virus stock will then be amplified and prepared for genomic sequencing. Full virus genomes of any "drug resistant" virus variant will be derived by deep-sequencing and annotated by a commercial source. All mutations will be mapped to the viral genomes. We expect that many mutations will map to the L gene of rCedV, however, both P and N proteins also comprise the replicase complex and mutations may appear in those gene products as well, which if identified also suggests the possibility of multiple drug combination testing going forward. We will validate key mutations found in drug resistant rCedV by engineering those mutations directly into the wild-type genome and re-recuse those rCedVs and assay for drug resistance. We will also confirm and correlate our drug targets by performing resistance selection of the best inhibitors using authentic NiV-B and HeV in BSL-4 by the UTMB BSL-4 Core.

D.2.4. Assess the binding properties by surface plasmon resonance (SPR). The NiV polymerase (L protein and a phosphoprotein P, or RdRp complex) will be prepared using a previously published protocol[60]. Biacore T200 and Biacore 8KSPR systems will be used to obtain information on binding specificity, binding affinity of the new lead inhibitors (K_D) to the RdRp protein, and kinetics [association rate constants (k_a), and dissociation rate constants (k_d)] as previously described.[61] RdRp protein will be immobilized on a CM5 chip using standard amine coupling protocols. Lead compounds at various concentrations (–.1 - 50 μM) will be injected over the flow channel surfaces, and sensorgrams will be fitted by either steady-state affinity or to a 1:1 Langmuir kinetic binding model. The equilibrium dissociation constants (K_D) will be calculated as $K_D = k_d/k_a$. This kinetic analysis will be performed by UIC RRC, as previously done by the **Rong lab.[62]**

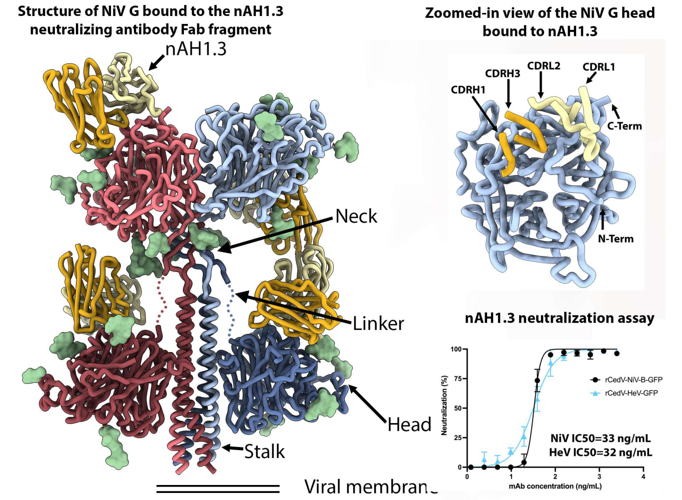

Figure 8. NiV G bound to the nAH1.3 neutralizing antibody Fab fragment. **A**) Ribbon diagram of the NiV G ectodomain bound to the broadly neutralizing nAH1.3 Fab fragment in two orthogonal orientations. Each of the four NiV G protomers is colored distinctly and resolved N-linked glycans are rendered as green surfaces. The nAH1.3 heavy and light chains are colored gold and yellow, respectively, and only the variable domains were modeled in density. The linkers connecting the neck to the two proximal head domains are shown as dashed lines due to weaker density in the cryoEM reconstruction. (**B**) Ribbon diagram of a NiV G head domain (blue) with the interacting nAH1.3 heavy and light chains CDRs rendered in gold and yellow. (**C**) nAH1.3-mediated neutralization of rCedV-NiV-B-GFP (black) and rCedV-HeV-GFP (blue).

D.2.5. Structure determination of recombinant proteins with bound inhibitors by CryoEM. The **Veesler lab** is a world leader in structural studies of viral glycoproteins and will carry out cryoEM studies of the most potent and broad inhibitors in complex with the NiV RdRp to visualize recognition at the atomic level and inform further optimization of target binding affinity. The **Veesler lab** has developed a streamlined high-resolution cryoEM pipeline enabling high-throughput structural studies of viral glycoproteins. We use the Leginon data collection software, which runs 24 hours per day and enables automated targeting and image acquisition, while keeping a relational database of all micrographs to expedite subsequent processing.[63] Many image processing tasks are automated as part of a workflow that allows assessing data quality in real time during acquisition, and prevents bookkeeping errors by storing all the details related to image acquisition and processing.[64,65] Complexes of small molecule inhibitors with the NiV RdRp will be vitrified and imaged using cryoEM to visualize directly the molecular basis of binding. As specimen preparation for cryoEM is often a bottleneck, we will leverage our extensive experience in overcoming specimen preferred orientation upon vitrification using ultrathin continuous carbon films,[66-70] mechanical stage tilting with gold grids[71,72] or detergents to modify surface tension[73]. To overcome possible conformational heterogeneity, we will use workflows developed in-house specifically for that purpose for previously characterized small molecules, miniprotein inhibitors and monoclonal antibody Fab fragments based on extensive (focused) 3D classification and local 3D refinement of subregions of the map to achieve 2.5-3.5Å resolutions.[71,74-80] Refinement of atomic models in cryoEM density maps will leverage the Rosetta software developed at the University of Washington.[81-83]

As cryo-EM structures of polymerase in complex with key inhibitors (i.e., **Z2** and additional derivatives) become available, MD studies of these systems will be conducted to reveal the dynamic nature of protein/ligand interactions[84-88], to explore the conformational landscape[89] of ligand binding events, and to capture conformational variability of intermediate states[90,91], which can be crucial to gain mechanistic knowledge of biological function.

The **Veesler and Broder labs** recently determined a high-resolution cryoEM structure of the NiV G glycoprotein ectodomain tetramer which has resisted structural characterization for 25 years, hindering both our understanding of immunity directed towards G and the rational design of vaccines. The structure was obtained in complex with a potent broadly neutralizing antibody Fab fragment (nAH1.3) (**Figure 8**), which recognizes an epitope distinct from the receptor-binding site and is a candidate for therapeutic development. This study revealed the ultrastructural organization of this key target of the immune system, informs the mechanism of henipavirus entry into host cells and provides a blueprint for guiding vaccine and therapeutic design. The know-how generated to achieve this groundbreaking result will directly support the proposed project.

Rigor and reproducibility. Maps and models will be thoroughly validated using standards widely accepted in the field. For cryoEM maps, these will include gold-standard projection matching refinements[92-94] and high-resolution noise substitution prior to Fourier shell correlation calculations[95] to avoid overfitting. Atomic models will be assessed using Molprobity,[96] EMringer[97] and Privateer.[98] The coordinates of the structures solved as part of this work, as well as the corresponding experimental data, will be made freely available through deposition in the RCSB Protein Data Bank (PDB) and Electron Microscopy Data Bank (EMDB).

Anticipated results. The structural studies outlined will provide a blueprint of the atomic interactions between the inhibitors and the RdRp which will enable iterative optimization of binding affinity and the design of improved inhibitors.

Pitfalls and alternate strategies. We do not anticipate any technical difficulties in this aim as these are commonly utilized techniques employed in the **Rong, Vessler, and Geisbert labs**. We have previously rescued a GFP reporter rCedV as well as rCedV that lacks a reporter. We do not anticipate that the HEK293T cells will be problematic; however, several other cell lines may be tested in the assay. Successful mechanism studies may allow us to determine a mechanism of action that defines a binding site for inhibitory furopyrimidines or quinazoline-4-ones. In the unlikely event we encounter protein complexes that cannot be vitrified using the strategies described, we will use the TTP Labtech Chameleon vitrification robot, which is available at the UW cryoEM center (**Dr. Veesler** as the co-director), and specifically designed to overcome these issues using self-wicking grids and ultra-fast (80-150ms) spot-to-plunge time (28–30). Alternatively, we will crystallize the RdRp in complex with inhibitors to determine X-ray diffraction structures, as routinely done in the **Veesler lab**.[99,100]

D.3. AIM 3: Evaluation of lead compounds *in vivo*.

A critical aspect of antiviral discovery that is often overlooked is the early-stage testing of lead compounds in well-studied and well-validated *in vivo* animal models. Here, our experimental plan has the benefit of such models for pathogenic henipaviruses (NiV and HeV) which includes the Syrian golden hamster and AGM.[2,101] PK/PD studies will be carried out in the NiV/HeV hamster model. Protective efficacy studies using select best-in-class drugs will be used in NiV-B and HeV infected hamsters. Final proof-of-concept protective efficacy studies with best-in-class drugs and/or nanobodies will be carried out in the NiV-B and HeV infected AGM models.

D.3.1. Pharmacokinetic studies in hamsters and AGMs. In order to enable *in vivo* efficacy studies, preliminary pharmacokinetic (PK) studies in hamsters and AGMs will be performed. Using intraperitoneal (i.p.) or intravenous (i.v.) administration for hamsters and i.v. administration for AGMs, these studies will examine the concentration of lead compounds in plasma over time in order to establish parameters such as bioavailability, volume of distribution, clearance, and half-life. This data will be used to select doses and dosing regimens to be investigated in pharmacodynamic (PD) studies using a commonly used PK/PD parameter for efficacy in antiviral drug development, which is the maintenance of the minimum plasma concentration (Cmin) above the EC_{90} in cellular assays. The PK/PD relationship and impact on antiviral activity will be assessed in hamster models of henipavirus disease. Lead compounds with good exposure-response antiviral activity in hamsters will then advance into AGM PK studies using similar dose administration and measured parameters as above. The data will help to select doses and dosing regimens for the subsequent protection studies in AGMs. Formulation stability and PK/Toxicity studies will be performed by **CRO**s.

D.3.2. *In vivo* testing of lead compounds in NiV/HeV infected Golden Syrian hamsters. The *in vivo* activity of the most potent compounds from Aim1 will be evaluated in a series of hamster infection studies. In brief, animals will be randomized to multiple study groups (n = 5 per group) and inoculated intranasally (i.n.) with ~ 5x10^6 PFU of NiV-B or HeV.[102-105] Animals will then be treated by i.p. or i.v. injection ~ 1 hour after virus challenge with different doses of drugs. Additional treatments may be given based on PK data. The control animals will be treated in parallel with sterile saline. Antiviral efficacy will be assessed by several methods, including weight loss, temperature, viremia (nasal swabs and blood), and survival. The treatment initiation time points will also be optimized in later studies. The candidates showing the most protection will be selected for further analysis below.

D.3.3. Define breakthrough conditions for anti-henipavirus agents in hamsters. This study will employ the most promising drugs from Aim 1 that are shown to completely protect hamsters against lethal henipavirus infection. The goal is to determine the time points of treatment initiation when the antiviral agents fail to confer protective efficacy. Hamsters will be randomized to multiple study groups (n = 5 per group) and inoculated i.n. with ~ 5×10^6 PFU of NiV or HeV.[102-105] Treatments will be initiated at various times after henipavirus infection, e.g., days 1, 2, 3, etc. to determine the initiation time point at which most hamsters succumb to disease.

D.3.4. *In vivo* testing of lead compounds in NiV/HeV infected nonhuman primates (NHP). A final proof of concept study will be performed in NHPs using the lead candidates providing the best protection against NiV/HeV infection in hamsters. Healthy, NiV/HeV-seronegative AGMs will be inoculated either by large particle aerosol using the LMA mucosal atomization device (MAD) as previously described[40] or by small particle aerosol as previously described[41,106] with a uniformly lethal challenge dose (~ 20,000 PFU of NiV or HeV). Importantly, the MAD system delivers atomized particles that range in size from 30 to 100 µm, which is highly consistent with the size of droplets exhaled by humans when coughing. Previous studies with AGMs infected with NiV-B using the MAD system resulted in lethality in 9/9 animals and a disease course that is highly consistent with human infection (T.W. Geisbert, unpublished data). The treatment groups (consisting of five animals each) will be treated with the lead antivirals by bolus i.v. infusion oral gavage up to 5 days after viral challenge (initiation time informed by hamster studies) while control animals will receive sterile saline. Additional treatments may be given. Antiviral efficacy will be assessed by respiration quality, physical appearance, clinical pathology, viremia (nasal swabs and blood), and survival. Based on the results, the study will be repeated to further define the therapeutic window, e.g., if all five animals treated with the test compound survive the follow up study will begin treatment at day 5 after NiV infection. Conversely, if any of the drug treated AGMs succumb the follow up study will begin treatment at day 3 after NiV infection. A third study will be done to assess the protective efficacy of the drug for treating HeV-infected AGMs; test conditions for the HeV study will be the same as the test conditions showing the best protection against NiV-B. Defining the therapeutic window is not only important in terms of translating preclinical animal data to humans but also in regard to combination treatment studies where it is important to establish breakthrough for each individual drug to be used in combination approaches in order to be able to show a benefit of combining drugs.

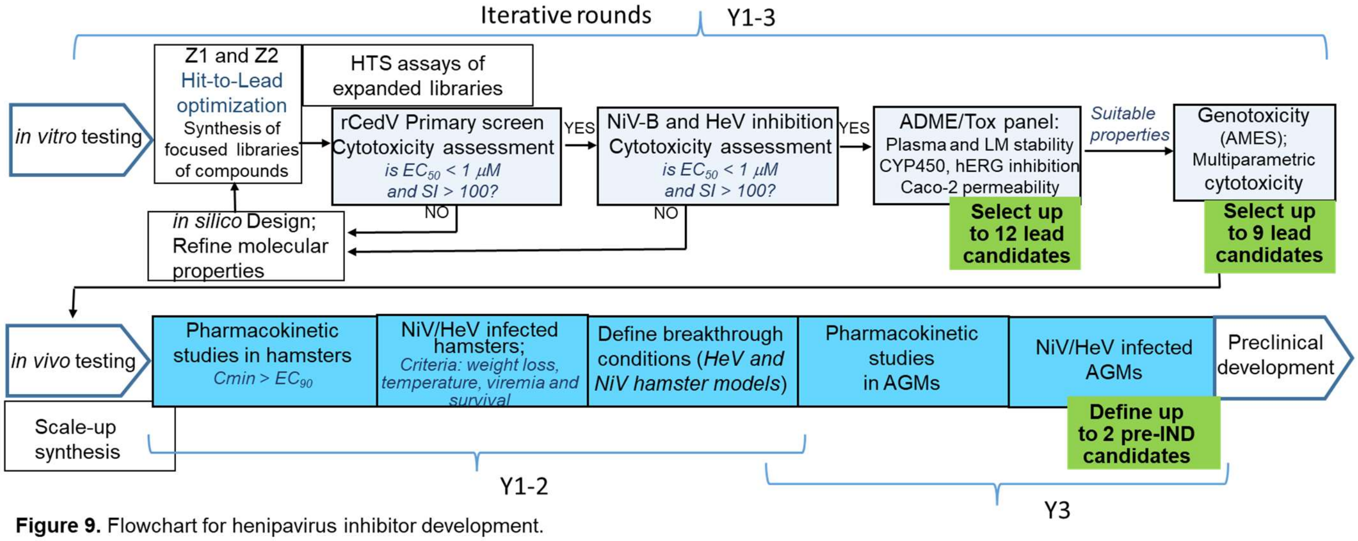

Figure 9. Flowchart for henipavirus inhibitor development.

General Methods, Scientific Rigor, and Biological Variables Criteria: All animal studies will be blinded to all staff performing animal procedures and assays, and to the veterinary pathologist performing gross and/or histological analysis of tissues. We will employ equal or near equal numbers of male and female animals and general age (infant or geriatric animals will not be used).

Here, we have established rigorous milestones to ensure the production of suitable advanced lead small molecule inhibitors, which will allow for the selection of preclinical candidates (**Figure 9**).

Product Development Plan. Our team will meet quarterly over zoom to discuss the project progress and prioritize promising lead inhibitors generated from each iterative round of synthetic medicinal chemistry-biological testing, from those with desired PK, good safety profile and *in vivo* efficacy, for further advancement.

In summary, the continued outbreaks of NiV across a large global region requires urgent translational countermeasure research to establish a readiness for the next NiV or related pathogenic henipavirus outbreak. We have discovered antiviral leads that show promise against NiV and HeV, and lay out a detailed plan to optimize, develop, and test these drugs. Together with the expertise, resources and experience within this proposal, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

Investment Results - Outcomes and Outputs

In this section, please provide specific details on the results this project will achieve.

"Outcome" is the ultimate or overall change(s) in systems, populations, or behaviors that a project seeks to achieve within the time frame of the grant.

❖ Describe what success looks like for the project by stating the intended outcome(s) of the project and how they relate to the activities funded by the grant.

Definition three advanced lead compounds that are inhibitory against NiV and HeV, and identification of a potential clinical candidate for further development.

"Output" or "**Funded Development**" means the products, services, processes, technologies, materials, software, data, other innovations, and intellectual property (IP) resulting from the project (including modifications, improvements, and further developments to Background Technology).

❖ Please populate the table below with the intended outputs of the project. Add more rows as needed.

Number	**Output/Funded Development Description**	**Target Completion Date**	**Is a Third-Party agreement required? If yes, by when?**	**Will any IP rights be filed/generated?***
1	Preparation of furopyrimidine compound library	[30/09/24]	No	Yes
2	Preparation of quinazolinone compound library	[30/09/24]	No	Yes
3	Define three advanced lead compounds from the above compound libraries	[30/09/24]	No	Yes
4	Identify a potential clinical candidate compound for further development	[30/09/25]	No	Yes

**Note: In future progress report(s) you will be required to report on these outputs, and to disclose and update intellectual property (IP) and include any links to IP applications, filings, or registrations, as applicable.*

❖ If necessary, please add further explanations below:

Global Access – Charitable Impact for Beneficiaries

To ensure a positive impact for the intended beneficiaries, the foundation requires that all projects and outputs be managed to ensure Global Access.

"Global Access" is a foundation policy requiring that: (a) the knowledge and information gained from the project be promptly and broadly disseminated; and (b) the Funded Developments be made available and accessible at an affordable price (i) to people most in need within developing countries, or (ii) in support of the U.S. educational system and public libraries, as applicable to the project. For more information and resources on Global Access, see the foundation's Global Access Statement and Global Access webpage.

❖ How will you disseminate the knowledge and information gained from the project? For additional information for peer-reviewed publications, see the foundation's Open Access policy.

Data generated from this project will be publish in Open Access journals and presented at the International Society for Antiviral Research conferences.

"Background Technology" means all products, services, processes, technologies, materials, software, data, or other innovations, and intellectual property created by you or a third party prior to or outside of the project and used as part of the project.

Please list any Background Technology that will be used in the project. Commonly available, off-the-shelf products (such as Microsoft Excel, Adobe, etc.) do not need to be disclosed. Add more rows as needed.

Note: Background Technology previously funded by the foundation will be considered a Funded Development for purposes of Global Access and any license to the foundation.

List each Background Technology to be used in the project	Is this Background Technology owned, controlled, or developed by you or sublicensable by you?	Do you need permission or a license from any third party to use this Background Technology to achieve Global Access?	If any permission/license is needed, please detail below, and describe your plan and timeline to obtain such permission/license or submit a copy of the agreement.	If this Background Technology is subject to Intellectual Property rights, please identify and include any links to applications, filings, or registrations, as applicable.
Provisional patent application NOVEL INHIBITORS OF HENIPAVIRUSES	Yes	No		application serial no. is 63/391,893
	No/Yes	No/Yes		
	No/Yes	No/Yes		

❖ How will you ensure affordable and meaningful access to the Funded Developments and Background Technology, if any?

Publication in Open Access Journals; Patent sub-license.

❖ Do you foresee any obstacles to achieving Global Access (e.g., third-party rights, restrictions on Background Technology, time frame, affordability)?

__X_No___Yes (please explain and describe the specific steps that you will take to address the obstacles)

❖ For Global Access purposes, please confirm that you will make available the funded developments and any Background Technology that is (a) owned, controlled, or developed by you, or in-licensed with the right to sublicense; and (b) either incorporated into a funded development or reasonably required to use the funded development. For more information, see the Global Access terms located in the foundation's standard grant terms and conditions.

_X__Confirmed___Not confirmed (please explain)

Data Access

It is anticipated that the activities of this project will generate or collect datasets that may be useful to the foundation, project collaborators, third-party researchers, and/or the public. Please answer the questions below with a level of detail appropriate to the project activities.

- What types of data and specific datasets will be generated from the project activities and/or collected from other sources?

  HTS dataset; *In vitro* inhibition of CedV, NiV-B and HeV; PK and ADME/Tox data for lead compounds; *In vivo* efficacy data for advanced lead compounds

- Do you plan to create a data management plan? If not, why not?

  Yes

- What data curation (e.g., organizing, describing, cleaning, enhancing, and preserving) activities are planned to enable reuse or secondary use of the datasets?

  We will create a database in which we will routinely organize and store chemical and biological information that can be accessed by our team. We will use ChemBioFinder, because this program has the capability of searching compounds by sub-structures or similarity, facilitating data analysis and information retrieval.

- Where and when will the datasets be deposited and preserved to enable reuse or secondary use and under what license?

  All data generated in the course of this project will be published in Open Access Journals.

- Please describe any informed consents, approvals, and/or agreements that may be required to enable use or reuse of the datasets by the foundation, project collaborators, and/or third-party researchers. What steps do you plan to take to obtain such consents, approvals, and agreements?

  Office of Technology Management at UIC. To process material transfer agreements (MTA).

BUDGET INFORMATION

The purpose of this section is to supplement the information provided in the Excel budget template by justifying how the budgeted items are necessary to implement project activities and accomplish project results. Please focus on key costs and risks and avoid repeating information contained in the budget template. Together, this narrative section and Excel budget template should provide a complete description that supports the proposed budget. For questions below that are not relevant to your project, answer "N/A".

For additional instructions and guidance on the budget template, see the Grant Budgeting & Financial Reporting Detailed Instructions.

Budget Summary

- Explain the major cost drivers and how costs relate to planned activities and target outcomes. Also, explain any potential risks in spending and any plans to mitigate those risks. In the Excel budget template, an *additional dimension* can be defined to break down costs beyond the standard expense categories (e.g., by geography, product candidate, projects within a portfolio, or other). If you are defining such an additional dimension, please use it as you explain the major cost drivers here.

  We request funding to purchase the "ChemDiv Antiviral Library" ($124,621 – quote RT10212021-UIC-A), which will be screened for new inhibitors by HTS rCedV-Luc assay.
  ADME/Tox and PK screening (Y1-$35,000; Y2-$60,000, and Y3-$50,000).

ADME panel	Price *	Species	Comments
Thermodynamic solubility in PBS	$80		Plan to test: up to 15 compounds in LM and plasma stability assays in Y1-2; up to 12 compounds in CYP inhibition assay; up to 10 compounds in Caco-2, TS in PBS and Stability in Hep assays; up to 10 compounds in PPB,
Thermodynamic solubility in FeSSIF, FaSSIF, FaSSGF, SIF or SGF	$100 /incubation ($400 total)		
Stability in Liver Microsomes 4 non-zero tps	$200 / species	Human, hamster, and monkey	
Stability in hepatocytes (1 non-	$220 / species	Human, hamster, and monkey	

zero tps)			thermodynamic solubility in FeSSIF, FaSSIF, FaSSGF, SIF
Plasma stability (4 non-zero tps)	$250 /species	Human, hamster, and monkey	
Caco-2 Bidirectional	$450		
Plasma protein binding	$280		
CYP inhibition (2C9, 2C19, 2D6, 3A4) 6 non-zero concs	$1,120		
Tox-Genotoxicity panel			Plan to test up to 10 compounds in Tox-Genotoxicity panel in Y1-2
hERG assay by manual patch-clamp (IC50, n = 2)	$450		
Nephrotoxicity (HK2 cells, IC50)	$300		
Cytotoxicity with primarily cultured neuronal model (IC50)	$600		
Cytotoxicity testing on primary human hepatocytes	$1,200		
Mini-Ames 5 strains	$1,350		
In vivo PK			
Screening PK in hamsters Plasma PK (IV and PO administration), n = 3, 8-9 time points	$3,000		Plan to test up to 9 compounds
Bio analysis of samples (LC/MS/MS/ method development)	$1,000		
Metabolite identification in biosamples	$1,000/sample (blood, brain) $2,000 total		
Monkey standard PK Plasma PK (IV and PO administration), n = 3, 8-9 time points	$9,700		Plan to test up to 3 compounds in Y2-3
Bio analysis of samples (LC/MS/MS/ method development)	$1,000		
Metabolite identification in biosamples (monkey)	$1,000/sample (blood)		
*Pharmaron *in vitro* ADME-Tox and *in vivo* PK Pricing (2022)			

Detailed Budget Information

In this section, please complete the sub-sections that apply to your project and associated budget, and answer “N/A” for those that do not apply.

