Acetalated Dextran: A Tunable and Acid-Labile Biopolymer with Facile Synthesis and a Range of Applications

Eric M. Bachelder*, Erica N. Pino, and Kristy M. Ainslie

Division of Pharmacoengineering and Molecular Pharmaceutics, Eshelman School of Pharmacy, University of North Carolina, Chapel Hill, North Carolina 27599, United States

* Supporting Information

Acetalated dextran (Ac-DEX) is a tunable acid-labile biopolymer with facile synthesis, aptly designed for the formulation of microparticles for vaccines and immunemodulation. Tunability of degradation is achieved based on the kinetics of reaction and the molecular weight of the parent dextran polymer. This tunability translated to differential rates of activation of CD8+ T cells in an in vitro ovalbumin model and illustrated that acid-labile polymer can activate CD8+ T cells at an increased rate compared to acid-insensitive polymers. In addition, Ac-DEX has been used to encapsulate small molecules, deliver nucleotides, transport inorganic molecules, formulate immune modulating therapies and vaccines, and trigger pH responsive constructs for therapy. Here we highlight the properties and results of Ac-DEX nano-/microparticles as well as the use of the polymer in other constructs and chemistries.

1. INTRODUCTION

Dextran is an FDA approved polysaccharide that has been used for decades as a plasma expander. The acetalation of dextran was first reported by Bachelder et al. wherein 2-methoxypropene was used to modify dextran, resulting in a biopolymer with dextran, methanol, and acetone as degradation products (Figure 1).[1] The acetalation of the dextran pendant hydroxyl group results in the polymer being hydrophobic, which allows the encapsulation of drugs through emulsion chemistry, similar to what is done with polyester polymers. This acetalized polymer (Ac-DEX) facilitated the encapsulation of hydrophobic and other drugs that would typically be difficult to deliver. Additionally, acetalated dextran (Ac-DEX) is an acid-sensitive polymer that degrades more rapidly at lower pH, such as in the endosome of phagocytic cells, tumors, or areas of inflammation, allowing for site-specific degradation of the polymer and subsequent release of the encapsulated therapeutic.

In the reaction of dextran with 2-methoxypropene, the kinetically favored acyclic acetals will initially form, followed by the thermodynamically stable cyclic acetals. Acyclic acetals degrade rapidly during hydrolysis and result in the generation of methanol and acetone. In contrast, cyclic acetals degrade more slowly through hydrolysis and result in the generation of acetone only. This differential acetal formation was shown to be dependent on the reaction time of the polymer and to result in varying degradation rates based on the ratio of cyclic to acyclic acetals. With the differential tunability of Ac-DEX came a marked difference in T cell activation using β-galactosidase reporter cells and the model antigen protein ovalbumin. Most notably, faster degrading materials at lower pHs resulted in the most significant major histocompatibility complex class I (MHC I) and MHC II presentation. When comparing fast and slow degrading Ac-DEX to other acid-sensitive (polyacrylamide), degradable (poly(lactic-*co*-glycolic acid) (PLGA)), and nondegradable (iron oxide) carriers,[2] fast degrading Ac-DEX displayed enhanced MHC I presentation and the best MHC II presentation over other carriers. CD8+ T cells are cytotoxic T cells that can kill infected cells indirectly by inducing apoptosis in the target cell, or can kill cells directly through the secretion of perforin. Therefore, CD8+ T cell

activation, via MHC I, is desirable to generate protective vaccine mediated immune responses against intracellular pathogens such as viruses, as well as some bacteria, parasites, and fungi. Moreover, MHC I presentation is required for the development of a therapeutic cancer vaccine. This tunability and enhanced MHC I class presentation illustrates Ac-DEX is a well-designed polymer for vaccine applications (Figure 2). Moreover, Ac-DEX particles displayed significantly greater CD4+ (MHC II) presentation in comparison to other biomaterials, exhibiting that Ac-DEX particles cross-presented to both CD4+ and CD8+ T cells, arming both the cellular and humoral responses that would be needed for many vaccines.[2]

Apart from enhanced activation of cellular immune responses, Ac-DEX has several other benefits when compared to other commonly used biopolymers. A primary benefit is its facile synthesis. Ac-DEX synthesis is a single vessel reaction with subsequent purification through precipitation.[3] Moreover, the degradation products of Ac-DEX are pH-neutral, unlike commonly used polyesters (e.g., poly beta amino esters (PBAEs), poly(lactic-co-glycolic) acid (PLGA), polycaprolactone (PCL)) and several polyanhydrides. This allows for minimal degradation of the payload due to low pH, without the addition of excipients.[4−6]

Other acid-sensitive polymers have been developed for drug delivery applications, including PBAEs, poly(ortho esters) (POEs), and polyketals. PBAEs, while associated with increased cellular internalization and transfection efficiencies over PLGA particles, have illustrated increased cytotoxicity, likely due to their highly positive zeta potentials from their cationic amines in the backbone.[7] In contrast to PBAEs, POEs are very biocompatible but have relatively slow degradation at pH 5.[8] Polyketals, another acid-sensitive polymer class, offer great polymer degradation control, but their difficult synthesis is less appealing than that of Ac-DEX.[9] In comparison to these polymers, Ac-DEX's inherent acid-sensitivity allows for tunable degradation profiles based on reaction time, thus allowing precise control over payload release. Since both sustained and burst release can be selectively achieved, Ac-DEX is an ideal carrier for a wide range of therapeutics. Ac-DEX is a unique biopolymer in that where other commonly used polymers degrade into acidic byproducts, all byproducts of Ac-DEX degradation are pH-neutral. This property gives Ac-DEX the following two advantages: first, a neutral pH should not adversely affect the encapsulated payloads; second, the environment surrounding Ac-DEX should not be harmed upon degradation as it could by the degradation of polymers with acidic byproducts, such as PLGA.

Ac-DEX stands alone as an easily made, tunable, and acid-sensitive polymer, which makes it understandable why it has been used in over 30 publications since 2008 and has been mentioned in five reviews.[10−14] Here we report its application to deliver a variety of compounds, including small molecules, proteins, peptides, nucleotides, and inorganic molecules. Moreover, the most common formulation of Ac-DEX, nano-/

microparticles, has been studied extensively in vitro and in vivo and has been delivered through parenteral and needle-free routes. In addition to the particulate constructs, Ac-DEX has been incorporated into a variety of copolymers and advanced designed delivery devices which rely on the polymer's acid sensitivity and tunable degradation rates (Supporting Information Table 1). The many publications that use Ac-DEX, as well as its broad range of applications, make it an emerging biomaterial for drug delivery.

2. ADJUVANT AND VACCINE DELIVERY

The original proposed application of Ac-DEX was the formation of nano-/microparticles as a subunit vaccine. Since subunit vaccines often rely on adjuvant activity for innate immune activation,[15] it goes hand-in-hand that adjuvant encapsulation in Ac-DEX would also be studied. If Ac-DEX microparticles (MPs) are of a certain size, they can passively target antigen presenting cells (APCs). Unlike most cell types in vivo, phagocytes (e.g., dendritic cells (DCs), macrophages) can internalize particles larger than 100 nm, thereby allowing uptake only by phagocytic cells if particles are greater than 100 nm.[16,17] Furthermore, passive targeting of professional APCs (DCs) is possible with further sizing. Studies have shown that MPs in the range of 1−2 μm are four times more likely to be phagocytosed by CD11c+/CD11b+ cells (DCs, professional APCs) than CD11c-/CD11b+ cells (e.g., macrophages). Also, in this same size range, when observing cells extracted from the local draining lymph nodes, approximately 50 times more CD11c+CD11b+ or CD11c+CD11b+ cells (DCs) phagocytosed the MPs, compared to CD11c-CD11b+ cells (macrophages). These results indicate that large particles (1−2 μm) are predominately transported by DCs from the injection site to the lymph nodes, whereas smaller particles are cleared by resident macrophages.[18] Moreover, once the MPs are taken up, the acid-sensitivity of particles leads to an enhanced release of cargo through more rapid degradation of the polymer, compared to degradation at neutral pH. This combination of acid-sensitivity and passive targeting makes Ac-DEX MPs apt carriers for adjuvants and vaccines.

2.1. Adjuvant Encapsulation

Primarily, toll-like receptor (TLR) agonists are the type of adjuvants that have been reported to be encapsulated in Ac-DEX particles. Of the TLRs studied, TLR 3 and TLR 7/8 are the most common, since these are intracellular Pathogen-Associated Molecular Patterns (PAMPs) found within the cell's phagolysosome, which is where Ac-DEX particles would reside after phagocytosis. Imiquimod, the active ingredient in Aldera cream and a TLR 7/8 agonist was first encapsulated into Ac-DEX particles by Bachelder et al.[19] A dose sparing of the hydrophobic adjuvant was observed in vitro in both macrophages and bone-marrow derived dendritic cells (BMDCs). A statistically significant difference in both mRNA and soluble cytokine responses was observed when BMDCs and macrophages were cultured with Ac-DEX MPs encapsulating imiquimod in comparison to empty Ac-DEX MPs and soluble imiquimod, at the same concentrations (Figure 3).[19] Resiquimod, a more hydrophilic imiquimod derivative, was later encapsulated into Ac-DEX MPs, and also displayed a dose sparing response in cytokine production in macrophages.[20] Moreover, by creating a library of polymers with unique cyclic acetal coverage and molecular weight, it has been illustrated that the loading of resiquimod as well as its release and bioactivity in macrophages can be controlled and illustrate dose sparing.[21]

In addition to the encapsulation of small molecule adjuvants, nucleotide adjuvants have been formulated into Ac-DEX MPs. Two adjuvant-based nucleotides, in particular, have been used: Poly I:C, which is an agonist for TLR 3, and CpG, which activates TLR 9. In contrast to TLR 8 expression, which is uniform across species, TLR 9 activity differs between mice and humans, where in it is significantly reduced in humans because it is limited to only plasmacytoid DCs and B cells.[22] Despite this, CpG is heavily studied and therefore a practical adjuvant for vaccine formulation. In the comparison of poly I:C encapsulation with Ac-DEX versus PLGA, there was a significant increase in adjuvant encapsulation efficacy (EE) at intermediate (71K) dextran molecular weights. Also, the more quickly degrading poly I:C loaded Ac-DEX MPs resulted in increased cellular activation compared to more slowly degrading Ac-DEX and PLGA. One or both degradation rates of Ac-DEX resulted in a dose sparing compared to soluble drug.[23] Increased EE in comparison to PLGA and dose sparing compared to soluble drug was also observed with the encapsulation of CpG in Ac-DEX MPs. Moreover, the viability of Ac-DEX MPs was shown to be comparable to that of PLGA MPs, indicating that increased cytotoxicity is not the cause of the increased adjuvant activity observed with Ac-DEX MPs. The encapsulation of adjuvant in Ac-DEX particles paves the way for formulation of subunit vaccines using the biopolymer.

2.2. Vaccine Formulations

The model antigen ovalbumin (OVA) was encapsulated into Ac-DEX to evaluate the effect of Ac-DEX encapsulation[1] and tunability[2] on MHC I and MHC II presentation using model cell lines (B3Z for MHC I presentation and KZO for MHC II presentation). Both cell lines will express β-galactosidase downstream of CD3 signaling when the immunodominant peptide of OVA is presented on APCs. The enhanced MHC I presentation (indicator of cellular activity) observed by

Bachelder et al. in the initial reporting of Ac-DEX is due in part because particle cross-presentation of protein antigen has resulted in both MHC II and MHC I expression of antigen.[24] Broaders et al. then illustrated that the acid-sensitivity of Ac-DEX generates a greater cellular response at more rapid degradation rates and in comparison to non-acid-sensitive formulations. It is this foundation in enhanced cellular responses compared to free protein as well as other biomaterials that leads to the formation of vaccines with Ac-DEX MPs.[2]

Using separate particles, a complete subunit vaccine comprised of Ac-DEX was formulated for protection against anthrax. Separate emulsion based particles were used for adjuvant and antigen because the adjuvant had poor EE using homogenization compared to sonication, but homogenization was less damaging to the protein antigen. For the study, ~400 nm homogenized particles encapsulated recombinant protective antigen (rPA) and ~200 nm sonicated particles loaded with resiquimod were used. Ac-DEX MPs were shown to be an efficacious vaccine carrier for both antigen and adjuvant over unencapsulated delivery. The study also indicated that high levels of total IgG antibody, significantly greater than Alum and rPA, were generated in the particle vaccine group; however, these antibodies were non-neutralizing, likely due to the denaturation of the protein during the emulsion fabrication process. Despite the poor neutralizing response, a Type 1 helper T-cell (Th1) response was observed in both the antigen recall study as well as by the generation of IgG2 antibodies (Figure 4). This illustrated that the protection observed with the lethal challenge could be the result of a cellular immunity,[25] which corresponds with the results of both Bachelder et al.[1] and Broaders et al.[2]

The work with the anthrax vaccine paved the way for the evaluation of a Burkholderia pseudomallei vaccine for the prevention of melioidosis. Using cell lysate as a crude antigen and resiquimod, again in separate particles, vaccination with Ac-DEX particles was shown to significantly delay time to death, after lethal challenge, in both a rapid and more traditional vaccine schedule. The particle formulation generated humoral and cellular immune responses greater than those of alum and lysate. Additionally, approximately 10% of mice were sterile (blood, liver, spleen) after challenge when treated with encapsulated resiquimod Ac-DEX particles, with and without antigen. This indicates a potential post exposure treatment for this bioterrorism agent.[26]

With the use of emulsion for both the anthrax and B. pseudomallei vaccine work, there were several inherent manufacturing limitations that needed to be addressed prior to additional development of the Ac-DEX vaccine platform. These limitations included: (1) batch processing, (2) high energy methods (e.g., sonication, homogenization) which could denature the protein antigen, (3) extended solvent and protein antigen contact times during the solvent evaporation process which can also cause denaturation of the protein; (4) limited control over the amount of drug and efficacy at which it is encapsulated, and (5) broad polydispersity of particles. The effects of protein denaturation can result in poor B cell activation, which was illustrated by the lack of neutralizing antibodies observed with the emulsion anthrax work.[25] To address these limitations, an Ac-DEX MP anthrax vaccine was formulated using scalable electrospray.[27] In contrast to emulsion, electrospray can be scaled by multiplexing the electrospray heads. Electrospray can have limited interaction with solvents, offers a broader range of control of EE of the payload, produces fairly monodisperse MPs, and uses slow flow rates, which translates to reduced shear stress (Figure 5). When electrospray was used to encapsulate PA, decreased protein denaturation was observed compared to emulsion, which resulted in increased toxin neutralization of generated antibodies (Figure 5). Also due to the flexibility of particle fabrication via electrospray, we were able to encapsulate both protein and adjuvant into a single MP. In comparison to separately encapsulated adjuvant and antigen, the coencapsulated group provided decreased survival in response to a lethal challenge (Figure 5), although both groups outperformed the FDA approved anthrax vaccine formulation, BioThrax. This work illustrates the feasibility of manufacturing an Ac-DEX MP

vaccine platform, and the platform's ability to protect better than the current standard vaccine.

Ac-DEX particles have not only been used to stimulate an effector immune response, but they have also been used to attenuate immune responses in an antigen-specific manner. By using a tolerizing agent (e.g., dexamethasone) with an antigen (Myelin Oligodendrocyte Glycoprotein (MOG)), the costimulatory signals required for generation of an effector response are absent in the education of the T cell by the DC. This can result in antigen-specific attenuation of the immune response via mechanisms such as the formation of T-regulatory cells, anergy, or T cell deletion. Using Ac-DEX particles to encapsulate MOG and dexamethasone into one particle, via emulsion, it was shown using a Multiple Sclerosis (MS) model (experimental autoimmune encephalomyelitis (EAE)) that mice could be taken, on average, from full hind and partial front paralysis to only exhibiting a limp tail. The application of Ac-DEX for these autoimmune therapies is reviewed by Chen et al.[10] and, later, by Northrup et al.[14] The application of Ac-DEX particles has gone beyond the model antigen to illustrate protective responses in

disease models, further illustrating the strong application of this biopolymer in a vaccine formulation.

3. DELIVERY TO MACROPHAGES

Like DCs, macrophages can be targeted by particles that are too large to be taken up by nonphagocytic cells. Moreover, since smaller particles are taken up and cleared by macrophages, one can also have a concentrated uptake in macrophages by sizing the particles between 100 nm and 1,000 nm.[18] Since macrophages serve as host cells to a variety of pathogens, including viral, bacterial, parasitic, and fungal, they can act as interdiction points for therapy. By disrupting the mechanisms the pathogen usurps to reside intracellularly, pathogen growth and survival can be decreased. These host-directed therapies (HDT) are thought to mitigate the emergence of drug resistance, since they are not targeting the pathogen directly. Ac-DEX has been used to formulate one HDT, AR-12 (also known as OSU-03012). AR-12 has illustrated broad spectrum activity against multiple bacteria, viruses, and the parasite Leishmania donovani,[12,28−33] and its activity has been reviewed by Collier et al.[31] Compared to unencapsulated drug, AR-12 in Ac-DEX particles had significantly reduced cytotoxicity and higher intracellular drug loading. Additionally, the particles were taken up freely by human monocyte derived macrophages (Figure 6).[33] In vivo, AR-12 in Ac-DEX particles displayed enhanced clearance of Francisella tularensis infection compared to the unencapsulated compound. When AR-12 in Ac-DEX particles were co-delivered with a suboptimum dose of antibiotic intranasally, there was a significant increase in mouse survival compared to free drug and free suboptimum antibiotic. In the host-directed treatment of intracellular parasite, L. donovani used intravenously delivered AR-12 in Ac-DEX particles and displayed a significant reduction in parasite burden over free AR-12, both alone and when co-delivered with amphotericin B. Overall, this work displays that Ac-DEX particles can more aptly deliver HDTs that target macrophages to reduce drug toxicity and increase drug efficacy.

4. CONTROLLED RELEASE

Probably the broadest application of Ac-DEX is its use as a controlled release drug delivery vehicle. Similar to the payloads seen with vaccine formulations, small molecules, proteins, peptides, and nucleotides have all been encapsulated or adsorbed to Ac-DEX to achieve a desired effect. In addition, inorganic based silver carbine has been encapsulated into Ac-DEX to serve as an antibacterial agent.[24] Many of these formulations are the traditional emulsion based nano-/microparticles that are used for both vaccine and macrophage targeting applications. By varying emulsion parameters with Ac-DEX, it has been shown that the encapsulation of rapamycin is dependent on the molecular weight of the base dextran,[35] which corresponds to what was observed with the encapsulation of poly I:C.[23] Also using traditional emulsion chemistry, it was shown that a model protein enzyme (horseradish peroxidase), encapsulated in Ac-DEX particles, had enhanced stability compared to unencapsulated protein. Moreover, Ac-DEX protected the enzyme and its activity from −20 to 45 °C, while PLGA melted at these higher temperatures. As expected, homogenized particles maintained better activity of the enzyme over sonicated particles (Figure 7).[36]

Using Ac-DEX to encapsulate proteins has advantages over polyesters and polyanhydrides because the degradation products are pH-neutral and can therefore be less damaging to the encapsulated protein. In contrast to Ac-DEX, when PLGA degrades, the core of the PLGA particle becomes extremely acidic.[4] It is then not surprising that Ac-DEX has been used to deliver proteins and peptides for therapeutic treatment. Henniget al. compared the EE of a peptide in Ac-DEX particles versus PLGA. They observed a decreased EE with Ac-DEX over PLGA for positively charged peptides for PLGA terminated with a carboxylic acid. The higher

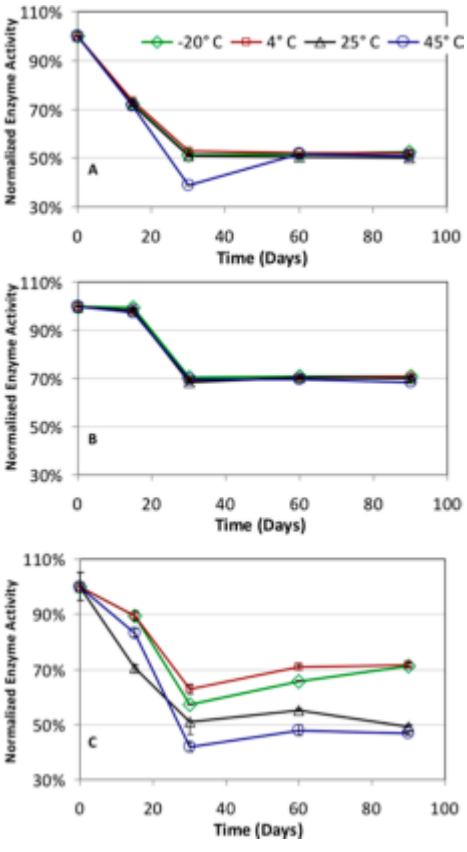

Figure 7. Activity of horseradish peroxidase when (A) encapsulated in sonicated Ac-DEX particles, (B) encapsulated in homogenized Ac-DEX particles, or (C) unencapsulated and stored at different temperatures as a dry powder. Reprinted with permission from ref 36. Copyright 2012 Elsevier.

encapsulation for PLGA is probably due to the interaction between the positive charge of the peptide and the negative charge of the carboxylic acid.[37] For neutral charged peptides and small molecules, Ac-DEX had higher EE. Other studies have encapsulated peptide into Ac-DEX particles[38] but have not compared their encapsulation to PLGA. Despite differences in EE, another advantage of Ac-DEX over polyesters is the tunable delivery. Suarez et al. illustrate this as an advantage in the delivery of basic fibroblast growth factor (bFGF) and myoglobin for treatment after myocardial infarction (MI). The tunability of release of these proteins afforded optimization of the release rates for the best therapeutic effect.[39] The temporal control of Ac-DEX was also illustrated to deliver a hepatocyte growth factor fragment for cardioprotective therapy.[40] As with the MI treatment, an optimum therapeutic effect was determined by varying the degradation rate of the polymer, underlining the importance of this Ac-DEX property.

For the delivery of nucleotides, polycations have been covalently attached to Ac-DEX to facilitate ionic absorption of siRNA,[41] resulting in increased knock-down compared to the free siRNA control. The increased intracellular trafficking over soluble siRNA of the Ac-DEX particles likely contributed to the increased siRNA efficacy.[41] Similarly, poly beta amino esters (PBAEs) were blended with Ac-DEX to deliver plasmid. Plasmid transfection in both HeLa and RAW macrophages was found to be dependent on the weight fraction of PBAE to Ac-DEX.[42]

Other constructs of Ac-DEX have been generated to offer controlled release, including porous microparticles, composite spray dried particles, electrosprayed microparticles, electrospun mats, and electrospun mat fragments called microconfetti (Figure 8). To mimic the large porous PLGA microparticles originally developed by Edwards et al.[43] Ac-DEX was made into porous microparticles, which display a significantly reduced density to volume ratio, compared to traditional emulsion particles. When modeled in a cascade impactor, the porous Ac-DEX particles had aerosol properties for deep lung penetration. The porous particles displayed a controlled release of the chemotherapeutic camptothecin as well as degradation-dependent release.[44] To advance lung delivery using Ac-DEX, nanoparticles made of the biopolymer were loaded with either tobramycin or paclitaxel[45,46] and then spray dried in a secondary matrix to form composite microparticles. Ac-DEX adjuvant microparticles, albeit not composite, have also been made through electrospray. Compared to emulsion, electrospray

affords a more scalable method that uses air as a continuous phase, in place of an aqueous or organic solution, resulting in increased EEs of compounds. The EE of resiquimod was increased almost 10-fold over emulsion with electrospray to form microparticles that could be delivered intravenously to treat L. donovani infection.[47] A method similar to electrospray, electrospinning, has also been used to generate controlled release nanofibrous scaffolds for Ac-DEX. By electrospinning Ac-DEX with different degradation rates, controlled release of resiquimod was observed, as well as a differential effect of resiquimod on macrophages.[47] The differential effect of Ac-DEX degradation rates aligns with the cardioprotective effects with the MI treatment with bFGF and myoglobin and also the release of saquinavir from electrospun fibers ground into injectable fragments called microconfetti.[48] Collier et al. illustrated that fragments of nanofibrous Ac-DEX scaffolds that are milled can afford nearly week-long release of the protease inhibitor saquinavir when injected subcutaneously. Microconfetti could not be fabricated from PLGA or PCL, even when milled under liquid nitrogen. The high glass transition temperature of Ac-DEX (~160−190 °C)[36] allowed electrospun nanofibrous scaffolds, loaded up to 50 w/w % with saquinavir, to be milled into small injectable pieces.[48]

Ac-DEX has also been used in the formation of Janus particles with PLGA.[49] By using electrohydrodynamic (EHD; electrospray) cojetting, Rahman et al. formed microparticles where one-half of the particle consists of PLGA, and the other half consists of a PLGA/Ac-DEX blend. They loaded the chemotherapeutic irinotecan into the part of the particle that consisted of Ac-DEX, and they were capable of releasing in a pH-sensitive manner.[50] Expanding on their previous work, Ross et al. then proceeded to use their Janus particles for the delivery of drugs to the cochlea in an animal model of cochlear implants. By using piribedil loaded microparticles, they were able to show extended release in vivo.[51] These controlled release studies illustrate that the range of degradation and processability afforded with Ac-DEX is much greater than that which is observed with PLGA, leading to better controlled release systems, as included in reviews by Miladi et al.[13] and Chifiriuc et al.[11]

5. DEVICES

The acid-sensitive acceleration in degradation as well as Ac-DEX's broadly tunable degradation make it an appealing candidate for incorporation into highly engineered devices. Ac-DEX has been used to more rapidly release insulin in response to changes in glucose,[52] as valves in mesoporous silicon,[53,54] and as vehicles to trap water for laser-assisted release of payload.[55] Gu et al. coated Ac-DEX microparticles with chitosan or alginate to give alternating charges. By creating a low acid environment with gluconic acid, one product of glucose and glucose oxidase, insulin encapsulated in the Ac-DEX particles is released at an accelerated rate in the presence of glucose. This device was shown to attenuate blood sugar in diabetic mice.[52] This is similar to the work that was done in the 1990s using poly ortho-esters as the pH-sensitive material.[8] Additionally, Wang et al. has incorporated anti-PD1 antibodies into Ac-DEX for microneedle applications.[56] By incorporating anti-PD1 into a polymeric microneedle, they show enhanced antibody efficacy. Also taking advantage of Ac-DEX's acid-sensitivity, two laboratories have reported the incorporation of the biopolymer into mesoporous silicon to work as valves to control the release of drug that has been absorbed into the inorganic material. Either by using different degradation rates of polymer or by exposing the composite particles to an acid-environment, drug can be released in a more controlled manner, compared to drug absorbed on mesoporous silicon alone.[53] Furthermore, Ac-DEX was used to functionalize the silicon, by attaching cell penetrating peptide to the biopolymer incorporated in the mesoporous silicon.[54] Beyond mesoporous silicon, Viger et al. trapped water in Ac-DEX microparticles fabricated via electrospray. They then heated the water into vapor using a near-IR laser, which results in destabilization of the Ac-DEX matrix and more triggered drug release.[55] These devices display the broad applicability of Ac-DEX.