Personnel and Benefits

- Provide a description of budgeted personnel (including staff to-be-hired) and their responsibilities as they relate to the project. For to-be-hired individuals, please make sure your budgeting assumptions factor in realistic timing for recruiting.

  Describe the components included in the benefits percentage (column R of the “Budget Details” sheet in the budget template). For example: pension, health insurance, expatriate costs, etc.

Dr. Lijun Rong, PI (0.13, 0.1, and 0.08 FTE), is a Professor and Director of High Throughput Screening (HTS) facility at the Department of

Microbiology and Immunology at the University of Illinois at Chicago (UIC). Dr. Rong has extensive research experience in studying the entry and replication mechanisms of several emerging viruses including SARS2, Ebola virus, influenza and henipaviruses, and in developing small molecule inhibitors against these viruses. As the PI, he will supervise and coordinate all aspects of the proposed experiments in this proposal He will be also responsible for communicating with the Co-Is and collaborators.
Dr. Irina N. Gaisina, Co-Investigator (2.88 Acad, 0.6 Sum. Y1; 2.16 Acad 0.6 Sum. Y2; 1.44 Acad, 0.6 Sum Y3), is a Research Associate Professor in the Department of Pharmaceutical Sciences, College of Pharmacy, UIC. She has extensive experience in hit-to-lead and lead optimization medicinal chemistry and preclinical drug development. Dr. Gaisina will assume overall responsibility for the medicinal chemistry work carried out at UIC, including coordinating the work of project personnel and writing reports associated with the project. Dr. Gaisina will directly supervise Dr. Argade, and TBN technician. She will work on structure-activity relationship development, including computational aspects, and lead optimization. As a key team member in the medicinal chemistry core at UIC's collaborative drug discovery center, UICentre, Dr. Gaisina has been leading multiple antiviral drug discovery projects. She has a well-established collaboration with Dr. Rong.
Dr. Malaika Argade, Research Scientist (8.25 Cal. Y1; 6.6 Cal. Y2; 3.3 Cal. Y3), a medicinal chemist at UICentre, will perform the proposed synthetic medicinal chemistry and optimize scaleup synthesis of lead compounds for the PK assessments and the proposed in vivo studies. Salary support plus applicable fringe benefits for effort are requested.
TBN, Technician (12 Cal. Y1-Y2; 9 Cal. Y3), with background in organic synthesis and/or medicinal chemistry will be recruited to join the research team. The technician will synthesize focused libraries of small molecule inhibitors of henipaviruses and characterize them using NMR spectroscopy and mass-spectrometry.
Ryan Bott, B.S. Research Specialist (0.63, 0.5, and 0.38), has started to work in Dr. Rong Lab as a research specialist since May 2021. Before that he worked in Rong Lab as an undergraduate lab aide for three years. He has been trained for basic lab techniques and will assist the proposed experiments in this proposal.
Dr. Laura Cooper, Postdoctoral Fellow (1.25, 1, and 0.75), was a PhD student in Dr, Rong lab and her PhD research focused on antiviral drug discovery and MOA studies of small molecule inhibitors. She has published more than 15 peer-reviewed papers since she joined Dr. Rong Lab. Her responsibilities include bioassay development and MOA studies in this application.

Salary support plus applicable fringe benefits for effort are requested. UIC's FY23 projected fringe rate is 37.17% for academic professionals.

Fringe benefits include pension, health, life and dental insurance, workers comp, term. vacation/sick, medicare (for those hired after 4/1/1986), OASDI (for certain appointment types).

Travel

- Describe the travel budgeted and the assumptions used to estimate the appropriate number of trips and associated costs.

$3,000 /year funding is requested for the PI and Co-I to attend antiviral research meetings, such as the International Society for Antiviral Research (ISAR) conferences and present the project. This travel budget covers airfare, lodging, and per diem associated costs.

Consultants

- Describe the work to be performed by consultants and any reimbursable expenses that have been budgeted in addition to consulting fees.

Dr. Norton P. Peet, Consultant, is Chief Scientific Officer for Chicago BioSolutions. Dr. Peet is a medicinal chemist who has over 30 years of experience with both multinational pharmaceutical and biotechnology companies. Dr. Peet has previous experience with the preclinical development of therapeutic agents and their advancement to a clinical setting. He will oversee the proposed ADME/Tox and PK studies (his consulting fee is $300/h).

Capital Equipment

- Describe any budgeted capital equipment items and explain why they are needed for the project. Only items with a unit cost of more than $5,000 (USD) and a "useful life" of more than one year should be included here, whereas items with a lower cost or shorter life should be budgeted under Other Direct Costs (see below).

none

Other Direct Costs

- Describe other items required for the project that fall under direct costs and are not part of any cost category above. For additional information on direct and indirect costs, please see the foundation's Indirect Cost policy.

Chemistry Lab:
1) Chemical and solvents including, but not limited to specialty chemicals, inorganic salts, ACS grade solvents for synthesis ($28,697 Y1;

$23,000 Y2; $19,000 Y3).
2) Chromatography supplies including, but not limited to tubes for fractionation, replacement HPLC columns, lamps for spectrophotometers, preloaded silica gel cartridges, LC-MS grade solvents for LC-MS and HPLC ($3,000/year).
3) Glassware and disposable plasticware supplies including, but not limited to flasks, vials, pipette tips, containers for sample storage ($3,000/year).
4) $17,000 per year is requested to cover instrumentation charges include routine NMR analysis and characterization of intermediates and products ($10/hr); charges for IT-TOF-MS at $52/hr; UIC Research Resources Center (RRC) services including mass spectrometry, high field NMR, surface plasmon resonance (SPR) to assess binding of small molecules to target protein, and bioinformatics.
Biology Lab:
1) HTS reagents and supplies
2) Tissue culture supplies
3) Reagents for DNA and protein work
4) Tissue culture supplies to characterize the lead inhibitors, and to study MOA of these inhibitors.
5) Assay kits and reagents (such as luciferase substrate, LiveBLAzer-FRET B/substrate).
6) Glassware, plasticware and other miscellaneous items.
Publication in Open Access Journals:
Funding is requested to cover the publication costs ($5,000/Year)

Subawards

Subawards are contracts or grants that you, as the prospective primary grantee, negotiate with other organizations who contribute to the completion of this project. A subaward is "under" the main grant award; as the primary grantee you will receive funds from the foundation and manage the disbursements to the subawardee. You are responsible for negotiating the subaward budget, overseeing the work of the subawardee, disbursing funds in accordance with the subaward agreement and ensuring all applicable policies are met. For additional information, see Exercising Expenditure Responsibility Over Subgrants.

If your project will include subawards, please include the following information:

❖ If you are an Indian organization/entity subject to India's Foreign Contribution Regulation Act (FCRA), then in compliance with FCRA, do you confirm that your proposed project will not include any subgrantees? This prohibition does not preclude subcontracts in the ordinary course of business.

_X__Not applicable ___Confirmed ___Not confirmed (please explain)

❖ In the Excel budget spreadsheet, please enter each subaward as a separate line item with the expected disbursement for each period broken out.

If your proposal includes any subawards greater than $1 million USD, please provide a separate budget spreadsheet for each subaward as an appendix to the proposal materials, using the foundations Excel budget template. Please reach out to your foundation contact if you need a blank budget template or have questions or concerns about using this format with any of your subawardees.

❖ In addition to the information included in the Excel budget template, please also list all subgrantees or subcontractors involved in this project in the table below. Add more rows as needed.

Type of Subaward (grant or contract)	**Organization Name**	**Organization Location** (Country)	**Website or Email** (please include email if subcontracting to an individual)
Contract	The University of Texas Medical Branch at Galveston	U.S.A.	
Contract	The University of Washington Seattle	U.S.A.	

❖ In the space below, provide the following additional information for each organization chosen to participate on this project as a subawardee:

Describe the work the subawardee is going to perform, what selection process was used, how the sub-budgets were negotiated, and what the key cost drivers are. If organizations are not yet known or "to-be-determined" (TBD), include the assumptions used to estimate the cost for the subaward, and the process and timeline you will use to select these organizations and negotiate budgets. Once subaward organizations are selected, you will be required to submit the subaward information and budget (as necessary) to the foundation in writing.

The University of Texas Medical Branch at Galveston: Evaluation of antiviral activity of advanced candidates against authentic NiV and HeV *in vitro* and i*n vivo* testing of lead compounds in NiV/HeV infected Golden Syrian hamster and AGM models.

Dr. Thomas W. Geisbert (**Co-I**), Professor, Department of Microbiology & Immunology at UTMB-Galveston and of the Galveston National Laboratory (GNL), will serve as the UTMB principal investigator for a subcontract for this project. He has expertise in nearly all technical aspects of this project. Dr. Geisbert has over 30 years' BSL-4 experience at USAMRIID and at the GNL. For these many years, his research interests have focused on the study of hemorrhagic fever viruses, and he has published extensively in this area. His group demonstrated complete protection of nonhuman primates against Ebola, Marburg, and Lassa viruses using a novel vaccine based on recombinant vesicular stomatitis virus. He will devote 0.6 calendar months in Periods 1-3 to project planning and performance and hands-on participation in these experiments. Dr. Geisbert's institutional base salary exceeds the current salary limitation for Executive Level II of the Federal Executive pay scale; therefore, the salary cap was used. Fringe rates are calculated using his actual institutional salary.

BSL-4 Research Scientist: Robert Cross, PhD, Assistant Professor, Department of Microbiology & Immunology at UTMB-Galveston and of the GNL will devote 0.8 calendar months per year in Periods 1-2 and 0.9 calendar months in Period 3 of the project assisting Dr. Geisbert with the conduct of this research. He will participate in the BSL-4 portions of the work including hands on procedures with the mice including necropsies. He will also assist in performing various assays including virology assays. Dr. Cross has seven years' BSL-4 experience.

BSL-4 Technical Director: Joan B. Geisbert has more than 35 years' hands-on BSL-4 laboratory experience and serves as the Associate Director for In Vivo Training at the GNL. Ms. Geisbert will serve as chief technical manager for all of the mouse challenge studies including laboratory set-up, supervision of the BSL-4 research technicians and graduate student, and hands-on participation in these experiments. She will devote 0.75 calendar months each year in all periods of the project. Ms. Geisbert will also perform animal challenges, treatments, clinical observations, and assist with necropsies. Ms. Geisbert will also oversee the select agent inventory and controlled substances inventory for this project.

BSL-4 Veterinary Pathologist: Karla Fenton, DVM, PhD, Senior Scientist, Department of Microbiology & Immunology at UTMB-Galveston and of the GNL will devote 0.8 calendar months each year in Periods 1-2 and 0.9 calendar months in Period 3 assisting Dr. Geisbert with the conduct of this research. Dr. Fenton is an ACVP board-certified veterinary pathologist and has been trained in BSL-4/ABSL-4 in the Geisbert laboratory. She will perform and oversee necropsies on the animals and will assist in animal challenges, treatments, clinical observations, and sample collection, and will perform gross and histological analysis of selected tissues and will prepare pathology reports. Dr. Fenton has six years' BSL4 experience.

BSL-4 Research Scientist: Abhishek Prasad, PhD, Department of Microbiology & Immunology at UTMB- Galveston and of the GNL, will devote 0.96 calendar months in Period 1-2 and 1.2 calendar months in Period 3 of the project assisting Dr. Geisbert with the conduct of this research. He will participate in the BSL-4 portions of the work, including hands on procedures with the mice and performing various assays including virology assays. Dr. Prasad has four years' BSL-4 experience.

BSL-4 Postdoctoral Fellow: Dylan Johnson, postdoctoral fellow in the Department of Microbiology & Immunology at UTMB- Galveston and of the GNL will devote 0.96 calendar months in all Periods of the project assisting Dr. Geisbert with the conduct of this research. He will participate in the BSL-4 portions of the work, including reverse genetics, hands-on procedures with the mice, and performing various assays including virology assays.

BSL-4 Postdoctoral Fellow: Alyssa Fears, postdoctoral fellow in the Department of Microbiology & Immunology at UTMB- Galveston and of the GNL will devote 0.96 calendar months in all Periods of the project assisting Dr. Geisbert with the conduct of this research. She will participate in the BSL-4 portions of the work, including reverse genetics, hands-on procedures with the mice, and performing various assays including virology assays.

BSL-4 Research Scientist: Courtney Woolsey, PhD, was a graduate student and postdoctoral fellow in Dr. Geisbert's laboratory and has since formerly assumed a role as a research scientist in the Department of Microbiology & Immunology at UTMB. Dr. Woolsey will devote 0.96 calendar months in Periods 1-2 and 1.2 calendar months in Period 3 assisting Dr. Geisbert with the conduct of this research. She will participate in the BSL-4 portions of the work, including performing various procedures including hematology, clinical chemistry, and virology assays.

BSL-4 Research Technician: Krystle Agans, BS, will devote 1.2 calendar months in Periods 1-2 and 1.5 calendar month in Period 3 of the project performing BSL-4 in vitro and animal studies. Ms. Agans will participate in the BSL-4 portions of the work including virology assays as well as the BSL-2 RT-PCR assays. She has over seven years' BSL-4 experience.

BSL-4 Research Technician: Daniel Deer, BS, will devote 1.2 calendar months in Periods 1-2 and 1.5 calendar month in Period 3 of the project performing BSL-4 in vitro and animal studies. Mr. Deer will participate in the BSL- 4 portions of the work including virology assays as well as clinical observations. He has over six years' BSL-4 experience.

BSL-4 Research Technician: Viktoriya Borisevich, MD, PhD will devote 1.2 calendar months in Periods 1-2 and 1.5 calendar month in Period 3 of the project performing BSL-4 in vitro and animal studies. Dr. Borisevich will participate in the BSL-4 portions of the work including sequencing and virology assays, as well as the BSL-2 RT-PCR assays. Dr. Borisevich has over eight years' BSL-4 experience.

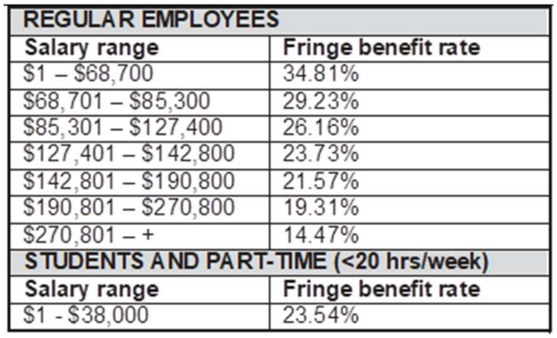
Research Technician: Brittany Franshaw will assist Dr. Borisevich in performing BSL-2 RT-PCR assays and will devote 1.2 calendar months each year in all Periods of the project. She is currently being trained in BSL-4 and will assist with various procedures including virology assays.

Research Technician: Rachel O'Toole will assist Dr. Borisevich in performing BSL-2 RT-PCR assays and will devote 1.2 calendar months each year in all Periods of the project. She is currently being trained in BSL-4 and will assist with various procedures including virology assays.

Histopathology Technician: Natalie Dobias, HT(ASCP), is a histologist with 11 years' experience (5 of those working with NHP tissue) who will be tasked with processing, embedding, sectioning, and staining mouse tissues as needed for the project. She will devote 0.8 calendar

months in Periods 1-2 and 0.96 calendar months in Period 3 of the project assisting Dr. Fenton with the histology studies.
Program Administrator: Sherry Haller, PhD, Associate Director, Center for Biodefense and Emerging Infectious Diseases, will oversee all administrative aspects of the project and will work with Dr. Geisbert to see that deliverables are being met. She will devote 0.2 calendar months per year in all Periods of the project.

The table below reflects staff effort to be devoted to this project.
Fringe Benefits: The UTMB-Galveston fringe benefit rate for FY22 is calculated by salary range as follows:



REGULAR EMPLOYEES	
Salary range	**Fringe benefit rate**
$1 – $68,700	34.81%
$68,701 – $85,300	29.23%
$85,301 – $127,400	26.16%
$127,401 – $142,800	23.73%
$142,801 – $190,800	21.57%
$190,801 – $270,800	19.31%
$270,801 – +	14.47%
STUDENTS AND PART-TIME (<20 hrs/week)	
Salary range	**Fringe benefit rate**
$1 - $38,000	23.54%

OTHER DIRECT COSTS
Materials and Supplies.

General lab supplies- Funds are requested for laboratory supplies to perform in vitro assays including costs for PPE (gloves, masks, etc.), cell culture material, plasticware, flasks, pipette tips and disinfectant as well as for in vivo work including costs to perform hematology, clinical chemistry, virology, animal procedures, and necropsies, based on historical usage of these items. We request $64,401 in Period 1, $29,321 in Period 2 and $32,562 in Period 3 for a total of $126,285.

Hamster purchase, shipping and per diems- Funds are requested for the purchase of 100 hamsters in Period 1 and 200 hamsters in Period 2. A total of $18,500 is requested in Period 1 and $37,000 in Period 2 to include the cost of purchasing the hamsters, shipping them to UTMB, and housing them in the UTMB Animal Resource Center for the duration of the studies.

NHP purchase, shipping and per diems- Funds are requested for the purchase of 12 African green monkeys in Period 3. African green monkeys currently cost $8,870 per animal plus shipping. A total of $152,000 is requested in Period 3 to include the cost of purchasing, testing and shipping the NHPs to UTMB. Also included are costs to cover per diem charges.

INDIRECT COSTS
According to the Pandemic Antiviral Discovery guidelines, the indirect costs for this work have been set at 10% of modified total direct costs for the project period.

The University of Washington Seattle: Structure determination of recombinant proteins with bound inhibitors by CryoEM.
Dr. David Veesler (**Co-I**), an Associate Professor of Biochemistry at UW and HHMI investigator (no salary requested), is a world leader in structural studies of viral glycoproteins and will carry out cryoEM and X-ray crystallographic studies of the most potent inhibitors in complex with the NiV or HeV polymerase.
Dr. Daniel Asarnow, Postdoctoral Fellow, (effort 69% FTE). Dr. Asarnow is an expert in biophysics and has a strong background in structural biology. Dr. Asarnow determined cryoEM and X-ray crystallographic structures of neutralizing coronavirus antibodies targeting the spike and will participate in structural determination efforts. Dr. Asarnow will be playing a major role in experimental design, data analysis and interpretation, writing manuscripts and will report directly to Dr. Veesler.
William Sharkey, Research Technician, (effort 75% FTE). Mr. Sharkey has extensive experience in recombinant glycoprotein production in mammalian cells, purification and biophysical characterization. His work will support cryoEM structural studies under the supervision of Dr. Veesler to whom he will directly report.
Zaneta Holman, Lab manager, (effort 7% FTE). Ms. Holman is in charge of ordering and stocking lab supplies and of interactions with vendors under the supervision of Dr. Veesler to whom she will directly report.

Mammalian cell culture, protein production and purification: Funds are requested to support the purchase of protein production materials and supplies including media, chromatography columns, gels, stains, ladders, purification reagents, concentrators, and buffer reagents. It will also include transfection reagents, cell culture media and plasticware for suspension cells to support structural biology efforts.

Microscope time. This will cover access to our Thermo-Fisher Titan Krios, Glacios and Tecnai T12 Spirit electron microscopes for screening and high-resolution data collection.

INDIRECT COSTS
According to the Pandemic Antiviral Discovery guidelines, the indirect costs for this work have been set at 10% of modified total direct costs for the project period.

Indirect Cost Rate

- Briefly explain the indirect cost rate being charged on this project and the rationale and assumptions behind it.

10% maximum amount per sponsor policy.

Currency Exchange

- What is the operating currency you will be using to manage project financials? If different from USD, please explain your organization's foreign exchange policy, including how and when U.S. Dollars are converted to local currency. (If no formal policy exists, explain the approach you plan to follow on this project.)

USD

- If the project is exposed to additional currencies, other than your operating currency and USD, please name these currencies and provide a rough estimate on how much will be spent in these currencies.

- Are there any measures you plan to take for reducing currency risk?

Other Sources of Support

- Beyond the requested funding from this grant, will the total cost of this project require contributions of funding from other sources (either from your organization or others)?

_X__No (skip questions below) ___Yes (please explain)

Please fill out the Total Project Cost and Funding Plan sections in the Excel Budget template and provide further context and explanations here, such as timing, uncertainties/dependencies and important restrictions that apply. If applicable, please also describe any expected in-kind contributions (e.g., drug donations, personnel time), and explain how dollar values were estimated.

- If any of the funding (other than this grant) is not yet secured, please describe what you will do if it does not become available.

Geography Served

- List all countries, sub-regions, and/or states that will benefit from this work and the associated dollar amounts for the full term of the grant. Please avoid listing "World," unless the work truly serves beneficiaries globally. If geographies include the United States, please indicate city and state. The total of "Foundation Funding" amounts should match the requested grant funding. Add more rows as needed.

For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Geography Served	Foundation Funding Amount (USD)
World	$2,954,167
	$
	$

Location of Work

- List all countries, sub-regions, and/or states where this work would be performed, and associated dollar amounts for the full term of the grant. This includes your location and any locations where you plan to make payments to individuals or organizations with grant funds. If locations include the United States, please indicate city and state. The total of "Foundation Funding" amounts should match the requested grant funding. Add more rows as needed.

  For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Location of Work	**Foundation Funding Amount (USD)**
United States of America, Illinois, Chicago	$1,655,106
United States of America, Michigan, Holland	$36,000
United States of America, Texas, Galveston	$780,000
United States of America, Washington, Seattle	$483,061

- Many countries, including India, Vietnam, Bangladesh, and Pakistan require organizations conducting activities funded with foreign funds to comply with local registrations or other requirements. These restrictions may apply to funds you disburse to sub-awardees under this project. Please confirm that your organization will ensure compliance with any such requirements, including taking reasonable steps to ensure that any subgrantees subject to India's Foreign Contribution Regulation Act (FCRA) are in compliance with this law and the regulations thereunder (e.g., depositing subgrant funds only into accounts maintained at the State Bank of India, New Delhi Main Branch and ensuring such subgrantees do not further subgrant funds).

  _X__Not applicable ___Confirmed ___Not confirmed (please explain)

Anti-Terrorism and Use of Funds

- Did you list any locations of work as "to be determined" (TBD) or geographic areas instead of specific countries (e.g., Sub-Saharan Africa or Middle East)?

  _X__No ___Yes

- Did you list any locations of work that are subject to U.S. government sanctions as identified below?

Comprehensive Sanctioned Countries	**List-based Sanctioned Countries**
___Cuba ___Ukraine's Crimea Region or so-called Luhansk or Donetsk People's Republics ___Iran ___North Korea ___Syria	___Countries subject to list-based sanctions* **Note: Countries subject to list-based sanctions can be found on the U.S. Department of Treasury website*

- If you selected 'yes' to TBD locations or locations that are not country-specific, and/or selected locations that are subject to U.S. government sanctions or believe that project work could reasonably occur in a location that is subject to U.S. government sanctions, please review the guidance in the Office of Foreign Assets Control (OFAC) Guidelines and confirm that: (a) you have discussed the location of work with your foundation contact, and (b) your organization will ensure compliance throughout the term of the project with the anti-terrorism clause in our grant agreement.