6. COPOLYMER AND OTHER ACETALATED POLYMERS

To further enhance Ac-DEX, functional groups have been covalently attached to the polymer and copolymers have been formed to create new micelles and other drug delivery vehicles. Initially Ac-DEX was modified with oxime chemistry to covalently link cell penetrating peptide to the particle surface. This chemistry was used to attach the peptide with a fluorophore that then displayed strong covalent attachment to the peptide.[57] Also for enhanced targeting of Ac-DEX particles, mannose was ligated to the biopolymer to actively target the mannose receptor, which is highly expressed in immune cells. Mannose targeting resulted in increased MHC I presentation of OVA over conventional Ac-DEX particles.[58] To cationically charge the Ac-DEX particles, spermine[59] and diethylenetriamine (DET) grated poly(L-aspartic acid)[60] have been covalently bound to Ac-DEX. The spermine functionalized Ac-DEX resulted in better knock-down than sham siRNA, without a marked difference in cell viability.[59] For the DET grated poly(L-aspartic acid) functionalized to Ac-DEX particles,

both doxorubicin and plasmid were delivered to cancer cells with polymeric particles formed through emulsion and micelles. These carriers resulted in significant uptake of doxorubicin in cancer cells.[60] In addition to the peptide-DET-Ac-DEX micelles formed, poly(ethylene glycol) (PEG) has been covalently attached in two ways to Ac-DEX to form copolymer micelles with pH-sensitive triggers. With the addition of PEG to Ac-DEX with varying degradation rates, micelles were formed to deliver doxorubicin. The Ac-DEX-PEG micelles released drug in a pH-sensitive manner and illustrated increased cell death compared to PEG-b-polylactide (PLA) pH-insensitive micelles at some concentrations when cultured with HeLa cells.[61] PEG was also attached to Ac-DEX by adenine termination of the biopolymer and thymine termination of PEG to form a triblock polymer. Using Ac-DEX at different degradation rates resulted in differential pH-sensitive release of doxorubicin. All triblock micelles loaded with doxorubicin resulted in a significant decrease in cell viability when cultured with HeLa cells.[62] In each of these cases, the acid-sensitivity and/or degradation tunability of Ac-DEX was used to help facilitate better drug delivery.

In addition to copolymers, two acetalated polymers have been produced that display similar properties as the original Ac-DEX. Ace-DEX, which was used in several of the previously mentioned results,[21,31,33,52] is formed by the reaction of dextran and 2-ethoxypropene (leading to the use of the e in Ace over Ac), resulting in ethanol, in place of methanol, as a degradation product. Ace-DEX displays similar degradation tunability as Ac-DEX as well as similar cytocompatibility (Figure 9).[63] Using similar chemistry, Ace-Inulin was formed (Figure 10). Whereas dextran is immunologically inert, inulin has naturally occurring immune stimulating properties, allowing Ace-Inulin to serve as its own adjuvant in vaccine formulations. Blending Ace-Inulin with Ace-DEX results in better encapsulation of protein, but decreased immune stimulatory activity, as measured through tumor necrosis factor-alpha (TNF-α) production by RAW macrophages. Overall, an Ace-Inulin blended OVA vaccine did elicit strong total IgG antibodies on order with OVA and alum.[64] Similarly, silylated dextran and inulin have shown tunable properties and generation of IgG.[65] These second generation Ac-DEX polymers have the same beneficial properties of Ac-DEX with some added features, including more benign degradation products and immune stimulating capabilities.

7. CONCLUSION

In conclusion, we have reviewed the emerging biopolymer acetalated dextran (Ac-DEX). Ac-DEX has several features which make it a unique biodegradable polymer, including facile synthesis, acid-sensitivity, and tunable degradation rates. For these reasons it has emerged as a top candidate for applications in vaccines, targeted host-directed therapies to macrophages, controlled release of drug, chemotherapeutic delivery, engineered drug delivery devices, and as copolymers in drug and vaccine carriers. Ac-DEX has displayed delivery of small molecules, proteins, peptides, nucleotides, and inorganic compounds, illustrating the broad applicability of this material. Moreover, it has been used to modify inorganic mesoporous silicon, spun into nanofibrous mats, made into microconfetti, and covalently bound to other polymers to form micelles. Current uses of this biopolymer are merely the tip of the iceberg, the applications of Ac-DEX will certainly expand in the coming years.

Biographies

Eric M. Bachelder gained extensive immunological experience while completing his graduate studies in Dr. Polly Matzinger's lab at the National Institutes of Health (NIH), National Institute of Allergy and Infectious Diseases (NIAID). During his graduate studies, he studied

DOI: 10.1021/acs.chemrev.6b00532
Chem. Rev. 2017, 117, 1915−1926

the interaction of T-cells and dendritic cells. After completing his Ph.D. in Chemical Engineering, he joined Prof. Jean Fréchet's lab at the University of California, Berkeley's chemistry department for a postdoc. While there, Dr. Bachelder invented various biodegradable polymers for vaccine and drug delivery applications, including Acetalated Dextran (Ac-DEX). Dr. Bachelder continued his work on Ac-DEX as an Assistant Professor at the Ohio State University and currently at the University of North Carolina at Chapel Hill. The focus of Dr. Bachelder's research program is to develop novel drug delivery moieties for the formulation of vaccines, infectious disease treatments, and autoimmune therapies.

Erica N. Pino received her B.S. in Biology from the Massachusetts Institute of Technology in 2013. Her undergraduate thesis work in the laboratories of Dr. Robert Desimone and Dr. Edward Boyden centered on characterizing heat and light propagation through rodent cortex to establish safe guidelines for optogenetic studies in nonhuman primates. Following graduation, she continued research in the Desimone lab, focusing on optogenetic inactivation of frontal eye field neurons during memory-guided saccade tasks. She is now a graduate student in the Ainslie lab, working toward her Ph.D. in the Division of Pharmacoengineering and Molecular Pharmaceutics at the University of North Carolina at Chapel Hill.

Kristy M. Ainslie is an Associate Professor with appointments in the Division of Pharmacoengineering and Molecular Pharmaceutics, within the Eshelman School of Pharmacy, and the Department of Biomedical Engineering at the University of North Carolina at Chapel Hill. Her research focuses on the use of novel micro- and nanoscaled carriers for the modulation of immune responses to create vaccines for and therapies against infectious diseases. Previously, she was an Assistant Professor in the Division of Pharmaceutics and Pharmaceutical Chemistry at The Ohio State University. As a postdoctoral scholar at the University of California, San Francisco, she researched the microfabrication of oral drug delivery vehicles and the immune response of nanobiomaterials. Previously, she studied biosensors at the Naval Research Laboratory in Washington, DC, and completed a Ph.D. in Chemical Engineering at The Pennsylvania State University in the application of nanobiomaterials for antifouling implant surfaces.

Received 14 September 2007/Accepted 10 December 2007

In 2003, severe acute respiratory syndrome coronavirus (SARS-CoV) emerged and caused over 8,000 human cases of infection and more than 700 deaths worldwide. Zoonotic SARS-CoV likely evolved to infect humans by a series of transmission events between humans and animals for sale in China. Using synthetic biology, we engineered the spike protein (S) from a civet strain, SZ16, into our epidemic strain infectious clone, creating the chimeric virus icSZ16-S, which was infectious but yielded progeny viruses incapable of propagating in vitro. After introducing a K479N mutation within the S receptor binding domain (RBD) of SZ16, the recombinant virus (icSZ16-SK479N) replicated in Vero cells but was severely debilitated in growth. The in vitro evolution of icSZ16-SK479N on human airway epithelial (HAE) cells produced two viruses (icSZ16-SK479N D8 and D22) with enhanced growth on HAE cells and on delayed brain tumor cells expressing the SARS-CoV receptor, human angiotensin I converting enzyme 2 (hACE2). The icSZ16-SK479N D8 and D22 virus RBDs contained mutations in ACE2 contact residues, Y442F and L472F, that remodeled S interactions with hACE2. Further, these viruses were neutralized by a human monoclonal antibody (MAb), S230.15, but the parent icSZ16-SK479N strain was eight times more resistant than the mutants. These data suggest that the human adaptation of zoonotic SARS-CoV strains may select for some variants that are highly susceptible to select MAbs that bind to RBDs. The epidemic, icSZ16-SK479N, and icSZ16-SK479N D22 viruses replicate similarly in the BALB/c mouse lung, highlighting the potential use of these zoonotic spike SARS-CoVs to assess vaccine or serotherapy efficacy in vivo.

Diseases caused by emerging viruses such as human immunodeficiency virus, Ebola virus, influenza virus H5N1, West Nile virus, and dengue virus have had a profound impact on global public health (28). In 2003, a novel coronavirus, severe acute respiratory syndrome coronavirus (SARS-CoV), emerged suddenly as the causative agent of SARS and spread worldwide, causing about 8,000 cases and ffi700 deaths (3, 17, 41). SARS-CoV most likely evolved from viruses circulating within the Chinese horseshoe bat and other bat species that are believed to be the natural animal reservoirs (18). Within live-animal markets in the Guangdong region of China, it is hypothesized that the close cohabitation of bats and palm civets allowed for subsequent cross-species transmission and amplification of bat strains in civets (9, 18). Palm civets then served as an intermediate host for the subsequent viral evolution of strains that could infect and transmit between humans (18). Clinical data suggest that the sporadic early human SARS-CoV infections were significantly less pathogenic than later ones and that a progressive series of adaptive mutations was necessary for increased human-to-human transmission and the expanding phases of the epidemic (2, 9, 41). Despite initial reports that civet strains SZ16 and SZ3 could be propagated in cell culture, subsequent studies have indicated that these viruses could not be successfully maintained in culture, thereby hampering our understanding of their pathogenicities and mechanisms of cross-species transmission in humans (19).

Within the past 4 years, multiple newly emerging coronaviruses of human relevance have been identified, highlighting the emerging disease potential of the coronavirus family (35, 41, 50, 53). SARS-CoV and human coronavirus HKU1 are newly emerging members of coronavirus genogroup II, and both cause pneumonic disease in humans, with SARS-CoV being the most pathogenic of the known human coronaviruses (7, 17, 41, 52, 53). Viruses related to the SARS-CoV epidemic strain have recently been found in Chinese horseshoe bats during surveillance of wild animals in Hong Kong (18). Since viruses similar to the epidemic strain have been found circulating within zoonotic pools, there is the potential for yet another reemergence (18). Moreover, a promiscuous RNA-dependent RNA polymerase coupled with high-frequency recombination rates makes the evolution of future human coronavirus pathogens a real possibility (6, 36, 57).

The coronavirus spike glycoprotein (S) is a key determinant of host specificity, and elucidating the molecular mechanisms of viral host expansion may help us understand the events that rendered SARS-CoV pathogenic to humans (16, 24). Virus sequence data isolated throughout the course of the epidemic suggest that the S gene was under heavy positive selection

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

during the early phase of the epidemic but eventually stabilized as the epidemic progressed (2). The S protein is 1,225 amino acids (aa) in length and can be divided into two main functional domains, S1 and S2. The S1 region (aa 17 to 756) contains the receptor binding domain (RBD; aa 318 to 510), while the S2 region (aa 757 to 1225) contains the two heptad repeat regions responsible for viral fusion and a transmembrane domain (aa 1189 to 1227) that anchors S to the viral envelope. SARS-CoV entry into the host cell is mediated by a receptor, angiotensin I converting enzyme 2 (ACE2), and perhaps other coreceptors (15, 22). ACE2 has been detected on the apical surfaces of ciliated cells within the lung epithelia as well as in the kidneys and colon (12). After S and receptor binding, the virus enters the cell by receptor-mediated endocytosis. Cleavage of the SARS-CoV S by cathepsin L within the endosome is required for SARS-CoV infection and precedes fusion (42).

Sequences isolated throughout the initial epidemic from 2002 to 2003 and during the reemergence from 2003 to 2004 chronicle the mutations in S that may have allowed for host expansion. During the epidemic and the reemergence, the early 2003 SARS-CoV animal isolate, SZ16, and the 2004 reemergent human isolate, GD03, were among the most divergent viruses isolated from civets and humans, respectively. SARS-CoV SZ16 was identified in palm civets in live-animal markets within the Guangdong region of China during the epidemic, and its S protein differs from that of the epidemic strain, SARS Urbani, in 18 amino acids, 16 of which reside in the S1 domain. Using pseudotyped viruses, recent work has shown that the mutation of residue 479 within the SZ16 RBD was sufficient to allow for the host range expansion of zoonotic SARS-CoV spike-bearing pseudovirus to infect human cells (21, 24).

In this study, we describe the synthetic construction and characterization of a SARS-CoV chimera bearing a zoonotic SZ16 S protein. Importantly, we find that the mutations acquired during the in vitro evolution of a zoonotic, S-bearing recombinant virus in human airway epithelial (HAE) cells can vary from those that occurred during the epidemic, highlighting the adaptive plasticity of the zoonotic S protein. Also, these data suggest that HAE cells can be used as a model to evaluate the possible avenues of SARS-CoV zoonotic S evolution toward the efficient infection of human cells. Lastly, recombinant viruses bearing zoonotic S proteins replicated efficiently in mice and will serve as a valuable tool in assessing the efficacies of vaccines and therapies.

MATERIALS AND METHODS

Viruses and cells. The recombinant epidemic virus strain "icSARS" (GenBank accession no. AY278741), icSZ16-S (GenBank accession no. AY304488), and the icSZ16-S K479N, icSZ16-S K479N D8, and icSZ16-S K479N D22 mutant strains were propagated on Vero E6 cells as described previously (58). Virus stocks used throughout this study were grown and titers were determined by plaque assays with Vero E6 cells as described previously (58). Vero E6 and delayed brain tumor (DBT) cells were grown in minimal essential medium (Invitrogen, Carlsbad, CA) supplemented with 10% FCII (HyClone, South Logan, UT) and gentamicin/kanamycin (UNC Tissue Culture Facility). Mink lung epithelial cells (Mv1lu) were grown in Dulbecco's minimal essential medium (Invitrogen, Carlsbad, CA) supplemented with 10% FCII (HyClone, South Logan, UT) and gentamicin/kanamycin (UNC Tissue Culture Facility). HAE cells were obtained from airway tissues harvested from patients undergoing elective surgery according to the UNC Institutional Review Board-approved protocols of the UNC Cystic Fibrosis Center Tissue Culture Core. Briefly, primary cells were expanded on plastic to generate passage 1 cells and plated at a density of 250,000 cells per well on permeable Transwell-Col (12-mm-diameter) supports (8, 33). HAE cell cultures were generated by the provision of an air-liquid interface for 4 to 6 weeks to form well-differentiated, polarized cultures that resemble in vivo pseudostratified mucociliary epithelia (33). All virus work was performed in a class II biological safety cabinet in a certified biosafety level 3 laboratory containing redundant exhaust fans and by laboratorians wearing Tyvek suits and powered air-purifying respirators as described previously (56).

Construction of chimeric SARS-CoVs bearing the SZ16 spike protein icSZ16-S. The infectious clone of the epidemic strain from R. Baric's laboratory is divided into six subgenomic cDNA clones (A to F) that span the SARS-CoV genome. The first two-thirds of the S gene is located within the icSARS E fragment (nucleotides [nt] 21492 to 24056), and the last third is located within the icSARS F fragment (nt 24057 to 25259). A synthetic DNA containing SZ16 nt 21541 to 24056 was purchased from Blue Heron Technology (Bothell, WA). The fragment was digested with AgeI and XbaI (NEB, Ipswich, MA) and cloned into the existing icSARS-E pSMART plasmid, replacing the Urbani S glycoprotein with the SZ16 variant sequence to create icSZ16-E pSMART. Within the SARS F fragment, the two remaining coding changes of the SZ16 S were introduced via PCR and the class II restriction enzyme AarI. Briefly, three amplicons, A, B, and C, were generated by PCR using Expand high-fidelity polymerase (Roche, Indianapolis, IN). The primer pairs used are as follows: amplicon A, PasIF (5′-CTGTTTTCCCTGGGATCGC-3′) and AarIM1NR (5′-NNNNNNCACCTGCTTTTGGGCAACTCCAATGCC-3′); amplicon B, AarIM1NF (5′-NNNNNNCACCTGCAGTTGCCCAAAATGTTCTCTATGA GAAC-3′) and AarIM2NR (5′-NNNNNNCACCTGCATTTCTTCTTGAATG TTGACGACAGAAG-3′); and amplicon C, AarIM2NF (5′-NNNNNNCACCT GCTCAAGAAGAAATTGACCGCCTC-3′) and BamHIR (5′-CATAAATTG GATCCATTGCTGG-3′). Amplicons A, B, and C were digested with AarI for 1.5 h at 37°C (Fermentas, Burlington, Ontario, Canada), gel purified, and ligated to create the fragment ABC. The ABC ligation products were gel purified, and TA was cloned into TOPO-XL (Invitrogen, Carlsbad, CA) to create pTOPO-XL ABC. The pTOPO-XL ABC subclones were confirmed by sequencing. pTOPO-XL ABC was BamHI digested at 37°C for 1 h, which released a 2,059-nt fragment containing the icSZ16 F fragment S sequence. icSARS F-pSMART was digested with BamHI at 37°C for 1 h, which excised the epidemic strain S sequence and released a 5,749-bp vector fragment. The 2,059-bp SZ16 insert and the 5,749-bp vector fragments were gel purified using a QIAquick gel purification kit (Qiagen, Valencia, CA) and ligated (NEB, Ipswich, MA) to create icSZ16 F-pSMART.

Construction of the chimeric icSZ16-S K479N mutant. The icSZ16-E pSMART sequence for S residue 479 was mutated from lysine (AAA) to an asparagine (AAT) using overlap PCR. Amplicon A (NcoIF [5′-TGTTTCTAA ACCCATGGGTACACAG-3′] and SZ16479R [5′-CCATAATCATTTAATGG CCAATAAC-3′]) and amplicon B (SZ16479NF [5′-GTTATTGGCCATTAAA TGATTATGG-3′] and XbaIR [5′-GGGCCCTCTAGAGATCGAGC-3′]) were generated using Expand high-fidelity polymerase (Roche, Indianapolis, IN). To join the fragments, amplicons A (1,010 bp) and B (1,153 bp) were used as templates in overlapping PCR with primers NcoIF and XbaIR. The final AB amplicon was purified using a Qiagen PCR purification kit (Qiagen, Valencia, CA) and digested with NcoI and XbaI (NEB, Ipswich, MA) for 1 h at 37°C. The digested amplicon (2.2 kb) was gel purified using a QIAquick gel purification kit (Qiagen, Valencia, CA), ligated to the 5.3-kb NcoI/XbaI fragment of icSARS SZ16-E pSMART, and sequence verified.

Isolation of recombinant viruses. From the ligation of appropriate infectious clone fragments, icSZ16-S or icSZ16-S K479N full-length chimeric cDNA was generated, and full-length transcripts were synthesized, mixed with polyadenylated N gene transcripts, and then electroporated into cells as previously described (56). Clarified supernatants from the icSZ16-S or icSZ16-K479N electroporations were passaged onto naive Vero E6 cells to confirm the presence of replicating virus. If a cytopathic effect (CPE) was not detected, viruses were passaged every 48 h onto Vero E6 cells until cytopathology was observed. With icSZ16-S K479N, a mild CPE was observed at passage 3 (p3), and a more robust CPE was seen by p6. The icSZ16-S K479N p3 and p6 viruses were plaque purified in Vero E6 cells. The S, 3a, E, and M genes of the recombinant viruses were sequence verified, and stocks were grown in T75 flasks and stored at −80°C for future use.

RT-PCR to detect the subgenomic leader containing transcripts. Reverse transcriptase (RT)-PCR to detect the subgenomic leader containing transcripts was performed to demonstrate viral replication. RNA from virus-infected cells was isolated using TRIzol reagent (Invitrogen, Carlsbad, CA), according to protocol. One to five micrograms of total RNA was used to generate cDNA by

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

Superscript II (Invitrogen, Carlsbad, CA), using random hexamer primers (Invitrogen, Carlsbad, CA). cDNA was then used as a template for the PCR using *Taq* polymerase (NEB, Ipswich, MA) with a leader forward primer (CTCTTG TAGATCTGTTCTCTAAACGAAC) and a reverse primer in the M gene (TT ACTGTACTAGCAAAGCAATATTGTCG). The detection of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (primer GAPDHF [5′-CATGGGGAA GGTGAAGGTCG-3′] and primer GAPDHR [5′-TTGATGGTACATGACAA GGTGC-3′]) messages by RT-PCR was done as a positive control. The PCR products were separated by gel electrophoresis on 1.8% agarose–Tris-acetate-EDTA gels and visualized by ethidium bromide staining.

In vitro evolution of icSARS SZ16 K479N in HAE cell cultures for 22 days. HAE cell cultures were created as described previously (43). The cultures were infected with 10^5 PFU of icSARS K479N in a 200-μl volume. After a 2-h infection, the inoculum was removed, and the cells were washed briefly with Dulbecco's phosphate-buffered saline (DPBS) and then maintained for 4 days. After 4 days of infection, the apical surfaces of the cultures were rinsed, and supernatants were placed onto the apical surfaces of fresh cultures for 1 h, washed, and maintained for another 4 days. Apical washes were then plaque purified to isolate the icSZ16-S K479N D8 virus. A total of 200 μl of day 8 supernatants was used to infect naive HAE cell cultures as described above, and the cultures were passaged two additional times at 4-day intervals and then three times every 48 h to preferentially enrich for more efficiently replicating virus variants. After 22 days of selection for efficient growth in HAE cells, the apical surfaces were rinsed and the supernatants were plaque purified to isolate the icSZ16-S K479N D22 virus. Plaques were expanded on 60-mm dishes, and RNA was isolated using TRIzol (Invitrogen Carlsbad, CA). Amplicons spanning from the S, 3a, E, and M genes were generated by RT-PCR and directly sequenced.

Generation of hACE2-expressing DBT cells. A plasmid carrying an N-terminal myc-tagged human ACE2 (hACE2) was kindly donated by M. Farzan of Harvard Medical School. The hACE2 gene was amplified by PCR using Expand high-fidelity polymerase (Roche, Indianapolis, IN) (ACE2For [5′-CACCATGTCAA GCTCTTCCTGGCTCC-3′] and ACE2Rev [5′-CTAAAAGGAGGTCTGAAC ATCATCAGTG-3′]). Amplicons were gel purified using the QIAquick gel purification kit (Qiagen, Valencia, CA) and cloned into pcDNA3.1/V5-His (Invitrogen, Carlsbad, CA) according to protocol to create pcDNA3.1/V5-His hACE2. The ACE2 gene plasmid was sequence verified. DBT cells were transfected with 4 μg of pcDNA3.1/V5-His hACE2 using Fugene reagent (Roche, Indianapolis, IN). After 24 h, the cells were placed under drug selection using 700 μg/ml of G418 (Invitrogen, Carlsbad, CA) in complete growth medium and remained under drug selection throughout all experiments. The cells were passaged four times, sorted for high ACE2 expression by flow cytometry, and then expanded under drug selection before use.

Growth curve analysis of HAE, Vero E6, DBT hACE2, or DBT cells. HAE cells were infected with 4.4×10^4 PFU of the recombinant epidemic strain icSARS, icSZ16-S K479N p3, icSZ16-S K479N D8, or icSZ16-S K479N D22 for 2 h at 37°C, after which the inoculum was removed and the apical surface rinsed with DPBS. At 0, 6, 12, 24, 36, 48, and 72 h postinfection (hpi), the apical surfaces of the HAE cells were rinsed with 200 μl DPBS and the samples stored at −80°C until titration by plaque assay. Vero E6 and DBT hACE2 cells were infected with icSARS, icSZ16-S K479N p3, icSZ16-S K479N p6, icSZ16-S K479N D8, or icSZ16-S K479N D22 at a multiplicity of infection (MOI) of 0.01 for 1 h at 37°C, after which the inoculum was removed, the monolayer was rinsed with DPBS, and growth medium was added. DBT cells were infected in a similar manner and with the same panel of viruses as the Vero E6 and DBT hACE2 cells, except that icSZ16-S K479N p3 was excluded from the experiment. The cell media were sampled at 0, 6, 12, 24, and 36 hpi, and the samples were stored at −80°C until titers were determined by plaque assay (56). The growth curve data presented are representative of two separate experiments.

Immunohistochemistry of infected HAE cells. To detect SARS-CoV antigens in HAE cells, infected or mock-infected cultures were fixed in 4% paraformaldehyde (PFA) for 24 h, transferred to 70% ethanol, and prepared as paraffin-embedded histological sections by the UNC Cystic Fibrosis Center Morphology and Morphometrics Core. After deparaffinization, histological sections were incubated for 1 h in PBS containing 3% bovine serum albumin. Primary antibodies directed against SARS N or tubulin were applied at a 1:100 dilution in PBS with 1% bovine serum albumin overnight and detected with fluorescein isothiocyanate or Texas Red secondary antibodies (anti-mouse antibodies conjugated to Texas Red; Jackson ImmunoResearch). Immunofluorescence was visualized with a Leica Leitz DMIRB inverted fluorescence microscope equipped with a cooled-color, charge-coupled digital camera (MicroPublisher, Q-Imaging). A tricolor filter cube set (green fluorescent protein-Texas Red-DAPI [4′,6-diamidino-2-phenylindole]) was used to show the morphology of the tissue section (by combining low autofluorescence levels across the three filters), thus aiding the determination of fluorescent-antibody localization to specific regions of the cells.

Plaque reduction neutralization titer assay. Neutralizing titers were determined by plaque reduction neutralization titer assay (PRNT) (40). Twenty-four hours prior to infection, six-well plates were seeded with 5×10^5 Vero E6 cells/well. A human monoclonal antibody (MAb), S230.15, directed against the SARS-CoV RBD and an isotype control antibody, D2.2, directed against cholera toxin were kindly provided by A. Lanzavecchia. The MAbs were serially diluted twofold and incubated with 100 PFU of either icSARS, icSZ16-S K479N p6, icSZ16-S K479N D8, or icSZ16-S K479N D22 for 1 h at 37°C. Virus and antibodies were then added to six-well plates of Vero E6 cells in duplicate and incubated at 37°C for 1 h, after which the cells were overlaid with 3 ml of 0.8% agarose in medium. The plates were incubated for 48 h at 37°C and stained with neutral red for 3 h, and the plaques were counted. The percentages of neutralization were calculated as follows: 1 − (number of plaques with antibody/number of plaques without antibody) × 100%.

Infection of 6-week-old and senescent BALB/c mice. Six-week-old female BALB/c mice (Charles River, Wilmington, MA) or 12-month-old female BALB/c mice were anesthetized with a ketamine and xylazine mixture administered intraperitoneally in a 50-μl volume. Each mouse was inoculated with 1×10^5 PFU/50 μl of icSARS, icSZ16-S K479N p6, or icSZ16-S K479N D22 intranasally (10 mice for each virus for the 6-week-old animals; 12 mice for each virus for the 12-month-old animals), and weight was monitored daily for 4 days postinfection. On days 2 and 4, three mice per group were sacrificed by isoflurane overdose, and the lungs were removed for virus titer determination. One-half of each lung was frozen at −80°C until titration by plaque assay. The lungs were weighed and homogenized, and PBS was added to generate a 20% solution. The solution was then clarified by centrifugation and serially diluted for use in a standard plaque assay with Vero E6 cells (56).

Phylogenetic analysis of SARS-CoV spikes and computer modeling. Nucleotide and protein sequence alignments of Urbani (GenBank accession no. AY27841), HKU3 (GenBank accession no. DQ022305), HC/SZ/61/03 (GenBank accession no. AY515512), SZ16 (GenBank accession no. AY304488), GD03 (GenBank accession no. AY525636), GZ02 (GenBank accession no. AY390556), and CUHK-W1 (GenBank accession no. AY278554) were created using ClustalX v1.83 (37). A neighbor joining tree was generated from the ClustalX nucleotide sequence alignment, bootstrapped 1,000 times, and exported into TreeView to create neighbor joining tree graphics (31). The numbers at each node represent the corresponding bootstrap values.

The crystal structure coordinates of the SARS-CoV RBD interacting with the hACE2 receptor (PDB code 2AJF) were used as a template to generate each set of mutations using the Rosetta Design web server (http://rosettadesign.med.unc.edu/) (21). In each case, the SARS-CoV RBD structure was analyzed using the molecular modeling tool MacPyMol (DeLano Scientific) to determine which amino acids were proximal to the amino acid(s) being targeted for replacement. Briefly, each amino acid to be altered was highlighted, and all other amino acids within an interaction distance of 5 angstroms were identified. Using the Rosetta Design website, the amino acid replacements were incorporated, and all amino acids within the 5-angstrom interaction distance were relaxed to allow the program to repack the side chains to an optimal energetic state. This process was repeated for each mutation and series of mutations. Ten models were generated for each set of mutations, and the best model, based on the lowest energy score, was selected and further evaluated using MacPyMol.

RESULTS

Construction and characterization of icSZ16-S and icSZ16-S K479N viruses. Public genetic databases and synthetic biology were harnessed to rapidly translate electronic S gene sequence information into S gene DNA fragments. The SZ16 virus was isolated in live-animal markets in China, and its sequence was published in 2003. When nucleotide sequences of S proteins isolated over the course of the epidemic are compared, the SZ16 S is similar to viruses isolated from Chinese horseshoe bats (HKU3) and to the evolved human-adapted strains (Fig. 1A). The SZ16 S differs from that of the epidemic strain in 18 amino acid positions, 16 of which reside in the S1 region and may well represent the progenitor strains for the 2003 human epi-

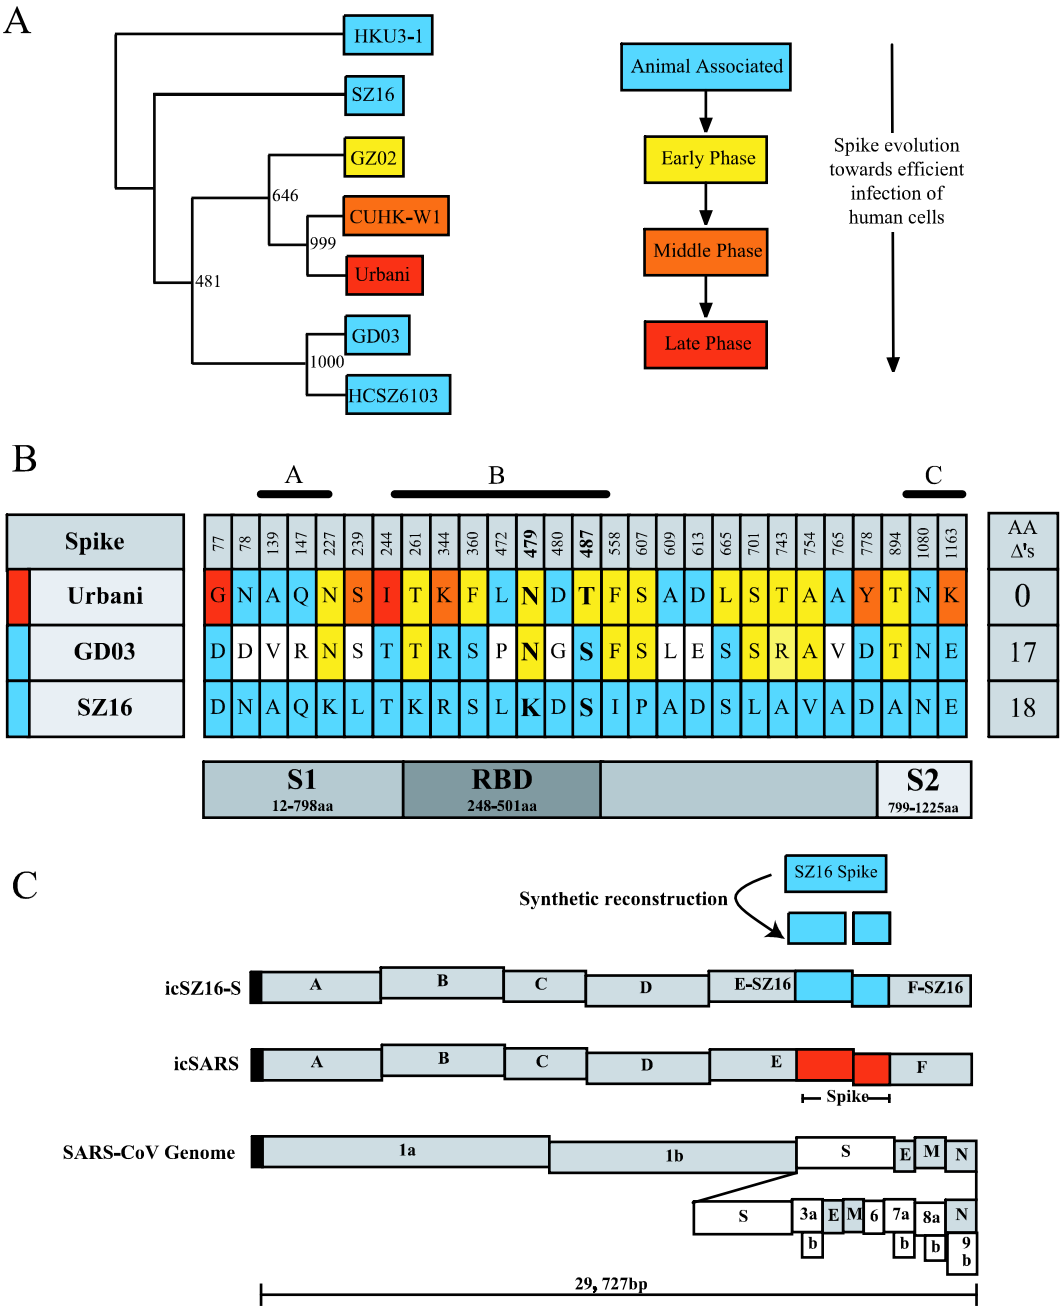

FIG. 1. Phylogenetic relationships of zoonotic SARS-CoV and construction of zoonotic spike protein chimeras within the SARS-CoV infectious clone. The colors in panels A, B, and C denote the phase of the SARS-CoV epidemic at which the viruses or amino acid residues evolved: blue, animal associated; yellow, early phase; orange, middle phase; and red, late phase. (A) Neighbor joining tree constructed from nucleotide sequences of various SARS-CoV S genes. The numbers represent bootstrap values based on 1,000 bootstrap replicates. (B) Spike protein amino acid differences between Urbani, GD03, and SZ16. Known neutralizing epitopes are denoted A, B, and C. (C) Schematic of infectious clone fragments A to F and the SARS-CoV genes contained therein. Using synthetic biology and site-directed mutagenesis, we reconstructed the SZ16 S that was then inserted into our infectious clone, replacing the epidemic strain S.

demic. Much of the SZ16 sequence variability maps in and around the three known neutralizing epitopes marked as regions A, B, and C in Fig. 1B, suggesting that human MAbs derived from human SARS-CoV infections might be less efficacious against SZ16 early civet isolates. As the SZ16 virus could not be successfully maintained in culture, we used synthetic biology and reverse genetics to molecularly resurrect a recombinant and genetically modifiable SARS-CoV bearing the SZ16 S glycoprotein (icSZ16-S) (Fig. 1C).

Although icSZ16-S recombinant virus infection was not evident by cytopathology-based assays or by plaque assay, RT-PCR confirmed the presence of virus replication within the electroporated cell culture by detecting the subgenomic leaders containing transcripts for open reading frames 3a, E, and M

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

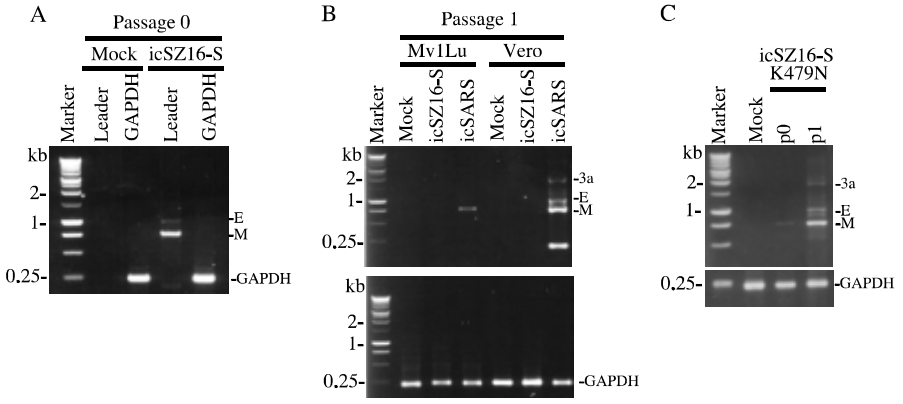

FIG. 2. SARS-CoV SZ16 spike protein chimera icSZ16-S replicates in Vero E6 cells, but infection cannot be passed in culture until a point mutation (K479N) is introduced within the RBD. The expected sizes of the target RT-PCR products are as follows: for 3a, 1,796 bp; E, 949 bp; M, 666 bp; and GAPDH, 235 bp. (A) RT-PCR for the leader containing transcripts detects actively replicating genomic RNA. RT-PCR using RNA extracted from Vero E6 cells transfected with genomic icSZ16-S RNA (passage 0) detects transcripts for the E and M genes of icSZ16-S. (B) The transfer of icSZ16-S supernatants from passage 0 to naive Vero E6 or mink lung epithelial Mv1Lu cells does not result in a productive infection. As a positive control, Vero E6 and Mv1Lu cells were successfully infected with epidemic strain supernatants, as replication was detected by the presence of the leader containing transcripts. (C) In contrast to wild-type icSZ16-S, a point mutation (K479N) in the icSZ16-S spike protein allows for passage of icSZ16-S K479N virus into Vero E6 cells.

(Fig. 2A). The transfer of the icSZ16-S supernatants from the electroporated cell culture to a naive Vero E6 or a mink lung epithelial (Mv1Lu) cell culture did not result in a productive infection, as the leader containing transcripts was not detected (Fig. 2B). As a positive control, we passaged icSARS supernatants to Vero E6 and Mv1Lu cell cultures, and both infections resulted in detectable wild-type virus replication by RT-PCR (Fig. 2B).

Since the icSZ16-S genomic RNA was capable of replicating in Vero E6 cells but the progeny virions were incapable of reinfection and amplification, we hypothesized that the infection was blocked due to inefficient S glycoprotein and ACE2 receptor interaction. In 2005, Li et al. crystallized the RBD of SARS-CoV bound to ACE2 and proposed that residues 479 and 487 of the civet S inhibited efficient usage of the hACE2 receptor (21). Using site-directed mutagenesis, we changed residue 479 of the SZ16 S from lysine to the more human tropic asparagine (K479N) and constructed and recovered the recombinant virus (icSZ16-S K479N). Unlike icSZ16-S virus infection, icSZ16-S K479N infection could be passed on to Vero E6 cell cultures by the transfer of supernatants to naive cell cultures (Fig. 2C), providing direct support for the hypothesis that SZ16 infection of human and/or primate cells is blocked by the civet S residue at position 479.

In vitro evolution of icSZ16-S K479N virus in primary HAE cell cultures. Zoonotic reintroductions represent the most likely mechanism for the reemergence of epidemic SARS-CoV strains in human populations. The SZ16 S K479N mutation permitted binding and entry into primate cells, but our preliminary data suggested that infections of HAE were inefficient (data not shown). To select for civet viruses with enhanced growth in HAE cells, cultures were apically infected with icSZ16-S K479N and maintained and passaged for a total of 22 days. The virus isolated after 8 days in culture, icSZ16-S K479N D8, contained one mutation from tyrosine to phenylalanine at position 442 within the RBD (Y442F). The virus recovered after 22 days in culture, icSZ16-S K479N D22, contained the Y442F mutation as well as an additional mutation within the RBD from leucine to phenylalanine at position 472 (L472F). No other coding mutations were found in the S, 3a, E, or M genes. Interestingly, both 442 and 472 are contact residues between S and ACE2 according to the reported crystal structure (21).

The evolved icSZ16-S K479N D8 and D22 viruses exhibit growth kinetics similar to those of the wild type in various cell types. The growth fitness of icSARS, icSZ16-S K479N p3, and the HAE-cell-evolved icSZ16-S K479N D8 and D22 viruses was assessed with HAE cells, Vero E6 cells, murine DBT cells stably expressing hACE2, and nonpermissive murine DBT cells. HAE cell cultures were infected with 4.4 # 10^4 PFU of virus for 2 h and then rinsed, and apical wash samples were taken at various intervals over 72 hpi to monitor virus growth. The epidemic strain, icSARS, grew to peak titers approaching 10^7 PFU/ml by 72 hpi (Fig. 3A). icSZ16-S K479N p3 grew poorly in the HAE cell cultures, with peak titers reaching only 10^3 PFU/ml (Fig. 3A). Compared to the epidemic strain, the icSZ16-S K479N D22 virus grew with similar growth kinetics at early time points, but peak titers were reduced by about 1 log and approached $ 10^6 PFU/ml by 72 hpi (Fig. 3A). The growth of the icSZ16-S K479N D8 virus lagged at early time points but recovered to peak titers similar to that of the icSZ16-S K479N D22 virus (Fig. 3A). In Vero E6 cells, the epidemic strain and the icSZ16-S K479N D22 virus reached peak titers of 10^7 PFU/ml 24 hpi, while icSZ16-S K479N D8, icSZ16-S K479N p3, and icSZ16-S K479N p6 grew to 10^5 PFU/ml (Fig. 3B).

To model the SARS S and hACE interactions within the primary HAE cells and to prove that these mutations were influencing docking and entry via hACE2, we constructed DBT cells that stably express hACE2. In comparison to those of HAE cells, viral growth kinetics were more rapid in DBT-hACE2, although the overall trends in growth among viruses were more or less conserved. In DBT-hACE2 cells, icSARS replicated to peak titers of 10^7 PFU/ml by 24 hpi and then diminished over time to 10^6 PFU/ml by 36 hpi (Fig. 3C).

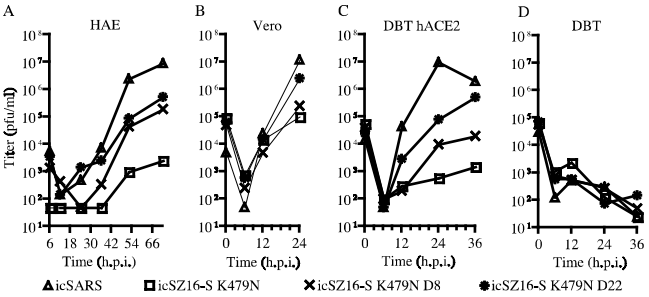

FIG. 3. Growth curve analysis of the mutant virus panel in HAE, Vero E6, DBT-hACE2, and DBT cells. (A) HAE cell cultures were infected with 4.4 # 10^4 PFU/200 " l of the indicated viruses for 2 h at 37°C. The inoculum was removed, and the apical surfaces were rinsed with DPBS. Apical-surface washes were performed at 0, 6, 12, 24, 36, 48, and 72 hpi. Virus titers were assessed for Vero E6 cells by a standard plaque assay. (B to D) Vero E6, DBT-hACE2, and DBT cells (respectively) were infected with the indicated viruses at an MOI of 0.01 for 1 h at 37°C. The inoculum was removed, cultures were rinsed with DPBS, and growth medium was added. The medium was sampled at 0, 6, 12, 24, and 36 hpi, and virus titer was assessed by plaque assay on Vero E6 cells. The data presented are representative of two separate experiments.

Similarly to the HAE model, early growth of the icSZ16-S K479N D22 virus was more rapid than that of the icSZ16-S K479N D8 virus in DBT-hACE2, but the growth of icSZ16-S K479N D8 virus never matched the icSZ16-S K479N D22 virus growth even after 36 hpi (Fig. 3C). Similarly to the HAE model, the icSZ16-S K479N p3 and the icSZ16-S K479N p6 viruses replicated poorly in DBT-hACE2 cells, reaching titers of only 10^3 PFU/ml by 36 hpi (Fig. 3C). DBT cells did not support the replication of any of the viruses within our panel, which supports the hypothesis that the expression of ACE2 within DBT-hACE2 cells is required for the growth of all viruses within our panel (Fig. 3D).

Immunohistochemistry of infected HAE cells. Host range expansion of other coronaviruses resulted in a change in cell tropism that was oftentimes associated with a change in receptor usage (4, 27). To determine the types of cells infected by the panel viruses in HAE, infected cultures were fixed and sectioned for the histological staining of SARS-CoV nucleocapsid antigen and tubulin for the staining of cilia. SARS N antigen was not detected in mock-infected cultures, though cilia on the apical surface of ciliated epithelial cells show bright staining (Fig. 4A). SARS N antigen is readily detected within the ACE2-expressing ciliated cells of icSARS (Fig. 4B)- and icSZ16-S K479N D22 (Fig. 4D)-infected cell cultures but is only sporadically detected in icSZ16-S K479N p6 (Fig. 4C)-infected cell cultures. Nevertheless, the HAE-evolved icSZ16-S K479N D22 virus and the parent zoonotic icSZ16-D K479N virus encode ciliated cell tropisms that are similar to those seen in late-phase epidemic strains.

PRNT using human MAb S230.15. Future outbreaks of SARS-CoV would most likely emerge from pools of zoonotic virus, and it is imperative that vaccinations or serotherapies be effective against both past and future emergent zoonotic strains. S230.15 is a human MAb that is broadly neutralizing through its binding to the RBD, though the specific location of the epitope is unknown (48, 59). The epidemic strain and the evolved icSZ16-S K479N D8 and icSZ16-S K479N D22 viruses are equally neutralized by S230.15 (50% neutralization at a concentration between 0.0625 and 0.125 " g/ml), but icSZ16-S K479N is eight times more resistant (50% neutralization at 0.5 " g/ml) (Fig. 5). Since icSZ16-S K479N and the evolved

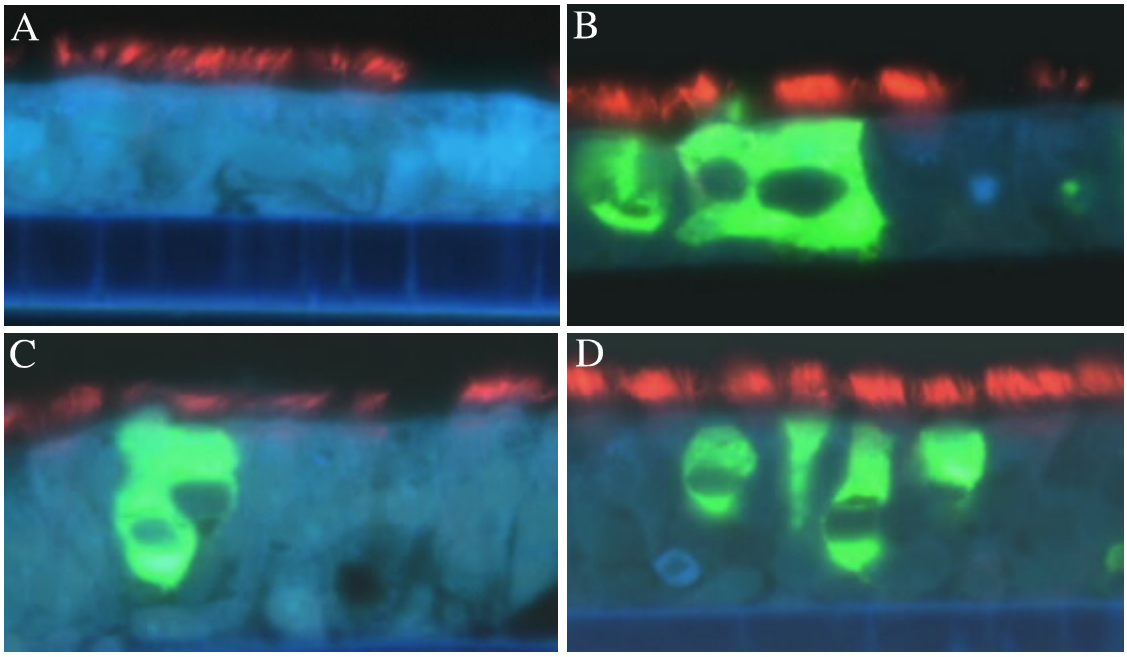

FIG. 4. Immunofluorescence staining of HAE cell cultures infected with the mutant virus panel. At 72 hpi, mock and infected HAE cell cultures were PFA fixed and paraffin embedded for tissue sectioning. Sections were stained for SARS-CoV N (fluorescein isothiocyanate) and tubulin within cilia (Texas Red) and viewed by fluorescence microscopy. (A) Mock; (B) icSARS; (C) icSZ16-S K479N; (D) icSZ16-S K479N D22.

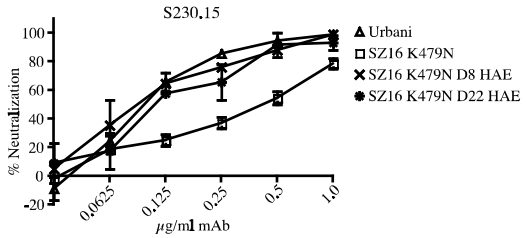

FIG. 5. PRNT assay of the mutant panel viruses using human MAb S230.15. One hundred PFU of the indicated virus was incubated at 37°C for 1 h with twofold dilutions of antibody or DPBS in duplicate. After the incubation, the virus-antibody cocktails were used to infect Vero E6 cell monolayers for 1 h, after which cultures were overlaid with growth medium containing agarose. After 48 h, plaques were enumerated. The percentages of neutralization were calculated as follows: 1 ! (number of plaques with antibody/number of plaques without antibody) # 100%. Error bars represent the standard errors of the means.