  ___Confirmed ___Not confirmed (please explain)

ROLES AND RESPONSIBILITIES

Conduct and Control

In answering the questions in this section, please consider all project activities, such as those involving: confidential or protected information (including personally identifiable information or protected health information); the inclusion of children or vulnerable populations; research involving human subjects; clinical trials; post-approval studies; field trials; experimental medicine; provision of medical services (diagnostic, prophylactic or treatment); product development; use of genetically modified organisms, human tissue, animals, radioactive isotopes, pathogenic organisms, recombinant nucleic acids, select agents or toxins, dual-use technology, or any substance, organism, or material that is toxic or hazardous; use of aircraft, unmanned vehicle systems, drones or satellites; and the import, export, transfer, approvals, consents, records, data, specimens, images, and materials related to any of the foregoing.

Please confirm that your organization:

- Will maintain the expertise necessary to conduct, control, manage, and monitor all aspects of the project in compliance with all applicable ethical, legal, regulatory, and safety requirements including applicable international, national, state, local, and institutional, school district or school network standards and policies and is responsible for determining and complying with these requirements and standards;
- Will not disclose any confidential or protected information to the foundation without obtaining prior written approval from the foundation and all necessary consents to disclose such information;
- Acknowledges that any activities by the foundation in reviewing documents, providing input or funding does not modify your organization’s responsibility for determining and complying with all applicable ethical, legal, regulatory, and safety requirements for the project in all places;
- Is a government agency, public institution or multilateral organization or will otherwise maintain insurance coverage sufficient to cover the activities, risks, and potential omissions of the project in accordance with generally-accepted standards and as required by law (for instance, general, professional, clinical trial, product liability, medical malpractice, workers' compensation, or otherwise); and
- Will not transfer any biological materials, chemicals, reagents, hazardous materials, or the like to the foundation.

_X__Confirmed ___Not confirmed (please explain)

❖ Does the project involve any of the following: clinical trial, other trial involving human subjects, post-approval study, experimental medicine, field trial of genetically modified organisms, or the provision of medical/health services?

_X__No ___Yes (please explain)

If yes, please list all approvals and consents required for each site and describe the time frame in which your organization will acquire the necessary approvals and consents.

❖ If yes, please identify the name of the entity that will be the sponsor/responsible party of any clinical trials, studies involving human subjects, experimental medicine studies, post-approval studies, products, or regulatory filings contemplated by the project.

Note: The foundation will not serve as the sponsor/responsible party nor accept delegation of any of these responsibilities. If the project will not involve such activities, please indicate not applicable or N/A below.

Advocacy and Lobbying

❖ While the foundation funds a broad range of advocacy activities, U.S. law prohibits foundation funds from being earmarked to support direct or grassroots lobbying communications. You should answer “Yes” to this question if this project will include engaging with the public or government partners to influence government policy decisions or actions. Does your project include advocacy activities?

_X__No ___Yes (please explain)

If “yes,” please describe how the project will be conducted to ensure foundation funds are not earmarked to support grassroots or direct lobbying, as summarized in the foundation’s Advocacy Guidelines, identifying any potential legislative actions related to your advocacy goals. Your response should demonstrate your understanding of the relevant restrictions and exceptions and explain how you will manage compliance during the term of the project. If relevant, also explain how you will comply with other pertinent lobbying rules or requirements (e.g., local, state, or federal disclosure rules).

SECTION B – PROGRESS NARRATIVE(S)

This section is for progress reporting on funded grants. For each required progress report, complete a version of this progress narrative section and submit the Investment Document to your foundation contact by the date indicated in your grant agreement or latest amendment. If you have any questions or need support, please reach out to your foundation contact. Please find contact information in Section A – Investment Details. The progress narrative is your opportunity to update the foundation on the following:

- Progress made toward achieving your project's stated outputs and outcomes
- Any adjustments to the project
- Financial update for the reporting period
- Feedback for the foundation

Reminder: This document must be submitted in English and as a Word file. PDFs and other file types will not be accepted.

IMPORTANT: For each subsequent progress report, do not overwrite existing progress narratives. Instead, copy the following questions and paste to the end of this section before Section C – Final Narrative.

PROGRESS REPORTING PERIOD 1

Progress Report Number	**Reporting Period Start Date**	**Reporting Period End Date**	**Progress Report Due Date**	**Scheduled Payment Amount** (if applicable)
	[DD Month YYYY]	[DD Month YYYY]	[DD Month YYYY]	$

Progress Details

❖ What progress have you made toward achieving the project's desired outcomes? Describe what you did in this reporting period and what work is planned or anticipated for the next period.

Outputs/Funded Developments and Background Technology Update

❖ Update the table below to reflect completed and/or adjusted outputs, and new outputs/Funded Developments not previously reported. See your original results table in Section A of your proposal for reference. Add more rows as needed.

Number	**Output/Funded Development Description**	**Newly Added Output/Funded Development?**	**Status** (e.g., planned, in progress, complete, canceled)	**Target Completion Date***	**Actual Completion Date**	**Third-Party agreement required? If yes, by when?**	**Will any IP rights be filed/ generated?**
1		No/Yes		[DD Month YYYY]	[DD Month YYYY]	No/Yes	No/Yes
2		No/Yes				No/Yes	No/Yes
3		No/Yes				No/Yes	No/Yes
4		No/Yes				No/Yes	No/Yes

**Note: For items that are complete or canceled, this should be the date that was stated in the most recent progress report or in the proposal if this is the first report. For items that are not yet complete, either restate the most recent target date or propose a revised target date (e.g., ~~30 Nov 2023~~ 31 Jan 2024).*

❖ If necessary, please add further explanation below.

❖ Are there any additional Background Technologies to report which were not described in any documents previously submitted to the foundation?

___No ___Yes (please explain)

Project Adjustments

- What adjustments to the project (scope, timeline, resources) have you made over the past period or are you proposing to make?

Global Access Update

- Are there any updates to your responses to the Global Access questions in Section A?

___No ___Yes (please explain)

Roles and Responsibilities Update

- Do you represent that the project activities were conducted in compliance with all applicable ethical, legal, regulatory and safety requirements?

___Yes ___No (please explain)

- Are all the project activities described in the documents previously submitted to the foundation?

___Yes ___No (please explain and describe any new project activities)

Financial Update

The purpose of this section is to help the foundation understand expenditures in relation to the work performed under this grant during the most recent reporting period and the upcoming one(s). Please provide actual expenditures for past periods and projected expenditures for future periods by updating the Excel budget template and use this narrative document to share additional explanations. Together, this narrative section and Excel budget should provide a complete quantitative and qualitative description of the current financial state of the project.

For additional instructions, see the Grant Budgeting & Financial Reporting Detailed Instructions.

Latest Period Variance

"Latest period variance" compares expenditures that occurred in the most recent reporting period against the projections that were provided at the beginning of the same period. See the "Financial Summary & Reporting" sheet in the Excel budget template for the calculated variance (for example, column AD, starting on row 29 for period 1). The budget template also includes an "Analytics" sheet for convenient calculation of variances.

- Did the project spend more or less than anticipated? At a high level, what are the reasons for spending more or less than projected (such as, programmatic changes, delays in recruitment, etc.)?

- Please provide a detailed explanation for any expense category in which the variance was greater than 10%. This should include an explanation of relevant project decisions or changes to actual costs compared to prior assumptions.

Future Period Projections

In the Excel budget template, please provide estimated expenditures ("projections") for all future periods of the grant (for example, in the "Financial Summary & Reporting" sheet, after period 1, populate the yellow cells in column T and following). It is important that your projections are realistic and consider the latest plan of activities with updated costs. For example, projections should not just carry forward previously unspent budget amounts into the next period without reassessing expected spending for each future period. In total, the projections should not exceed the total approved grant amount. The budget template's "Analytics" sheet may be helpful for comparing current to previous projections.

Note: Over the course of a grant's life, the foundation may adjust the timing and amounts disbursed to the grantee. This is done to avoid oversized cash balances on grantee bank accounts when spending is slower than originally budgeted. Realistic and up-to-date projections are a crucial input for right-sizing disbursements.

❖ How have your projections for the remaining periods changed compared to your previous projections (from your most recent progress report, or original proposal if this is the first report) and why? Please discuss any project adjustments and shifts in scope, assumptions, timing, decisions etc. which will affect spending. If you had previous discussions with the foundation on changes, please mention.

Subawards (if applicable)

❖ If you are an Indian organization/entity subject to India's Foreign Contribution Regulation Act (FCRA), then in compliance with FCRA, do you confirm that your project does not include any subgrantees? This prohibition does not preclude subcontracts in the ordinary course of business.

___Not applicable ___Confirmed ___Not confirmed (please explain)

❖ In the table below, please provide information for all subgrantees or subcontractors receiving grant funds. The total of the column titled *Amount disbursed to subawardee in most recent reporting period* should equal the actual subaward expenses reported for this period in the Excel budget template's "Financial Summary & Reporting" sheet. Add more rows as needed.

Type of Subaward (grant or contract)	**Organization Name**	**New and/or newly identified subawardee?**	**Amount disbursed to subawardee in most recent reporting period (USD)**	**Total amount disbursed to subawardee to date* (USD)**	**Total amount spent by the subawardee to date* (USD)**	**Total subaward amount (USD)**
		No/Yes	$	$	$	$
		No/Yes	$	$	$	$
		No/Yes	$	$	$	$
		Total	**$**	**$**	**$**	**$**

**As of the end of the most recent reporting period and since the grant start date.*

❖ If not already addressed in your answers above, please provide additional explanations on subaward spending below. In particular, for subawards that are large or where actual and projected spending are significantly different from prior projections, please explain. *Note: The foundation may request updated budget files for large subawards.*

Other Sources of Support and External Factors (if applicable)

❖ Please provide an update on other sources of support and external factors that affect the financial situation of this project. This may include information on co-funding (updates to the sources listed in the Funding Plan, recent commitments secured, funding gaps and contingency plans). Please also comment on interest earned/spent, and currency exchange impacts (as applicable).

Geography Served

❖ List all countries, sub-regions, and/or states that benefit from this work and the associated dollar amounts for the full term of the grant. The total of "Foundation Funding" amounts should match the approved and/or most recently amended grant total. If any of the amounts have changed since your last report (or original proposal if no prior report), please mark with an 'X' in the third column below. As a reminder, please avoid listing "World," unless the work truly serves beneficiaries globally. If geographies include the United States, indicate city and state. Add more rows as needed.

For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Geography Served	**Foundation Funding Amount (USD)**	**Has the amount changed since the proposal or last report?** (if yes, mark with an 'X')
	$	
	$	
	$	

Location of Work Updates (if applicable)

- List all locations (countries, sub-regions, and/or states) where this work is being performed and the associated dollar amounts for the full term of the grant. The total of "Foundation Funding" amounts should match the approved and/or most recently amended grant total. If any of the amounts have changed since your last report (or original proposal if no prior report), please mark with an 'X' in the third column below. As a reminder, if locations include the United States, please indicate city and state. Add more rows as needed.

  For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Location of Work	**Foundation Funding Amount (USD)**	**Has the amount changed since the proposal or last report?** (if yes, mark with an 'X')
	$	
	$	
	$	

- If you listed any TBD locations or locations that are not country-specific, and/or locations that are subject to U.S. government sanctions or believe that project work could reasonably occur in a location that is subject to U.S. government sanctions, please review the guidance in the Office of Foreign Assets Control (OFAC) Guidelines and confirm that: (a) you have discussed the location of work with your foundation contact, and (b) your organization will ensure compliance throughout the term of the project with the anti-terrorism clause in our grant agreement.

  ___Confirmed ___Not confirmed (please explain)

Feedback for the Foundation

- What are 1–3 ways that the foundation successfully enabled or supported your work during this project? What are 1–3 ways that the foundation can improve?

Grantee Confirmation

By submitting this report, I declare that I am authorized to certify, on behalf of the grantee identified under Section A – Investment Details, that I have examined the responses provided and related attachments, and that to the best of my knowledge, they are true, correct, and complete.

I also confirm that the grantee identified under Section A – Investment Details has complied with all of the terms and conditions of the grant agreement, including but not limited to the clauses regarding Use of Funds, Anti-Terrorism, Subgrants and Subcontracts, and Regulated Activities.

Your Name	**Report Submitted Date**
	[DD Month YYYY]

SECTION C – FINAL NARRATIVE

For completed grants only. At the end of your grant, complete this final narrative section and submit to your foundation contact by the date indicated in your grant agreement or latest amendment. If you have any questions or need support, please reach out to your foundation contact. Please find contact information under Section A – Investment Details.

This is your final update to the foundation, please include:

- The results you achieved for the entire project
- Your perspective on what you learned
- Final financial update
- Feedback you have on the foundation's support of your work

Grant Start Date	**Grant End Date**	**Final Report Due Date**	**Remaining / Unexpended Grant Funds** (if applicable)	**Remaining / Unexpended Interest** (if applicable)	**Remaining / Unexpended Currency Gains** (if applicable)
[DD Month YYYY]	[DD Month YYYY]	[DD Month YYYY]	$	$	$

Final Results

❖ Provide information about what you achieved during the grant and your progress towards achieving the project's desired outcomes and outputs.

Outputs/Funded Developments and Background Technology

❖ Please update the results table below to reflect completed and/or adjusted outputs, and new outputs/Funded Developments not previously reported. Add more rows as needed.

Number	**Output/Funded Development Description**	**Newly Added Output/Funded Development?**	**Status** (e.g., planned, in progress, complete, canceled)	**Target Completion Date***	**Actual Completion Date**	**Third-Party agreement required? If yes, by when?**	**Were any IP rights be filed/ generated?**
1		No/Yes		[DD Month YYYY]	[DD Month YYYY]	No/Yes	No/Yes
2		No/Yes				No/Yes	No/Yes
3		No/Yes				No/Yes	No/Yes
4		No/Yes				No/Yes	No/Yes

**Note: For items that are complete or canceled, this should be the date that was stated in the most recent progress report or in the proposal if this is the first report. For items that are not yet complete, either restate the most recent target date or propose a revised target date (e.g., ~~30 Nov 2023~~ 31 Jan 2024).*

❖ If necessary, please add further explanation below.

❖ Do you confirm that you have provided a full and accurate disclosure of all outputs/Funded Developments and Background Technology as applicable to the project?

___Yes ___No (please explain)

Global Access

- Do you confirm that you have ensured and will continue to ensure Global Access for the Funded Developments of the project and, as applicable, Background Technology?

  ___Yes ___No (please explain)

Financial Update

The purpose of this section is to help the foundation understand expenditures in relation to the work performed under this grant during the most recent reporting period. Please provide actual expenditures for past periods by updating the Excel budget template and use this narrative document to share additional explanations. Together, this narrative section and Excel budget should provide a complete quantitative and qualitative description of the financial state of the project.

For additional instructions, see the Grant Budgeting & Financial Reporting Detailed Instructions.

Latest Period Variance

"Latest period variance" compares expenditures that occurred in the most recent reporting period against the projections that were provided at the beginning of the same period.

- Did the project spend more or less than anticipated? At a high level, what are the reasons for spending more or less than projected?
- Please provide a detailed explanation for any expense category in which the variance was greater than 10%. This should include an explanation of relevant project decisions or changes to actual costs compared to prior assumptions.

Subawards (if applicable)

- If you are an Indian organization/entity subject to India's Foreign Contribution Regulation Act (FCRA), then in compliance with FCRA, do you confirm that your project did not include any subgrantees? This prohibition does not preclude subcontracts in the ordinary course of business.

  ___Not applicable ___Confirmed ___Not confirmed (please explain)

- In the table below, please provide information for all subgrantees or subcontractors receiving grant funds. The total of the column titled *Amount disbursed to subawardee in most recent reporting period* should equal the actual subaward expenses reported for this period in the Excel budget template's "Financial Summary & Reporting" sheet.

Type of Subaward (grant or contract)	**Organization Name**	**New and/or newly identified subawardee?**	**Amount disbursed to subawardee in most recent reporting period (USD)**	**Total amount disbursed to subawardee to date* (USD)**	**Total amount spent by the subawardee to date* (USD)**	**Total subaward amount (USD)**
		No/Yes	$	$	$	$
		No/Yes	$	$	$	$
		No/Yes	$	$	$	$
		Total	**$**	**$**	**$**	**$**

**Over the life of the grant, from start date to end date*

- If not already addressed in your answers above, please provide additional explanations on subaward spending below. In particular, for subawards that are large or where actual spending was significantly different from prior projections, please explain. *Note: The foundation may request separate updated budget files for sub-awards.*

Other Sources of Support and External Factors (if applicable)

- ❖ Please provide an update on other sources of support and external factors that affected the financial situation of this project. This may include information on co-funding, interest earned/spent, and currency exchange impacts (as applicable).

Geography Served

- ❖ List all countries, sub-regions, and/or states that benefit from this work and the associated dollar amounts for the full term of the grant. The total of "Foundation Funding" amounts should match the approved and/or most recently amended grant total. If any of the amounts have changed since your last report (or original proposal if no prior report), please mark with an 'X' in the third column below. As a reminder, please avoid listing "World," unless the work truly serves beneficiaries globally. If geographies include the United States, indicate city and state. Add more rows as needed.

For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Geography Served	**Foundation Funding Amount (USD)**	**Has the amount changed since the proposal or last report?** (if yes, mark with an 'X')
	$	
	$	
	$	

Location of Work Updates (if applicable)

- ❖ List all locations (countries, sub-regions, and/or states) where this work is being performed and the associated dollar amounts for the full term of the grant. The total of "Foundation Funding" amounts should match the approved and/or most recently amended grant total. If any of the amounts have changed since your last report (or original proposal if no prior report), please mark with an 'X' in the third column below. As a reminder, if locations include the United States, please indicate city and state. Add more rows as needed.

For additional information, see the Geography and Location of Work – Frequently Asked Questions.

Location of Work	**Foundation Funding Amount (USD)**	**Has the amount changed since the proposal or last report?** (if yes, mark with an 'X')
	$	
	$	
	$	

- ❖ Do you confirm that you have complied throughout the term of the project with the anti-terrorism clause in our grant agreement?

___Confirmed ___Not confirmed (please explain)

Lessons Learned

- What are 1–3 lessons that you learned from this project? If you were to do this project again, how would you approach things differently?

Feedback for the Foundation

- What are 1–3 ways that the foundation successfully enabled or supported your work during this project? What are 1–3 ways that the foundation can improve?

Grantee Confirmation

By submitting this report, I declare that I am authorized to certify, on behalf of the grantee identified under Section A – Investment Details, that I have examined the responses provided and related attachments, and that to the best of my knowledge, they are true, correct, and complete.

I also confirm that the grantee identified under Section A – Investment Details has complied with all of the terms and conditions of the grant agreement, including but not limited to the clauses regarding Use of Funds, Anti-Terrorism, Subgrants and Subcontracts, and Regulated Activities.

Your Name	**Report Submitted Date**
	[DD Month YYYY]

QUICK START GUIDE

This page provides a quick overview of the BMGF budget template to orient you before getting started.
As you populate the sheets, you will find direct links to specific instructions with examples throughout the template.

*The **full instruction document** can be accessed here.*

Click here for a **video** explaining how to create a **simple budget**

***Frequently Asked Questions (FAQs)** can be accessed here.*

Click here for a **video** explaining how to create a **financial report**

Main Sheets
These first three sheets need to be filled out by the grantee for every grant.

Grantees do not enter information into this sheet, but can preview the auto-generated schedule.

General Information

*Enter the required basic information into this sheet **before** populating any of the other sheets.*

→

Budget Details

For each of the 6 expense categories, enter the items that collectively make up the grant budget into this sheet.

→

Financial Summary & Reporting

Review the summary tables from the Budget Detail sheet and add further information (where applicable). This sheet is also used to enter actual and projected expenditures as part of reporting.

→

Payment Schedule

This sheet creates an auto-generated payment schedule; BMGF may make changes before incorporating it into the grant agreement.

Important information for working with the template

Legend for cell formatting

Input **cells are colored** according to the following scheme. At the time of budgeting, populate only light yellow cells.

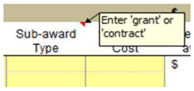
Enter information into light yellow cells
Enter actual expenditures into green cells
Blue cells are intended to be populated by BMGF

Cash vs. Projected Actuals (Accruals)

All **actual** amounts reported should be based on ***cash spent***, not PROJECTED (or ACCRUED) for the remainder of the period.

Hints for specific data entry fields

For some fields, a **red triangle in the upper right corner** indicates that a hint is available when hovering the mouse over the cell.



Error checking

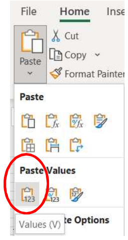
For some cells, an automatic error check will show its **value in red** if it appears to be populated incorrectly or if the calculation yields a result that is inconsistent with another value.

incorrect entry
01-Jan-22

Inconsistent result
$ 124,237

Copying data into the template

Use ***Paste Values*** whenever transferring data from an external source into the template. If not, the template can become corrupted



*In addition to the three sheets described above, there are **several additional sheets** included in the template, some of them optional and/or hidden. Grantees **do not need to use** these additional sheets, but for transparency, you will find an overview below.*

*If you would like to include additional information (or are asked for it by BMGF) in this file, it is **OK to add extra sheets** for this purpose. However, please **do not make any changes to the structure, formatting or formulas of the existing sheets.***

BMGF Work Sheets
These three sheets are primarily used by BMGF to analyze and manage the grant. You may use them yourself, but please do not enter or alter any data or formulas.

Payment Schedule

This sheet is used by the grantee to review an auto-generated preliminary payment schedule and by BMGF to make any changes before incorporating it into the grant agreement.

Analytics

Contains two analytic features: a set of Basic Charts and a Comparison Tool

Budget Pivot
(typically hidden)

Excel Pivot table that can be used to analyze the data in the Budget Detail sheet.

Historic or Background Information
These sheets are used by BMGF to preserve historic information throughout the grant or for administrative purposes. Please do not make any changes to these sheets.

[Historic Budget Details]
0, 1 or more sheets (typically hidden)

If a grant budget revision takes place, the previous version of the Budget Detail sheet can be preserved as a separate sheet for reference.

Historic Budget Summaries
(typically hidden)

If grant budget revisions take place, this sheet can be used to preserve previous versions of the Budget Summary for reference.

Config
(typically hidden)

Used for administrative purposes to populate dropdown lists etc. throughout the template.

HTS for small molecule drug development for henipaviruses
University of Chicago

BILL & MELINDA
GATES foundation

Prepared by: Megan Konley

Date submitted:

Template version 2022-01-04

Legend for cell formatting:
Enter information into light yellow cells
Enter actual expenditures into green cells
Blue cells are intended to be populated by BMGF

GENERAL INFORMATION

Go to instructions for this page…

Proposal Information

Organization Name	HTS for small molecule drug development for henipaviruses
Investment Name	University of Chicago
Investment ID	INV-048917
Is this a Subaward Budget?	No
Requested Grant Amount	**$2,954,167**
Total Project Cost	**$2,954,167**

Budgeting & Reporting Periods

Please ensure that you are selecting the correct reporting cadence before inputting the budget details. If you need to readjust the reporting periods, the budget details will need to be revised as well to reflect the date changes.
Note that if your grant is an Expenditure Responsibility (ER) grant, you must select "**Align with fiscal year**" as the reporting cadence.