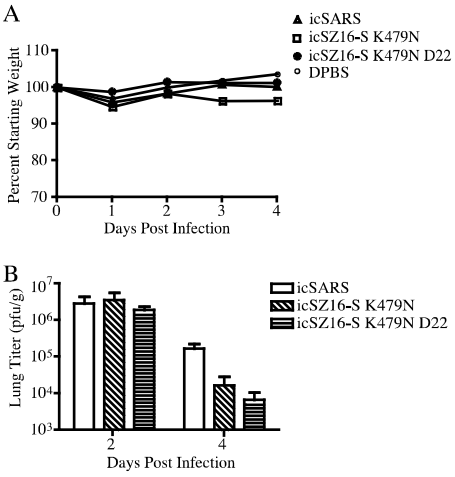

FIG. 6. Clinical signs and lung virus titers of 6-week-old BALB/c mice infected with DPBS, icSARS, icSZ16-S K479N, or icSZ16-S K479N D22. (A) Mice were infected with 10^5 PFU/50 " l intranasally (10 mice per virus), and weight was monitored daily. (B) Lungs were removed on days 2 and 4 postinfection (3 mice per group per day), homogenized, and centrifuged to pellet debris. Supernatants were used in a standard plaque assay to determine lung virus titers (PFU/g).

icSZ16-S K479N D8 virus only differ in 1 amino acid within the S protein, these data suggest that the S230.15 epitope resides near residue 442. Moreover, these data suggest that as SZ16-like zoonotic SARS-CoVs adapt to the hACE2 receptor in the human airway, they may become more susceptible to S230.15 neutralization, especially if they evolve with mutations at residue 442. As an isotype control, an irrelevant cholera-toxin-specific antibody (D2.2) was used in a PRNT assay with the mutant virus panel, and none of the viruses were neutralized at any concentration of the antibody (data not shown).

The icSZ16-SK479N and icSZ16-SK479N D22 viruses replicate in the lungs of young BALB/c mice but do not cause clinical signs in young or senescent BALB/c mice. Since the epidemic strain may not exist in nature and future epidemic SARS-CoV strains would most likely evolve from zoonotic pools of virus, it is prudent to employ an antigenically divergent panel of zoonotic challenge viruses to assess their therapeutic efficacies and cross-reactivities. To this end, it is imperative that the challenge viruses behave similarly in current animal models used to assess vaccine efficacy. Infection of young BALB/c mice with SARS Urbani typically does not cause clinical symptoms (5, 39). Young mice that were either mock infected or infected with the icSARS, icK479N-S K479N, or icSZ16-S K479N D22 viruses did not lose weight or present with other clinical signs (Fig. 6A). Clinical outcomes in senescent mice infected with icSZ16-S K479N or icSZ16-S K479N D22 mirrored those of young mice, with senescent mice losing little to no weight following infection (data not shown). The icSZ16-S K479N and icSZ16-S K479N D22 viruses replicated in the lungs of young BALB/c mice to titers similar to the epidemic strain on day 2 postinfection ($ 3 # 10^6 PFU/g) (Fig. 6B). By day 4 postinfection, the titers of the civet viruses were about 1 log lower than the epidemic strain, suggesting that the civet viruses might be cleared more rapidly (Fig. 6B).

Rosetta Design modeling of S RBD and ACE2 interactions. Rosetta Design was used to model hACE2's interactions with the RBDs of the SZ16, SZ16 K479N, icSZ16-S K479N D8, and icSZ16-S K479N D22 viruses. In contrast to the epidemic strain N479 residue, the SZ16 K479 residue appears to electrostatically clash with the ACE2 binding partners K31 and H34. After a point mutation (K479N) is introduced in the civet S RBD, the repulsive forces of the civet K479 are eradicated, allowing for S and ACE2 binding (Fig. 7A, B, and C). The Urbani RBD residues 442 and 479 are predicted to have single hACE2 binding partners (residue 442 interacts with H34; residue 479 interacts with K31) (Fig. 7A). Though residues 442 and 479 of the SZ16 K479N RBD are identical to Urbani, residues 442 and 479 are predicted to compete for hACE2 binding partner H34, and residue 442 is also predicted to interact with H34 and K31 of hACE2 (Fig. 7C). The difference in binding efficiencies of the seemingly similar Urbani and K479N RBDs is likely due to subtle alterations of the RBD hydrogen bonding network created by mutations at the peripheral RBD residue 487. Residue S487 of the SZ16 K479N RBD binds to one ACE2 residue, but T487 of Urbani binds to three residues of ACE2, thereby enhancing S and ACE2 binding interactions (Fig. 7C). The Rosetta Design model predicts that the Y442F mutation within the icSZ16-S K479N D8 S protein creates an RBD architecture similar to that of SARS Urbani, where S residues F442 and N479 have singular and unique hACE2 binding partners (residue 442 binds K31 of hACE2, and residue 479 binds H34 of hACE2) while retaining the S487 and Y41 interaction and the hydrogen bonding network (Fig. 7C and D). Finally, while the icSZ16-S K479N D8 L472 residue is predicted to have only two potential ACE2 binding partners (L79 and M82), the L472F mutation of the icSZ16-S K479N D22 S protein is predicted to increase the numbers of possible binding partners of ACE2 to three residues (L79, M82, and Y83), thereby strengthening S binding (Fig. 7D and E).

DISCUSSION

The past and present sporadic reemergences of the Chikungunya, Ebola, and Nipah viruses highlight the severe pathogenic and epidemic potential of zoonotic viruses, and the identification of the animal reservoir host is often elusive (13, 20, 25, 47, 51). Live-animal markets in China and elsewhere have

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

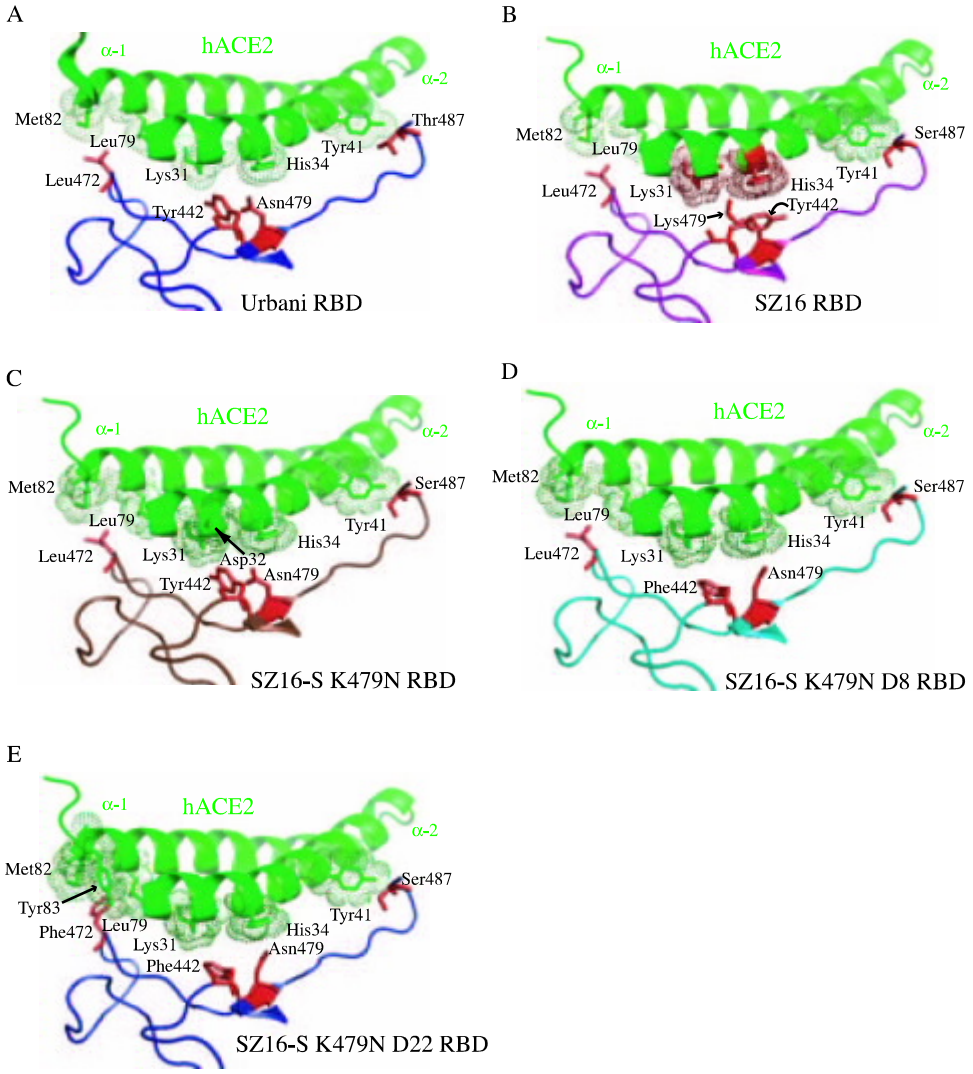

FIG. 7. Rosetta Design modeling of "evolved" mutations that enhance spike protein binding to ACE2. Rosetta Design was used to generate structural models of SZ16 and mutant RBDs that were then superimposed onto the existing crystal structure of the SARS Urbani RBD bound to ACE2. (A) Epidemic strain and hACE2 RBD architecture. (B) SZ16 and hACE2 interaction is inhibited by steric clashing, shown as red dots, of K479 of S and residues K31 and H34 of hACE2. (C) Electrostatic repulsion at residue 479 is eradicated, allowing S and ACE2 binding, but local remodeling within the RBD due to hydrogen bonding differences at residue 487 creates cross-reactions whereby residues 442 and 479 of K479N compete with each other for interaction partners H34, K31, and D32 of hACE2. (D) The Y442F mutation of icSZ16-S K479N D8 restores an optimal RBD, allowing for favorable packing to create an architecture similar to that of the wild type. (E) Leucine 472 of the icSZ16-S K479N and icSZ16-S K479N D8 S interacts with L79 and M82 of ACE2. The icSZ16-S K479N D22 L472F mutation is predicted to have hydrophobic interactions with three potential partners, L79, M82, and Y83, of hACE2 that will increase the stability of the binding. Green dots on hACE2 indicate residues which are within 4 angstroms and thus are predicted to interact with the S residues shown in red.

been proven to be an important factor in cultivating food-borne illnesses and cross-species transmission of SARS-CoV, avian influenza viruses, and other pathogens (29, 54, 55). Within the live-animal markets of China, dense human and animal populations mix, creating an environment ripe for the exchange of viruses from animals to humans and from humans to animals. During the SARS-CoV epidemic, the Himalayan palm civet was identified as the principal source of the SARS-CoV zoonosis even though 1,107 civets on farms that supplied the markets tested negative, suggesting that the civets were infected within the markets (16). Moreover, sequence analysis of bat- and civet-associated SARS-CoV has provided more definitive evidence that bat-associated SARS-CoV jumped the species barrier to infect civets and that bat and civet viruses are similar yet distinct from late-phase epidemic strain isolates (2, 9, 18, 26, 34, 41).

After the identification of ACE2 as the cellular receptor for SARS-CoV, several investigators have defined the molecular determinants of the virus and receptor interactions that allowed for the epidemic SARS-CoV host expansion. Prior to this report, key residues in the civet S gene responsible for changes in the host range were identified using SARS-CoV S pseudotyped retroviruses, but these results had not yet been confirmed in the context of wild-type SARS-CoV infection in vivo or in vitro. In support of data from Li et al., we demonstrate that the civet-spiked icSZ16-S virus was capable of a

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

single round of replication following transfection of full-length genomic RNA but was incapable of infecting naive Vero E6 cells in subsequent rounds of infection (21). However, the introduction of a single amino acid mutation (K479N) in the icSZ16-S virus S protein allowed for low-level spread and passage in Vero E6 cells. Both icSZ16-S K479N p3 and p6 viruses grew similarly in Vero and DBT-hACE2 cells, suggesting that the slight differences in their abilities to cause CPE did not affect virus binding, entry, or replication fitness during the time observed and at the MOI used in our assays. Though we did not use icSZ16-S K479N p6 in our HAE cell growth studies, we would expect both p3 and p6 isolates to perform similarly, since their growth kinetics in Vero and DBT-hACE2 cells were similar. Importantly, the K479N mutation did not result in a virus capable of efficient replication in HAE or DBT-hACE2 cells, supporting the argument that additional mutations are required to enhance the SZ16 S interaction with the human ACE2 receptor. The differences seen in icSZ16-S K479N growth in HAE and Vero E6 cells highlight the strength and relevance of the HAE model of the human airway. Even though the contact residues of primate and human ACE2 are predicted to be similar, the differences in icSZ16-S K479N growth in HAE and Vero E6 cells suggest that differences in primate and human ACE2 proteins (89% similar on the amino acid level) subtly influence binding efficiency or that the abundance of mucus and a unique extracellular matrix on the surfaces of HAE cells differentially antagonize virus entry. Thus, in order to study and model S protein and hACE2 interactions, HAE or DBT-hACE2 cells should be used as more relevant alternatives to Vero E6 cells. Importantly, the expression of hACE2 in a nonpermissive DBT cell line rendered these cells permissive for icSARS, icSZ16-S K479N, icSZ16-S K479N D8, and icSZ16-S K479N D22 virus infection, which strongly supports earlier hypotheses that ACE2 is the principal receptor required for the docking and entry of both human and zoonotic strains (24).

For both the canine parvovirus (CPV) and the 1918 Spanish influenza virus H1N1, point mutations in the viral structural proteins responsible for binding to the host cell were sufficient to catalyze host range expansion (14, 46). In 1978, two mutations in the capsid protein of feline parvovirus that were sufficient to catalyze host expansion evolved, causing severe canine infection and a worldwide epidemic of CPV-naive canine populations (14, 32). In 1918, the zoonotic H1N1 influenza virus acquired two mutations in hemagglutinin, changing the preferential binding from the avian to the human sialic acid receptor. When the hemagglutinin mutations were coupled with a few additional mutations in the genome, a human pandemic ensued with estimated deaths of 20 million to 40 million (32, 46). Similarly to those of the CPV and H1N1 viruses, analyses of the zoonotic and human SARS-CoV S sequences show a logical progression of S protein mutations that most likely fostered host range expansion and increased human pathogenesis (16). Of the 14 amino acids of S that contact 18 amino acids of ACE2, the K479N and S487T mutations have been shown to be equally essential for civet S adaptation to human ACE2 (21). The K479N mutation removed an electrostatic clash, allowing the S protein RBD to interact with human ACE2, while S487T appears to have subtly remodeled the RBD through hydrogen bonding differences that optimized hACE2 binding. Considering our in vitro evolution data and sequence data from the SARS epidemic, we hypothesize that at least two independent mutational pathways can optimize hACE2 binding. The first was observed during the epidemic, where the S487T mutation optimized binding as described above. The second route occurred during our in vitro evolution, whereby the Y442F mutation optimized hACE2 binding in the presence of the S487 variant. ACE2-expressing ciliated epithelial cells in the airway are targets for SARS-CoV infection in humans, primate and rodent models making the HAE model an important in vitro system for studying the molecular mechanisms of animal S adaptation to the human host (10, 11, 30, 38, 39). Since the icSZ16-S virus could not be propagated in Vero E6 cells, we introduced the K479N point mutation in the virus S that was sufficient to allow multiple rounds of replication of the civet-spiked icSZ16-S K479N virus in cell culture. Passage of the icSZ16-S K479N recombinant virus in HAE cells resulted in the emergence of S variants that could replicate more efficiently. Surprisingly, S487T was not selected with the passage of SZ16 K479N, but new mutations evolved within contact residues of the icSZ16-S K479N D8 and icSZ16-S K479N D22 virus RBDs (Y442F and L472F) that enhanced virus infection of HAE, Vero E6, and DBT-hACE2 cells. To rule out non-receptor-specific cell culture adaptations that enhance entry into cells in vitro, we infected DBT cells and did not see evidence of virus growth with any of the viruses tested. Moreover, our immunohistochemistry of infected HAE cell cultures (Fig. 4) suggests that in vitro-evolved viruses and the epidemic strain infect similar cell types, providing further support that non-receptor-specific entry adaptations had not occurred in our model. Recent passage of a related coronavirus, mouse hepatitis virus, in cell lines resulted in variants with an expanded host range due to the acquisition of a common non-receptor-specific cell culture adaptation using heparin sulfate for virus entry into cells (4). Most recently, McRoy and Baric demonstrated that the passage of mouse hepatitis virus in cell lines resulted in an expanded host range through mutations within the fusion peptide and heptad repeats, demonstrating that host range can be governed by changes in spike fusogenicity (27). From sequence analysis, we concluded that the in vitro evolved mutations of icSZ16-S K479N had not created a heparin consensus binding site (XBXBBX) and that our adaptive mutations were constrained to the RBD.

To determine the potential impact of the mutations acquired during HAE passage, we used Rosetta Design to generate structural models of the SZ16, icSZ16-S K479N, icSZ16-S K479N D8, and icSZ16-S K479N D22 RBDs and then superimposed these models onto the existing crystal structure of the SARS Urbani RBD bound to hACE2 (PDB code 2AJF) (Fig. 7A). Similarly to Li et al., we observed that residue K479 of the SZ16 S inhibited binding to hACE2 by sterically clashing with residues K31 and H34 (Fig. 7B). After the K479N mutation, the electrostatic repulsion at residue 479 is eradicated, but Rosetta Design predicts that local remodeling within the RBD creates cross-reactions whereby residues 442 and 479 of the K479N RBD compete with each other for interaction with partners H34, K31, and D32 of ACE2 (Fig. 7C). It appears that Y442 could interact with all three hACE2 residues, but N479 is predicted to interact only with H34 of hACE2. We predict that this network of competing interactions reduces the avidity be-

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

tween the K479N RBD and the hACE2 receptor by misaligning other key residues in the RBD. Of note, the only difference in the RBDs of SZ16 K47N and Urbani occurs at position 487. The fact that SZ16 K479N is compromised in growth compared to Urbani suggests that the hydrogen bonding differences between S487 of SZ16 K47N and Thr487 of Urbani influence the receptor interaction. During the 2003 epidemic, S487T likely evolved to eliminate this putative inhibitory effect. Interestingly, the icSZ16-S K479N D8 Y442F mutation also restores an optimal RBD by allowing for favorable amino acid packing that recreated an RBD architecture similar to that of the wild type (Fig. 7A and D). In this case, the icSZ16-S K479N D8 RBD residues 442 and 479 have distinct and unique interaction partners in hACE2, which likely restores avidity to near wild-type levels and may explain why the icSZ16-S K479N D8 virus grows more efficiently than the icSZ16-S K479N virus in cells expressing hACE2 (Fig. 3C and 7D). Thus, at least two independent routes of evolution could increase S RBD and human ACE2 interactions. Leucine 472 of the icSZ16-S K479N RBD and the icSZ16-S K479N D8 RBD interacts with L79 and M82 of ACE2. The icSZ16-S K479N D22 virus RBD is mutated at position 472 from leucine to phenylalanine, which Rosetta Design predicts will induce strong hydrophobic interactions between F472 and partners L79, M82, and Y83 of ACE2 (Fig. 7E). The icSZ16-S K479N D22 virus F472 mutation likely strengthens the binding interface of the icSZ16-S K479N D22 virus over the icSZ16-S K479N D8 strain, which may explain why the icSZ16-S K479N D22 virus has a growth advantage over the icSZ16-S K479N D8 virus in HAE, Vero E6, and DBT-hACE2 cells. Of note, it is possible that these viruses acquired replication-enhancing mutations in structural or nonstructural genes that we did not sequence. Nevertheless, these data demonstrate the plasticity of the RBD-ACE2 interface site and its ability to subtly remodel the RBD and hACE2 binding interface to promote efficient entry and growth. Clearly, multiple genetic pathways likely exist to allow for zoonotic SARS-CoV host range expansion, and it will be interesting to determine if other contact interface point mutations can enhance zoonotic virus infection of HAE cell cultures.

Since viruses similar to the epidemic strain are currently circulating in bats in China, we may see yet another emergence of human SARS-CoV from zoonotic pools of virus. Therefore, it is imperative that current vaccinations and passive serotherapies be effective against all known SARS-CoV zoonotic strains and their human-adapted progeny. Previous work by Deming et al. has highlighted the value of using zoonotic strains as challenge viruses to assess vaccine efficacy (5). Deming et al. demonstrated that sera from animals vaccinated with epidemic strain antigens were not as effective in neutralizing the zoonotic icGD03-S virus as they were in neutralizing the epidemic strain (5). Within this study, we demonstrated that two zoonotic spiked viruses, icSZ16-S K479N and icSZ16-K479N D22, grew to peak titers in the mouse lung similar to those of the epidemic strain 2 days postinfection. In contrast to recombinant SARS-CoV bearing early human (GZ02) or civet S glycoprotein (HC/SZ/61/05) S proteins that were extremely pathogenic in aged animals, icSZ16-S K479N and icSZ16-S K479N D22 caused little to no disease in either young or senescent BALB/c mice (40). Although the SZ16 and HC/SZ/61/03 viruses are both of civet origin, their S proteins differ by 18 amino acids (9; G. Yi, SARS coronavirus HC/SZ/61/03 complete genome). The 7-month period of time between the isolation of SZ16 (May 2003) and the isolation of HC/SZ/61/03 (December 2003) may help explain their sequence differences (9; G. Yi, SARS coronavirus HC/SZ/61/03 complete genome [http://www.ncbi.nlm.nih.gov/entrez/viewer.fcgi?db %nuccore&id %42556132]). Zoonotic SARS-CoV infection of humans is typically less severe than infection with human strains, but it is possible that the sequence differences between the SZ16 and the HC/SZ/61/03 S proteins alter the structure of the S proteins such that the viruses bearing the HC/SZ/61/03 S are lethal in mice, while our SZ16 lineage viruses are attenuated (2, 9, 19, 23, 40, 45). Nevertheless, the icSZ16-S K479N and icSZ16-S K479N D22 viruses grow to levels similar to those of the epidemic strain in mice and could be useful as challenge viruses to assess the efficacies of vaccines or serotherapies. The human MAb S230.15 binds within the RBD, although the specific epitope has yet to be defined (48, 59). Recent data from Traggiai et al. and Zhu et al. have shown MAbs S230.15 and, to a lesser extent, m396 to be potent and cross-neutralizing antibodies against human and zoonotic SARS-CoV isolates (48, 59). We have demonstrated that the "evolved" icSZ16-S K479N D8 and D22 viruses were equally susceptible to neutralization by S230.15 but that icSZ16-S K479N was eight times more resistant. In this instance, these data suggest that zoonotic virus adaptation to the human ACE2 receptor may enhance susceptibility to neutralization by S230.15. Since there was a dramatic difference in neutralization between icSZ16-S K479N and icSZ16-S K479N D8, these data suggested that the epitope of S230.15 is in close proximity to or was affected by structural changes associated with residue 442 of the S protein. Future efforts to revive the divergent wild-type icSZ16-S virus in vitro will be especially helpful with mapping the S230.15 epitope, since it is possible that the K479N mutation may contribute to enhanced S230.15 binding. Even though S230.15 is less effective at neutralizing icSZ16-S K479N in vitro, recently published passive transfer studies in mice have shown that the S230.15 antibody is extremely potent and broadly neutralizing in vivo where replication of SARS Urbani, icGD03-S, and icSZ16-S K479N were not detected in the mouse lung (59). These data highlight the power and utility of zoonotic strains in assessing the efficacy of passive serotherapy both in vitro and in vivo.

In conclusion, synthetic biology has been employed to rapidly construct and assemble a completely synthetic and infectious 5.3-kb bacteriophage, poliovirus, 1918 influenza virus, and a panel of SARS viruses bearing animal and human S glycoproteins (1, 5, 40, 44, 49). We provide yet another example of the utility of synthetic biology by resurrecting the civet SZ16 S. We have shown that a single point mutation (K479N) in the SZ16 S facilitates host range expansion, but additional mutations must occur for robust infection of human cells. Mutations of residues 479 (K479N) and 487 (S487T) occurred during the early phase of the SARS-CoV epidemic to help facilitate host range expansion. Though we did not generate a mutant SZ16 S containing S487T, previous studies have shown that the inclusion of a mutation at either position 479 or 487 in pseudotype virus bearing the civet S allowed for the infection of human cells, but this approach provides little information on

Downloaded from jvi.asm.org at UNIVERSITY OF NORTH CAROLINA on December 20, 2008

growth efficiency and spread. Through our in vitro evolution of the icSZ16-S K479N virus, we discovered a novel evolutionary path by which SARS-CoV S can interface with hACE2 to allow for the efficient infection of human cells. When S mutations acquired during our in vitro evolution are compared to mutations that occurred during the evolution of the epidemic strain, the plasticity of the SARS-CoV S protein becomes starkly apparent. Through the use of HAE cell cultures, synthetic biology, reverse genetics, and animal models, we have created a system to isolate and characterize novel genetic pathways of zoonotic SARS-CoV S adaptation to the human ACE2 receptor. We have also generated antigenically divergent SARS-CoV zoonotic strains that might be useful in assessing the efficacies of SARS-CoV vaccines or serotherapies. Since the future emergence of SARS-CoV will most likely evolve from zoonotic pools of virus, it is imperative that current vaccinations and passive serotherapies be effective against the zoonotic virus, the epidemic virus strain, and all of the evolutionary permutations in between.

ACKNOWLEDGMENTS

We thank Michael Farzan at Harvard Medical School for kindly providing the hACE2 expression plasmid. We also thank Antonio Lanzevecchia at the Institute for Research in Biomedicine, Bellinzona, Switzerland, for graciously providing MAbs S230.15 and D2.2 and Boyd Yount for superb technical assistance and expert cloning advice.

This work was supported by research grants (R01 AI059136 and AI059443) to R.B. from the National Institutes of Health, Division of Allergy and Infectious Diseases.

Zoonotic severe acute respiratory syndrome coronavirus (SARS-CoV) likely evolved to infect humans by a series of transmission events between humans and animals in markets in China. Virus sequence data suggest that the palm civet served as an amplification host in which civet and human interaction fostered the evolution of the epidemic SARS Urbani strain. The prototypic civet strain of SARS-CoV, SZ16, was isolated from a palm civet but has not been successfully cultured in vitro. To propagate a chimeric recombinant SARS-CoV bearing an SZ16 spike (S) glycoprotein (ic SZ16-S), we constructed cell lines expressing the civet ortholog (DBT-cACE2) of the SARS-CoV receptor (hACE2). Zoonotic SARS-CoV was completely dependent on ACE2 for entry. Urbani grew with similar kinetics in both the DBT-cACE2 and the DBT-hACE2 cells, while ic SZ16-S only grew in DBT-cACE2 cells. The SZ16-S mutant viruses adapted to human airway epithelial cells and displayed enhanced affinity for hACE2 but exhibited severe growth defects in the DBT-cACE2 cells, suggesting that the evolutionary pathway that promoted efficient hACE2 interactions simultaneously abolished efficient cACE2 interactions. Structural modeling predicted two distinct biochemical interaction networks by which zoonotic receptor binding domain architecture can productively engage hACE2, but only the Urbani mutational repertoire promoted efficient usage of both hACE2 and cACE2 binding interfaces. Since dual species tropism was preserved in Urbani, it is likely that the virus evolved a high affinity for cACE2/hACE2 receptors through adaptation via repeated passages between human and civet hosts. Furthermore, zoonotic SARS-CoV was variably neutralized by antibodies that were effective against the epidemic strain, highlighting their utility for evaluating passive immunization efficacy.

Within the wet markets in China, a wide range of common and exotic food animals like bats and civets are sold live or as fresh meat for human consumption, in part to improve health and for sexual performance (2, 8, 32, 34). In southern China, the consumption of exotic animals is especially common during the winter months when most respiratory tract infections are highly prevalent (32). Since many zoonotic viral pathogens are shed in stool, densely housed birds and mammals shedding excreta in the wet marketplace create a rich atmosphere for zoonotic virus transmission to human consumer populations (32). Most recently, wet markets in Southeast Asia have been associated with cultivating the cross-species transmission of avian influenza H5N1 and the newly emerged severe acute respiratory syndrome coronavirus (SARS-CoV) (8, 13, 32).

In 2002, a novel coronavirus, SARS-CoV, emerged as the causative agent of severe acute respiratory syndrome and spread worldwide, causing about 8,000 cases and more than 700 deaths (3, 23, 32). Viruses similar to the epidemic strain SARS-CoV Urbani were isolated from animals for sale within wet markets in China during the epidemic in 2003 and the reemergence in 2004 (2, 8). Genome sequences of viruses isolated from bats, civets, and humans suggest that viruses circulating in bats crossed the species barrier to infect civets, which then served as an amplification host for yet another host range shift to generate a human-tropic virus (2, 8, 13, 19). Recent surveys of animal populations in North America, Africa, and China implicate bats as reservoirs of a diverse array of coronaviruses, including SARS-CoV-like progenitors (5, 6, 13, 14, 20, 31–33). As some bat species were found to be coinfected with more than one coronavirus lineage, the recombination between and within genogroups and the subsequent emergence of novel coronaviruses are real possibilities (14). In 2007, surveys of wild Asian leopard cats and Chinese ferret badgers revealed the presence of yet more novel and highly divergent coronaviruses circulating in animals typically sold in wet markets in China (6). Since viruses similar to the epidemic strain of SARS-CoV are currently circulating in zoonotic pools, the future emergence of another SARS-CoV-like virus may occur. Therefore, it is imperative that current vaccination and passive immunization therapies are effective in protecting humans from infection by a wide range of epidemic and zoonotic SARS-CoV. Unfortunately, bat SARS-CoV and the prototypical civet SARS-CoV strain SZ16 have not been successfully cultured in vitro, hampering our ability to evaluate their epidemic potential, pathogenesis, and susceptibility to current therapeutic interventions within in vitro and in vivo models (13, 15).

The SARS-CoV spike (S) gene sequences isolated from human cases during the early phase of the epidemic in 2002 to 2003 and during the reemergence from 2003 to 2004 are very similar to those of the SZ16 strain (2, 8, 12). SZ16 was isolated from the palm civet in wet markets within the Guangdong

region of China during the epidemic, and its S protein differs from the that of the epidemic strain by 18 amino acids, 16 of which reside in the S1 domain containing the receptor binding domain (RBD) (8). The SARS-CoV strain GD03 sequence was isolated from a sporadic human case during the epidemic's reemergence in 2003 to 2004 and closely resembles those viruses isolated from civets and raccoon dogs from the wet markets (2). The SARS-CoV GD03 S protein differs from that of the epidemic strain by 17 amino acids, 16 of which reside in the S1 domain (2). Recently, we have shown that the recombinant SARS-CoV bearing the SZ16 S gene (icSZ16-S) was capable of replication within Vero E6 cells, but progeny virions were unable to infect naïve cell cultures, supporting evidence that the binding of the civet S protein to the human SARS-CoV receptor (human angiotensin-converting enzyme II [hACE2]) or a very closely related primate ortholog was inefficient (19). Since clinical SZ16 isolates and our recombinant chimeric icSZ16-S virus strains could not be successfully cultured in vitro, the biology of the SZ16 S protein and its effect on virus growth and pathogenesis remain elusive.

In this study, we describe the recovery and growth of the icSZ16-S strain in culture using delayed brain tumor (DBT) cells stably expressing the civet ortholog (cACE2) of hACE2. Like the epidemic strain, and in contrast to an earlier report, both icSZ16-S and icGD03-S are completely dependent on ACE2 for entry (36). In DBT-cACE2 cells, icSZ16-S grows with kinetics similar to that of the epidemic strain, but point mutations in the SZ16 S glycoprotein that enhance growth in hACE2-expressing cells abrogate growth in cACE2-expressing cells. The epidemic strain grows equally well in cACE2- and hACE2-expressing cells, suggesting that the epidemic strain probably evolved through repeated exchanges of virus between civet and human, thereby providing the evolutionary pressure to retain dual host tropism. icSZ16-S and icGD03-S are moderately susceptible to neutralization by the human monoclonal antibody (hu-MAb) S230.15. Unlike the epidemic strain, zoonotic viruses are resistant to hu-MAb S3.1, suggesting that therapeutics successfully directed against the epidemic strain may not work as well against the zoonotic viruses. These data highlight the utility of employing an antigenically diverse zoonotic S panel of SARS-CoV in the study of host range expansion and antiviral therapy efficacy.

MATERIALS AND METHODS

Viruses and cells. The recombinant epidemic virus strain "icSARS" (GenBank accession no. AY278741) and icSZ16-S (GenBank accession no. AY304488), icGD03-S (GenBank accession no. AY525636), icCUHK-W1 (GenBank accession no. AY278554), icGZ02 (GenBank accession no. AY390556), icSZ16-S K479N, icSZ16-S K479N D8, and icSZ16-S K479N D22 were propagated on Vero E6 or DBT cells stably expressing cACE2 (DBT-cACE2) as described previously (4, 22, 25, 26, 37). The icSZ16-S virus supernatant from the electroporated cell culture (passage 0) was passaged on DBT-cACE2 cells four times at 48-h intervals, after which a robust cytopathic effect was observed. icSZ16-S was then plaque purified on DBT-cACE2 cells, and plaques were expanded in six-well dishes of DBT-cACE2 cells. Six-well-dish supernatant was used to infect a T175 flask of DBT-cACE2 cells to generate a virus stock that was harvested 20 h postinfection (hpi). Viral RNA from the icSZ16-S virus stock was isolated using TRIzol (Invitrogen, Carlsbad, CA), cDNA was synthesized using Superscript II reverse transcriptase (SSII; Invitrogen, Carlsbad, CA), and amplicons spanning the S, 3a, E, and M genes were generated by reverse transcription-PCR (RT-PCR) and sequenced directly. The virus stocks used throughout this study were grown and titers were determined by plaque assay with Vero E6 and/or DBT-cACE2 cells as described previously (38). Vero E6 and DBT cells were grown in minimal essential medium (Invitrogen, Carlsbad, CA) supplemented with 10% Fetal Clone II (HyClone, South Logan, UT), kanamycin (0.25 ffg/ml), and gentamycin (0.05 ffg/ml) (UNC tissue culture facility). DBT-cACE2 and DBT-hACE2 cells were grown in Vero/DBT growth media supplemented with 700 ffg/ml G418 (Invitrogen, Carlsbad, CA). All work with viruses was performed in a class II biological safety cabinet in a certified biosafety level 3 laboratory containing redundant exhaust fans while wearing Tyvek suits and powered air-purifying respirators as described previously (38).

Generation of cACE2-expressing DBT cells. Plasmids encoding N-terminal Myc-tagged hACE2 and cACE2 were kindly provided by M. Farzan, New England Primate Research Center. Construction of the DBT-hACE2 cell line was carried out as described by Sheahan et al. (26). The cACE2 gene was amplified by PCR using Expand High Fidelity polymerase (cACE2F primer, 5ffCACCAT GTCAGGCTCTTTCTGGCTCC-3 ffland cACE2R primer, 5ffAAATGAAGTC TGAACGTCATCAG-3 ffl. Amplicon was gel purified and cloned into pcDNA3.1/V5-His according to the protocol. The cACE2 reverse primer did not contain a stop codon, allowing for a read through and the inclusion of a six-His tag on the 3ffl end. The pcDNA cACE2-His plasmids were sequenced and found to have two amino acid changes, G354D and R736Q, compared to those of the published sequence (GenBank accession no. AY881174), one of which (G354D) resides at a proposed interaction site with SARS-CoV S residues Y491 and G488, but these changes were also found in the parent gifted plasmid. cACE2 is polymorphic at residue 354, where sequences containing D354 and G354 can be found in civet tissue samples (personal communication with Michael Farzan) (18). Murine DBT cells were transfected with 4 ffg of pcDNA3.1/V5-His expressing cACE2-His or green fluorescent protein (GFP)-His, using Fugene reagent (Roche, Indianapolis, IN). After 24 h, cells were placed under continuous drug selection using 700 ffg/ml G418 (Invitrogen, Carlsbad, CA). DBT-cACE2-His, DBT-hACE2, and DBT-GFP-His cells were passaged four times under drug selection and then sorted for high ACE2 or GFP expression levels and expanded for future use.

Cell sorting and fluorescence-activated cell sorter analysis of ACE2-expressing DBT stable cell lines. A total of 10^6 DBT (control), DBT-hACE2, and DBT-cACE2-His cells were blocked with Dulbecco's phosphate-buffered saline (DPBS)-5% fetal bovine serum and stained with polyclonal goat anti-hACE2 (R&D Systems, Minneapolis, MN), followed by a secondary anti-goat immunoglobulin G (IgG)-fluorescein isothiocyanate (FITC; Invitrogen, Carlsbad, CA) antibody. Stained DBT, DBT-hACE2, and DBT-cACE2-His and unstained DBT-GFP-His cells were sorted on a Cytomation Inc. MoFlo cell sorter (Dako, Denmark) for FITC or GFP expression, and sorted cells were expanded by four passages, after which stocks of DBT, DBT-hACE2, DBT-cACE2-His, and DBT-GFP-His cells were cryopreserved for future experiments. To assess transgene expression in postsorted cell stocks, 5 ! 10^5 DBT, DBT-hACE2, DBT-cACE2-His, DBT-GFP-His, or Vero E6 cells were seeded into six-well dishes. Twenty-four hours later, medium was removed, and the cells were removed from the plate, with versene (UNC tissue culture facility). Cells were stained for fluorescence-activated cell sorter analysis as described above and analyzed for FITC/GFP expression by FACScan (BD Biosciences, San Jose, CA).

Western blot analysis of ACE2-expressing DBT stable cell lines. To assess transgene expression in postsorted cell stocks by Western blot analysis, DBT, DBT-hACE2, DBT-cACE2-His, DBT-GFP-His, and Vero E6 cells were seeded in six-well dishes at 5 ! 10^5 cells/well. Twenty-four hours later, cells were lysed with protein lysis buffer (1% Triton X-100, 0.5% sodium dodecyl sulfate [SDS], in 1! Tris-buffered saline [TBS]). Twenty microliters of cell lysate was heated at 70°C in 1! NuPage buffer-4% beta-mercaptoethanol, loaded on a NuPage 12% bis-Tris SDS polyacrylamide gel (Invitrogen, Carlsbad, CA) and separated at 150 V for 2 h. Proteins were transferred to a nylon membrane, using the NuPage transfer apparatus according to the manufacturer's protocol. Membranes were blocked with 5% milk and probed with either polyclonal goat anti-human ACE2 (R&D Systems, Minneapolis, MN) or mouse anti-penta-His antibody (Qiagen, Valencia, CA). Membranes were washed with 1! TBS-0.1% Tween 20 and then probed with either rabbit anti-goat horseradish peroxidase (HRP) (Invitrogen, Carlsbad, CA) or anti-mouse IgG-HRP antibody (Amersham, Piscataway, NJ). After membranes were rinsed, they were treated with ECL Plus reagent (Amersham) and then exposed to radiographic film (Amersham).

RT-PCR to detect viral subgenomic leader-containing transcripts, ACE2, and GAPDH transcripts. RT-PCR to detect subgenomic leader-containing transcripts was performed to detect viral replication as described by Sheahan et al. (26). DBT, DBT-GFP-His, DBT-cACE2, DBT-hACE2, or Vero E6 cells were seeded at 5 ! 10^5 cells/well in a 24-well dish. Twenty-four hours later, cells were infected with 100 ffl of viral supernatant from the initial icSZ16-S transfection or icSARS virus supernatants or were mock infected. At 24 hpi, total RNA was

Downloaded from jvi.asm.org at University of North Carolina - Chapel Hill on December 20, 2008

isolated using TRIzol reagent (Invitrogen, Carlsbad, CA) according to the manufacturer's protocol. One microgram of total RNA was used to generate cDNA by Superscript II (Invitrogen, Carlsbad, CA) using random hexamer primers (Invitrogen, Carlsbad, CA). cDNA was then used as the template for PCR using *Taq* polymerase (New England Biolabs, Ipswich, MA). Evidence of SARS-CoV replication and subgenomic mRNA 3a, E, and M (amplicon sizes, 1,796, 947, and 666 bp, respectively) was detected by using a leader forward primer (CTCTTG TAGATCTGTTCTCTAAACGAAC) and a reverse primer in the M gene (TT ACTGTACTAGCAAAGCAATATTGTCG). Detection of ACE2 transcripts was performed with a conserved primer set capable of detecting primate, human, and civet ACE2 (258 bp) (ACE2RTF2 primer, 5′-AGCCTAAAAT CAGCTCTTGG-3′ and ACE2RTR2 primer, 5′-CCGGGACATCCTGATG GC-3′). Detection of GAPDH (glyceraldehyde-3-phosphate dehydrogenase) (235 bp) (GAPDHF primer, 5′-CATGGGGAAGGTGAAGGTCG-3′ and GAPDHR primer, 5′-TTGATGGTACATGACAAGGTGC-3′) signals detected by RT-PCR was used as a positive control. PCRs were separated by gel electrophoresis on 1.8% agarose Tris-acetate-EDTA (TAE) gels and visualized by ethidium bromide staining.

Virus growth curve analysis within Vero E6, DBT-cACE2, DBT-hACE2, or DBT cells. Vero E6, DBT-cACE2, DBT-hACE2 or DBT cells were infected with the icCUHK-W1, icGD03-S, icGZ02, icSZ16-S K479N p6, icSZ16-S K479N D22, icSARS, or icSZ16-S strain, at a multiplicity of infection (MOI) of 0.01 for 1 h at 37°C, after which the inoculum was removed, the monolayer was rinsed with DPBS, and the growth medium was added. Virus stock titers generated by plaque assay in DBT-cACE2 cells were used to calculate the MOI for the DBT-cACE2 cell growth curve. Virus stock titers generated by plaque assay in Vero E6 cells were used to calculate the MOI for the Vero E6 and DBT-hACE2 growth curves. Twenty-five microliters of cell medium was removed at 0, 6, 12, 24, and 36 hpi, and samples were stored at " 80°C until titers were determined by plaque assay. For all growth curves except those performed within DBT cells, the cell type used for growth curve analysis was also utilized for the titration of growth curve samples by plaque assay. For example, titers of samples generated from growth curves performed within DBT-cACE2 cells were determined with DBT-cACE2 cells. All DBT cell growth curve titers were determined with DBT-cACE2 cells. Since previous experiments suggested that Vero E6 and DBT-hACE2 cells were not permissive for icSZ16-S infection, icSZ16-S samples from DBT-hACE2 and Vero E6 growth curve titers were determined with DBT-cACE2 cells. Growth curves were performed in duplicate on two independent occasions, and the data shown are from one representative experiment.

ACE2 blockade experiments with DBT-cACE2 cells. DBT-cACE2 cells were seeded at 5 ! 10^5 cells/well in six-well dishes. On the following day, cell medium was removed, and cells were incubated with 10, 5, 2.5, 1.25, or 0.625 μg/ml polyclonal anti-ACE2 or anti-ACE antibody (R&D Systems, Minneapolis, MN) or with DBPS for 1 h at 37°C. After the 1-h pretreatment with antibody, 100 PFU/50 μl of icSARS, icSZ16-S, or icGD03-S was added to the antibody mixture and incubated for 1 h at 37°C. After the infection, the inoculum was removed, and the monolayer was rinsed twice with 1 ml of DPBS and then overlaid with 0.9% agarose in complete growth medium. After 48 hpi, plates were stained with neutral red, and plaques were counted. The average percentage of blockade was calculated by dividing the average number of plaques per Ab dilution by the average number of plaques in the DPBS no-Ab controls. Virus stock titers generated by plaque assay in DBT-cACE2 cells were used to calculate virus concentrations for the blockade experiment. Blockade experiments were performed in duplicate on two separate occasions.

PRNT assay. Neutralizing titers were determined by plaque reduction neutralization titer (PRNT) assay as described by Rockx et al. (21, 22) and Sheahan et al. (26). Briefly, 24 h prior to infection, six-well plates were seeded with 5 ! 10^5 DBT-cACE2 cells/well. hu-MAbs S230.15 and S3.1 directed against the SARS-CoV S protein and an isotype control antibody directed against cholera toxin D2.2 were kindly provided by A. Lanzavecchia. hu-MAbs were serially diluted twofold and incubated with 100 PFU of either icSARS, icSZ16-S, or icGD03-S for 1 h at 37°C. Virus and antibodies were then added to six-well plates of DBT-cACE2 cells in duplicate and incubated at 37°C for 1 h, after which the cells were overlaid with 0.8% agarose in medium. Plates were incubated for 48 h at 37°C and stained with neutral red for 3 h, and plaques were counted. The percentage of neutralization was calculated as 1 " (number of plaques with antibody/number of plaques without antibody) ! 100%.

Computer modeling of RBD interactions with cACE2 and hACE2. Structural models for SZ16, SZ16-K479N, and SZ16 K479N D22 RBD were based on the crystal coordinates reported for SARS-CoV Urbani RBD interacting with the hACE2 receptor (Protein Data Bank [PDB] code 2AJF) as previously reported (17, 26). Using the RosettaDesign website, we incorporated the amino acid replacements, and all amino acids within the 5-Å interaction distance were relaxed to allow the program to repack the side chains to an optimal energetic state. This process was repeated with each mutation and series of mutations. Ten models were generated for each set of mutations, and the best model, based on the lowest energy score, was selected and evaluated further using Macintosh PyMOL software. In addition, the crystal structure coordinates for the SARS-CoV RBD interacting with the hACE2 receptor (PDB code 2AJF, chains A and E) were used as a template to generate a homology model for the cACE2, using Modeler software (version 8.2). Briefly, chain E of the 2AJF template was aligned to the cACE2 sequence, and five models were generated under the automodel class. The model with the lowest objective function score was selected for further analyses. The PDB files generated by this program were visualized with PyMOL for Macintosh molecular modeling (DeLano Scientific) and Chimera software.

RESULTS

Construction and characterization of ACE2-expressing stable cell lines. At the amino acid level, primate ACE2 (Vero E6) and cACE2 are 89% and 84% similar to hACE2, the human SARS-CoV receptor, respectively. In comparison to the contact interface of hACE2 with the SARS-CoV S glycoprotein, that of cACE2 differs greatly, but primate ACE2's contact interface is identical (Fig. 3E). Since previous efforts to culture either the SARS-CoV SZ16 wild type or the recombinant icSZ16-S strain were unsuccessful, we used a cell-based approach to resurrect icSZ16-S (15, 26). We constructed stable cell lines expressing cACE2-His, hACE2, and GFP-His in the DBT cell background. The gifted cACE2 gene utilized to construct our stable cells varied by two amino acids (G354D and R736Q) compared to that of the published sequence, but both G354 and D354 polymorphisms in ACE2 can be found in civet tissues (personal communication with M. Farzan) (18). Stable cells were sorted for ACE2 or GFP expression, and cultivated master cell stocks were analyzed by flow cytometry and Western blotting (Fig. 1). ACE2 expression was detected by Western blotting in cell lysates generated from DBT-hACE2, DBT-cACE2, and Vero cell cultures but was not detected in wild-type DBT cells or in DBT-GFP-His control cells (Fig. 1B). To generate quantitative data for ACE2 expression levels within our stable cells, the cell cultures were analyzed by flow cytometry. ACE2 expression in DBT-hACE2 cells appears to be greater than the expression within Vero E6 cells, while expression in DBT-cACE2 appears to be the lowest of the three ACE2-expressing cell types (Fig. 1A and C). Since the polyclonal primary antibody used to stain the cells for flow cytometry was raised against the ectodomain of hACE2, the differences we see in expression levels may be mediated by less efficient interactions between the antibody and Vero E6 ACE2 (89% amino acid homology to hACE2) or cACE2 (84% amino acid homology to hACE2) in their natural conformations. Positive control DBT-GFP-His cells exhibited a high level of GFP expression by flow cytometry and Western blot analysis. ACE2 expression was not detected in untransfected DBT cells.

Resurrection of icSZ16-S in DBT-cACE2 cells. To assess virus replication and ACE2 transgene expression in our cell panel, we employed a highly sensitive RT-PCR-based assay. In the coronavirus model of discontinuous transcription, subgenomic messages all contain the same 5′-leader sequence (24). Thus, active SARS-CoV mRNA synthesis can be detected by RT-PCR for viral subgenomic leader-containing transcripts. In our assay, we used a forward primer directed

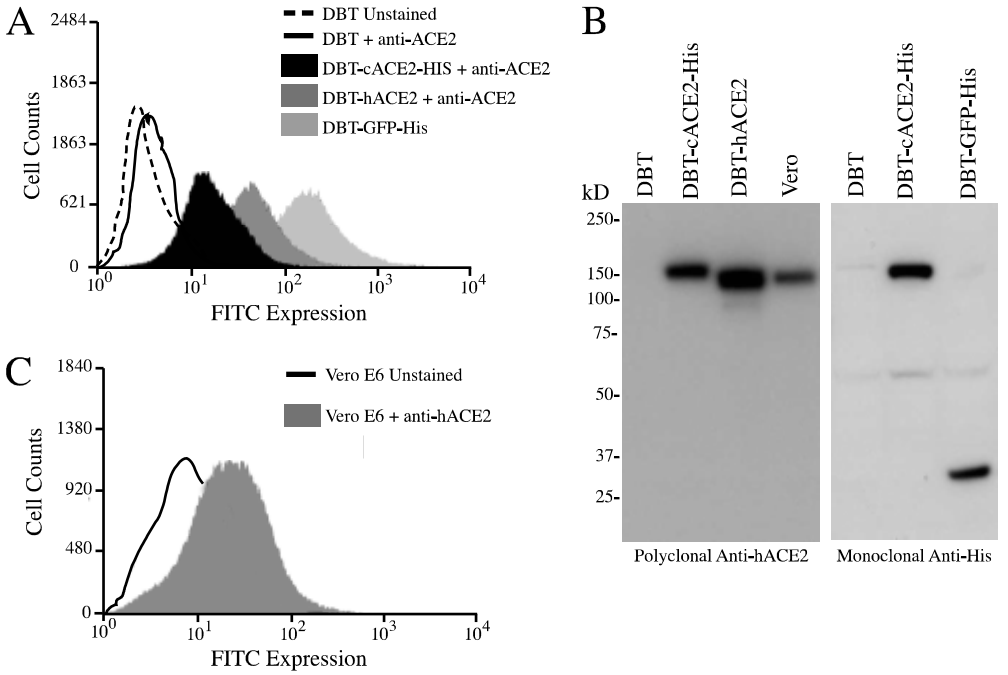

FIG. 1. Characterization of cACE2- and hACE2-expressing DBT cells by flow cytometry and Western blotting. ACE2 expression levels in Vero E6 cells or DBT cells stably expressing cACE2, hACE2, or GFP were assessed by flow cytometry and Western blotting. DBT cells stably transfected with plasmids carrying cACE2-His, hACE2, or GFP-His were passaged four times, after which cells were stained for ACE2 expression (primary antibody, polyclonal anti-hACE2; secondary antibody, anti-goat-FITC) and sorted for mid-to-high ACE2 expression (FITC). GFP control cells were also sorted for mid-to-high expression. (A and C) To assess ACE2 expression in expanded postsorted cell stocks and in Vero E6 cells, cells were stained as described above and analyzed for FITC/GFP expression by flow cytometry. (B) To assess ACE2 expression in Vero E6 cells and in postsorted cell stocks by Western blotting, similar numbers of Vero E6, DBT, DBT-hACE2, DBT-cACE2-His, and DBT-GFP-His cells were lysed and separated on a NuPage 12% bis-Tris SDS-polyacrylamide gel. After membrane transfer, blots were probed with either polyclonal goat anti-human ACE2 or mouse anti-penta-His antibody. After membranes were washed, they were probed with either rabbit anti-goat HRP or anti-mouse IgG-HRP antibody. Membranes were rinsed and treated with ECL Plus reagent and exposed to radiographic film.

against the leader sequence and a reverse primer in the M gene, allowing us to preferentially detect subgenomic transcripts encoding the open reading frame (ORF) of the 3a, E, and M genes. ACE2 transcripts were detected by RT-PCR in mock-infected cell cultures of DBT-hACE2, DBT-cACE2, and Vero E6 cells (Fig. 2A). ACE2 transcripts were not detected in DBT cells, corroborating our flow cytometry and Western blot results. As expected, GAPDH-positive control transcripts were

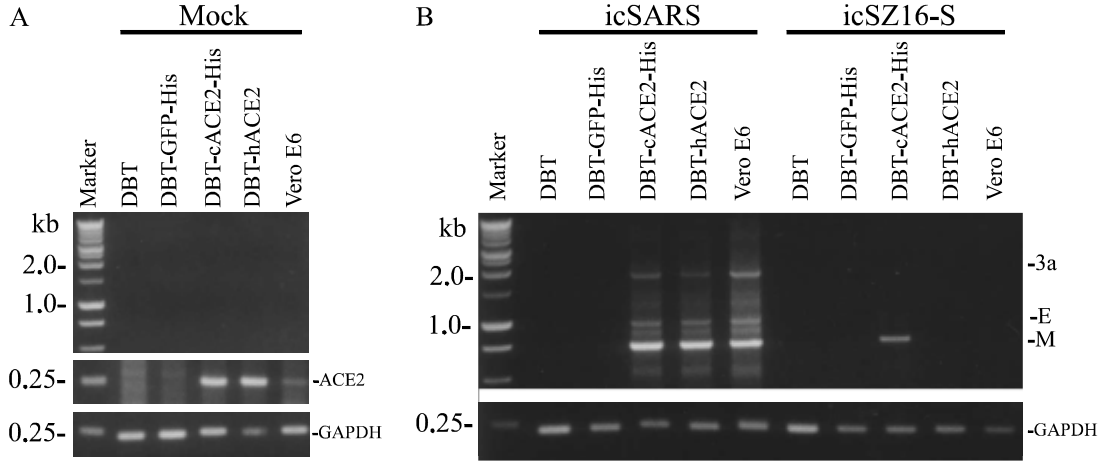

FIG. 2. Resurrection of icSZ16-S with DBT-cACE2 cells. RT-PCR to detect subgenomic leader-containing transcripts was performed to detect viral replication. DBT, DBT-GFP-His, DBT-cACE2, DBT-hACE2, or Vero E6 cells were infected with 100 ffil of viral supernatant from the initial icSZ16-S transfection, or the icSARS supernatants (B), or they were mock infected (A). At 24 hpi, total RNA was isolated, and cDNA was generated and then used as template for PCR. Evidence of SARS-CoV replication and subgenomic transcription, ACE2 gene expression, and control GAPDH gene expression was detected by the production of amplicons (SARS-CoV, 3a [1,796 bp], E [947 bp], M [666 bp]; control, 235 bp GAPDH; ACE2, 258 bp) visualized by electrophoresis using a 1.8% agarose TAE gel.