Anticipated Start Date	01-Oct-22
Anticipated End Date	30-Sep-25
Project Duration (months)	36

Preferred Reporting Cadence Custom periods

Reporting Periods	Period 1	Period 2	Period 3	Period 4	Period 5	Period 6	Period 7	Period 8	Period 9	Period 10
Period Start Date	**01-Oct-22**	**01-Jan-24**	**01-Jan-25**							
Period End Date	**31-Dec-23**	**31-Dec-24**	**30-Sep-25**							
Number of Months	15.0	12.0	9.0							
Custom Period End Dates	31-Dec-23	31-Dec-24	30-Sep-25							

Indirect Cost Rate(s)

Please enter indirect cost rates in accordance with the indirect cost policy:
Read BMGF Indirect Cost policy…

Organization Type U.S. university

Indirect Cost Rate on Primary Grantee's Portion	10.00%	*Maximum rates for selected organization type are 10%.*
Primary Grantee's Indirect Cost Rate on Subaward Portion	10.00%	

Other Budget Factors

More info..	**Will the financials of this project be managed in a currency other than USD?**	No
More info..	**Will the budget be broken down by an additional dimension?** (e.g. outcomes/outputs, project components/phases)	No
More info..	**Will the total cost of this project require contributions of funding from sources other than BMGF?** (e.g. either by your organization or others)	No
More info..	**Is this a new version of a previously approved budget?** (e.g. supplement)	No

---

Hi all,

Fyi, we just submitted the full proposal to Gates Foundation. I assume they will work with us to make it fit their requirements.
Hopefully we will be funded (cautiously optimistic).

Best,
Lijun

Hi Lijun,
We don't require any signature at this point as we shape the proposal documents. Once both parties have agreed on the final proposal documents (we typically go back and forth on a few iterations of the Investment Document and budget), we will then create the Grant Agreement that references both proposal documents. It is the Grant Agreement that will need a signature from UIC.
Hope that helps!

Hi Rob and Linu,

Megan will help us to get the proposal and budget together here at UIC. We need some clarification on the institutional approval.
What do you need from UIC, a letter or email from UIC? Thank you so much for the information.

Best regards,
Lijun

Hi Lijun,
Thursday July 7 at 1p seems like a good time to meet. Please invite others who will participate in the proposal. Lisa Galaites (cc'd) will provide the grant template, budget template and instructions for the proposal. We would like to receive a full proposal for review by July 22. Two areas that we would like to discuss are your plans for medicinal chemistry and overlap with AViDD programs. I will send the meeting invitation for 1p PST July 7.
We look forward to speaking with you soon.
Best regards,
Rob

Dear Rob and Linu,

We have very pleased and honored to be accepted to submit a full proposal from the PAD program, and we are eager to learn about the next step, and seek your guidance on it.

I am available next week:

Thursday July 7, 3 pm-5 pm (Central time) or Pacific time: 1-3 pm
Friday July 8th 3-5 pm (CT), or PT: 1-3 pm

Does that work out for you?

Also is it OK if I include Dr. Irina Gaisina to this meeting since she will work with me on the full proposal?

We look forward to talking with you!

Best,
Lijun

Subject: PAD henipavirus RFP

Dear Lijun,

Congratulations on being accepted to submit a full proposal for the PAD program. It would be good for us to have a quick call to answer questions and make sure we're on the same page with the process. We would like to have the full proposal submitted by July 22 if possible so that we can go through the internal review process and make any adjustments as needed. I will be the senior program officer (SPO) managing this proposal and my colleague Linu John will be helping as the secondary program officer.

Please let me know a few dates and times next week (after July 5) that you might be available for a call.

We look forward to working with you on this interesting project.
Best regards,
Rob

RESUME AND SUMMARY OF DISCUSSION: This application proposes to investigate the drivers of spillover events of henipavirus from bats to domesticated animals to humans. The characterization of transmission routes as well as molecular and serological analyses to assess exposure to henipavirus are highly significant and address an important knowledge gap. The work is performed by an outstanding team of investigators with complementary expertise in virology, epidemiology, zoonotic diseases; as well as a solid track record of working together with collaborators in Bangladesh. Strengths of the application also include highly significant biomedical and public health problems being addressed, well-developed approach including comprehensive sampling and multiplex pan-henipavirus assays, the integration of modeling input on weather patterns, and the use of camera trapping observations to determine interactions between domesticated animals with bats. Most of the critiques from previous review are adequately addressed including additional details of biosafety protocols on handling the virus. A minor concern identified during the discussion is the lack of details on statistical analysis method. Overall, the application is considered outstanding and high enthusiasm is expressed by the review committee.

DESCRIPTION (provided by applicant): Until and unless we better understand and prevent spillovers of bat-borne viruses into intermediate hosts and humans, we will be severely limited in our ability to stop pandemics. Henipaviruses are bat-borne, RNA viruses that spillover through this route. Nearly half of all reported human henipavirus infections have been associated with contact with sick domesticated animals, though our understanding of drivers of henipavirus spillovers and specific transmission pathways remains severely limited. Building on preliminary data about bat, domesticated animal and human infections, this multidisciplinary study integrates epidemiology, ecology, and anthropology to identify spillover pathways for henipaviruses into domesticated animals in Bangladesh and the risk they pose to human health. Our first aim is to identify drivers of henipavirus spillovers into domesticated animals in Faridpur, Bangladesh. We will use multiplex pan-henipavirus assays to identify infections in Pteropus medius bats and domesticated animals living nearby this roost through cross-sectional and prospective studies. Combined with intensive studies of bat-domesticated animal interactions and weather data, we will build statistical models to identify the relative contribution of each of these factors. Our second aim is to describe which henipaviruses are being transmitted from bats to domesticated animals. Serologic studies of animals in Bangladesh show that they are frequently infected with non-Nipah henipaviruses. Through surveillance for and sampling of sick domesticated animals, we will describe the specific viruses that spillover from bats in Faridpur. Our third aim is to determine the risk of henipavirus transmission from domesticated animals to humans. We hypothesize that undetected henipavirus spillovers in humans are occurring through contact with sick domesticated animals and will conduct cross-sectional and prospective serosurveys of humans who have close contact with sick animals in Faridpur. We remain ignorant about henipavirus spillovers through intermediate hosts – including the specific viruses spilling over, the frequency and distribution of spillovers, and the pathways of transmission – at our own peril. The knowledge gained from this study will be immediately applicable to human and animal health programs in Bangladesh and other countries where henipaviruses circulate in bats. By learning about which henipaviruses infect humans, and how they are infected, we can advise public health surveillance programs on how to optimize detection and epidemiologic investigation of cases across Bangladesh. Our investigations about spillovers in Faridpur can also be scaled- up to other areas of Bangladesh and countries where henipaviruses circulate in bats so that we can truly begin to appreciate the scale of henipavirus spillovers in the global landscape.

PUBLIC HEALTH RELEVANCE: We remain ignorant about bat henipavirus spillovers through intermediate hosts – including the specific viruses spilling over, the frequency and distribution of spillovers, and the pathways of transmission – at our own peril. Until and unless we better understand and prevent spillovers of bat-borne viruses into intermediate hosts and humans, we will be severely limited in our ability to stop pandemics. The knowledge gained from this study will be immediately applicable to human and animal health programs because if we know which henipaviruses infect humans and domesticated animals, and how they are infected, we can advise public health surveillance programs on how to optimize detection and prevention of infections.

CRITIQUE 1:

Significance: 1
Investigator(s): 1
Innovation: 1
Approach: 3
Environment: 1

Overall Impact: This proposal addresses a highly significant and timely set of questions around spillover of viruses from animals to humans with a focus on the role of understudied intermediate hosts. The investigators propose to obtain a comprehensive picture of viral transmission at the animal-human interface, with a focus on henipavirus. There is a well-considered strategy for sampling both animals and humans that addresses a gap and bias in existing surveillance data identified by the investigators. The study team has tremendous experience both in the technical areas as well as working with this community, and this comes through clearly in the proposal. The revised proposal has addressed the major concerns from the initial review around biosafety with a select agent and have provided details about safety protocols for both the study team and for the collaborating laboratory in the US. There are some areas of the proposal where further detail about the statistical analysis plan could be further developed, but this was a minor concern. Overall, the successful completion of this project would yield novel insights into routes of viral spillover at the animal-human interface.

1. Significance:

Strengths

- Spillovers of henipavirus are a major concern, and the proposed work will provide a comprehensive understanding of how those spillovers occur.
- The role of intermediate hosts has been understudied due to typical sampling protocols.

Weaknesses

- None noted.

2. Investigator(s):

Strengths

- PI Dr. Gurley and collaborators have long track record working on Nipah virus in the region.
- Combined study team is highly interdisciplinary.
- Strong collaboration with researchers at icddr,b.

Weaknesses

- None noted.

3. Innovation:

Strengths

- Interdisciplinary combination of epidemiology, anthropology, ecology, immunology is innovative.
- Focus on potential gaps in current reactive sampling schemes with a focus on intermediate hosts.
- Strong conceptual model that identifies weaknesses in current data.

Weaknesses

- None noted.

4. Approach:

Strengths

- Comprehensive sampling of multiple animal species and humans will allow for a comprehensive view of spillover pathways.
- Possibility to detect novel/unexpected viruses.

Weaknesses

- The statistical analysis/model for Aim 1could be better developed. These are complex time series data with many outcomes.
- As the investigators acknowledge, the number of events is unpredictable, which could limit the ability to make strong inferences.

5. Environment:

Strengths

- Facilities at Rocky Mountain labs appropriate for BSL-4 work.
- Facilities at USUHS and Johns Hopkins are appropriate for the proposed work.
- icddr,b has tremendous experience conducting field studies with humans and animals in Bangladesh.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections.

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically.
- Race/Ethnicity: Distribution justified scientifically.

- Inclusion/Exclusion Based on Age: Distribution justified scientifically.

Vertebrate Animals:

YES, all criteria addressed.

Biohazards:

Acceptable protocols in place for handling the pathogens.

Resubmission:

The investigators were highly responsive to previous reviews, including comments about biosafety and questions about the assays.

Applications from Foreign Components:

icddr,b in Bangladesh is a key partner in this proposal and necessary for the completion of the Aims.

Select Agents:

BSL-4 work will be conducted at Rocky Mountain Laboratories in the US; Personnel in Bangladesh will handle shipments for shipping at BSL-2 and will inactivate sera prior to testing in the BSL-2 lab.

Resource Sharing Plans:

Acceptable.

Authentication of Key Biological and/or Chemical Resources:

Not included.

Budget and Period of Support:

Recommended as requested.

CRITIQUE 2:

Significance: 3
Investigator(s): 2
Innovation: 2
Approach: 3
Environment: 1

Overall Impact: This reversed application seeks to identify spillover pathways for henipaviruses into domesticated animals in Faridpur, Bangladesh and identify the risk they pose to human health. They report that nearly half of all reported human henipavirus infections have been associated with contact with sick domesticated animals, though our understanding of drivers of henipavirus spillovers and specific transmission pathways remains severely limited. Preventing spillovers of bat-borne viruses into intermediate hosts is critical to stopping pandemics. In Aim 1 they will identify drivers of henipavirus spillovers into domesticated animals. To do this they will use multiplex pan-henipavirus assays to identify infections in bats and domesticated animals living nearby roosts. They speculate that that there is also substantial temporal variation in domesticated animal spillovers driven by infection dynamics in bats, weather patterns, and domesticated animal contact with bats. They will build statistical models to identify the relative contribution of each of these factors to spillover into potential intermediate hosts. In Aim 2, they will describe which henipaviruses are being transmitted from bats to domesticated animals. They will sample sick animals in Faridpur and will sequence any detected henipaviruses. In Aim 3, they will determine the risk of henipavirus transmission from domesticated animals to humans. They will identify human henipavirus infections following contact with domesticated animals and identify the types of contact associated with transmission. Strengths of the application include the public health importance and potential relevance of findings to other zoonotic viruses, the superb study team with prior collaborative work in the study site, the clear enrollment and sampling strategy, and inclusion of children who have potential to care for sick animals. Weaknesses are minor and include reliance of aims on detecting virus and reliance of aims on prior aims although this is inherent in nature of this study and a mitigation plan is outlined. Overall enthusiasm for this application is high.

1. Significance:

Strengths

- Need to better understand spillovers of bat-borne viruses into intermediate host to improve ability to prevent pandemics.
- Spillovers into intermediate hosts represent important opportunities for bat-borne viruses as they adapt and become more infectious to humans.
- Goal of updating public health surveillance systems to reduce pandemic risk is critical.

Weaknesses

- Unclear generalizability of findings to other pathogens although given public health importance of knowledge gained this could be viewed as minor.

2. Investigator(s):

Strengths

- Expertise in epidemiology, virology, infectious disease, microbiology, zoonotic diseases, anthropology, modeling.

Weaknesses

- None noted.

3. Innovation:

Strengths

- Use of multiplex pan-henipavirus assay.
- Planned field work to study pathway from bats to intermediate host to humans.
- Study setting is optimal for proposed analyses.

Weaknesses

- None noted.

4. Approach:

Strengths

- Optimal study site (Faridpur District) for proposed analyses.
- Use of the multiplex pan-henipavirus assay will be used to detect all five known henipaviruses (Nipah virus, Hendra virus, Cedar virus, Ghana virus and Mojiang virus).
- Planned modeling will factor in weather patterns, changes in domesticated animal-bat contacts; use of camera tracking for data collection.
- Responsive to prior reviewer comments and plan for keeping field worker/veterinarian going to assist with sick animals clearly outlined.
- Phylogenetic analysis is planned to examine relationships between viruses identified in domesticated animals and bats within each of the six-month sampling periods.
- Inclusion of children who have potential to care for sick animals.

Weaknesses

- They acknowledge they may identify too few spillovers to make strong inferences about the drivers of those spillovers and may not identify sick animals. However contingency plans outlined so this could be viewed as minor.
- Aim 3 reliant on success of prior two aims.
- Unclear number humans planned to be enrolled with discrepancy between research strategy and the 3000 included in targeted enrollment table.

5. Environment:

Strengths

- Superb for carrying out proposed analyses.
- Existing collaboration exists in Bangladesh.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections.

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically.
- Race/Ethnicity: Distribution justified scientifically.
- Inclusion/Exclusion Based on Age: Distribution justified scientifically.

Vertebrate Animals:

YES, all criteria addressed.

Biohazards:

Acceptable.

Resubmission:

Responsive to prior comments.

Applications from Foreign Components:

Justified.

Select Agents:

Acceptable.

Resource Sharing Plans:

Acceptable.

Authentication of Key Biological and/or Chemical Resources:

Unacceptable. Not included.

Budget and Period of Support:

Recommend as Requested.

CRITIQUE 3:

Significance: 2
Investigator(s): 2
Innovation: 2
Approach: 2
Environment: 2

Overall Impact: This is a resubmission of an R01 investigating the potential risk of spillovers of henipaviruses into domesticated animals and subsequently into man. The proposal will define the drivers and variability factors of spillover into domesticated animals and whether certain henipaviruses are more often found outside of bats than others, and finally will assess the risk of subsequent transmission into humans. The significance of the work is strong, given the substantial risk from henipaviruses and repeated regional/seasonal outbreaks. There were major concerns about the safety of the sampling within the study, but these issues have been addressed in the resubmission. There are also other improvements as suggested, including broader screening for novel spillover pathogens. The proposed work by a very experienced team should lead to important insights into the ecosystem for henipaviruses at the intersection between wildlife, domesticated animals, and humans.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections.

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically.
- Race/Ethnicity: Distribution justified scientifically.
- Inclusion/Exclusion Based on Age: Distribution justified scientifically.

Vertebrate Animals:
YES, all criteria addressed.

Budget and Period of Support:
Recommended as requested.

THE FOLLOWING SECTIONS WERE PREPARED BY THE SCIENTIFIC REVIEW OFFICER TO SUMMARIZE THE OUTCOME OF DISCUSSIONS OF THE REVIEW COMMITTEE, OR REVIEWERS' WRITTEN CRITIQUES, ON THE FOLLOWING ISSUES:

PROTECTION OF HUMAN SUBJECTS: ACCEPTABLE.

INCLUSION OF WOMEN PLAN: ACCEPTABLE.

INCLUSION OF MINORITIES PLAN: ACCEPTABLE.

INCLUSION ACROSS THE LIFESPAN: ACCEPTABLE.

VERTEBRATE ANIMALS: ACCEPTABLE.

COMMITTEE BUDGET RECOMMENDATIONS: The budget was recommended as requested.

ADMINISTRATIVE NOTE: Applications proposing the use of key biological and/or chemical resources are expected to include a one-page PDF attachment describing plans for Authentication of Key Biological and/or Chemical Resources (see NOT-OD-17-068). Reviewers were asked to consider information provided in this attachment as part of their evaluation of your application. This attachment was missing from your application and the information could not be assessed.

Footnotes for 1 R01 AI168287-01A1; PI Name: Gurley, Emily Suzanne

NIH has modified its policy regarding the receipt of resubmissions (amended applications).See Guide Notice NOT-OD-18-197 at https://grants.nih.gov/grants/guide/notice-files/NOT-OD-18-197.html. The impact/priority score is calculated after discussion of an application by averaging the overall scores (1-9) given by all voting reviewers on the committee and multiplying by 10. The criterion scores are submitted prior to the meeting by the individual reviewers assigned to an application, and are not discussed specifically at the review meeting or calculated into the overall impact score. Some applications also receive a percentile ranking. For details on the review process, see http://grants.nih.gov/grants/peer_review_process.htm#scoring.

Great reviews, Emily. It is interesting to see the panel is almost all human infectious disease people. So it's great that you were able to get a One Health proposal through and with such strong reviews.

> Dear colleagues,

We've received scores back on our resubmission. Impact score is 20 and we're at the 5% percentile. With these numbers, we should expect to be funded. Congratulations.

I've heard from our Program Officer about timelines. Funding will start in fiscal year 2023, which begins on Oct 1, 2022. Her best guess is that we'll be funded to begin before the end of 2022, but exact timing will depend on when the US government approves their annual budget.

I look forward to working with you all on this exciting study.

Emily

Subject: plans for R01 submission

Dear colleagues,

Happy New Year to you all!

I'm writing to follow up and move us forward with plans to resubmit the R01. The date for submission is Feb 7th, but it's likely that our admin team will require documents well before that. Clif is working to put together our timeline now – updates shortly.

Based on my understanding, these are the updates that need to happen to respond to our last round of reviews:

1. Add in reference to preprint from Eric's group on the sero assay
2. Add in appendix with biosafety protocols from icddr,b, including staff safety, and perhaps letter from biosafety committee at icddr,b
3. Updating research plan to mention these updates, and address question of collecting some additional samples from sick animals (per reviewer comment)
4. Drafting one page response to reviewers to include in resubmission

I will draft the response to reviewers for your review and comment. Eric, grateful for updates and reference for your preprint. Rajib, look forward to receiving the biosafety SOPs (and thoughts on letter) as soon as you're able.

I assume that there are no changes required to budget. If this assumption is incorrect for you, please get in touch with me ASAP with the changes you'd like to include. However, there are new updates to biosketches that could be time consuming – Clif will send out guidance on this so please be on the lookout.

Look forward to getting this back in!

Expert Panel Discussion for Vaccine Library virus selection #2

1. Introduction/overview of next steps.

2. Presentation and discussion of Spillover program- Dr. Mazet

3. Questions for panel discussion.

What below factors in selecting viruses for a potential Disease X emergence do you believe are important in selecting a virus for a Disease X emergence?

1. RNA vs DNA virus with RNA>DNA
2. Virus characteristics: mutation rate of the virus, ability to reassort and/or recombine, fitness, tropism, number of recognized generic lineages ie genetic diversity?
3. Mode of human to human transmission: respiratory > oral-fecal > vector-borne (mosquito >tick>midge>sandflies) > sexual transmission > water-borne > fomite > others? A virus that uses several modes of transmission ie vector plus sexual would this increase its importance?
4. Zoonotic transmission: NHP>wild birds > bats>domestic animal ie (cattle>pigs>horses>birds>camels>fish) > market food (bush meat, civets, snakes, snails)> others?
5. Is the type of zoonotic transmission important and can it be ranked: wild-birds > domestic birds > cattle > pigs > sheep> horse > domestic dogs/cats > goats > camels > NHP > guinea pigs > others?
6. Should we consider viruses with a successful vaccine ie measles, chickenpox, polio or should we anticipate escape mutants that aren't protected by a current vaccine and develop vaccines against these pathogens that are more broadly protective?
7. R_0 if known of the virus or within a family?
8. Reported human outbreaks of viruses in a family and if they are: sporadic outbreaks, cyclical, annual, endemic, pandemic pathogens.
9. Number of spillover events from zoonotic to humans in total, per year; spillover to human with human-to-human transmission, spillover to vector to human?
10. If vector-borne, characteristics of the vector ie stable distribution, expanding due to environmental changes, number of viable vectors, phylogenetic distance ie diversity in the vectors?
11. Susceptible population: for example, restricted regional occurrence leaving a large population susceptible.
12. Potential disease impact/burden, mortality, and/or morbidity?

Do you think the human outbreak characteristics of one virus in a family could be a potential characteristic of other viral pathogens within a family ie do they share potentially common virulence factors? For example Lassa fever and Junin viruses would they elevate specific viruses in the viral family of arenaviruses that may share common characteristic but are not known human pathogens yet? Knowing the potential of SARS-Cov and MERS before Covid-19 would that have elevated the concerns for other coronaviruses

In the selection of viruses within a family, do you believe there is short-term heterotypic protection from one virus within or beyond a genera and this should be considered in selecting viruses for the vaccine library? For example, acute DENV-1 may provide short-term protection against other serotypes, JEV vaccination may provide short-term protection against DENV infection. If yes, is this specific for a virus family and not generic across many families?

4. Summary

Please highlight your 10 to 15 viruses selection by highlighting or filling in the box with red.

Genus	**Spillover rank of 887/risk score**	**Zoonotic**	**Human**									**Notes**

Dear all,

Please see attached the agenda for tomorrow’s Expert panel meeting #2.
Included also is the spreadsheet for the virus rankings for the paramyxo and arenaviruses.

Looking forward to a good discussion tomorrow.
Thank you. Best regards,

Luz on behalf of Tim

Summary

Members of the family *Arenaviridae* produce enveloped virions containing genomes consisting of 2 to 3 single-stranded RNA segments totaling about 10.5 kb (Table 1.*Arenaviridae*). Arenaviruses are currently classified into four genera (*Antennavirus*, *Hartmanivirus, Mammarenavirus*, and *Reptarenavirus*). These viruses infect fish (antennaviruses), snakes (hartmaniviruses and reptarenaviruses) and mammals (mammarenaviruses). Some reptarenaviruses cause boid inclusion body disease in captive snakes, whereas some mammarenaviruses can infect humans and other primates, causing mild, severe, and sometimes fatal diseases.

Table 1.*Arenaviridae.* Characteristics of members of the family *Arenaviridae.*

Characteristic	Description*
Typical member	lymphocytic choriomeningitis virus Armstrong 53b [S segment: AY847350; L segment: AY847351], species *Lymphocytic choriomeningitis mammarenavirus*, genus *Mammarenavirus.*
Virion	Enveloped, pleomorphic virions 40–200 nm in diameter with trimeric surface spikes
Genome	Two or three single-stranded, usually ambisense coding arrangement, RNA molecules called small (S), medium (M), and large (L)
Replication	Ribonucleoprotein (RNP) complexes are generated that contain anti-genomic

	RNA serving as coding templates for synthesis of genomic RNA
Translation	Proteins are produced from capped and non-polyadenylated mRNAs. The 5′-cap structure is derived by polymerase slippage or cap-snatching from cellular mRNAs
Host range	Fish (antennaviruses), predominantly small mammals (mammarenaviruses), and reptiles (hartmaniviruses and reptarenaviruses), but potentially also bats and ticks
Taxonomy	Realm *Riboviria*, phylum *Negarnaviricota*, subphylum *Polyploviricotina*, class *Ellioviricetes*, order *Bunyavirales*. The family includes 4 genera and 50 species

* mostly based on experiments with mammalian arenaviruses

Viruses assigned to each of the 4 genera form a monophyletic clade based on phylogenetic analysis of large protein/RNA-directed RNA polymerase (L/RdRP) and nucleoprotein (NP) sequences. Viruses from all four genera share one or more of the following characteristics: (i) enveloped spherical or pleomorphic virions; (ii) segmented single-stranded, ambisense RNA genome without polyadenylated tracts at the 3′-termini; (iii) genomic 5′- and 3′-end sequence complementarity; (iv) nucleotide sequences that could form one or more hairpin configurations within non-coding intergenic regions (IGRs) of genomic segments; (v) capped but not polyadenylated virus mRNAs; and (vi) induction of a persistent and frequently asymptomatic infection in reservoir hosts, in which chronic viremia and/or viruria occur (Radoshitzky et al., 2015).

Piscine host

Genus *Antennavirus*. This recently established genus currently includes 2 species for 2 viruses discovered in actinopterygian fish. Antennaviruses are notable for having genomes consisting of 3, rather than 2, genomic segments and likely not encoding the zinc -binding matrix (Z) protein, which is encoded by mammarenaviruses and reptarenaviruses.

Reptilian host

Genus *Hartmanivirus*. This recently established genus currently includes 4 species for 6 viruses discovered in captive snakes with boid inclusion body disease (BIBD). Hartmaniviruses are notable for genomes lacking a gene encoding the Z protein, which is encoded by mammarenaviruses and reptarenaviruses.

Genus *Reptarenavirus*. This genus currently includes 5 species for 8 viruses discovered in captive snakes, some of which were suffering from BIBD. Reptarenaviruses are notable for their transmembrane surface GP2 glycoproteins, which are more closely related to those of ebolaviruses (order *Mononegavirales*, family *Filoviridae*) than to those of antennaviruses, hartmaniviruses, mammarenaviruses or other bunyaviruses. Reptarenaviruses are also unusual in that they are prone to cause co-infections, with multiple distinct S and L segments, not necessarily in a 1:1 ratio, being detectable in snakes.

Mammalian host

Genus *Mammarenavirus*. The genus currently includes 39 species for 46 viruses. These viruses have been detected in rodent hosts, apart from Tacaribe virus (TCRV) which has been found only in phyllostomid bats and ixodid lone star ticks. Mammarenavirus infections of their natural rodent hosts are generally asymptomatic. In humans, some mammarenaviruses, such as Western African Lassa virus (LASV) or several viruses of South American origin, can cause severe and often fatal diseases with hemorrhagic manifestations. Lymphocytic choriomeningitis virus (LCMV), the typical mammalian arenavirus, can also cause disease in humans and poses a serious threat to immunocompromised individuals.

Virion

Morphology

Virions are spherical or pleomorphic in shape, 40–200 nm in diameter, with dense lipid envelopes (Figure 1**.***Arenaviridae*). The virion surface layer is covered with club-shaped projections with distinctive stalk and head regions. These projections are made of trimeric spike structures of two virus-encoded membrane glycoprotein (GP) subunits (GP1 and GP2) and in case of some arenaviruses, a third component (stable signal peptide [SSP]). Isolated RNP complexes are organized into "beads-on-a-string"-like structures (Hetzel et al., 2013, Li et al., 2016, Neuman et al., 2005, Buchmeier 2002, Charrel and de Lamballerie 2003, Jay et al., 2005, Meyer et al., 2002, Hepojoki et al., 2018).

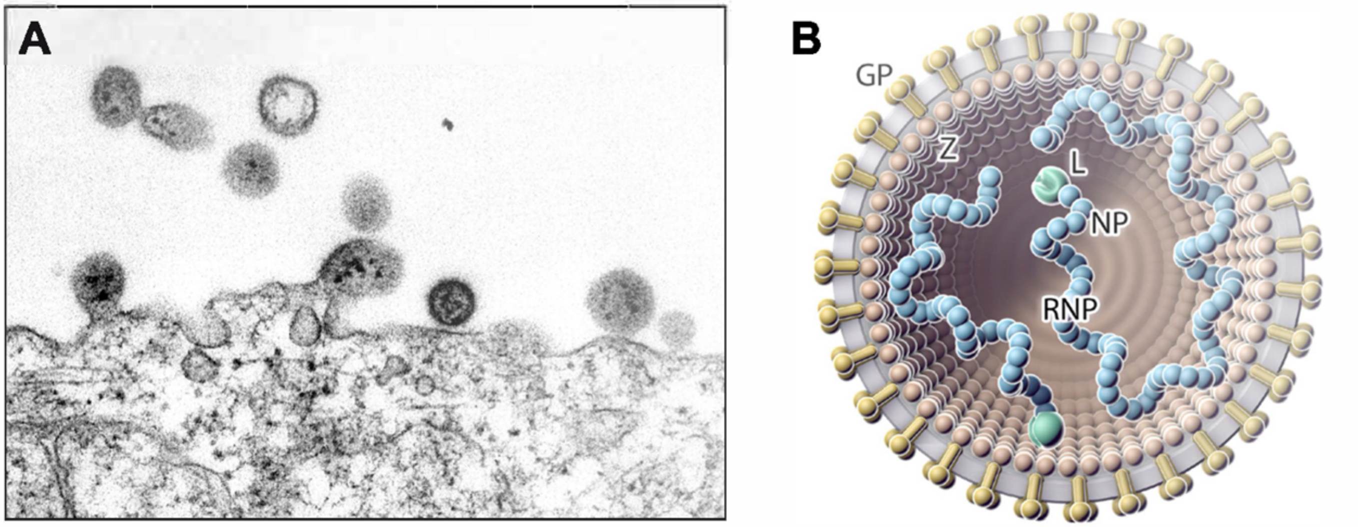

Figure 1.*Arenaviridae.* A) Electron micrograph of (mammalian) arenavirus particles, showing dark internal inclusion bodies (Latin: *arena*, sand), budding from an infected cell. **B)** Schematic illustration of an arenavirus particle. Shown is the spherical and enveloped (grey) particle that is spiked with glycoproteins (GP, gold) around a layer of zinc-binding matrix proteins (Z, brown; missing in hartmaniviruses). The small (S) and large (L) ribonucleoprotein (RNP) complexes inside the particle consist of nucleoprotein (NP, blue) and RNA-directed RNA polymerase (L, green).

Physicochemical and physical properties

Mainly known for members of the genus *Mammarenavirus* (see section on genus page).

Nucleic acid

Arenavirions typically contain 2 or 3 linear, ambisense or negative-sense single-stranded RNA segments that are encapsidated independently. These RNAs are uncapped (Leung et al., 1977) and contain a single non-templated G at each of the 5′-ends (Garcin and Kolakofsky 1990, Raju et al., 1990, Shi et al., 2018). No poly(A) tracts are present at the 3′-termini. The termini of the RNAs ends have inverted complementary sequences encoding transcription and replication initiation signals (Hepojoki et al., 2018, Salvato et al., 1989, Harnish et al., 1993, Young and Howard 1983).

Proteins

Arenaviruses express 3 (hartmaniviruses) or 4 (antennaviruses, mammarenaviruses, reptarenaviruses) structural proteins. The most abundant structural protein in virions is the nucleoprotein (NP), which encapsidates the virus genomic segments. The least abundant protein is the RNA-directed RNA polymerase (L), which mediates virus genome replication and transcription. The zinc-binding matrix (Z) protein, which is absent in antennaviruses and hartmaniviruses, is a matrix protein. Glycoproteins (GP1 or G1, GP2 or G2) are derived by post-translational cleavage of an intracellular GP precursor, the “glycoprotein-cell-associated” preprotein (GPC) by the cellular S1P/SKI protease. A third GPC cleavage product, the signal peptide, stays attached to the GP complex in hartmaniviruses and mammarenaviruses (stable signal peptide [SSP]), but not in reptarenaviruses (signal peptide [SP]). The GP structure of antennaviruses is unknown (Hepojoki et al., 2018, Shi et al., 2018, Buchmeier et al., 1987, Kunz et al., 2003, Lenz et al., 2001, Koellhoffer et al., 2014, Bederka et al., 2014, Eichler et al., 2003, York et al., 2004).

Lipids

Only known for members of the genus *Mammarenavirus* (see section on genus page).

Carbohydrates

Only known for members of the genus *Mammarenavirus* (see section on genus page).

Genome organization and replication

The arenavirus genome typically consists of two or three single-stranded, typically ambisense RNA molecules, termed S, (M), and L. Some of these RNAs encode two proteins in non-overlapping open reading frames (ORF) of opposite polarities (ambisense coding arrangement) that are separated by non-coding intergenic regions (IGRs) (Figure 2.*Arenaviridae*). The S RNA encodes NP in the virus genome-complementary sequence, and, in many cases, the GPC in the virus genome-sense sequence. The L RNA encodes L in the virus genome-complementary sequence, and, in some case, Z in the virus genome-sense sequence. Antennaviruses and hartmaniviruses lack the Z ORF, and antennaviruses encode at least one protein of unknown function. The IGRs form one or more energetically stable stem-loop (hairpin) structures and which function in structure-dependent transcription termination and in virion assembly and budding.

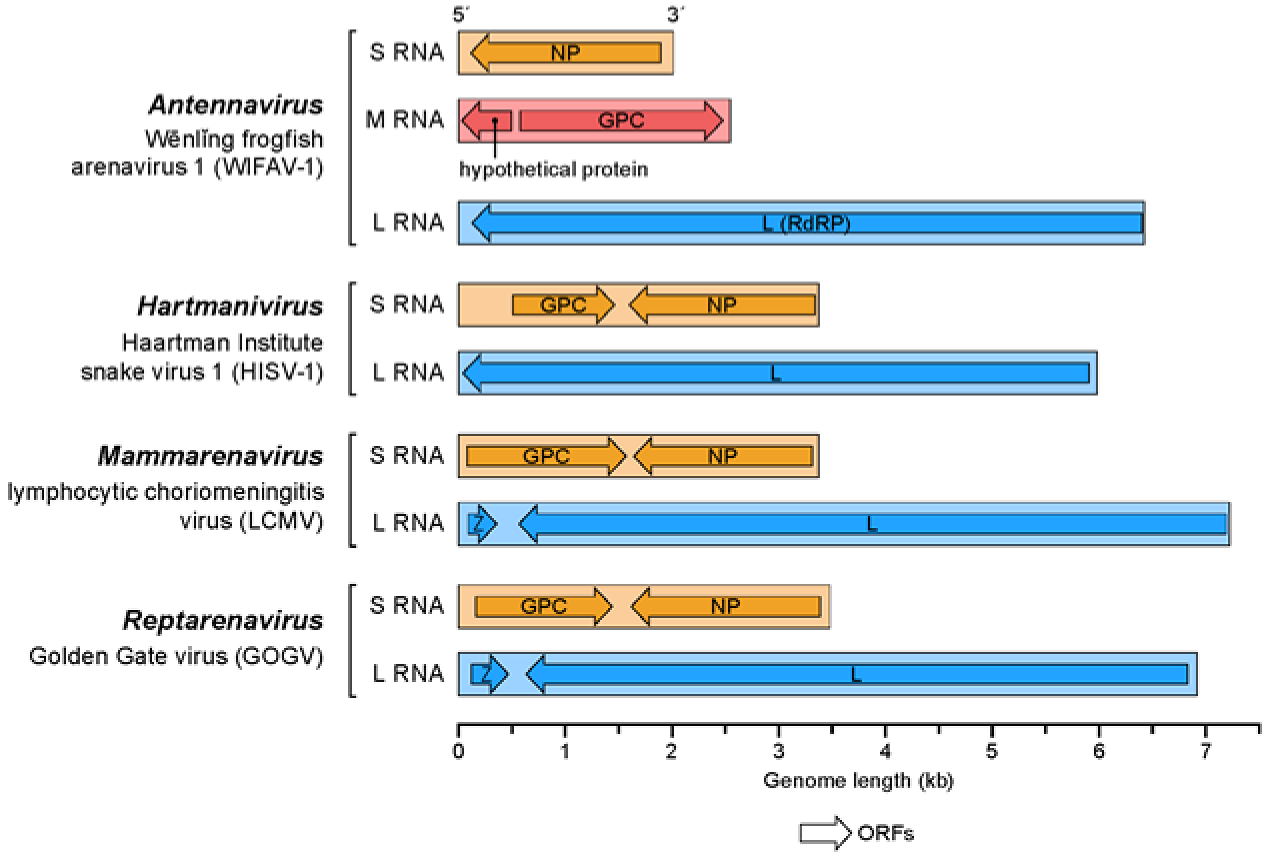

Figure 2.*Arenaviridae*. Schematic representation of the bi- or tri-segmented arenavirus genome organization. The 5′- and 3′-ends of all segments (S, [M], and L) are complementary at their termini, likely promoting the formation of circular ribonucleoprotein complexes within the virion. GPC, glycoprotein precursor; L, RNA-directed RNA polymerase; NP, nucleoprotein; Z, zinc-binding matrix

protein. Open reading frames are separated by non-coding intergenic regions (IGRs), with predicted hairpin structures (not shown).

Arenavirus infection starts with attachment to cell-surface receptors and entry via the endosomal route (Martinez et al., 2007, Vela et al., 2007, Borrow and Oldstone 1994, Radoshitzky et al., 2007, Cao et al., 1998, Raaben et al., 2017, Glushakova and Lukashevich 1989) (Figure 3.*Arenaviridae*). pH-dependent fusion with late endosomes releases the virion RNP complex into the cytoplasm. In the case of some mammalian arenaviruses (LASV), this fusion event involves a pH-dependent switch to an intracellular receptor, lysosomal associated membrane protein 1 (LAMP1) (Jae et al., 2014). The virus RNP directs both RNA genome replication and gene transcription (Meyer et al., 2002). During replication, L reads through the IGR transcription-termination signal and generates uncapped antigenomic and genomic RNAs (Leung et al., 1977). Because these RNAs contain a single non-templated G at the 5′-ends (Garcin and Kolakofsky 1990, Raju et al., 1990), replication initiation might involve a slippage mechanism of L on the nascent RNA (Garcin and Kolakofsky 1992). In case of ambisense coding arrangements, only mRNAs encoding NP or L can be synthesized from genomic RNAs. Transcription of mRNAs encoding GPC or Z occurs only after the first round of virus replication, during which S and L antigenomes are produced.

Virus proteins are synthesized from subgenomic capped mRNAs that lack terminal poly(A) (Meyer and Southern 1993, Singh et al., 1987, Southern et al., 1987). The 5′-ends of virus mRNAs contain several non-templated bases, suggesting that arenaviruses use either polymerase slippage or a cap-snatching mechanism similar to that used by other members of the subphylum *Polyploviricotina* (Garcin and Kolakofsky 1990, Raju et al., 1990, Meyer and Southern 1993). Cap-snatching would require an endonuclease presumed to be present in the N-terminal part of L, which cleaves cellular mRNAs to generate a cap leader that is subsequently used to prime arenavirus transcription. The 3′-termini of the mRNAs have been mapped to locations in the IGRs.

Virion budding occurs from the cellular plasma membrane, thereby providing the virion envelope (Dalton et al., 1968, Eichler et al., 2004, Perez et al., 2003, Strecker et al., 2003).

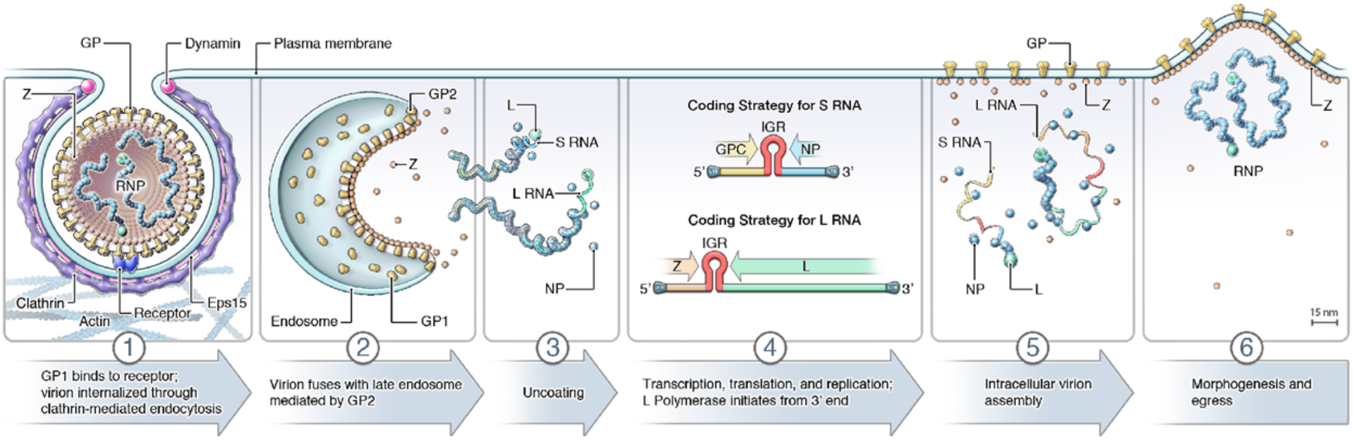

Figure 3.*Arenaviridae*. Lifecycle of arenaviruses. (1) Virion uptake; (2) virus-cell membrane fusion;

(3) uncoating; (4) transcription, translation, and replication; (5) virion assembly; and (6) virion budding. GP, glycoprotein; IGR, intergenic region; L, RNA-directed RNA polymerase; NP, nucleoprotein; RNP, ribonucleoprotein; Z, zinc-binding matrix protein. Note that antennaviruses and hartmaniviruses do not encode Z.

Biology

Arenaviruses are ecologically diverse: they have been isolated from fish (antennaviruses) (Shi et al., 2018), rodents, bats, and ticks (mammarenaviruses) (Downs et al., 1963, Sayler et al., 2014), and snakes (reptarenaviruses, hartmaniviruses) (Hetzel et al., 2013, Hepojoki et al., 2018, Hepojoki et al., 2015, Stenglein et al., 2012). The geographic distribution of arenaviruses overlaps with the distribution of their hosts. Most mammalian arenaviruses infect rodents of preferentially one or a few species and are, therefore, geographically constrained to their hosts, but LCMV, which infects the ubiquitous house mouse (*Mus musculus* Linnaeus, 1758) appears distributed globally (Childs 1993). The natural distribution of reptilian arenaviruses is unknown as they have only been detected in captive snakes thus far (Hetzel et al., 2013, Hepojoki et al., 2018, Hepojoki et al., 2015, Stenglein et al., 2012). A diverse range of vertebrate cell lines are permissive to mammalian arenavirus infection *in vitro*; certain reptilian cell lines support replication of reptilian arenaviruses (Hepojoki et al., 2018, Stenglein et al., 2012, Lukashevich et al., 1983).

Antigenicity

Systematic antigenicity studies have only been reported for mammarenavirions (see section on *Mammarenavirus* genus page).

Genus demarcation criteria

Classification of arenaviruses is currently based on pairwise sequence comparisons (PASC) of coding-complete genomes. Based on the most current sequence dataset, S segment and L segment nucleotide sequence identities for viruses within the same genus need to be higher than 40% and 35%, respectively (Radoshitzky et al., 2015). Four genera have been established to date. Viruses assigned to a genus form a monophyletic clade in well-supported maximum likelihood trees using complete L and NP nucleotide sequences and/or core L palm domain sequences. Use of L and NP for taxonomic purposes is justified by the presence of broadly conserved domains and the rarity of reassortment between genetic segments, at least in mammarenaviruses. Hence, the availability of at least coding-complete sequences of all genome segments may be sufficient for arenavirus classification in the absence of a cultured isolate. Classification is also possible when at least a coding-complete genomic S segment sequence is available together with a cultured isolate (Radoshitzky et al., 2015). However, at the present time, classification also includes the consideration of phenotypic characters such as significant differences in member virus genome architecture, virion antigenicity, and virus ecology (e.g., host range, pathobiology, and transmission patterns).

Derivation of names

Arenaviridae: from the Latin *arenosus* meaning “sandy” and *arena* meaning “sand,” in recognition of the “sandy” appearance of mammarenavirus particles observed in electron-microscopic thin sections (Rowe et al., 1970a).

Relationships within the family

Phylogenetic relationships across the family have been established from maximum likelihood trees generated using complete L amino acid sequences (Figure 4.*Arenaviridae*). Phylogenetic relationships between viruses assigned to more closely related genera and within genera can also be established using other structural protein genes, notably NP.

Figure 4.*Arenaviridae*. Maximum likelihood phylogenetic tree inferred from PRANK alignment (Löytynoja and Goldman 2008) of the complete L amino acid sequences of 50 arenaviruses assigned to the genera *Antennavirus* (blue dots, blue rings for unclassified viruses the genus), *Hartmanivirus*(green dots), *Mammarenavirus* (red dots) and *Reptarenavirus* (yellow dots), along with representative viruses of other bunyavirus families (other colors of dots). The best-fit model of protein evolution (LG+G) was selected using ProtTest 3 (v. 3.4.2) (Darriba et al., 2011). The maximum likelihood tree with 1,000 bootstrap replicates was produced using RAxML (v. 8) (Stamatakis 2014). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap is shown next to branch nodes (when ≥ 70%). The tree was visualized using FigTree (http://tree.bio.ed.ac.uk) and is mid-point rooted. This phylogenetic tree and corresponding sequence alignment are available to download from the Resources page.

Relationships with other taxa

Arenaviruses are closely related to Húběi myriapoda virus 5 (*Bunyavirales*: *Mypoviridae*) (Shi et al., 2016).

Related, unclassified viruses

Additional unclassified arenaviruses that are probable members of existing genera are listed under individual genus descriptions.

Virus name	Accession number	Virus abbreviation

Summary

The family *Paramyxoviridae* consists of large enveloped RNA viruses infecting mammals and birds, or in some cases reptiles and fish (Table 1.*Paramyxoviridae*). Many paramyxoviruses are host-specific and several such as measles virus, mumps virus, Nipah virus, Hendra virus and several parainfluenza viruses are pathogenic for humans. Virus transmission is horizontal, mainly through direct contact and airborne routes; no vectors are known.

Table 1.*Paramyxoviridae*. Characteristics of members of the family *Paramyxoviridae*

Characteristic	**Description**
Typical member	measles virus, Ichinose-B95a (AB016162), species *Measles morbillivirus*, genus *Morbillivirus*
Virion	Enveloped, pleomorphic (mostly spherical) virions with a diameter of 300–500 nm enclosing a ribonucleoprotein
Genome	Negative-sense, non-segmented RNA genomes of 14.6–20.1 kb
Replication	Cytoplasmic, by the virus ribonucleoprotein complex, involves replication of antigenome and transcription of 6–8 positive-sense mRNAs
Translation	Cytoplasmic, by cellular machinery from capped and poly-adenylated mRNAs
Host range	Mammals, birds, fish and reptiles

Taxonomy	Realm Riboviria, phylum *Negarnaviricota*, class *Monjiviricetes*, order *Mononegavirales*. Currently 4 subfamilies, 17 genera and 78 species

Virion

Morphology

Virions are 150 nm or more (up to 500nm) in diameter, pleomorphic, but usually spherical in shape in vitreous ice. Virions consist of a lipid envelope surrounding a nucleocapsid. The envelope is derived directly from the host cell plasma membrane by budding and contains two transmembrane glycoproteins (Figure 1.*Paramyxoviridae*). These are present as homo-oligomers and form spike-like projections, 8–12 nm in length, spaced 7–10 nm apart (depending on virus genus affiliation). Also, depending on the genus, one or two additional transmembrane proteins may be present. One non-glycosylated membrane or matrix protein is associated with the inner face of the envelope. The virus nucleocapsid consists of negative-sense virus genome RNA and the nucleocapsid protein (N). The nucleocapsid has helical symmetry and is approximately 18 nm in diameter with a 7 nm pitch; its length can be up to 1,000 nm in viruses of some genera. The ribonucleoprotein (RNP) complex in the virion consists of the nucleocapsid together with the polymerase-associated or phosphoprotein (P) and the L protein (L, including RNA-directed RNA polymerase, capping and cap methylation activities) (Lamb and Parks 2007). Multiploid virions are found, although the vast majority of virions contain a single functional genome.