Downloaded from jvi.asm.org at University of North Carolina - Chapel Hill on December 20, 2008

detected at similar levels in all mock-infected cell cultures, while none of the mock-infected cultures was positive for SARS-CoV replication (Fig. 2A). In the icSARS virus-infected cell panel, DBT-cACE2, DBT-hACE2, and Vero E6 cells were clearly capable of supporting efficient SARS-CoV replication. Under identical conditions, SARS-CoV leader-containing transcripts were not detected in control DBT and DBT-GFP-His cells (Fig. 2B). Interestingly, only cACE2-expressing cells efficiently supported the replication of icSZ16-S (Fig. 2B). Importantly, icSZ16-S was successfully passaged and maintained in DBT-cACE2 cells in vitro, producing a robust cytopathology after four passages at 48-h intervals. Passage-four virus was plaque purified, stocks were grown, and the S, 3a, E and M genes were sequenced. Only one coding mutation (Y107H) was found in the 3a gene.

Assessment of virus growth in DBT, DBT-cACE2, DBT-hACE2, and Vero cells. Prior to this report, zoonotic SARS S virus and h/cACE2 interactions were evaluated by using pseudovirus bearing the GD03 and SZ16 S proteins, but these assays were unable to address virus growth fitness (19, 36). Moreover, one study suggested that the GD03 S protein was not dependent on ACE2 for docking and entry (36). Consequently, we assessed the growth fitness of recombinant virus bearing various S glycoproteins derived from the early, middle, and late phases of the SARS epidemic in China. We employed recombinant SARS-CoV bearing the S genes isolated from humans during the early (icGZ02), middle (icCUHK-W1), and late (icSARS) phases of the epidemic and one isolate from a sporadic human case in early 2004 (icGD03-S). The GD03, GZ02, and CUHK-W1 S glycoproteins differ from the those of the epidemic strain by 17, 8, and 2 amino acids, respectively (Fig. 3D). We also evaluated the growth of the icSZ16 parent virus and two SZ16 mutants, previously described by Sheahan et al., which were selected for efficient growth in HAE cells (26). The SZ16, SZ16-K479N, and SZ16-K479N D22 S glycoproteins differ from those of the epidemic strain by 18, 17, and 19 amino acids, respectively (26). The growth fitness of the virus panel was assessed in DBT, DBT-cACE2, DBT-hACE2, and Vero E6 cell cultures (Fig. 3A, B, and C). Cultures were infected at an MOI of 0.01 for 1 h and washed to remove input virus, and growth medium was added; then, cultures were sampled at various times postinfection. DBT cells that were not transfected with the SARS receptor ACE2 were not permissive to infection by any of the viruses tested (data not shown). In DBT-cACE2 cells, icSARS, icSZ16-S, icGZ02, and icGD03-S grew to similar peak titers by 36 hpi (Fig. 3A). In DBT-cACE2 cells at 12 hpi, the icSZ16-S titers were approximately one log higher than those of all of the other viruses tested (Fig. 3A). Interestingly, CUHK-W1 had severely delayed growth kinetics within the cACE2-expressing cells. Similarly, icSZ16-S K479N and icSZ16-S K479N D22 exhibited little to no growth in the DBT-cACE2 cells, though their S protein sequences differ from that of SZ16 by one (K479N) and three (D22) amino acids (Fig. 3A). Within DBT cells expressing hACE2, the epidemic strain exhibited superior growth fitness compared to those of the other viruses tested, with a 1 to 2 log titer advantage at 12 hpi, but icSARS, icCUHK-W1, icGZ02, icGD03-S, and icSZ16-K479N D22 grew to similar peak titers by 36 hpi. As we had seen previously, icSZ16-K479N grew poorly in the DBT-hACE2 cells, reaching titers of less than 10^4 PFU/ml, and icSZ16-S did not grow at all (Fig. 3B). Vero E6 cell growth kinetics for icSARS, icCUHK-W1, icGZ02, and icSZ16-S K479N D22 were quite similar, reaching titers of around 10^7 PFU/ml by 36 hpi, while icSZ16-S K479N and icGD03-S grew much less efficiently (# 10^5 PFU/ml at 36 hpi) (Fig. 3C). As we had seen by RT-PCR, the Vero E6 cell was not permissive to infection by icSZ16-S (Fig. 3C).

icGD03-S and icSZ16-S are dependent on ACE2 for entry. Using pseudotyped viruses, previous reports have suggested that some zoonotic SARS-CoV do not use ACE2 for entry (36). Since the SARS S pseudotyped viruses lack the other SARS-CoV structural proteins found in the SARS-CoV envelope (E, M, 3a, and 7a) and the amounts of S protein present on the surface of pseudovirus may differ from those found on the surface of a natural SARS-CoV particle, the use of SARS S pseudotyped viruses to study binding and entry might not faithfully recapitulate natural virus-cell interactions. To assess the receptor dependence of the recombinant SARS-CoV strains bearing zoonotic S proteins, we utilized a receptor antibody blockade assay (Fig. 4). Twofold dilutions of antibody (polyclonal anti-ACE2) or control antibody (polyclonal anti-ACE) were used to block ACE2 within DBT-cACE2 cells. The blocked cells were subsequently infected with 100 PFU of icSARS, icGD03-S, or icSZ16-S, rinsed and overlaid with medium containing agarose. All three viruses tested were equally dependent on ACE2 for entry, exhibiting a dose-dependent response to anti-ACE2 receptor blocking antibody (Fig. 4). Control antibody (polyclonal anti-ACE) was not capable of blocking entry of any of the viruses tested in a dose-dependent manner, firmly establishing the fact that ACE2 is a receptor for both the epidemic and the civet strains of SARS-CoV (Fig. 4).

hu-MAb S230.15 and S3.1 neutralization profiles differ between epidemic, in vitro-evolved, and zoonotic strains of SARS-CoV. hu-MAbs S230.15 and S3.1 were isolated from a convalescent SARS patient's B cells (21, 30). To assess the neutralization efficacy of these hu-MAbs, we employed a PRNT assay with the following challenge viruses: icSARS (epidemic strain S protein), icGD03-S (divergent human strain S protein), icSZ16-S (civet strain S protein), icSZ16-S K479N (SZ16 S protein mutated at residue 479 from lysine to asparagine), and icSZ16-S K479N D22 (in vitro-evolved mutant with enhanced growth in human cells whose S protein is mutated at Y442F and L472F). The broadly neutralizing hu-MAb S230.15 was able to neutralize 50% ($PRNT_{50}$) of icSARS virus and the evolved icSZ16-S K479N D22 virus, using less than 0.03125 ffig/ml of antibody, while icGD03-S, icSZ16-S K479N and icSZ16-S were approximately four times more resistant ($PRNT_{50}$ $ 0.125 ffig/ml) (Fig. 5A). The S3.1 hu-MAb was not as effective at neutralizing the viruses tested ($PRNT_{50}$ for icSARS and icSZ16-S K479N was 0.25 ffig/ml and for icSZ16-S K479N D22 was 0.625 ffig/ml) (Fig. 5B). Unlike hu-MAb S230.15, hu-MAb S3.1 was weakly efficacious against icGD03-S ($PRNT_{50}$ % 1 ffig/ml) and completely ineffective against icSZ16-S (Fig. 5B).

Structural models of SARS and ACE2 interactions. To gain a better understanding of the structural changes associated with the mutation of both the S and the ACE2 proteins, we developed predictive structural models of S and cACE2/hACE2 interactions using RosettaDesign and Modeler software. Our models suggest that additional methyl groups in E30 and Y34 of cACE2 likely

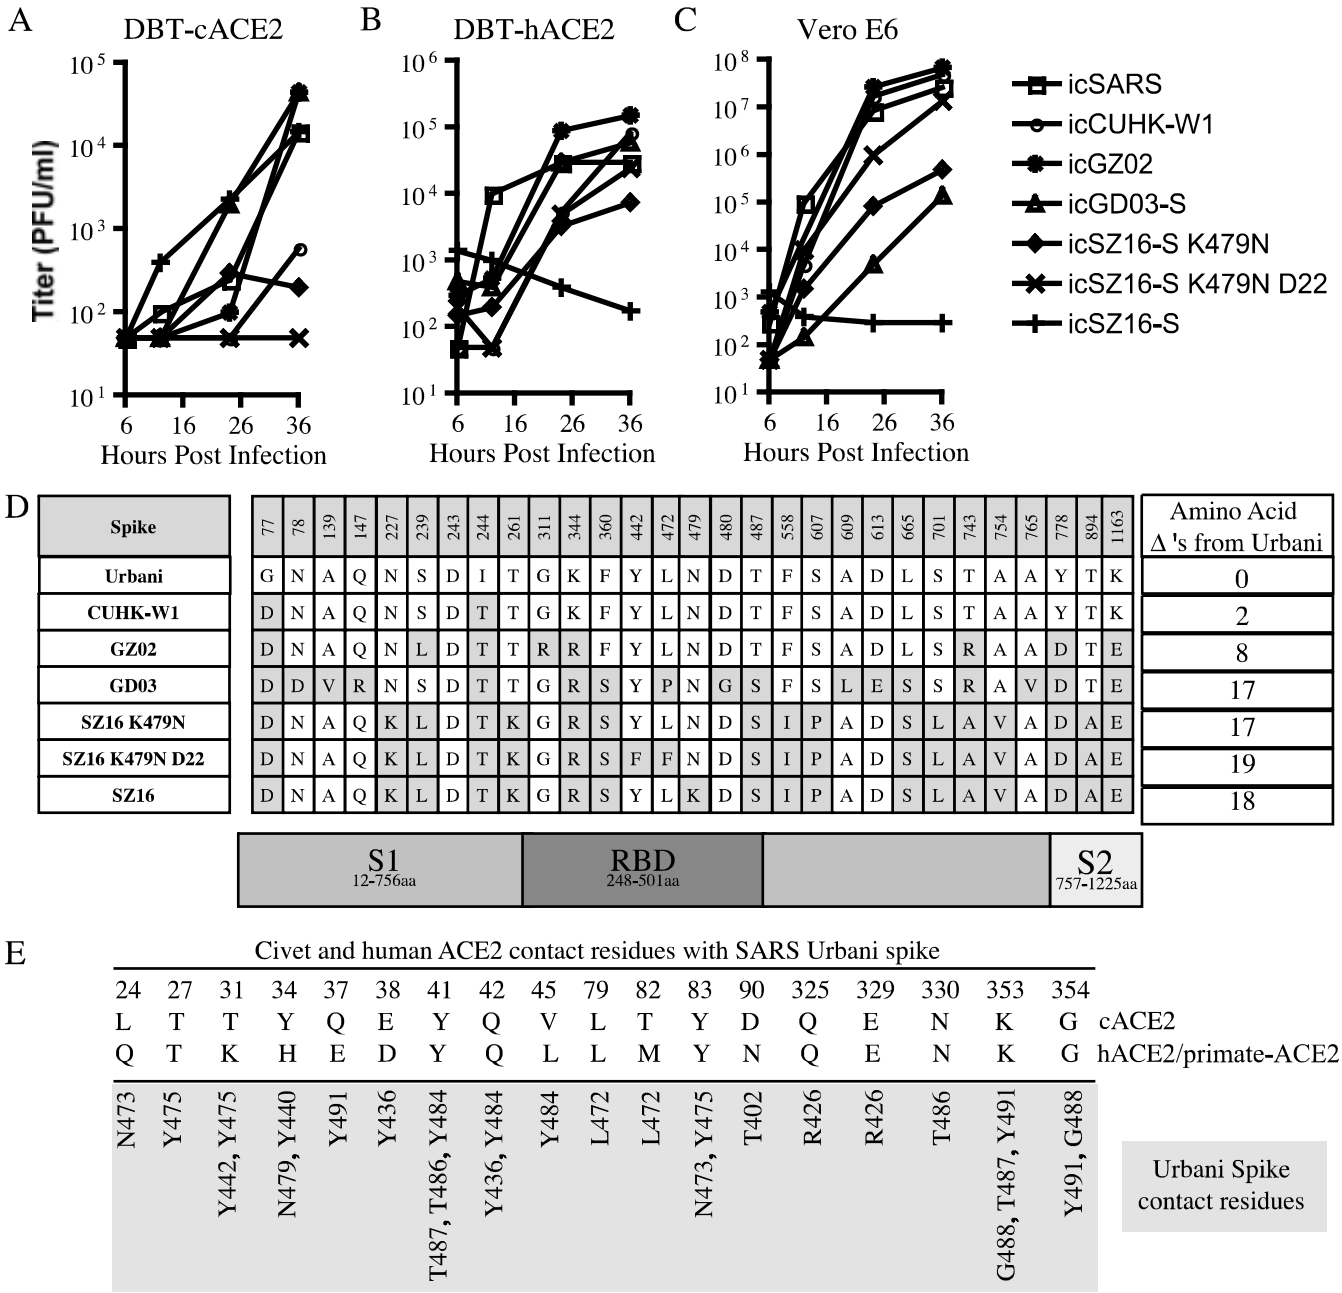

FIG. 3. Assessment of virus growth in DBT, DBT-cACE2, DBT-hACE2, and Vero cells, the spike amino acid variation in our recombinant virus panel, and the ACE2 contact residues with the Urbani spike. DBT-cACE2 (A), DBT-hACE2 (B), Vero E6 (C), or DBT (data not shown) cells were infected with icCUHK-W1, icGD03-S, icGZ02, icSZ16-S K479N p6, icSZ16-S K479N D22, icSARS, or icSZ16-S at an MOI of 0.01 for 1 h at 37°C. Cell medium (25 ffil) was removed at 0, 6, 12, 24, and 36 hpi, and samples were stored at " 80°C until titers were determine by plaque assay. Growth curves were performed in duplicate on two separate occasions, and the data shown are representative of one experiment. (D) The location of spike amino acid differences among the recombinant virus panels. (E) Urbani, cACE2, primate-ACE2, and hACE2 contact residues, adapted from the crystal structure published by Li et al. (17).

create a protrusion from the binding interface that is enhanced compared to that of hACE2. The architecture of the Urbani RBD can accommodate this protrusion on the cACE2 binding interface, thus retaining efficient binding to both cACE2 and hACE2 (Fig. 6A and B). We and others have previously published structural models that suggest that K479 of the SZ16 S protein inhibits binding to hACE2 because of electrostatic clashes with the hACE2 binding partners K31 and H34, but the SZ16 binding partners within cACE2 are different (Y34 and E30) and allow for efficient binding of SZ16 S (Fig. 6C) (17, 19, 26). Interestingly, the human ACE2 adaptive mutations in SZ16 K479N and SZ16 K479N D22 that progressively remodel the RBD binding interface to enhance binding to hACE2 (Fig. 6D and F) create a steric clash between the RBDs V404/Y440 and E30/Y34 of cACE2

Downloaded from jvi.asm.org at University of North Carolina - Chapel Hill on December 20, 2008

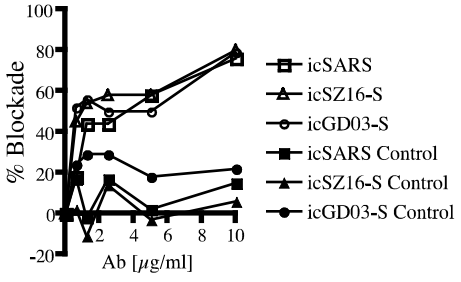

FIG. 4. icGD03-S and icSZ16-S are dependent on ACE2 for entry. DBT-cACE2 cells were seeded at 5 ! 10^5 cells/well in six-well dishes. The following day, cell medium was removed, and cells were incubated with 10, 5, 2.5, 1.25, or 0.625 ffg/ml polyclonal anti-ACE2 or anti-ACE or DBPS for 1 h at 37°C. After the 1-h pretreatment with antibody, 100 PFU/50 ffil of icSARS, icSZ16-S, or icGD03-S was added to the monolayer and incubated for 1 h at 37°C. After the infection, the inoculum was removed and the monolayer was rinsed with DPBS and then overlaid with 0.9% agarose in complete growth medium. At 48 hpi, plates were stained with neutral red, and plaques were counted. The average percentage of blockade was calculated by dividing the average number of plaques per Ab dilution by the average number of plaques in the DPBS no-Ab controls. Blockade experiments were performed in duplicate on two separate occasions.

(Fig. 6E and G). Similar to that which we had seen with in vitro growth analysis, the SZ16 K479N and D22 binding interfaces cannot accommodate the enhanced protrusion of cACE2 and are unable to bind efficiently.

DISCUSSION

The recent emergence of viruses like SARS-CoV, Ebola, influenza H5N1, Marburg, and Nipah virus highlights the pathogenic and epidemic potential of zoonoses in human populations (7, 10, 16, 29, 32). The identification of zoonotic virus animal reservoirs is often unsuccessful, hampering our ability to understand the epidemiology of zoonotic diseases and the conditions required for zoonotic host range expansion. Extensive virus sequencing efforts allowed the identification of palm civets as a potential amplification host for SARS-CoV and Chinese horseshoe bats as the potential SARS-CoV animal reservoir within a short span of 2 years (2, 8). Though sequencing efforts have revealed much about the biology of zoonotic SARS-CoV, bat and civet isolates have not yet been cultured in vitro (13, 15). Using synthetic biology and reverse genetics, we constructed a SARS-CoV bearing a civet SZ16 S glycoprotein. In corroboration with Lau and Peiris, we have shown that icSZ16-S could not be maintained by passage in cell cultures that normally support SARS-CoV infection (15). Without the successful cultivation of zoonotic SARS-CoV, their mechanisms of host range expansion and pathogenic potential remain elusive, and the efficacy of current therapies against zoonotic strains remains unknown.

Rather than mutate the SZ16 S glycoprotein to promote growth in cell culture, we constructed a stable cell line expressing the cACE2 orthologue of the human SARS-CoV receptor (hACE2). Compared to the published gene sequence, the cACE2 gene utilized to construct our stable cells differed by two residues, G354D and R736Q, but only the residue G354 resides at a proposed interaction site with the SARS S RBD (Y491 and G488) (17). Residue 354 is polymorphic in nature, where some civet samples contain the G354 ACE2 mutation, while others contain the D354 ACE2 mutation (personal communication, M. Farzan) (18). All of the viruses used within this study have the same amino acid at residues 491 (tyrosine) and 488 (glycine) (Fig. 3E). In turn, if the G354D mutation in our cACE2 protein has a deleterious effect on binding and entry, we predict that all viruses would be affected equally. As our data regarding Urbani and SZ16 binding to cACE2 and hACE2 are concordant with previously published data by Li et al., it is unlikely that the G354D mutation in cACE2 is altering our virus growth phenotypes, and this hypothesis is supported by our predictive structural modeling which suggests that the G354D mutation does not affect the conformation of the cACE2 binding interface (data not shown) (19).

Using DBT-cACE2 cells, we have demonstrated that icSZ16-S can be grown, maintained, and plaque purified. In support of Li et al., we have shown that civet SARS-CoV utilizes cACE2 but cannot utilize hACE2 or Vero E6 ACE2,

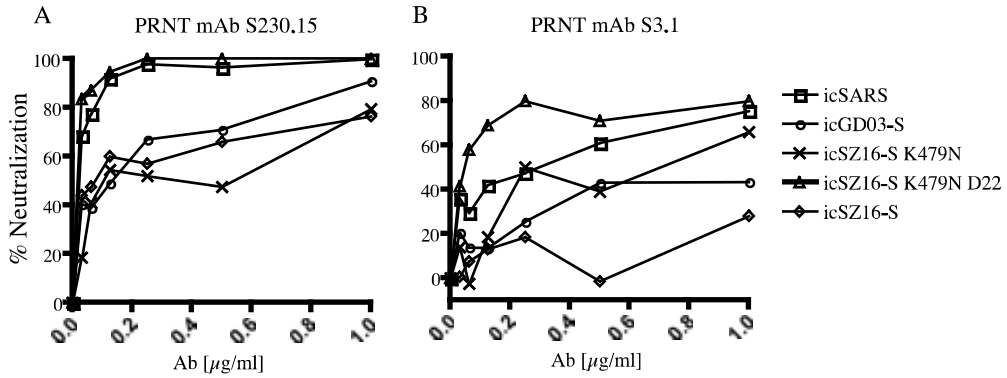

FIG. 5. hu-MAb S230.15 and S3.1 neutralization profiles differ between the epidemic, the in vitro-evolved, and the zoonotic strains of SARS-CoV. Neutralizing titers were determined by PRNT assay. Twenty-four hours before cells were infected, six-well plates were seeded with 5 ! 10^5 DBT-cACE2 cells/well. hu-MAb S230.15 and S3.1 and an isotype control antibody directed against cholera toxin, D2.2, were serially diluted twofold and incubated with 100 PFU of either icSARS, icSZ16-S, or icGD03-S for 1 h at 37°C. Virus and antibodies were then added to six-well plates of DBT-cACE2 cells in duplicate and incubated at 37°C for 1 h, after which the cells were overlaid with 3 ml of 0.8% agarose in medium. After 48 h, plates were stained with neutral red, and plaques were counted. The percentage of neutralization was calculated as 1 " (number of plaques with antibody/number of plaques without antibody) ! 100%.