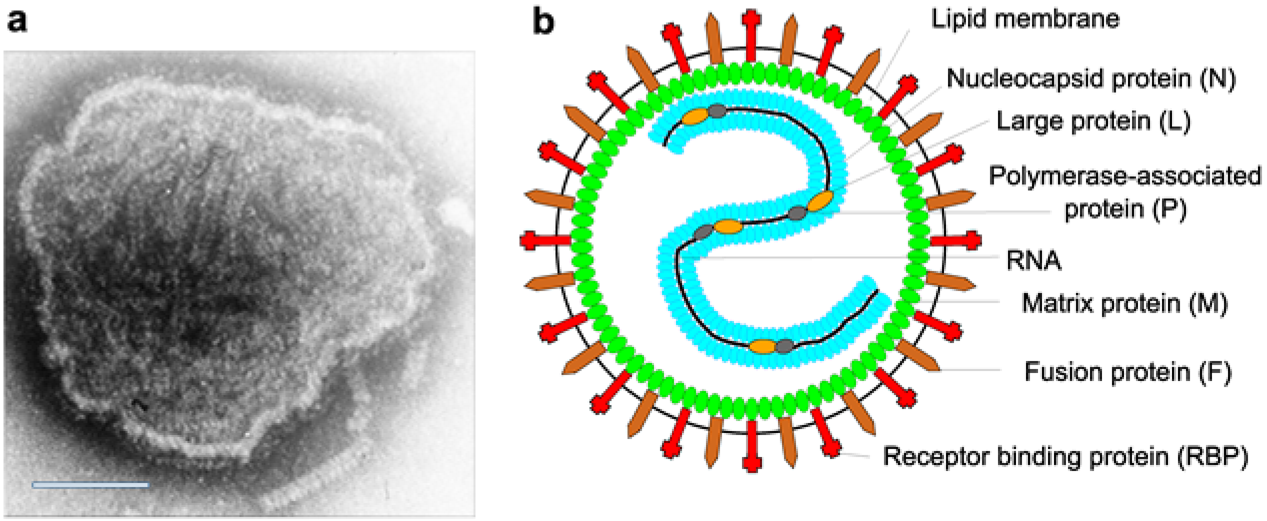

Figure 1.*Paramyxoviridae.* Paramyxovirus virion structure. (A) Negative-contrast electron micrograph of intact measles virus particle (genus *Morbillivirus*). Scale bar = 100 nm. (B) Schematic diagram of paramyxovirus particle in cross-section.

Physicochemical and physical properties

Virion Mr is about 500 ×10^6, and much greater for multiploid virions. Virion buoyant density in sucrose is 1.18–1.20 g cm^{-3}. Virion $S_{20,w}$ is at least 1000S. Virions are very sensitive to heat, lipid solvents, ionic and non-ionic detergents, formaldehyde and oxidizing agents.

Nucleic acid

Virions contain a single molecule of linear, negative-sense, single stranded RNA that is not infectious alone but is infectious if the RNP complex is introduced into the cytoplasm. The RNA genome varies from 14,296 nucleotides for Antarctic penguin virus B to 20,148 nt for Pohorje Myodes paramyxovirus 1. Genomes of all viruses in the family *Paramyxoviridae* are multiples of 6 nt, which is a requirement for efficient replication (Calain and Roux 1993). Some virions may contain positive-sense RNA and so partial self-annealing of extracted RNA may occur. Intracellularly, or in virions, genome-length RNA is found exclusively encapsidated in ribonucleocapsids (RNPs). The genome RNA does not contain a 5′-cap, nor a covalently linked protein. The genome 3′-end is not polyadenylated.

Proteins

Members of the family *Paramyxoviridae* encode 6–10 proteins (5–250 kDa) of which several can be derived either from gene editing events in the P locus and an overlapping ORF in the P gene itself (Figure 2.*Paramyxoviridae*). Virion proteins common to all genera include: three nucleocapsid-associated proteins, i.e., an RNA-binding nucleocapsid protein (N), a polymerase-associated phosphoprotein (P) and a large protein (L, including an RNA-directed RNA polymerase (RdRP), mRNA guanylyl- and methyltransferases, and methylation functions required for the capping of mRNAs), and three membrane-associated proteins, i.e., an unglycosylated inner membrane or matrix protein (M) and two glycosylated envelope proteins, comprising a fusion protein (F) and an attachment or receptor-binding protein (RBP, designated variably as HN, haemagglutinin-neuraminidase protein, H, haemagglutinin or G, glycoprotein). The F protein is synthesized within infected cells as a precursor (F_0) that is activated following cleavage by cellular protease(s) to produce the virion disulfide-linked F_1 and F_2 subunits (order: N-F_2-S-S-F_1-C). Some viruses also encode putative non-structural proteins (C), a cysteine-rich protein that binds Zn^{2+} (V) that can be structural or non-structural depending on the virus, a small integral membrane protein (SH) and transmembrane proteins (tM). Some virus genomes, such as that of the fer-de-lance virus, contain transcription units encoding proteins with unidentified functions. Virion enzyme activities include the RNA-directed RNA polymerase and mRNA guanylyl- and methyltransferases functionally encoded in the L protein. Variously represented among the genera are neuraminidases associated with the RBP.

Lipids

Lipids in the virus envelope are derived from host cell plasma membrane.

Carbohydrates

Virions are composed of approximately 6% carbohydrate by weight; composition is dependent on the host cell. Fusion and RBP proteins are glycosylated by *N*-linked carbohydrate side chains.

Genome organization and replication

The genome organization is illustrated in Figure 2.*Paramyxoviridae* for viruses representing 14 of the genera in the family.

Figure 2.*Paramyxoviridae.* Genome organization (3′-to-5′) of viruses in the family *Paramyxoviridae*. Each box represents a separately encoded coding sequence; slashes indicate where multiple distinct ORFs are present within mRNA transcripts. Co-transcriptional editing leads to expression of the V or the P protein: the first shown is derived from the unedited sequence. The lengths of the boxes are approximately to scale although the non-coding sequences (NCS) are not to scale. Certain viruses express additional C proteins by the using multiple secondary translational start sites within the P

gene. In human parainfluenza virus 1 and human parainfluenza virus 3 of the genus *Respirovirus*, the V ORF may be a non-expressed relic, the function of which may be partially compensated by an edited D protein. U is an additional transcription unit between the N and P genes in ferlavirus genomes.

After attachment to cell receptors, virion entry is achieved by fusion of the virion envelope with the cell surface membrane. This can occur at neutral pH. Virus replication occurs in the cell cytoplasm and is thought to be independent of host nuclear functions. The genome is transcribed processively from the 3′-end by the virion-associated RdRP into 6–8 separate positive-sense mRNAs. Transcription is guided by short (10–13 nt) conserved gene start (GS) and gene end (GE) signals flanking the intergenic sequence. The mRNAs are capped by the guanylyl- and methyltransferase activities of the L protein and possess 3′-poly(A) tracts synthesized by reiterative copying of U tracts in GE sequence. Intergenic regions are highly conserved in length (3 nt) and sequence (CUU with few exceptions see Table 2.*Paramyxoviridae* for details) in the orthoparamyxoviruses and metaparamyxoviruses. Neither, the length or sequence of the intergenic sequences is conserved in avulavirus or rubulavirus genomes. RNA replication occurs through an intermediate, the antigenome, which is an exact positive-sense copy of the genome.

RNP assembly occurs in the cytoplasm and is tightly linked to RNA synthesis. RNPs are enveloped by budding at the cell surface plasma membrane at sites containing virion envelope proteins. Orthoparamyxovirus genomes contain 6–8 transcriptional elements that encode 7–11 proteins. Each element encodes a single mRNA with the exception of the P/V element. This element is transcribed into an exact copy mRNA (P or V mRNA, depending on genus) and into alternative versions in which the RNA transcriptase ‘stutters’ on the template at an editing motif midway down the element. This stuttering results in the insertion of one or more pseudo-templated G nucleotides (“RNA editing”) and shifts the reading frame to access alternative ORFs. The exact copy and edited mRNAs synthesize two alternative proteins, P and V, which have identical amino-terminal domains but due to the insertions of G residues have different carboxy-terminal domains. Other truncated, or chimeric, proteins (called I, W, or D, depending on the virus) can be produced by shifting into the third reading frame. The C ORF present in henipavirus, morbillivirus, narmovirus, jeilongvirus, aquaparamyxovirus and respirovirus genomes overlaps the P ORF and can initiate synthesis at an AUG codon that is accessed by ribosomal choice or at alternative start codons in the same ORF.

Biology

Paramyxoviruses have been conclusively identified only in vertebrates and mostly in mammals and birds, although they have recently also been detected in reptiles and fish, including boneless fish. Most viruses have a narrow host range in nature but can infect a broader range of cultured cells. Infection of cultured cells is generally lytic, but temperate or persistent infections are common in this family *in vitro*and *in vivo*. Other features of infection include the formation of inclusion bodies and syncytia. Host cell surface molecules reported to serve as receptors for the attachment for members of the family vary (Thibault et al., 2017). Respiroviruses, some rubulaviruses and all avulaviruses use sialoglycoproteins and glycolipids as receptors. The cell surface proteins signaling lymphocytic activation molecule family member 1 (SLAMF1, aka CD150) and nectin cell adhesion molecule 4 (nectin 4) are major receptors for measles virus and other morbilliviruses. Henipaviruses use ephrin B2 (EFNB2) and B3 (EFNB3) proteins as cellular entry receptors (Table 2.*Paramyxoviridae*).

[#] The nomenclature for RBP (G, H or HN) used in the accessions in the data bank submissions is shown in quotation marks.

[*] The canonical NRKSCS sequence at the start of propeller blade 2 (Langedijk et al., 1997) is shown in bold lettering; in the *Avulavirinae* and *Rubulavirinae* intergenic sequences vary widely in length and sequence and hence are not recorded in the Table.

Nucleocapsids associate with virus membrane proteins at the plasma membrane and are enveloped by budding out at the membrane.

Transmission of paramyxoviruses is horizontal, mainly through airborne and direct contact routes; no vectors are known. Paramyxovirus infection typically begins in the respiratory tract and may remain at that site (e.g., human parainfluenza virus 1 [HPIV-1]) or spread to secondary sites (e.g., lymphoid and endothelial tissues for measles virus (MV) (Griffin 2007), the parotid gland, CNS and endothelial tissues for mumps virus (MuV) (Carbone and Rubin 2007) or lung and CNS for Hendra virus (HeV) and Nipah virus (NiV) (Eaton et al., 2007). In general, paramyxovirus infections are limited, and eliminated, by host immunity. However, virus can sometimes be shed for periods of weeks or months in healthy and, especially, in immunocompromised individuals. Latent infection is unknown. However, long-term persistent infection is known for several morbilliviruses such as MV in subacute sclerosing panencephalitis, a rare complication that involves persistence of a defective measles virus in the CNS for periods of, on average, 8 years. Old dog distemper can involve persistence of defective or fully infectious canine distemper virus for weeks or months in healthy and, especially, immunocompromised animals. Feline morbillivirus has been shown to be shed for long periods from the kidneys of cats. The recurrence of neurological manifestations has also been noted in NiV patients more than 4 years after recovery from acute encephalitis (Eaton et al., 2007).

Antigenicity

The RBP and F proteins are of primary importance in inducing virus-neutralizing antibodies and immunity against reinfection. Antibodies to N and, variably, to other virus proteins also are induced by infection. Following processing into small peptides the virus proteins also stimulate cell-mediated immune responses.

Derivation of names

Avula: from avian and rubula

Cynoglossusvirus: from the genus *Cynoglossus* of the fish from which the virus sequence was obtained

Henipa: from Hendra and Nipah viruses, the first isolates assigned to this genus

Hoplichthysvirus: from the genus *Hoplichthys* of the fish from which the virus sequence was obtained

Meta: from Greek *meta*, meaning “after, beyond”.

Morbilli: from Latin *morbillus*, diminutive of *morbus*, “disease”.

Ortho: from Greek *orthos*, “straight”.

Paramyxo: from Greek *para*, “by the side of”, and *myxa*, “mucus”.

Pneumo: from Greek *pneuma*, “breath”.

Respiro: from Latin *respirare*, “respire, breathe”.

Rubula: from *Rubula inflans* – old name for the disease mumps from Latin *Rubula,* red; *inflans,* swelling or puffing up.

Scoliodonvirus: from binomial name *Scoliodon macrorhynchos* (Bleeker 1852) of Pacific spadenose shark from which the virus sequence was obtained

Subfamily, genus and species demarcation criteria

The current paramyxovirus taxonomic structure is based on a comparison of complete L protein amino acid sequences. The *Paramyxoviridae* Study Group decided to use this as a sole criterion on the basis of the likely monophyly of this large and complex virus protein (Wolf et al., 2018, Dolja and Koonin 2018)consequential upon the ICTV decision to classify viruses even if only known from their genome sequences (Simmonds et al., 2017) . The genetic-based classification reflected previous classifications based on biological characteristics, which are unlikely to be known for all the new paramyxovirus sequences that have become available (Rima et al., 2018). Four subfamilies have been established on the basis of their genetic distance from the node distinguishing the family *Paramyxoviridae* from the *Sunviridae*, which is the closest related outlier family. These distances (substitutions per site) are respectively 0.64 for the *Metaparamyxovirinae*, 0.80 for the *Avulavirinae*, 0.82 for the *Orthoparamyxovirinae* and 0.90 for the *Rubulavirinae*.

Relationships within the family

Phylogenetic analysis of complete L protein amino acid sequences (Figure 3.*Paramyxoviridae*) supports the classification of paramyxoviruses into four subfamilies and fourteen genera based on genetic distances; in addition, three viruses are members of species that are not assigned to a genus or subfamily

Figure 3.*Paramyxoviridae.* Phylogenetic analysis of complete L protein amino acid sequences of members of the family *Paramyxoviridae*. Complete L protein amino acid sequences were aligned by Clustal W with gap generation penalties of 5 and extension penalties of 1 in both multi and pairwise alignments. The evolutionary history was inferred by using the Maximum Likelihood method and JTT matrix-based model. The tree with the highest log likelihood (-258124.74) is shown. The percentage of 500 trees in which the associated taxa clustered together is shown next to the branches where this was > 70%. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using a JTT model, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. This analysis involved 78 amino acid sequences. There were a total of 2745 positions in the final dataset. Evolutionary analyses were conducted in MEGA X (Kumar et al., 2018). This phylogenetic tree and corresponding sequence alignment are available to download from the Resources page.

Relationships with other taxa

The member viruses of the family *Paramyxoviridae* have a similar strategy of gene expression and replication and gene order to those of other mononegaviruses, specifically filoviruses and rhabdoviruses.

AGREEMENT INFORMATION	
Project Name:	[●] Virus Expert Panel for Disease X Vaccine Libraries
Effective Date:	January 17, 2022
Expiration Date:	[●] January 17, 2023
This Agreement includes and incorporates by reference:	The agreement (referred to as the “**Agreement**”) means this Agreement Summary together with the following: - Terms and Conditions (“T&Cs”) (Annex A)

THIS AGREEMENT is between the Counterparty and CEPI (each as defined above) and comes into force as of the Effective Date. Each party to this Agreement may be referred to individually as a "**Party**" and together as the "**Parties**".

This Agreement sets out the terms and conditions governing the exchange of information between the Parties and their representatives in the context of the selection of viruses for the Disease X vaccine library **(**the “**Purpose**”). As a pre-condition of this information exchange, the Parties enter into this Agreement by having their authorized representatives sign below.

Non-Disclosure Agreement - Terms and Conditions

1. Definitions

1.1 In this Agreement, terms shall have the following meaning:

1.2 "**Applicable Laws**" means all national and supranational laws and regulations and other mandatory professional regulations applicable to a Party or any activities carried out or to be carried in order to achieve the Purpose or a Party's activities or obligations described under or pursuant to this Agreement;

1.3 "**Business Day**" means a day which is not a Saturday or Sunday, or a bank or public holiday in England, Norway, and/or the country in which a Party's mailing address (as set out in the Agreement Summary) is located;

1.4 "**Confidential Information**" means any and all non-public information which by its nature or the manner of its disclosure is reasonably identifiable as Confidential Information, including but not limited to data, results, know-how, software (further including non-open source code), plans, details of research work, discoveries, inventions, intended publications, intended or pending patent applications, designs, technical information, business plans, budgets and strategies, business or financial information or other information in any medium, and any physical items, prototypes, compounds, samples, components, non-public regulatory filings, non-public submissions to regulatory authorities or other articles or materials disclosed on or after the Effective Date of this Agreement by one Party to the other Party whether orally or in writing or in any other form. Confidential information will not include:

a. information that is or was already known to the receiving Party at the time of disclosure, as shown by written records, without any obligation to keep it confidential;

b. information that is independently developed by employees of the receiving Party who have not had access to the Confidential Information of the disclosing Party as evidenced by contemporaneous written records;

c. information that at the time of being disclosed or obtained by the receiving Party or at any time thereafter, is published or otherwise generally available to the public other than due to default by the receiving Party of its obligations hereunder;

d. information properly obtained by the receiving Party from a source which, to the best knowledge of the receiving Party, is not known to be bound by a confidentiality agreement, fiduciary obligation or other legal or contractual restriction that may prohibit the disclosure of such Confidential Information;

e. information necessarily disclosed by the receiving Party pursuant to a statutory obligation and the Party required to make that disclosure has informed the other, within a reasonable time after being required to make such disclosure, of the requirement to disclose and the information required to be disclosed; and

f. information approved for release in writing by an authorised representative of the disclosing Party.

1.5 "**CEPI Group**" means the nodes of CEPI established in Norway, England, India, the United States of America and any other node of CEPI which may be established from time to time.

1.6 "**Group**" means in relation to a company (other than CEPI), that company, any subsidiary or any holding company from time to time of that company, and any subsidiary from time to time of a holding company of that company. Each company in a Group is a member of the Group;

1.7 all terms defined in the Agreement Summary shall have the same meaning throughout the Agreement.

2. Confidentiality; Restricted Use

2.1 All Confidential Information shall be used by the receiving Party ("**Receiving Party**") exclusively for the Purpose, unless otherwise expressly agreed to in writing by the disclosing Party ("**Disclosing Party**").

2.2 Each Party undertakes that during the term of this Agreement and for a period of five (5) years after its termination or expiry, it shall keep confidential and not disclose any Confidential Information of the other Party disclosed to or obtained by it in connection with this Agreement or the Purpose other than representatives, employees, agents, consultants, professional advisers, sub-contractors, regulatory authorities of itself or members of its Group and, in the case of CEPI, its funders or members of the CEPI Group, in each case who have a need to know Confidential Information of the other Party disclosed to or obtained by it in connection with the Purpose.

2.3 Each Party shall ensure that all representatives, employees, agents, consultants, professional advisers, sub-contractors (to the extent it can legally do so) and third parties to which Confidential Information of the other Party is disclosed are:

a. informed of the confidentiality provisions of this Agreement and

b. bound by obligations of confidentiality and non-use at least as protective as the provisions contained herein, it being understood that where such person is a natural person (i.e. individual), such person shall not be allowed to disclose the Confidential Information to any other person.

2.4 Each Party shall take reasonable security precautions to protect against unauthorized disclosure of Confidential Information.

2.5 **Required Disclosure.** The disclosure of information that is required to be disclosed by a competent Court or regulatory authority or otherwise by Applicable Law may be disclosed as required, provided that where it is free to do so, the Receiving Party shall give notice of such disclosure to the Disclosing Party as soon as reasonably practicable and all such information shall be marked as “Confidential”.

2.6 **Permitted Disclosures.** Notwithstanding the above, nothing in this Agreement shall restrict a Party’s (or any of its representatives, employees, agents, consultants, professional advisers, sub-contractors) right to

a. disclose the existence of a relationship between the Parties for the purpose of declaring a potential conflict of interest;

b. disclose Confidential Information to any committee or regulatory body in furtherance of Party’s statutory or regulatory duties.

3. Refusal

3.1 Each Party shall have the right to refuse to accept any information under this Agreement prior to any disclosure; information disclosed despite such a refusal is not covered by the confidentiality obligation under this Agreement. Nothing herein shall require either Party to disclose any particular information.

4. No Licence

4.1 Each Party reserves all rights in its Confidential Information. The disclosure of Confidential Information by one Party does not give the other Party or any other person any licence or other right in respect of any Confidential Information beyond the rights expressly set out in this Agreement.

5. No Warranty

5.1 Except as expressly stated in this Agreement, neither Party makes any express or implied warranty or representation concerning its Confidential Information, including but not limited to the accuracy or completeness of the Confidential Information.

5.2 The disclosure of Confidential Information by the parties shall not form any offer by, or representation or warranty on the part of, that party to enter into any further agreement with the other party in relation to the Purpose.

6. Termination

6.1 This Agreement shall come into force on the Effective Date and shall automatically expire five (5) years later. It may be prematurely terminated by mutual agreement of the Parties or by one Party upon thirty (30) days' prior written notice to the other Party of its intention to terminate. The rights and obligations of the Parties which have accrued prior to termination shall, however, survive the termination of this Agreement for a period of five (5) years.

7. Return

7.1 Within sixty (60) days after termination or expiry of this Agreement the disclosing Party may request in writing from the Receiving Party that the Receiving Party at the Disclosing Party's discretion either return or destroy all Confidential Information received from the Disclosing Party and stored electronically and/or on record-bearing media as well as any copies thereof. The Receiving Party shall confirm in writing such destruction or return the Confidential Information as well as any copies thereof to the Disclosing Party within fourteen (14) days after receipt of the Disclosing Party's request.

7.2 The Parties acknowledge that return and/or destruction of Confidential Information constitutes an administrative burden, and agree to keep requests for return and/or destruction of Confidential Information to the minimum required.

7.3 The provisions of Clause **Error! Reference source not found.** above shall not apply to copies of electronically exchanged Confidential Information made as a matter of routine information technology backup and to Confidential Information or copies thereof which must be stored by the receiving Party according to provisions of mandatory law or to the receiving Party's internal compliance guidelines, provided that such Confidential Information or copies thereof shall be subject to an indefinite confidentiality obligation according to the terms and conditions set forth herein until returned and/or destroyed, as the case may be.

8. Resolving Differences

8.1 **Escalation process**. Any question, difference or dispute which may arise concerning the construction, meaning or effect of this Agreement, or concerning the rights or liabilities of the Parties hereunder, or any other matter arising out of or in connection with this Agreement shall first be submitted to the Chief Executive Officer of CEPI and to the Chief Executive Officer of the other Party (the "**Senior Officers**") for resolution (each of whom may call on others to advise them as they see fit). The Senior Officers shall discuss the matter arising in good faith and in a timely manner and endeavour to reach a mutually agreeable solution. If the Parties are unable to resolve such dispute through such negotiations within sixty (60) days of such dispute being escalated to the Senior Officers, then in respect of any dispute, controversy or claim the Parties irrevocably submit to arbitration in accordance with Clause **Error! Reference source not found.**.

8.2 **Arbitration**. All disputes arising out of or in connection with this Agreement, including disputes on its conclusion, binding effect, amendment and termination, shall be resolved by arbitration, in accordance with the arbitration rules of the United Nations Commission of International Trade Law (UNCITRAL Arbitration rules) then-current in force. The appointing authority shall be the President of the Swiss Arbitration Association. The number of arbitrators shall be one, unless the parties agree otherwise. The arbitration proceedings shall take place in Geneva. The language of the arbitration shall be in English. The Parties agree to be bound by any award made by the arbitrator(s). An award shall be final and not be subject to any setting aside proceedings before any court absent fraud or misconduct. This clause shall be governed by and construed in accordance with the law of England and Wales without giving effect to any choice of law or conflict of law provisions or rules that would cause the application of the laws of any other jurisdiction.

8.3 **Good faith cooperation in resolving differences**: The Parties will cooperate in good faith to resolve differences and disputes pursuant to this Clause **Error! Reference source not found.**.

9. Limitation and exclusion of liability

9.1 **Liability cap**. Unless otherwise agreed by the Parties in writing, each Party's maximum liability in aggregate to the other Party arising out of this Agreement shall not exceed the higher of:

(a) US Dollars $10,000; and

(b) the amount (if higher) that such Party can recover from its insurer for the liability in question.

9.2 **Exclusions**. Neither Party shall be liable to the other Party for any loss of an indirect or consequential nature, nor for any loss of turnover, profits, business or goodwill, whether in contract, warranty, negligence, tort, strict liability or otherwise, arising out of any breach of or failure to perform any of the provisions of this Agreement.

9.3 **Exclusions from Liability Cap**. Notwithstanding the foregoing, nothing in this Agreement shall limit the liability of either Party in respect of: personal injury or death arising out of that Party's negligence or wilful misconduct; or fraud or fraudulent misrepresentation or wilful misconduct; or for any other liability which cannot be limited or excluded as a matter of Applicable Laws.

10. General Provisions

10.1 **Choice of law**. This Agreement and any dispute or claim (including non-contractual disputes or claims) arising out of or in connection with it or its subject matter or formation shall be governed by and construed in accordance with the law of England and Wales without giving effect to any choice of law or conflict of law provisions or rules that would cause the application of the laws of any other jurisdiction.

10.2 **No Rights for Third Parties**. A person who is not a Party to this Agreement has no right under the Contracts (Rights of Third Parties) Act 1999 or otherwise to enforce or to enjoy the benefit of any term of this Agreement.

10.3 **Notices**. Any notice to be given pursuant to this Agreement shall be in writing in the English language and shall be delivered by overnight courier, by registered, recorded delivery or certified mail (postage prepaid) to the address of the recipient Party provided in the Agreement Summary or such other address as a Party may from time to time designate by written notice. Any notice given pursuant to this clause shall be deemed to have been received on the day of receipt, provided receipt occurs on a Business Day of the recipient Party or otherwise on the next following Business Day of the recipient. The Parties agree that email and fax are not valid methods of giving notice under this Agreement.

10.4 **No Waiver**. Neither Party shall be deemed to have waived any of its rights or remedies under this Agreement unless the waiver is expressly made in writing and signed by a duly authorized representative of that Party.

10.5 **Assignment.** Neither this Agreement nor any rights and obligations under this Agreement may be assigned or delegated by either Party without the prior written consent of the other Party, such consent not to be unreasonably withheld.

10.6 **Entire Agreement**. This Agreement, including its Agreement Summary and Annex(es), constitutes the entire agreement and understanding between the Parties relating to its subject matter and together they supersede and replace all prior arrangements, whether written or oral, between the Parties relating to the subject matter of this Agreement.

10.7 **Export regulations.** The Parties shall abide by the applicable export license regulations of the respective country(ies) and, if required, the disclosing Party shall apply for an export license grant prior to any transmission of Confidential Information and to inform the receiving Party sufficiently of any existing limitation.

10.8 **Variation**. No variation, amendment, modification or supplement to this Agreement will be valid unless and until it is made in writing and signed by a duly authorised representative of each Party.

Dear Expert Panel, from all of us at CEPI we are grateful for your taking the time and agreeing to serve on our expert panel to select viruses for our vaccine library efforts to meet the 100-day mission of having a vaccine available for the next Disease X outbreak. The task at hand in which we need your expertise is to help us in selecting 10-15 viruses from each of our two pilot vaccine projects to develop vaccine libraries for the paramyxoviruses and the arenaviruses.

Organization of the Expert Panel: Attached is a listing of the participants in the expert panels for the paramyxoviruses and the arenaviruses. Some of the experts will be serving on both panels because of your broad expertise. Others will be serving on one due to time constraints or a particular interest in one family. However, if those serving on one panel would like to be involved in both please let me know as you will be welcome to participate. If you see an essential expert I should have invited but failed to please let me know.

Housekeeping: Per CEPI procedure we request that you complete with your information and sign the attached NDA. For members of our Scientific Advisory Committee your current NDA with us will suffice. For those of you who can accept an honorarium we would like to provide a $1,000 honorarium for your participation on each panel. This of course doesn’t cover your time commitment to this project but hope you will accept this as our appreciation for your efforts.

Background Information: Attached you will find some background information on the viruses from each family as listed in the ICTV by subfamilies and genera. I also highlighted those that are human pathogens and those that are zoonotic. In the excel file I merged in information from the UC Davis Spillover program on the spillover likelihood of some specific viruses. These are combined and also in a separate file. The spillover program lists viruses recently identified that are not yet listed in the ICTV or assigned a genera. Dr Bird and Dr Mazet who are on the expert panel are part of the DARPA sponsored Spillover program and will provide more information on this dataset in our general discussion meeting. Also attached are some general information and the latest phylogenetic trees from ICTV. As we progress we at CEPI are available to do the leg work on any additional information you will need ie research papers etc and please send me requests and I’ll make sure they are available prior to the meetings.

Organization of Meetings: Due to travel constraints all meetings will be held by zoom meetings. I will be sending out a doodle poll for availability for our first Zoom meeting. Our participants cross 5 different time zones so will try for early morning meetings US time which will be late afternoon for our UK members and early evening for those in SE Asia. For the first meeting I would like both expert panels for each virus family to participate as I'll give details in a presentation on our Disease X vaccine planning process as well as regulatory approach to meet the 100-day mission and the objectives for this panel to select 10-15 viruses with a likelihood for Disease X emergence for each virus family. I am planning a 1.5 hour first meeting leaving time for discussion and feedback. I envision that for each virus family we will need an additional two 1.5 hour meetings consisting of a general discussion on factors to be considered and a final meeting for virus selection. We can schedule additional meetings if needed. After the general discussion I'll send out a listing of the viruses and for each of you to select 10-15 viruses you think should go into the library. I'll then consolidate the information for our final virus selection meeting as I suspect we will have consensus on a portion of the viruses and can focus on the other viruses for discussion and a final consensus selection. First up will be the paramyxoviruses then the arenaviruses.

Please let me know if you would like additional information or recommendations on ways to improve this selection process.

Again thank you for your participation and very excited to have you involved in this.

Best,

Tim

Horses as Sentinels of Emerging Infectious Disease

Which pathogens are causing neurological and respiratory symptoms in Hendra negative horses?

Testing Hendra negative horses to Discover Emerging Pathogens causing Hendra like illnesses.

Driven by the hypothesis that:

Some cases of severe Hendra virus-like disease in Australian horses is due to spillover infection by related but divergent bat borne paramyxoviruses such as those in the Rubulavirus and Henipavirus families of which our awareness is emerging.

Researchers target new wave of emerging infectious diseases

Penelope Arthur
16 Jul 2018, 5 a.m.

The work on emerging infectious zoonotic diseases associated with horses is funded by the Dalara Foundation and is a collaboration between the University of Sydney, School of Veterinary Science, Marie Bashir Institute for Infectious Diseases and Biosecurity and the CSIRO Australian Animal Health Laboratory (AAHL).

The project aims to:

- Identify pathogens in horse cases where the Hendra Virus was confirmed negative
- Confirm and characterise unknown pathogens
- Develop additional diagnostic testing tools for the diagnosis of equine respiratory and neurological diseases and see them incorporated into state diagnostic laboratories.

Veterinary Professional Body

Core Science Infectious Disease Research

Vet informed that routine sample testing did not detect HeV, but that given the disease consistency with infectious-like illness and the possibility of emerging or novel zoonotic pathogen involvement, they should continue appropriate biosecurity and case management and that the case has been included in targeted disease surveillance based on the presenting disease syndrome.

Table 1. Infectious disease prioritization categories (with examples) used in this study to identify Hendra-negative equine disease cases with highest likelihood of similar undiagnosed viral cause from larger cohort for further investigation

Infectious disease priority	Description	Example
Category 1 Highest infectious disease suspect	Case features ‘pyrexia’ or ‘abnormal mucous membranes AND one or more other clinical signs related to infectious disease OR the presence of either change AND ‘epidemiological observation indicative of infectious cause’ based on temporal and/or spatial relationship to similar disease cases	Pyrexia with tachycardia and acute onset respiratory consolidation and/or secretions. Pyrexia and neurological symptoms. Pyrexia and ‘injected/congested’ mucous membranes. ‘Congested/injected mucous membranes’ with acute severe respiratory dysfunction. Clustering of similar cases on same or neighboring properties
Category 2 High infectious disease suspect	Pyrexia OR other clinical signs associated with infectious disease of interest	Acute onset abnormal respiratory secretions. Fever of unknown origin. Colic with the presence of neurological symptoms
Category 3 Moderate infectious disease suspect	Clinical signs may be associated equally with infectious and non-infectious causes	Colic with the presence of dehydration and mucous membrane changes. Ataxia with the absence of pyrexia or known trauma
Category 4 Low infectious disease suspect	Non-infectious etiologies more common or most likely on differential diagnosis list, but infectious cause still possible	Ataxia following known traumatic event. Traumatic wounds following unusual behavioral event. Acute lethargy following chronic non-infectious disease condition
Category 5 No infectious disease suspect	No clinical signs of illness or no infectious cause considered likely	Traumatic wounds in the absence of underlying disease. Screening in unvaccinated horses to manage biosecurity risk prior to invasive procedures addressing non-infectious disease such as is a common requirement for dentistry or admission to equine hospitals in Australia
Category 6 Confirmed infectious disease	Other infectious disease confirmed via diagnostic testing	A case submitted for HeV testing, found negative and then testing positive for alternative known infectious disease such as ABLV, WNV, EHV or RRV*

*ABLV, Australian bat lyssavirus; EHV, Equine herpes virus; HeV, Hendra virus; RRV, Ross River Virus; WNV, West Nile virus

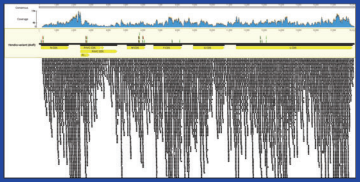
Important update for HeV surveillance in humans and animals.
Hendra-virus-variant - Horse South-East Qld 2015



A Hendra virus variant (HeV-var) detected:

- 2015 South-east Queensland case of fatal equine disease;
- Previously found negative by routine state PCR testing for HeV at the time;
- Not detected by the molecular methods routinely relied upon due to sufficient nucleotide mismatches in genomic sequence (approx. 15%).
- Equine HeV disease caused by this variant was clinically indistinguishable from the most severe reported form of acute HeV disease.
- This 2015 horse HeV-variant shares near-identical genomic sequence to that detected in a grey-headed flying fox (*Pteropus poliocephalus*) from Adelaide in 2013.

2013 viral sequence was shared with us in good-will prior to publication will by relevant CSIRO scientists.

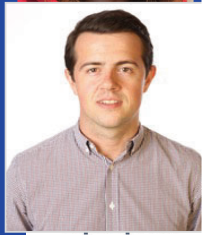
Hendra virus variant primers shared with Human and Animal Health laboratory and biosecurity network 24th February 2021 courtesy of *'Horses as Sentinels Research' group in recommendation for urgent prepublication use on compassionate grounds. Primer design by JS Eden WIMR and I Smith CSIRO.*



Initial action:

- Timely communication with state biosecurity research partners and CVO allowing for immediate actions relevant to local stakeholders.
- Redesigned PCR assays suitable for routine biosecurity screening and shared these with state and national human and animal health laboratory network.
- Undertook genomic and phenotypic analysis of the HeV-variant to support the understanding that immune-protection should be afforded as for the prototypic HeV by both the Equivac HeV® vaccine in horses and the mono-clonal antibody m102.4 post-exposure therapy in humans.

It should be emphasized, that the HeV RBP shares only 79% amino acid identity to NiV RBP, yet the HeV-sG subunit vaccine provides 100% protection against lethal challenge with both HeV and NiV in animal models (11).

Both the higher similarity between the HeV-var and HeV RBP (92.5% amino acid identity) and structural consistency of critical epitopes mentioned above, suggest that current vaccination utilizing the HEV RBP will elicit similarly protective antibodies against this HeV-var. Current serological assays based on the HeV RBP are not expected to distinguish between exposure to the variants.

Comparison of the translated amino-acid sequence of this HeV-var and prototypic HeV RBP *in silico* revealed the ephrin-B2 entry receptor binding site and that of mAb m102.4 to be unchanged. Similarly, m102.4 neutralization was confirmed *in vitro* with HeV-var as for HeV. As such, it is expected that current PEP utilizing mAb m102.4 will remain effective against this HeV-var.

HeV and ABLV are both severe zoonotic diseases
that circulate amongst Australian bats
and are lethal to both horses and humans.

While they are likely ancient viruses,
our awareness of them is relatively recent and emerging.

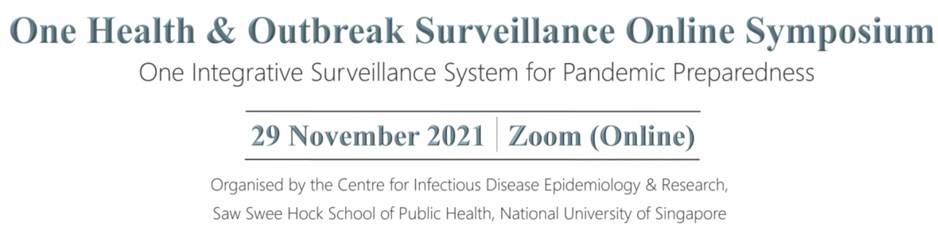
Hi JS, Ina, Chris, Peter, Kai, Ali, Raina, Andrew, Anne, Nicki, John, Ibrahim and Beth (Jenny-Ann, Ruth, Phil and Cheryl),

Updating here that I have had a late call up facilitated by Navneet (Cc'd - who is giving a keynote at the same event) to present the HeVg2 findings at:

One Health & Outbreak Surveillance Symposium 2021, Singapore (online) on Monday - https://blog.nus.edu.sg/ciderohs/ - in the lunchtime abstracts session.



One Health & Outbreak Surveillance Online Symposium

One Integrative Surveillance System for Pandemic Preparedness

29 November 2021 | Zoom (Online)

Organised by the Centre for Infectious Disease Epidemiology & Research,
Saw Swee Hock School of Public Health, National University of Singapore

The title of the abstract is: **Horses as Sentinels for Emerging Infectious Disease Research Discovery (2021) of a variant genotype of Hendra virus (HeVg2) affording prospective spillover detection (2021) and revision of geographical spillover risk.**

Sharing pdf of slides for your records.

I've had to send the slides in advance already but if anyone has any particular requests for edits let me know and I'll see if it can be accommodated. Ali and Raina – this is the same slide I used (while perhaps a little clearer) in the AVA VET Fest presentation on Thursday night which went very well by the way.

Cheers

Ed

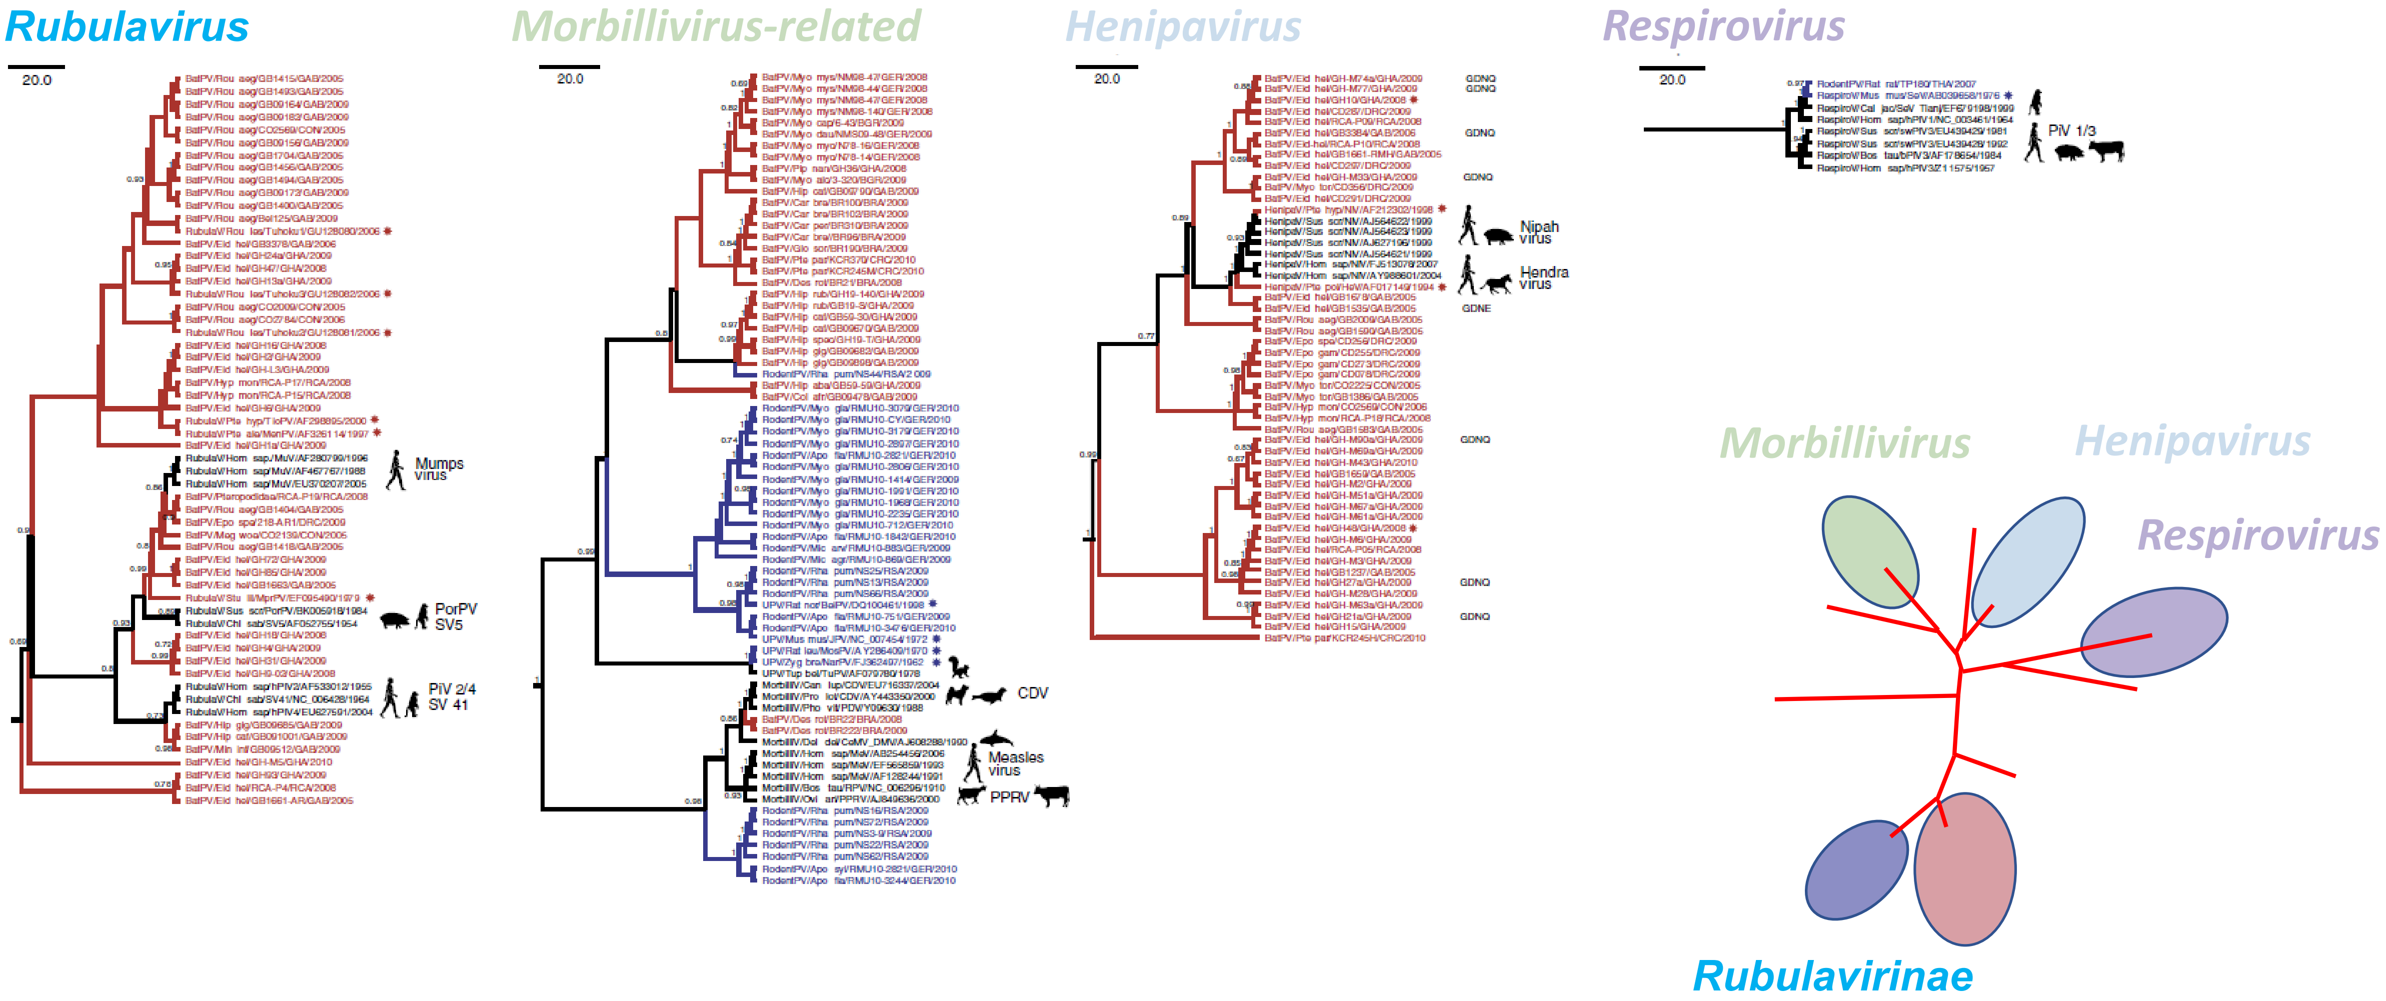
THE IMPORTANCE OF VIRAL ECOLOGY



Paramyxoviridae

- Brief history of the subfamilies we are focusing on – including info on recently identified members of the family.
- Also – do we need to summarize the basic biology of these???

Paul to finish tomorrow

BASIC BIOLOGY: KEY GAPS

- There are differences between clinical isolates laboratory-adapted strains. *Can we develop and provide model reagents for clinical strains to overcome this issue?*
- Wide breadth of immune memory. *How does the immune response vary between the different viruses? What would be the primary antigen target? Are there conserved key epitopes?*
- Persistence is common. *What is the mechanism? What are the implications for pathogen emergence?*
- Neurotropism is common. *What is the molecular basis of neurovirulence?*
- All existing vaccines are live-attenuated. *What is the molecular basis of attenuation? What can we learnt from what we have?*

BASIC BIOLOGY: KEY GAPS

- There is a difference in the level of protection after infection with a systemic versus a respiratory tract-limited virus. *Why are some paramyxoviruses systemic while some are limited to the respiratory tract?*
- Receptor binding is a hallmark. *Can we get a better understanding of glycoprotein evolution and determinants of cross-reactivity?*
- Non-structural protein are important. *How does viral protein variation affect innate immune activation?*
- Some genera are very diverse. *How stable are these viruses? What types of decontamination are effective and does this differ between paramyxoviruses?*

MODELS OF DISEASE: KEY GAPS

Cell culture/non-animal models:

- We need better human derived systems that are approachable and affordable.