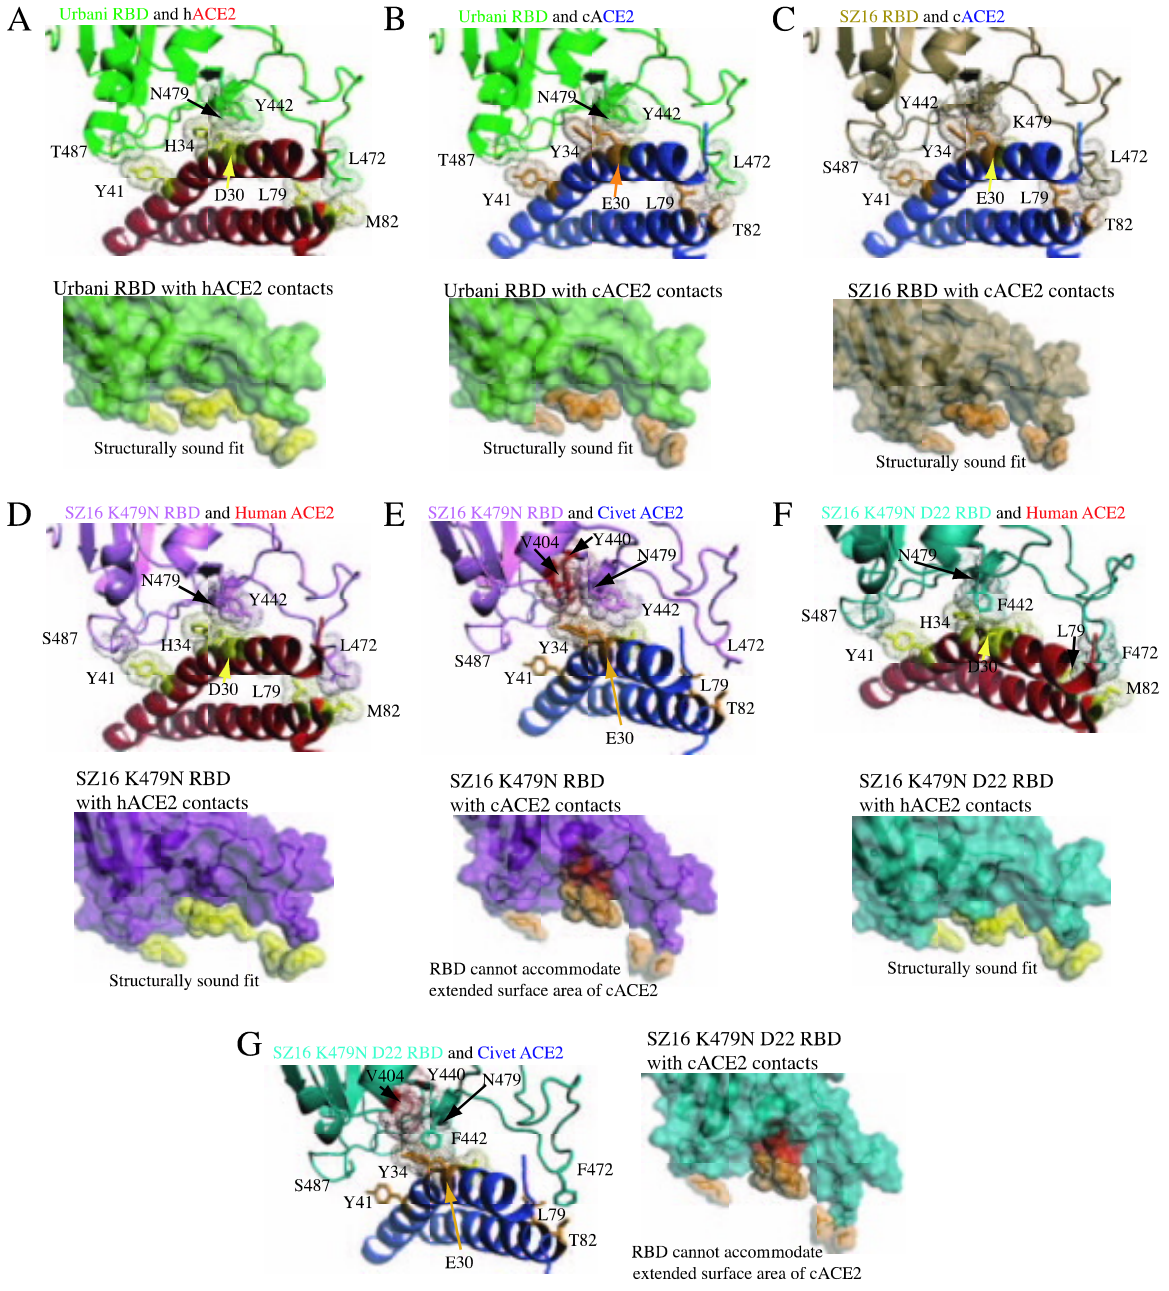

FIG. 6. Molecular modeling demonstrating structural mechanisms of ACE2 tropism. Based on the reported crystal coordinates of SARS Urbani RBD interacting with the hACE2 receptor, we generated models of Urbani, SZ16, SZ16-K479N, and SZ16 K479N D22 RBD interactions with either cACE2 or hACE2, using RosettaDesign and Modeler software. Ribbon structures and "space filling" schematics of each RBD and ACE2 combination are shown. Dotted spheres around the RBD and ACE2 residues indicate they are within 4 Å and thus are predicted to interact. Red spheres around the RBD and ACE2 residues indicate a steric clash. (A) Urbani RBD and hACE2 architecture. (B) Additional methyl groups of the cACE2 E30 and Y34 mutations add a surface protrusion to the contact interface. The Urbani RBD can accommodate the increased surface protrusion of cACE2, thereby retaining an efficient binding interface. (C) Similar to the Urbani RBD, the SZ16 RBD can accommodate the increased surface protrusion of cACE2 for efficient binding. (D) The N479 mutation in SZ16 K479N remodels the SZ16 binding interface to promote binding to hACE2. (E) The remodeling of the SZ16 K479N binding interface by the N479 mutation creates a clash between S residues (V404 and Y440) and cACE2 residues (E30 and Y34), blocking S and ACE2 binding. The SZ16 K479N RBD cannot accommodate the extended surface protrusion of the cACE2 RBD. (F) In addition to the N479 mutation, the F442 and F472 mutations further remodel the SZ16 K479N D22 RBD, further enhancing the binding efficiency to hACE2. (G) Similar to the SZ16 K479N RBD interaction with cACE2, the interaction of the SZ16 K479N D22 RBD cannot accommodate the protrusion of cACE2, abrogating binding.

confirming that the civet SZ16 virus is restricted in its host range (Fig. 2B). Using pseudotyped lentivirus, Li et al. showed that the SARS Urbani S protein was capable of utilizing both cACE2 and hACE2, and we confirmed these data by showing that icSARS is capable of infecting both cACE2- and hACE2-expressing cells and replicating to a high titer (Fig. 2B and 3A and B). In support of our RT-PCR data suggesting that icSZ16-S was restricted in its host range (Fig. 2B), icSZ16-S

Downloaded from jvi.asm.org at University of North Carolina - Chapel Hill on December 20, 2008

grew only within cACE2-expressing cells and grew to titers similar to those of the epidemic strains icGD03-S and icGZ02 (Fig. 3 A, B, and C). Interestingly, icSZ16-S exhibited a clear growth advantage at 12 hpi, suggesting that it might gain entry into cACE2-expressing cells more rapidly than the other viruses tested. The icSZ16-S K479N and D22 viruses were adapted for efficient growth on a primary HAE cell culture, which is known to be a robust and relevant model of the complex human airway epithelium (27). Importantly, these viruses did not grow efficiently within DBT-cACE2 cells, suggesting that HAE cell growth-enhancing mutations in the civet S (K479N, Y442F and L472F) proteins diminished binding of the icSZ16-S K479N/D22 S protein to cACE2. To conclusively demonstrate that differences in the cACE2 binding affinities of the icSZ16-S, icSZ16-S K479N, and D22 viruses account for the observed differences in growth kinetics, binding and entry assays will be performed in the future. In hACE2-expressing cells, the epidemic strain displayed a clear growth advantage at 12 hpi, but most all of the viruses tested grew to similar peak titers by 36 hpi. In Vero E6 cells, the viruses bearing S proteins that were more similar to that of the epidemic strain (CUHK-W1, GZ02) grew to peak titers that were far greater than those of viruses bearing the S proteins that were more civet-like (SZ16, GD03, and SZ16 K479N). As we had expected, icSZ16-S was not capable of growth within DBT-hACE2 or Vero E6 cells, but mutations in the SZ16 S protein at select interaction sites with ACE2 (K479N, Y442F, L472F) rescued and promoted growth in hACE2 or Vero E6 cells. These data suggest that the SARS-CoV S and receptor interactions are quite specific and capable of restricting the host range or limiting infection efficiency. Moreover, these data also suggest that very few mutations in the civet S protein can enhance infection of human cells (K479N, Y442F, L472F) and simultaneously abrogate infection of cACE2-expressing cells. A corollary is seen in the more human-tropic strains. icCUHK-W1, a middle-phase epidemic isolate whose S protein differs from that of Urbani by two amino acids, is quite capable of infecting cells expressing hACE2 while it grows very poorly in cACE2-expressing cells compared to the epidemic strain. These data suggest that G77 and/or I244 of the epidemic strain enhances growth in cACE2-expressing cells. Though G77 and I244 reside outside of the RBD (amino acids 248 to 501), their close proximity to the RBD may either promote a conformational rearrangement of the S protein, subtly altering the S binding interface through long-range protein interactions, or somehow contribute to binding or entry by an unknown mechanism. Through the passage of zoonotic S-bearing SARS-CoV on Vero E6 cells, Rockx et al. described mutations just outside of the RBD (HC/SZ/61/03; amino acid positions 578; and A031G, amino acid position 577) that seemed to enhance growth, suggesting that mutations outside of the RBD may influence the architecture of the binding interface or enhance binding and entry by an unknown mechanism (22). All together, the growth curve data highlight the plasticity of both zoonotic and human-tropic SARS-CoV S proteins, where the subtle remodeling RBD can both enhance and abrogate binding to ACE2.

Serological evaluation of workers in wet markets suggests that zoonotic SARS-CoV was transmitted to humans, though these seropositive individuals did not present clinically with SARS (1). These data support the hypothesis that repeated transfer of zoonotic SARS-CoV from civet to human and/or from human to civet fostered the evolution of the epidemic strain. Alternatively, repeated single introductions of civet SARS-CoV into the human population may eventually have resulted in the generation of a human-tropic SARS-CoV that coincidently retained affinity for cACE2. Our growth curve analyses demonstrating that the epidemic strain is equally fit at growth within cACE2- or hACE2-expressing cells supports both evolutionary hypotheses. In fact, recent data suggest that civets infected with human-tropic SARS-CoV develop symptoms and a pathology similar to those seen in human cases of SARS-CoV infection (35). Our predictive RBD and ACE2 structure model data provide a possible explanation of how the dual host tropism of SARS Urbani is retained. The cACE2 molecule differs from that of hACE2 by two key residues (E30 and Y34), which likely creates a pronounced protrusion from the cACE2 binding interface. The Urbani RBD is able to accommodate the various binding interfaces of both cACE2 and hACE2, thus retaining dual host tropism. We also demonstrate that the SZ16 lineage viruses passaged with HAE cells, in the absence of cACE2, evolved a mutant RBD that allowed for more efficient binding of hACE2 (icSZ16-S K479N, D22) but simultaneously lost the ability to efficiently infect cACE2-expressing cells. Our predictive structural models suggest that the human adaptive RBD mutations in icSZ16-S K479N and D22 abrogate their abilities to accommodate the protrusive cACE2 binding interfaces. Therefore, we hypothesize that in the absence of evolutionary pressure to retain the ability to grow within both cACE2- and hACE2-expressing cells, a series of mutations are acquired to enhance binding to only one of the two receptors. We might have been able to generate a strain more similar to the dual tropic epidemic strain had we done repeated passages of the icSZ16-S virus, alternating between cACE2- and hACE2-expressing cells. Nevertheless, these data suggest that the natural evolution of the epidemic strain probably occurred through repeated transfer of virus from civet to human and from human to civet over a long period of time, providing the evolutionary pressure to retain dual ACE2 tropism. This hypothesis is supported by three serological surveys performed to determine the prevalence of SARS-CoV-specific IgG in healthy subjects in China. First, samples collected from volunteers in Guangdong province in China, in May 2003, demonstrated that SARS virus-specific IgG was found in animal traders (13%; n = 508), hospital workers (2.9%; n = 137), Guangdong CDC workers (1.6%; n = 63), and healthy adults at the clinic (1.2%; n = 84) (1). The second study was a retrospective serological survey performed with 1,621 serum samples from March 2002, isolated from healthy 18-year-old male Chinese soldiers from 17 provinces, including Guangdong (39). Of these 1,621 samples, 0.68% tested positive for SARS-CoV by enzyme-linked immunosorbent assay, though the provinces that the SARS-CoV IgG-positive soldiers inhabited were not mentioned. A third study retrospectively examined 938 serum samples collected in May of 2001 from healthy adults in Hong Kong. Shockingly, 1.8% of these samples collected 2 years prior to the epidemic tested positive for SARS-CoV by immunofluorescence assay (40). These data suggest that less serious or asymptomatic cases of SARS-CoV existed at least 2 years prior to the beginning of the epidemic in various geographical locations in

China. If the populations sampled in the May 2003 cohort are representative of the Guangdong province population (estimated population of 100,000,000), there were probably many more unreported or less serious cases (%1,000,000) of SARS-CoV infection prior to the evolution of the highly pathogenic epidemic strain of 2002 to 2003.

Though molecular evolution studies of SARS-CoV genomes have demonstrated that the S gene had undergone a significant amount of mutation and positive selection during the early phases of the epidemic, the nonstructural ORF1a demonstrated a similar pattern (2). We have chosen to focus on the importance of the S mutation and ACE2 interaction for viral evolution and host range expansion, but the molecular genetic data clearly suggest that mutation of nonstructural genes may also have been important for the efficient adaptation to new hosts.

In 2005, Yang et al. reported that pseudoviruses bearing the zoonotic S (GD03 and SZ3) protein were much less dependent on ACE2 for entry in 786-O cells (36). Using 786-O cells and similar pseudoviruses bearing the Tor2, GD03, or SZ3 S proteins, both Li et al. and He et al. were not able to infect 786-O cells with pseudoviruses (9, 19). Since SARS S pseudotyped viruses lack SARS-CoV membrane-bound proteins (E, M, 3a, 7a) and may contain unnatural amounts of surface SARS S glycoprotein, pseudovirus may produce false-positive or false-negative results for binding and entry assays. Moreover, the pseudovirus systems are limited to the evaluation of binding and entry and are unable to evaluate the effects of zoonotic glycoproteins on replication and growth. To reevaluate the pseudovirus findings in the context of natural SARS-CoV infection, we constructed SARS-CoV strains bearing zoonotic S proteins. The SZ3 S protein differs from that of SZ16 by one amino acid outside of the RBD (SZ3 F558, SZ16 I558). Since our molecular and growth curve data suggested that icSZ16-S efficiently infects only cACE2-expressing cells, we performed receptor blockade experiments with DBT-cACE2 cells. We found that icSARS, icSZ16-S, and icGD03-S were similarly blocked from entry in a dose-dependent manner, using an antibody directed against ACE2, while the control antibody had little effect. Though we did not achieve 100% blockade with the highest concentration of antibody tested, we believe that polyclonal anti-hACE2 may interact less efficiently with native cACE2. Alternatively, we may not have completely saturated the available surface cACE2, which would result in an incomplete blockade. At this time, we believe it is more likely that our inability to block 100% of infection was due the technical issues discussed above and less likely that zoonotic viruses gain entry into cells via alternative receptors. Since the viruses we evaluated could not productively infect nontransfected DBT cells, it is unlikely that the incomplete block in entry with the Ab was due to entry via alternative receptors. However, coreceptors (L-SIGN) have been reported for SARS-CoV, but to our knowledge, the ability of zoonotic SARS-CoV to engage these receptors has not been rigorously examined (11). Therefore, we believe we most likely did not block 20% of the surface ACE2 with 10 ffig/ml Ab.

Since it is impossible to predict the antigenic identity of future emergent SARS viruses, the development of highly cross-reactive antibody, drug, or vaccination therapies would provide the greatest potential benefit to public health. Recently, we and others have shown that hu-MAb S230.15 was less effective at neutralizing icSZ16-S K479N in vitro but was very effective in passive transfer studies with mice, lowering viral titers of both icGD03-S and icSZ16-S K479N below the detectable limit (41). In in vitro PRNT assays, icSZ16-S and icGD03-S were also more resistant to neutralization by S230.15 than the epidemic strain. Since icSZ16-S and icGD03-S are similarly neutralized by S230.15 in vitro, passive transfer studies by Zhu et al. suggest that S230.15 would be effective against icSZ16-S in vivo as well (41). Yang et al. described an antibody-dependent enhancement phenomenon using hu-MAb S3.1 in neutralization assays with 786-O cells, using the GD03 and SZ16 pseudoviruses (36). We performed PRNT assays with cACE2 cells, using icSARS, icSZ16-S, and icGD03-S, and found that S3.1 is moderately effective against icSARS, weakly effective against icGD03-S, and ineffective against icSZ16-S. Since there was such a dynamic range of neutralization efficacies using S3.1 against a panel of epidemic and zoonotic SARS-CoV, these data highlight the pitfalls of using only the epidemic strain when passive immunization or vaccination therapies are evaluated. Of note, ter Meulen et al. explored the possibility of antibody-dependent enhancement in human macrophages using SARS-CoV and subneutralizing concentrations of monoclonal antibodies and found that SARS-CoV is taken up by macrophages but does not productively infect the cells (28).

Coronaviruses similar to SARS Urbani are currently circulating within bat species in China. Constant surveillance and biological evaluation of zoonotic pools of coronavirus are impractical, making it quite difficult to predict the antigenic identity of emergent SARS-CoV-like viruses in the future. Therefore, it is imperative that current antiviral therapies be broadly cross-reactive against all known SARS-CoV, thereby maximizing the potential public health benefit. We have constructed a SARS-CoV bearing the prototypic civet S protein from the SZ16 strain. Prior to this publication, SARS-CoVs bearing the SZ16 S protein were not able to be propagated in vitro, hampering the study of the SZ16 biology and its pathogenic potential. We have demonstrated that icSZ16-S can be propagated in vitro in DBT-cACE2 cell cultures, that it is dependent on ACE2 for entry, and that it is incapable of using hACE2 for entry. We have also demonstrated that point mutations in the SZ16 S protein that enhance virus growth in primary HAE or DBT-hACE2 cells severely diminish growth in DBT-cACE2 cells, while the epidemic strain retains dual ACE2 tropism. These data and retrospective serological surveys in China suggest that the natural evolution of the epidemic strain probably occurred over a long period of time through the repeated transfer of virus from civet to human and from human to civet and that this dual host evolutionary scenario provided the evolutionary pressure to retain dual ACE2 tropism. We have also demonstrated that both icGD03-S and icSZ16-S are neutralized by hu-MAb S230.15 but are more resistant to S3.1, highlighting the utility of using an antigenically diverse SARS-CoV panel to assess serotherapy efficacy. The icSZ16-S virus is yet another antigenically divergent zoonotic S protein-bearing SARS-CoV that will prove useful in evaluating future serotherapies or vaccination therapies.

ACKNOWLEDGMENTS

We thank Michael Farzan, Harvard Medical School, Boston, MA, for kindly providing the cACE2 and hACE2 expression plasmids. We also thank Antonio Lanzevecchia, Institute for Research in Biomedicine, Bellinzona, Switzerland, for graciously providing hu-MAbs S230.15, S3.1, and D2.2. We also thank Amy Sims and Boyd Yount for world-class technical assistance and superb cloning advice.

This work was supported by research grants (R01 AI059136 and AI059443) to R.B. from the National Institutes of Health, Division of Allergy and Infectious Diseases.

DEFENSE ADVANCED RESEARCH PROJECTS AGENCY
675 NORTH RANDOLPH STREET
ARLINGTON, VA 22203-2114

Dr. Peter Daszak
EcoHealth Alliance
460 West 34th Street, 17th Floor
New York, NY 10001

Ref. #: HR001118S0017-PREEMPT-BAA-FP-019, Project DEFUSE: Defusing the Threat of Bat-borne Coronaviruses

Dear Dr. Daszak:

This letter is in response to the proposal referenced above, submitted in response to the Defense Advanced Research Projects Agency (DARPA) Broad Agency Announcement (BAA) HR001118S0017, PREventing EMerging Pathogenic Threats (PREEMPT). Your submission has been reviewed in accordance with the criteria set forth in that announcement.

Based on that review, your proposal was not selected for funding. We understand the time and effort it takes to put together a proposal, but unfortunately, we are unable to select all concepts that we receive. If you would like an informal feedback session to discuss your proposal, we request that you e-mail the BAA Mailbox (PREEMPT@darpa.mil) within three weeks of the date of this letter. Thank you for your interest in DARPA and the Biological Technologies Office.

Sincerely,

GIMLETT.JAMES.L.1470429883 Digitally signed by GIMLETT.JAMES.L.1470429883 Date: 2018.06.12 20:29:17 -04'00'

James Gimlett, Ph.D.
Program Manager
Biological Technologies Office

	09:50-10:10 S-03	**Title:** Recent advances in developing therapeutics monoclonal antibodies Against Ebola Virus Infection **Speaker: Xiangguo Qiu** Special Pathogens Program, National Microbiology laboratory, Public Health Agency of Canada
	10:10-10:30 S-04	**Title:** Nipah virus and Hendra Virus: Basic Science to Global Countermeasures **Speaker: Christopher Broder** Department of Microbiology, Uniformed Services University, Bethesda, MD, USA
	10:30-10:50 S-05	**Title:** Immunopathogenesis of Nipah virus infection **Speaker: Branka Horvat** International Center for Infectiology Research - CIRI, INSERM U1111, University Lyon 1, France
	10:50-11:10 S-06	**Title:** Incorporation of NS1 and PrM/M confer more effective protection for ZIKA virus vaccine **Speaker: Ling Chen** Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China

11:10-11:30 S-07	**Title:** Antiviral RNAi immunity – from basic to translation **Speaker: Xi Zhou** Wuhan Institute of Virology, Chinese Academy of Sciences
11:30-11:50 S-08	**Title:** The role of MVP in viral infection **Speaker: Shi Liu** College of Life Sciences, Wuhan University, China
11:50-12:05 Sponsor Presentation	Newly Technology development of Cryo TEM by JEOL **By Jianzhong Yuan** TEM product manager of JEOL in China
12:05-14:00	Lunch/午餐
Day 1, Afternoon Session /第一天下午	
14:00-17:30	**Session 2: Emerging viral pathogens** **Session Chairs: Zhengli SHI, Peter DASZAK**
14:00-:14:30 Keynote Speech S-09	**Title:** To be determined **Speaker: Hualan Chen** Harbin Veterinary Research Institute, Chinese Academy of Agricultural Sciences, Harbin, China
14:30-14:50 S-10	**Title:** Forecasting future viral pandemics and the Global Virome Project **Speaker: Peter Daszak** EcoHealth Alliance, New York, USA
14:50-15:10 S-11	**Title:** Infection and Immune Responses of Jamaican Fruit Bats (*Artibeus jamaicensis)* Experimentally Challenged with a Bat HL18NL11 Influenza A Virus **Speaker: Tony Schountz** Department of Microbiology, Immunology and Pathology, College of Veterinary Medicine and Biomedical Sciences, Colorado State University
15:10-15:30 S-12	**Title:** To be determined **Speaker: Di Liu** Wuhan Institute of Virology, Chinese Academy of Sciences
15:30-15:50	Coffee Break and Poster Presentation/茶歇和展板
15:50-16:10 S-13	**Title:** Risks of MERS-cluster coronaviruses in China **Speaker: Peng Zhou** Wuhan Institute of Virology, Chinese Academy of Sciences
16:10-16:30 S-14	**Title:** Molecular mechanisms for cross-species transmissions of SARS and MERS coronaviruses **Speaker: Fang Li** Department of Veterinary and Biomedical Sciences, University of Minnesota
16:30-16:50 S-15	**Title:** Human coronavirus OC43 (HCoV-OC43) and bovine coronavirus (BCoV) **Speaker: Astrid Vabret** Laboratory of Virology, University Hospital of Caen, France

	16:50-17:10 S-16	**Title:** Origin and cross-species transmission of bat coronaviruses in China **Speaker: Alice Latine** EcoHealth Alliance, New York, USA
	17:10-17:30 S-17	**Title:** Coronaviruses phylogenetics and intra-colony evolution of the SARS-CoV sister-clade Betacoronavirus in bats in western Palearctics **Speaker: Meriadeg Ar Gouilh** Groupe de Recherche sur l'Adaptation Microbienne, Normandy University, France
	18:00-20:00	Banquet 会议晚宴

Program of
The 8th International Symposium on Emerging Viral Diseases

Date 日期	Time 时间	Content 议程
Monday 星期一 **Oct. 22, 2018** **10** 月 **22** 日	**Day 2, Morning Session /第二天上午**	
	08:30-12:10	**Session 3: Virus-Host Interaction** **Session Chairs: Xi ZHOU, Ralph BARIC**
	08:30-09:00 Keynote Speech S-18	**Title:** To be determined **Speaker: Ralph Baric** Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA
	09:00-09:30 Keynote Speech S-19	**Title:** Peptide-based Virus Entry Inhibitors against Class I and II Enveloped Viruses **Speaker: Shibo Jiang** Basic Medical College, Fudan University, Shanghai, China
	09:30-09:50 S-20	**Title:** Small molecules as filoviral entry inhibitors and chemical probes **Speaker: Lijun Rong** Department of Microbiology and Immunology, College of Medicine, University of Illinois at Chicago, Chicago, IL, USA
	09:50-10:10 S-21	**Title:** Entry mechanisms of highly pathogenic coronaviruses: MERS-CoV and SARS-CoV **Speaker: Yi Shi** CAS Key Laboratory of Pathogenic Microbiology and Immunology, Institute of Microbiology, Chinese Academy of Sciences, Beijing, China
	10:10-10:30	Coffee Break and Poster Presentation/茶歇和展板
	10:30-10:50 S-22	**Title:** Pathology of and development of antiviral therapy with favipiravir for severe fever with thrombocytopenia syndrome **Speaker: Masayuki Saijo** Department of Virology, National Institute of Infectious Diseases, Tokyo, Japan
	10:50-11:10 S-23	**Title:** Epistasis and complementation contribute to the evolution of the Rabies virus phosphoprotein in the face of severe functional constraints within the replication complex **Speaker: Hervé Bourhy** Institut Pasteur, Unit of Lyssavirus Dynamics and Host Adaptation, Paris, France
	11:10-11:30 S-24	**Title:** Influenza A virus-derived siRNAs increase in the absence of NS1 yet fail to inhibit virus replication **Speaker: Kevin Tsai** Department of Molecular Genetics and Microbiology, Duke University Medical Center, Durham, North Carolina, USA

	11:30-11:50 S-25	**Title:** Mechanisms of Herpesvirus capsid assembly and maturation **Speaker: Xiangxi Wang** Institute of Biophysics, Chines Academy of Sciences, Beijing, China
	11:50-12:10 S-26	**Title:** To be determined **Speaker: Yu Chen** College of Life Sciences, Wuhan University, China
	12:10-13:40	Lunch/午餐
	Day 2, Afternoon Session /第二天下午	
	13:40-17:30	**Session 4: Arbovirus** **Session Chairs: Zhihong HU, Pei-Yong SHI**
	13:40-14:10 Keynote Speech S-27	**Title:** Zika Virus: Emergence and Vaccine Development **Speaker: Pei-Yong Shi** University of Texas Medical Branch, Galveston, Texas, USA
	14:10-14:30 S-28	**Title:** Replicase Proteins of Alphaviruses as Determinants of Viral Pathogenesis and Vector Transmission **Speaker: Andres Merits** Institute of Technology, University of Tartu, Estonia
	14:30-14:50 S-29	**Title:** Identification of prognostic biomarkers for Dengue disease severity through an integrated 'omics analysis of patient serum **Speaker: Andrew Davidson** University of Bristol, Bristol, United Kingdom
	14:50-15:10 S-30	**Title:** Zika virus tropism for neural stem cells: the bad and the good **Speaker: Cheng-Feng Qin** Beijing Institute of Microbiology and Epidemiology, Academy of Military Medical Sciences, Beijing, China
	15:10-15:30 S-31	**Title:** A gut commensal bacterium promotes mosquito permissiveness to arboviruses **Speaker: Gong Cheng** Tsinghua-Peking Center for Life Sciences, School of Medicine, Tsinghua University, Beijing, China
	15:30-15:50	Coffee Break 茶歇
	15:50-16:10 S-32	**Title:** The fabulous NSs protein of Rift Valley fever virus **Speaker: Pierre-Yves Lozach** Cluster of Excellence and Center for Integrative Infectious Disease Research, University Hospital Heidelberg, Germany
	16:10-16:30 S-33	**Title:** Novel delivery of a live-attenuated chikungunya virus vaccine candidate **Speaker: Adam Taylor** Griffith University, Southport, Queensland, Australia