Animal models of human pathogens alongside real animal diseases:

- Some paramyxoviruses don’t have good animal models (e.g. mumps).
- Some paramyxoviruses can only use NHP as good models (e.g. measles).
- CDV pathogenesis in ferrets is critical, systemic model – but to date this is not a human pathogen.
- While there are solid animal models for henipaviruses, the viruses are primarily BSL-4 (except for Cedar), making these challenging to work with for most researchers.
- Mouse models are not good for many (most) paramyxoviruses – we need to develop reagents for animal species beyond mice.
- Can we improve the predictive power of animals models for humans?

MEDICAL COUNTERMEASURES

Vaccines available for paramyxoviruses:

- Measles, mumps vaccines have been used for decades, though there are still questions about the molecular basis of attenuation and they a ALL live-attenuated.
- CDV vaccines have been developed, and there are many studies of the immune response in animals to these vaccines.
- A Hendra G protein vaccine is used in horses, and correlates of protection are currently being investigated. This vaccine is cross-protective for Nipah. It demonstrated subunit vaccines for paramyxoviruses are possible.

Monoclonals for paramyxoviruses:

- A henipavirus monoclonal antibody is through Phase 1 trials.

OVERALL SUMMARY: SCIENTIFIC GAPS

Basic Biology

- Mechanisms of viral transmission dynamics, cell entry, long-term persistence
- Systemic vs tissue-limited viral replication, disease manifestations (molecular and cellular basis)
- Differences between clinical isolates and lab viral strains; Glycoprotein evolution and determinants of cross-reactivity
- Immune response differences and similarities across viral family; Primary antigenic target; Immune epitope landscape (conserved key epitopes?); Role of innate immunity

Models

- Cell culture/non-animal models: human derived systems that are approachable and affordable
- Animal model development for some viruses in family
- Immunologic reagents for non-murine animal models (mouse - poor model for most family members)

Countermeasures

- Mechanisms of protection still unknown for successful licensed vaccines in family (e.g., measles)
- Correlates of protection for many paramyxoviruses
- Shorten mAb identification, development and production timelines
- Approaches to move promising candidates beyond Phase I trials (determine efficacy etc)

TOUGH
DECISIONS
AHEAD

PROTOTYPE PATHOGENS: ADDITIONAL CONSIDERATIONS

Henipaviruses

Issues with choosing as prototype pathogen:

- The BSL-4 nature creates considerable challenge for the wider research community.
- Significant funding is already directed towards vaccine development through CEPI.
- The consistent low R_0 value for Hendra and Nipah decreases the concerns about evolution to a highly transmissible agent.

However:

- The on-going outbreaks and high mortality rate make *Henipaviruses* a critical genus for continued research.
- Cedar virus could be considered as it is BSL-2+

PROTOTYPE PATHOGENS: POTENTIAL CHOICES

Morbilliviruses

- High transmissibility
- Propensity to jump species
- A number of emerging morbilliviruses have been identified
- *Key data needed*: what level of protection to novel morbilliviruses is provided by measles vaccination?
- Potential choices: canine distemper virus; bat morbilliviruses

PROTOTYPE PATHOGENS: POTENTIAL CHOICES

Respiroviruses

- Need to be prepared for both possible new systemic (e.g., pararubula) and respiratory-limited (respiroviruses) paramyxoviruses
- Novel respiroviruses have been recently identified, including from pangolins and squirrels
- Potential choices: HPIV1 or 3 (established pathogens), bat respiraoviruses

PROTOTYPE PATHOGENS: POTENTIAL CHOICES

Rubulaviruses

- High degree of viral diversity
- Novel members found in animal reservoirs, zoonotic transmission observed.
- Demonstrated ability to infect numerous cell types
- Current mumps vaccine doesn’t induce durable immunity, reducing potential protection to new members of this genus
- Potential choices: Menagle virus, Sosuga virus, Tioman virus, Achimotaviruses (all recently identified viruses); human parainfluenza virus 2, parainfluenza virus 5 or mumps (established) bat rubulaviruses

Subject: NIH Pandemic Preparedness discussions: draft slides
Date: Friday, November 5, 2021 10:54:22 AM
Attachments: Paramyxoviridae presentation.pptx

Dear All,

We promised to get you a draft of the slides for next week. Becky and I are meeting this afternoon to finalize. We have been tag-teaming preparation, life and calendars.

Please don't worry about format just content.

ACTION

If anyone has useful slides to contribute to paramyxovirus background please can you send them to me – it would save us some time over the weekend

Please look at the summary slide we tried to capture what drover our recommendation, remembering not all columns are weighted equally. The colors are simply our best guess if anyone has strong opinions and how we have rated anything or if we have totally miscalled please let us know.

I have tried to really simplify the taxonomy … Benhur and Felix can you give this a good look at those slides.

If anyone finds it easier to chat I am around this afternoon from 14:00. Remember there's only 5 hours between EDT and CET at the minute.

Thanks so much in advance.

Kind regards

Paul and Becky

The pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV) cause severe respiratory illness and encephalitis in both animals and humans with human case fatality rates ranging from 40-100%. The NiV-Bangladesh strain (NiV-B) is associated with multiple rounds of human-to-human transmission and is a pathogen of pandemic concern for which there are no vaccines or antivirals approved for human use. We have recently shown that the nonpathogenic Cedar henipavirus (CedV) is a useful surrogate platform for high throughput screening (HTS) for antiviral drug discovery, and for virus neutralization assays. This proposal focuses on developing antiviral small molecule and nanobody countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach. We created reporter gene-encoding recombinant CedVs and discovered a series of fused heterocycles, e.g., 4-aminoquinazoline-based, antivirals, and showed that a representative quinazoline CBS1437 was an effective inhibitor of rCedV replication and also both NiV-B and HeV, with EC_{50} values in the low µM range and minimal cytotoxicity. Neutralizing antibodies to the henipavirus F and G glycoproteins have also shown therapeutic promise, but antiviral nanobodies as potential immunotherapeutics represent a novel area of NiV and HeV countermeasure development. This proposal will screen, identify, develop, characterize and test both small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Aim 1 will focus on optimizing lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. Viral polymerase-targeting lead molecules will be selected using NiV-B and HeV assays and mechanism of action (MOA) studies, and best-in-class drugs will be developed by chemical modifications aimed to improve drug-like properties, increase potencies, decrease toxicity, and improve pharmacokinetic properties. Aim 2 will isolate and fully characterize nanobodies broadly neutralizing NiV-B and HeV derived by immunization of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using phage display technology of cloned nanobody gene fragments. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails. Aim 3 will focus on *in vivo* efficacy evaluation of lead compounds and nanobodies in animal models. Both monotherapies and combination therapeutic modalities will be tested, along with testing antiviral nanobody delivery by aerosol. These two unique henipavirus-targeted antiviral development directions will generate novel countermeasures that may display more broad effectiveness.

SPECIFIC AIMS

The emergence and reemergence of pathogenic viruses represent continuous infectious disease threats to public health. Among these, the paramyxoviruses, which include many human and animal pathogens, also include two zoonoses of particular importance: the pathogenic henipaviruses; Nipah virus (NiV) and Hendra virus (HeV).[1] NiV and HeV cause severe respiratory illness and encephalitis in both animals and humans with impressive lethality.[2] Two strains of NiV, Malaysia (NiV-M) and Bangladesh (NiV-B) together have human case fatality rates ranging from 40-100%, and some outbreaks of NiV-B are associated with multiple rounds of human-to-human transmission.[3] Indeed, the 2018 NiV-B outbreak in Kerala, India had a 91% case fatality rate among 23 total cases, leaving only 2 survivors.[4] Twenty-two cases were from virus transmission in 3 hospital settings, with coughing and close proximity to aerosol droplet infection were major risk factors. NiV-B is a pathogen of pandemic concern, and there are no vaccines or antiviral agents approved for human use. Indeed, the detection of cross-reactive henipavirus antibodies in humans and Pteropus bats in Africa underscored that 2 billion people worldwide live in regions threatened by spillovers.[5] As part of the Respiratory Pathogen Aerosol Antiviral Drug Discovery (RAViD) Center, this proposal focuses on developing countermeasures to combat the pathogenic henipaviruses including therapeutic modalities by an aerosol delivery approach.

Recently, Cedar henipavirus (CedV) was identified in bats and is the only known henipavirus that is nonpathogenic in well-established animal models of NiV and HeV pathogenesis.[6] We developed a reverse genetics platform for recombinant CedV (rCedV) construction which is suitable for BSL-2 use, and performed an extensive characterization of its cellular infection tropism and also developed reporter rCedVs suitable for high throughput antiviral screening (HTS).[7-9] We validated and published on the utility of rCedV encoding luciferase in HTS assays and discovered a series of fused heterocycles, e.g., 4-aminoquinazolines, and showed a representative quinoline was an effective inhibitor of rCedV replication that also extended to both NiV-B and HeV, with an EC_{50} value of 3.3 µM against NiV-B replication with minimal cytotoxicity. The further development of small molecules together with more extensive compound library screening using rCedV will yield testable antiviral agents with potential pan-henipavirus effectiveness. Our collaborative team also has extensive experience in developing henipavirus neutralizing antibodies to both the fusion (F) and attachment (G) proteins. In this proposal, we have initiated a completely different approach for developing antiviral nanobodies which are acceptable for the goals of this program. Nanobodies are versatile potential immunotherapeutics and have been shown to recognize epitopes that are often inaccessible to conventional antibodies and to achieve ultra-potent antiviral activity.[10] These nanobody accessible epitopes may also have the potential to be more conserved across viral strains, potentially exhibiting greater cross-reactivity. In this proposal we will screen, identify, develop, characterize and test both viral polymerase-targeting small molecule inhibitors and antiviral nanobodies to pathogenic henipaviruses. Specifically, we will:

Aim 1. Optimize lead anti-henipavirus small molecules and conduct cell-based antiviral HTS assays. First, the 4-aminoquinazoline scaffold will be used to develop and test improved drug candidates. We will also conduct new compound library HTS assays and identify new lead candidates. We will use resistance selection assays and SPR binding assay for target identification; advanced lead molecules will be selected using NiV-B and HeV assays, and best-in-class drugs will be developed using predictive software to improve drug-like properties, increase potencies, decrease toxicity, and improve cell permeability and favorable pharmacokinetic properties.

Aim 2. Isolate and fully characterize nanobodies to the F and G glycoproteins of Nipah and Hendra virus. Immunizations of transgenic mice that produce nanobodies from alpacas, dromedaries and Bactrian camels, using native-like oligomeric G and F proteins will be completed. Phage libraries of cloned nanobody gene fragments will be constructed by the Nanobody Core followed by panning and isolation of F and G specific nanobodies. Best-in-class, cross-reactive nanobodies will then be characterized in binding and neutralization assays and structurally analyzed in complex with their viral targets to delineate the recognition sites, mode of action and guide formulation of nanobody cocktails.

Aim 3. Evaluation of lead compounds *in vivo*. Protective efficacy studies using select best-in-class drugs and nanobodies will be conducted early in NiV/HeV-infected hamsters using both conventional intraperitoneal delivery (drug or nanobody) and later, best-in-class nanobodies will be also tested by aerosol delivery. PK/PD studies of lead drugs (Aim 1) and nanobodies (Aim 2) will be carried out in hamsters. Combination studies of drug with nanobody studies will also be conducted and final proof-of-concept protective efficacy studies will be carried out in the HeV and NiV-B African green monkey models.

This project brings together a highly-experienced team in henipavirus countermeasure discovery, development and testing. Together with the expertise, resources and track record within the proposed RAViD center, we will deliver preclinical antiviral candidate treatment modalities against henipavirus mediated disease.

A. BACKGROUND AND SIGNIFICANCE

For several decades, the major agents of emerged or newly identified infectious diseases in humans have been viruses of zoonotic origins.[11-13] Among these, two paramyxoviruses of importance are Nipah virus (NiV) and Hendra virus (HeV); the prototype species of the genus *Henipavirus* and are single-stranded, negative sense, enveloped RNA viruses.[14] HeV appeared in 1994, in an outbreak of severe respiratory disease in horses in Australia, with the death of 14 horses and their trainer.[15,16] NiV (Malaysia strain, NiV-M) appeared in an outbreak of encephalitis in pig farmers in Malaysia in 1998.[17,18] NiV outbreaks have since been seen in Bangladesh and India by a related strain NiV-Bangladesh (NiV-B).[19] Pteropid fruit bats are the major reservoir hosts for henipaviruses.[6,20] NiV and HeV have broad host tropism, infecting at least 18 species across 6 orders of mammals. Among these, NiV and HeV will cause a systemic and often fatal respiratory and/or neurological disease in at least 11 species including humans, with human fatality rates ranging from 40-100%.[2,21] A third henipavirus isolate, Cedar virus (CedV), was discovered in 2010.[22] However, CedV is not known to be zoonotic and has been shown to be nonpathogenic in HeV and NiV animal models.[22-24] Two additional henipaviruses are also known, Ghana bat virus and Mojiang virus, but only from sequence data.[25-27] Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and 3 outbreaks in India.[28] In 2014, an outbreak of NiV-M occurred in the Philippines with 9 fatalities of 11 human cases, with horse-to-human and human-to-human transmission.[29] The combined NiV case fatality rate is ~60% across a large region of Asia in five countries.[3] The recent 2018 NiV outbreak in Kerala, India was significant, occurring in a new geographic region, with a case fatality rate of 91% and 22 of 23 cases the result of from human-to-human transmission, underscoring both the transmissibility and the lethal nature of this virus.[4]

Human NiV/HeV infection is generally accepted to occur via the oronasal route with an incubation period of 1 to 2 weeks.[4,30] Acute NiV/HeV infection in people is systemic and likely via hematogenous viral spread from the respiratory system.[31] Disease onset is characterized by fever, myalgia, shortness of breath, and cough.[16,32] Human HeV infections have resulted in both fatal respiratory or encephalitic disease, and also recovery.[30,33] The predominant clinical feature in the Malaysia outbreak was encephalitis, but respiratory symptoms were also common.[32,34] The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease and in the 2018 NiV-B outbreak in Kerala, 83% of cases had acute respiratory distress syndrome (ARDS).[4,35] The key findings of human NiV/HeV infection are wide-spread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected.[36,37] Human NiV/HeV infection can also be prolonged following apparent recovery, and some patients can experience a late-onset or relapsed encephalitis.[33,38] Relapsed encephalitis caused by NiV appears to be a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later,[39] NiV and HeV are biosafety level-4 (BSL-4) viruses and classified as Category C priority pathogens and transboundary agents by several US agencies. Also, both NiV-M and NiV-B can cause lethal infection in nonhuman primates (NHPs), the African green monkey (AGM), when delivered by small particle aerosol.[40-42] NiV and henipaviral diseases (HeV) are included on the WHO's Blueprint List of Priority Pathogens.[43] NiV is a potential pandemic threat because of its high case-fatality rates, capacity for human-to-human transmission and potential to mutate, and a human-adapted strain in a region of high population density, could lead to rapid spread.[44] *There are presently no approved vaccines or therapeutic modalities for NiV/HeV infections in people.*

The viral RNA-dependent-RNA polymerases of paramyxoviruses are attractive targets for antiviral compound discovery, but antiviral drug discovery for NiV and HeV has been hampered by requirements of BSL-4 containment. We recently developed and optimized an authentic henipavirus replication cell-based system using a recombinant CedV (rCedV) encoding luciferase (rCedV-Luc) for high-throughput screening (HTS) applications at BSL-2 and identified several inhibitory compounds that were further validated with authentic NiV-B and HeV.[7] Those leads provide the rationale for the current application. Our ability to employ rCedV provides an opportunity for anti-henipavirus drug discovery not previously available, that also allows for discovery across the whole replication cycle, not restricted to only the viral polymerase. Another well-exploited stage of virus infection is the attachment and entry process.[45] NiV/HeV possess two membrane anchored glycoproteins required for infection; one for attachment, the G glycoprotein, and the other for membrane fusion the F glycoprotein.[46] The viral G and F glycoproteins are the major antigenic targets of neutralizing antibodies and all vaccine strategies.[28] Although an effective post-exposure human monoclonal antibody (mAb) therapy targeting the NiV and HeV G glycoprotein (m102.4) has been extensively examined,[47-51] its delivery must be within several days following infection in NHPs. An unexplored alternative but related antibody-based strategy are antiviral nanobodies. A nanobody, is an antibody fragment comprised of just a single monomeric variable antibody domain.[52] Nanobodies were first engineered from variable heavy chain domains of camelid heavy chain

antibodies (VHHs), and camelid VHHs retain full antigen specificity and are only a fraction of the size of a human antibody, and they have extended complementarity determining regions (CDRs) which can allow them to bind epitopes not normally accessible to conventional antibodies, such as conserved viral epitopes often masked by glycan shields.[10] Our expertise in henipavirus F and G structural and functional analyses together with anti-F and G mAb development and therapeutic application, will facilitate the development and testing of a new and understudied area of nanobody-based immunotherapeutic against NiV and HeV.

B. INNOVATION

There are several innovative aspects within the present application which capitalize on the ongoing collaborative research and expertise of the investigators in this proposal. *First,* the cell-based high throughput screening (HTS) assay makes use of an authentic henipavirus infection and replication luciferase reporter-gene system, which provides an HTS platform for antiviral drug discovery that targets all stages of the virus lifecycle. Of additional significance, this recombinant Cedar virus (rCedV) based platform requires only BSL-2 containment. Also, because of the close phylogenic relatedness of CedV to NiV and HeV, including the use of the same principal entry receptor (ephrin-B2) and replication mechanisms, there is high potential that identified inhibitors may well have activity across related members of the henipavirus genus. *Second,* our native-like, recombinant soluble tetrameric G and trimeric F NiV and HeV glycoproteins are now being used to immunize novel engineered mice that produce VHHs (nanobodies). *Third,* together with newly created rCedV chimeras and the establishment of a high-throughput NiV/HeV GFP reporter-gene, neutralization assays, the screening, identification and characterization of large numbers of nanobodies for their NiV and HeV specific neutralization potency and cross-reactivity features is now possible. *Fourth,* the rCedV platform allows for authentic henipavirus antiviral escape studies for variant selection and target identification. Finally, the rCedV based reporter-gene system allows rapid and quantitative antiviral combination testing and the ability to measure synergistic activity with small molecules or nanobodies or combinations of both.

Small molecule antiviral drug discovery. Anti-whole NiV or HeV immune sera shows cross-reactivity with CedV, however, such sera or even specific high-titer anti-CedV F or G antisera will not cross-neutralize HeV or NiV. Nevertheless, several CedV proteins show high amino acid (aa) identity to those in NiV and HeV, with highly conserved domains particularly in the N, M and L proteins.[22] Interestingly, the CedV L polymerase protein is 257-aa larger in comparison to NiV and HeV L, and the largest polymerase in the order *Mononegavirale*, yet it shares high aa identity to NiV and HeV L proteins. Indeed, CedV L is ~56% aa identical overall to the NiV-B and HeV L proteins; aa identities of L domains are: catalytic domain ~59.5%; the mRNA capping domain ~64.7%; methyltransferase domain ~50.5% (NiV-B) and ~52% (HeV); C-terminal domain ~51% (NiV-B) and ~52% (HeV); and the 2-O-ribose methyltransferase domain ~60.8% (NiV-B) and ~61.7% (HeV). This overall high degree of identity, shared between CedV and that of NiV and HeV, suggests that antivirals that target the L polymerase, could be identified and also offer the possibility of identifying pan-henipavirus countermeasures. We recently tested this possibility and optimized a rCedV encoding firefly luciferase (rCedV-Luc) for HTS assays and conducted a small molecule library screening project to identify inhibitors of rCedV replication.[7] Several small molecule inhibitors have been validated *in vitro* using infectious HeV and NiV, demonstrating proof-of-concept and the feasibility of using this CedV-based HTS platform for inhibitor screening against HeV and NiV, and providing a strong foundation for this drug discovery project. This rCedV HTS system will be used to support **Aim 1** to optimize our current best-in-class leads and also screen large libraries of compounds.

Nanobodies. In contrast to mouse and human antibody binding domains (which are ~50 kDa in size), camelid VHHs retain full antigen binding specificity but are only ~15 kDa in size. Other advantageous features of nanobodies are their extended CDR elements that engage their antigen targets and thus possess abilities to bind epitopes that are often less accessible to conventional antibodies, and they can also be readily humanized and have been shown to be safe with low immunogenicity in clinical trials.[53-55] Nanobodies can be isolated using the same phage library construction methods and phage panning procedures routinely employed for mAb discovery, which allows for *in vitro* production of various amounts and their rapid characterization. Nanobody development will be carried out by **Dr. Jianliang Xu** (Nanobody Core Lead), who engineered transgenic mice that produce VHHs (nanobodies) from alpacas, dromedaries and Bactrian camels.[10] Immunized mouse cohorts are in progress using recombinant F and G glycoproteins of NiV-B and HeV. We except to be able to make rapid progress in **Aim 2.**

By utilizing an integrated approach in medicinal chemistry that includes synthesis and antiviral testing of new compounds, *in silico* prediction of compound properties, and the utilization of *in vitro* ADME prediction assays, in both building on our preliminary findings and new discovery initiatives, we expect to derive multiple lead anti-henipaviral molecules that will be testable as part of the goals of **Aim 3**. In addition, we expect to discover, and

characterize batteries of new and novel anti-henipavirus nanobodies specific to the F and G glycoproteins of NiV and HeV, and test their therapeutic activities in **Aim 3**. **Taken together, the combinations of new small molecule drugs and nanobodies to be developed in this proposal, with their specificities tailored to the henipaviruses through the applications of our novel proposed approaches, may lead to novel therapeutic modalities capable of treating NiV and HeV disease.**

C. PRELIMINARY RESULTS

C.1. Project Team. All aspects of the proposed research are new extensions of productive research endeavors between: **Dr. Christopher Broder, USU** (Henipavirus Project 1 lead); **Dr. Lijun Rong, UIC** (Co-Investigator lead on small molecule discovery) and **Drs. Norton Peet, Irina Gaisina, and Terry Moore, UIC and Chicago BioSolutions Inc.** (Co-Investigators and leads on medicinal chemistry); **Dr. David Veesler, UW** (Co-Investigator lead on structural henipaviral biology), **Dr. Moushimi Amaya, USU** (Co-Investigator lead on rCedV tools), **Dr. Jianliang Xu,** (Nanobody Core Lead, Zalgen Labs), and **Dr. Thomas Giesbert, UTMB** (Co-Investigator and BSL-4 and ABSL-4 Core lead). **Chicago BioSolutions, Inc**. is a privately held, product-focused biopharmaceutical company engaged in the research and development of small molecule antiviral drugs that address commercially significant medical markets and unmet medical needs.

C.2. Preliminary Data: Identification of small molecule inhibitors of henipaviruses.

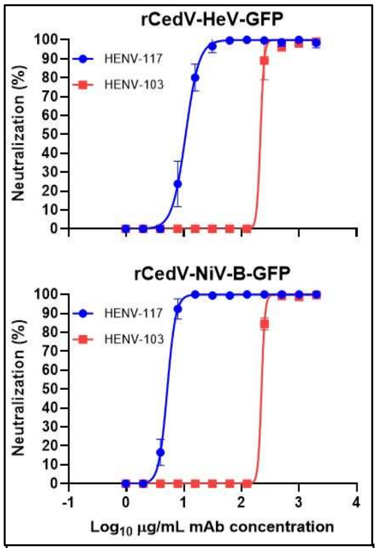

Figure 1. Neutralization curves for HENV-117 and HENV-103 mAbs against rCedV-HeV-GFP (top) and rCedV-NiV-B-GFP (bottom). Data are from a single experiment performed in technical triplicate.