	16:30-16:50 S-34	**Title:** Viromes of ticks reveals highly potential risks of tick-borne viral diseases in Xinjiang, China **Speaker: Fei Deng** Wuhan Institute of Virology, Chinese Academy of Sciences
	16:50-17:10 S-35	**Title:** Species-specific disruption of STING-dependent antiviral cellular defenses by the Zika virus NS2B3 protease **Speaker: Qiang Ding** School of Medicine, Tsinghua University, Beijing, China
	17:10-17:30 S-36	**Title:** ISG15 regulates Zika Virus Replication through Jak/STAT Signaling pathway and its ISGylation **Speaker: Yancui Wang** Institute of Blood Transfusion, Chinese Academy of Medical Sciences and Peking Union Medical College, Chengdu, China
	17:30-17:40	**Closing Remarks**
	18:00-19:00	Dinner/晚餐

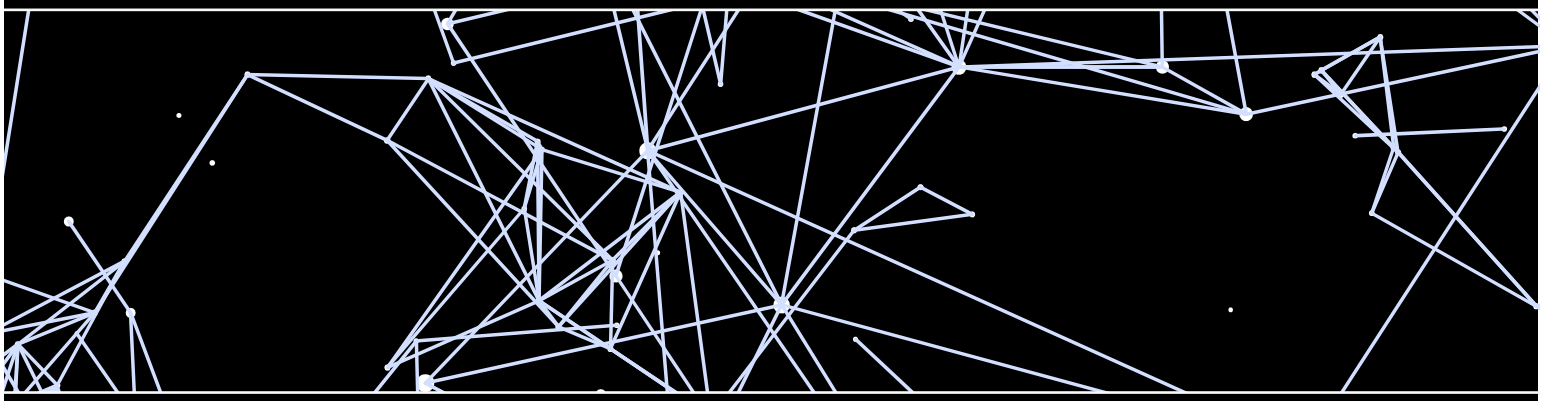
EcoHealth Alliance leads cutting-edge research into the critical connections between human and wildlife health and delicate ecosystems. With this science we develop solutions that prevent pandemics and promote conservation.

THE NATIONAL SCIENCE FOUNDATION



PROPOSAL & AWARD POLICIES AND PROCEDURES GUIDE

Effective January 29, 2018
NSF 18-1
OMB Control Number 3145-0058

Significant Changes and Clarifications to the *Proposal & Award Policies & Procedures Guide* (PAPPG)

Effective January 29, 2018

Overall Document

Editorial changes have been made to either clarify or enhance the intended meaning of a sentence or section. The document has been updated to ensure consistency with data contained in NSF systems or guidance located in other NSF or Federal policy documents. Throughout the PAPPG, website, address and document references and organizational names have been updated to reflect current information.

Significant Changes

- **Chapter I.E, Who May Submit Proposals,** incorporates new coverage on the eligibility of international branch campuses of US institutions of higher education. The definition of colleges and universities in Chapter I.E.1 has been updated to now refer to institutions of higher education, for consistency with 2 CFR § 200. In addition, changes have been made to the eligibility requirements for foreign organizations.

- **Chapter II.C.1.e, Collaborators & Other Affiliations Information,** has been significantly revised to request information regarding collaborators and other affiliations (COA) be provided through use of a standard NSF COA template. Footnotes also have been added to address frequently asked questions relating to the new COA template.

- **Chapter II.C.2.d, Project Description**, has been modified to reflect that the Project Description must now contain a separate section specifically identified as “Intellectual Merit”.

- **Chapter II.C.2.g, Budget and Budget Justification,** has been revised to increase the number of pages allowed for the budget justification to no more than five pages per proposal. This change applies to budget justifications for both proposers and subawardees.

- **Chapter VII.A.2, Grantee Notifications to NSF**, has been restructured to remove information on requests for NSF approval. In addition, Exhibit VII-1 has been deleted, as coverage on grantee requests for approval from NSF is contained in the *Research Terms and Conditions* Appendix A and Chapter X.A.3.

- **Chapter X.A.3, Prior Written Approvals,** has been updated to reference the *Research Terms and Conditions* Appendix A, which is the authoritative source of NSF prior approval requirements.

Clarifications and Other Changes

- **Section B, Foreword,** has been modified to refer to the applicable standard grant conditions, instead of solely the NSF *Grant General Conditions*, now that the *Research Terms and Conditions* have been implemented.

- **Section D, Definitions & NSF-Grantee Relationships,** provides additional guidance on the types of cooperative agreements awarded by NSF.

- **Section E, NSF Organizations,** has been revised to reflect the current responsibilities of the organizations that are normally of most direct interest to the NSF proposer and grantee community.

- **Chapter II.C.1.f, Submission of Proposals by Former NSF Staff,** incorporates new coverage to address submission of proposals from former NSF staff and the procedures that must be followed in such circumstances.

- **Chapter II.C.2.d(iii), Results from Prior NSF Support**, clarifies the timeframe during which any PI or co-PI that has received NSF support must report on such funding. Chapter II.E.7 on conference proposals, II.E.8 on equipment proposals, II.E.9 on travel proposals and Exhibit II-1, the Proposal Preparation Checklist, also have been updated with this guidance.

- **Chapter II.C.2.g(i)(a), Senior Personnel Salaries & Wages Policy**, has been supplemented with guidance that reflects it is the proposing organization's responsibility to define and apply the term "year" and include the definition in the budget justification.

- **Chapter II.C.2.g(viii), Indirect Costs**, has been updated to state that amounts for indirect costs should be specified in the budget justification.

- **Chapter II.C.2.j, Special Information and Supplementary Documentation,** includes additional guidance on the content for data management plans that involve collaborative activities.

- **Chapter II.D.4, Proposals Involving Vertebrate Animals,** has been revised to enhance the clarity of guidance on the use of vertebrate animals for research or education on NSF supported projects. For projects at an international organization that involve the use of vertebrate animals, a statement from the international organization will need to be provided.

- **Chapter II.D.5, Proposals Involving Human Subjects**, has been supplemented with additional language regarding international projects.

- **Chapters II.D.6 and XI.B.5, Life Sciences Dual Use Research of Concern (DURC)**, include new coverage regarding NSF's funding of research that would be considered to lead to a gain of function of agents. The title of these sections also has been changed for consistency with the *US Government Policy for Institutional Oversight of Life Sciences Dual Use Research of Concern.*

- **Chapter II.E.11, Research Infrastructure Proposal**, has been revised to reflect current practices and provide greater clarity in the description of these types of proposals.

- **Exhibit II-1, Proposal Preparation Checklist**, has been updated to reflect relevant changes made to Chapter II of the PAPPG. Additional checklist components also have been added to assist proposers in the pre-submission administrative review of proposals to NSF.

- **Chapter V, Renewal Proposals,** has been modified to update reference information regarding recompetition of expiring awards. Section B on Accomplishment-Based Renewals has been updated to provide greater clarity regarding the submission of reprints.

- **Chapter VII.B.2.e, Substitute (Change) PI/PD or co-PI/co-PD**, has been supplemented with guidance on the reappointment of prior NSF staff as PI.

- **Chapter VII.B,3, Subawarding or Transferring Part of an NSF Award (Subaward)**, has been modified for consistency with terminology in 2 CFR § 200.

- **Chapter VII.D.2, Final Project Report**, has been updated to reflect that when PIs submit the report, they are indicating that the scope of work is complete and no further administrative actions are anticipated on the grant.

- **Chapter VIII.E.6, Award Financial Reporting Requirements and Final Disbursements**, has been supplemented to clarify the intent of NSF notifications regarding canceling appropriations.

- **Chapter X.B, Direct Costs and X.C, Other Direct Costs,** have been modified to remove coverage that is redundant with 2 CFR § 200 and other sections of the PAPPG. Terminology on rearrangement and reconversion costs has been updated for consistency with 2 CFR § 200.462.

- **Chapter XI.A, Non-Discrimination Statutes and Regulations,** has been revised to provide current information on NSF grantee obligations to comply with civil rights laws and regulations. These changes provide NSF grantees and applicants for NSF grants with an overview of relevant civil rights regulatory obligations and compliance mechanisms. Information also has been included on how grantee program participants can file complaints with NSF alleging discrimination in an NSF grantee's programs.

- **Chapter XI.B.1, Human Subjects and XI.B.3, Vertebrate Animals,** include the relevant new award-specific condition on organizational responsibilities. In addition, language has been added on post-award responsibilities.

- **Chapter XI.D.1.d, Intellectual Property**, has been updated to specify that grantees are required to use iEdison to disclose NSF subject inventions. In addition, NSF now reserves the option to request an Annual Utilization Report or a Final Invention Statement and Certification.

- **Chapter XI.M.4, Executive Order 13788, Buy American and Hire American,** is a new section which serves as NSF's implementation of Executive Order 13788.

Introduction:

A. About the National Science Foundation

The National Science Foundation (NSF) is an independent Federal agency created by Congress in 1950 to "promote the progress of science; [and] to advance the national health, prosperity and welfare" by supporting research and education in all fields of science and engineering.

From those first days, NSF has had a unique place in the Federal Government: it is responsible for the overall health of science and engineering across all disciplines. In contrast, other Federal agencies support research focused on specific missions such as health or defense. The Foundation also is committed to ensuring the nation's supply of scientists, engineers, and science and engineering educators.

NSF funds research and education in most fields of science and engineering. It does this through grants and cooperative agreements to approximately 2,000 colleges, universities, K-12 school systems, businesses, informal science organizations and other research organizations throughout the US. The Foundation accounts for about one-fourth of Federal support to academic institutions for basic research.

The Foundation considers proposals[1] submitted by organizations on behalf of individuals or groups for support in most fields of research. Interdisciplinary proposals also are eligible for consideration.

NSF does not normally support technical assistance, pilot plant efforts, research requiring security classification, the development of products for commercial marketing, or market research for a particular project or invention. Research with disease-related goals, including work on the etiology, diagnosis or treatment of physical or mental disease, abnormality, or malfunction in human beings or animals, is normally not supported. Animal models of such conditions or the development or testing of drugs or other procedures for their treatment also are not eligible for support. However, research in bioengineering, with diagnosis- or treatment-related goals, that applies engineering principles to problems in biology and medicine while advancing engineering knowledge is eligible for support. Bioengineering research to aid persons with disabilities also is eligible.

NSF does not have any programs involving the construction of public works in metropolitan areas, no development assistance programs, no programs requiring State plans as a condition of assistance, none involving coordination of planning in multi-jurisdictional areas and no programs of grants to State and local governments as defined in Section 6501(4) of Title 31 of the United States Code (USC).

NSF receives over 50,000 proposals each year for research, education and training projects, of which approximately 11,000 are funded. In addition, the Foundation receives over 15,000 applications for graduate and postdoctoral fellowships. One of NSF's flagship programs, the NSF Graduate Research Fellowship Program (GRFP) helps ensure the vitality and diversity of the scientific and engineering workforce; the program awards about 2,000 fellowships each year. Guidance regarding the GRFP program may be found in the program solicitation, as well as in the GRFP Administrative Guide. The agency operates no laboratories itself but does support National Research Centers, user facilities, certain oceanographic vessels and Antarctic research stations. The Foundation also supports cooperative research between universities and industry, US participation in international scientific and engineering efforts, and educational activities at every academic level.

NSF is structured much like a university, with divisions/offices for the various disciplines and fields of science and engineering and for science, technology, engineering and mathematics education. NSF also uses a variety of management mechanisms to coordinate research in areas that cross traditional disciplinary boundaries. The Foundation is assisted by advisors from the scientific and engineering communities who serve on formal committees or as *ad hoc* reviewers of proposals. This advisory system, which focuses on both program directions and specific proposals, involves approximately 50,000 scientists and engineers each year. NSF staff members who are experts in a certain field or area make award recommendations; Principal Investigators (PIs) receive unattributed verbatim copies of peer reviews.

[1] For purposes of this Guide, the term "proposal" is interchangeable with the term "application."

Grantees are wholly responsible for conducting their project activities and preparing the results for publication. Thus, the Foundation does not assume responsibility for such findings or their interpretation.

Facilitation Awards for Scientists and Engineers with Disabilities provide funding for special assistance or equipment to enable persons with disabilities to work on NSF-supported projects. See Chapter II.E.6. for instructions regarding preparation of these types of proposals.

NSF has Text Telephone (TTY) and Federal Information Relay Service (FIRS) capabilities that enable individuals with hearing or speech impairments to communicate with the Foundation about NSF programs, employment or general information. TTY may be accessed at (703) 292-5090 and (800) 281-8749, FIRS at (800) 877-8339.

The NSF Information Center may be reached at (703) 292-5111.

B. Foreword

The *Proposal & Award Policies & Procedures Guide (PAPPG)* is comprised of documents relating to the Foundation's proposal and award process for the assistance programs of NSF. The PAPPG, in conjunction with the applicable standard award conditions incorporated by reference in the award[2], serve as the Foundation's implementation of 2 CFR § 200, *Uniform Administrative Requirements, Cost Principles, and Audit Requirements for Federal Awards*. If the PAPPG and the award conditions are silent on a specific area covered by 2 CFR § 200, the requirements specified in 2 CFR § 200 must be followed.

It has been designed for use by both our customer community and NSF staff and consists of two parts:

- Part I sets forth NSF's proposal preparation and submission guidelines. The coverage provides guidance for the preparation and submission of proposals to NSF. Some NSF programs have program solicitations that modify the general provisions of the PAPPG, and, in such cases, the guidelines provided in the solicitation must be followed.

  The policy and procedural guidance contained in the *NSF Grants.gov Application Guide* should be followed when preparing and submitting proposals to NSF via Grants.gov.

- Part II of the NSF PAPPG sets forth NSF policies and procedures regarding the award, administration, and monitoring of grants and cooperative agreements. Coverage includes the NSF award process, from issuance and administration of an NSF award through closeout. Guidance is provided regarding other grant requirements or considerations that either are not universally applicable or do not follow the award cycle. Part II also implements other Public Laws, Executive Orders (E.O.) and other directives insofar as they apply to grants, and is issued pursuant to the authority of Section 11(a) of the NSF Act (42 USC § 1870). When NSF Grant General Conditions or an award notice reference a particular section of the PAPPG, then that section becomes part of the award requirements through incorporation by reference.

The PAPPG does not apply to NSF contracts. For information relating to NSF contracts, consult the Guide to the NSF Contracting Process.

General information about NSF programs may be found on the NSF website at: https://www.nsf.gov/funding/. Additional information about special requirements of individual NSF programs may be obtained from the appropriate Foundation program office. Information about most program deadlines and target dates for proposals are available on the NSF website at: http://www.nsf.gov/funding/pgm_list.jsp?org=NSF&ord=date. Program deadline and target date information also appears in individual program announcements and solicitations and on relevant NSF Divisional/Office websites.

Catalog of Federal Domestic Assistance

NSF programs fall under the following categories in the latest Catalog of Federal Domestic Assistance (CFDA) issued by the Office of Management and Budget and the General Services Administration:

47.041 -- Engineering
47.049 -- Mathematical and Physical Sciences
47.050 -- Geosciences
47.070 -- Computer and Information Science and Engineering
47.074 -- Biological Sciences
47.075 -- Social, Behavioral and Economic Sciences
47.076 -- Education and Human Resources
47.079 -- Office of International Science & Engineering
47.083 -- Office of Integrative Activities

Any questions or comments regarding the NSF PAPPG should be addressed to the Policy Office, Division of Institution & Award Support, at (703) 292-8243 or by e-mail to policy@nsf.gov.

[2] See Chapter VI.C. for additional information on NSF award conditions.

C. Acronym List

ABR	Accomplishment-Based Renewal
ACH	Automated Clearing House (US Treasury)
ACM$	Award Cash Management Service
AD	Assistant Director
ADPE	Automatic Data Processing Equipment
APHIS	Animal and Plant Health Inspection Service
AOR	Authorized Organizational Representative
BFA	Budget, Finance & Award Management
CA	Cooperative Agreement
CA/FATC	Cooperative Agreement Financial/Administrative Terms and Conditions
CAP	Cost Analysis and Pre-award Branch
CA/PTC	Cooperative Agreement Programmatic Terms and Conditions
CEQ	Council on Environmental Quality
CFR	Code of Federal Regulations
CGI	Continuing Grant Increment
CMIA	Cash Management Improvement Act
COA	Collaborators and Other Affiliations
COI	Conflict of Interest
CSA	Cooperative Support Agreement
co-PD	co-Project Director
co-PI	co-Principal Investigator
DACS	Division of Acquisition and Cooperative Support
DAS	Division of Administrative Services
DCL	Dear Colleague Letter
DD	Division Director
DFM	Division of Financial Management
DGA	Division of Grants and Agreements
DHHS	Department of Health and Human Services
DIAS	Division of Institution and Award Support
DOC	Department of Commerce
DUNS	Data Universal Numbering System
DURC	Dual Use Research of Concern
EAGER	EArly-Concept Grants for Exploratory Research
EFT	Electronic Funds Transfer
E.O.	Executive Order
F&A	Facilities & Administrative Costs
FAPIIS	Federal Awardee Performance and Integrity Information System
FAQs	Frequently Asked Questions
FAR	Federal Acquisition Regulation
FASED	Facilitation Awards for Scientists and Engineers with Disabilities
FDP	Federal Demonstration Partnership
FEMA	Federal Emergency Management Agency
FIRS	Federal Information Relay Service
FOIA	Freedom of Information Act
FWA	FederalWide Assurance
GC-1	Grant General Conditions
GOALI	Grant Opportunities for Academic Liaison with Industry
GOE	Government-Owned Equipment
GPO	Government Publishing Office
GSA	General Services Administration
IACUC	Institutional Animal Care and Use Committee
IBC	Institutional Biosafety Committee
IPA	Intergovernmental Personnel Act
IRB	Institutional Review Board
IRS	Internal Revenue Service
ISE	International Science & Engineering
LEP	Limited English Proficiency
LFM	Large Facilities Manual
LFO	Large Facilities Office
LOI	Letters of Intent
MREFC	Major Research Equipment and Facilities Construction Account
NASEM	National Academies of Science, Engineering and Medicine
NEPA	National Environmental Policy Act
NIH	National Institutes of Health
NSB	National Science Board
NSF	National Science Foundation
ODI	Office of Diversity and Inclusion
OGC	Office of the General Counsel
OHRP	Office for Human Research Protections
OIA	Office of Integrative Activities
OIG	Office of Inspector General
OLAW	Office for Laboratory Animal Welfare
OMB	Office of Management and Budget
ONR	Office of Naval Research
PAPPG	Proposal & Award Policies & Procedures Guide
PD	Project Director
PHS	Public Health Service
PI	Principal Investigator
PNAG	Prospective New Awardee Guide
PO	Program Officer
RAISE	Research Advanced by Interdisciplinary Science and Engineering
RAM	Resolution and Advance Monitoring Branch
RAPID	Rapid Response Research
REU	Research Experiences for Undergraduates
ROA	Research Opportunity Awards
RTC	Research Terms and Conditions
RUI	Research in Undergraduate Institutions
SAM	System for Award Management
SBA	Small Business Administration
SBIR	Small Business Innovation Research
SF	Standard Form
SF LLL	Disclosure of Lobbying Activities

SPO	Sponsored Projects Office
SSN	Social Security Number
STTR	Small Business Technology Transfer
TDD	Telephonic Device for the Deaf
TTY	Text Telephone
URL	Uniform Resource Locator
USC	United States Code
USDA	US Department of Agriculture
VSEE	Visiting Scientist, Engineer or Educator

D. Definitions & NSF-Grantee Relationships

1. Definitions

a. An AUTHORIZED ORGANIZATIONAL REPRESENTATIVE (AOR)/AUTHORIZED REPRESENTATIVE means the administrative official who, on behalf of the proposing organization is empowered to make certifications and assurances and can commit the organization to the conduct of a project that NSF is being asked to support as well as adhere to various NSF policies and grant requirements.

b. A GRANT AGREEMENT[3] means a legal instrument of financial assistance between NSF and a grantee that, consistent with 31 USC 6302, 6304:

(1) Is used to enter into a relationship the principal purpose of which is to transfer anything of value from NSF to the grantee to carry out a public purpose authorized by a law of the United States (see 31 USC 6101(3)); and not to acquire property or services for NSF's direct benefit or use;

(2) Is distinguished from a cooperative agreement in that it does not provide for substantial involvement between NSF and the grantee in carrying out the activity contemplated by the NSF award.

NSF awards the following two types of grants:

(a) A STANDARD GRANT means a type of grant in which NSF agrees to provide a specific level of support for a specified period of time with no statement of NSF intent to provide additional future support without submission of another proposal.

(b) A CONTINUING GRANT means a type of grant in which NSF agrees to provide a specific level of support for an initial specified period of time, usually a year, with a statement of intent to provide additional support for the project for additional periods, provided funds are available and the results achieved warrant further support.

c. A COST REIMBURSEMENT AWARD means a type of grant under which NSF agrees to reimburse the grantee for work performed and/or costs incurred by the grantee up to the total amount specified in the grant. Such costs must be allowable in accordance with the applicable cost principles. Accountability is based primarily on technical progress, financial accounting and fiscal reporting. Except under certain programs and under special circumstances, NSF grants and cooperative agreements are normally cost reimbursement type awards.

d. A FIXED AMOUNT AWARD means a type of award in which NSF provides a specific level of support without regard to actual costs incurred under the award. This type of NSF award reduces some of the administrative burden and recordkeeping requirements for both the grantee and NSF. Accountability is based primarily on performance and results.

e. A COOPERATIVE AGREEMENT means a legal instrument of financial assistance between NSF and an awardee that, consistent with 31 USC 6302–6305:

(1) Is used to enter into a relationship the principal purpose of which is to transfer anything of value from NSF to the grantee to carry out a public purpose authorized by a law of the United States (see 31 USC 6101(3)); and not to acquire property or services for NSF's direct benefit or use;

[3] For purposes of this Guide, except where explicitly noted, the term "grant" is interchangeable with the term "cooperative agreement", and the term "grantee" is interchangeable with the "awardee" of a cooperative agreement.

(2) Is distinguished from a grant in that it provides for substantial involvement between NSF and the grantee in carrying out the activity contemplated by the NSF award.

In the case of NSF, assistance awards involve the support or stimulation of scientific and engineering research, science and engineering education or other related activities. NSF is authorized to use grants or cooperative agreements for this purpose. Grants, however, are the primary mechanism of NSF support.

f. A GRANTEE means the organization or other entity that receives a grant and assumes legal and financial responsibility and accountability both for the awarded funds and for the performance of the grant-supported activity. NSF grants are normally made to organizations rather than to individual Principal Investigator/Project Director(s). Categories of eligible proposers may be found in Chapter I.E.

g. PRINCIPAL INVESTIGATOR/PROJECT DIRECTOR (PI/PD) means the individual(s) designated by the proposer, and approved by NSF, who will be responsible for the scientific or technical direction of the project. NSF does not infer any distinction in scientific stature among multiple PIs, whether referred to as PI or co-PI. If more than one, the first one listed will serve as the contact PI, with whom all communications between NSF program officials and the project relating to the scientific, technical, and budgetary aspects of the project should take place. The PI and any identified co-PIs, however, will be jointly responsible for submission of the requisite project reports. The term "Principal Investigator" generally is used in research projects, while the term "Project Director" generally is used in centers, large facilities, and other projects. For purposes of this Guide, PI/co-PI is interchangeable with PD/co-PD.

2. NSF-Grantee Relationships

a. Grants will be used by NSF when the accomplishment of the project objectives requires minimal NSF involvement during performance of the activities. Grants establish a relationship between NSF and the grantee in which:

(1) NSF agrees to provide up to a specified amount of financial support for the project to be performed under the conditions and requirements of the grant. NSF will monitor grant progress and assure compliance with applicable standards.

(2) The grantee agrees to: perform the project as proposed; the prudent management of the funds provided; and carry out the supported activities in accordance with the provisions of the grant. (See Chapter VI.B for the documents that comprise an NSF grant.)

b. Cooperative agreements will be used by NSF when the accomplishment of the project objectives requires substantial ongoing Foundation involvement during the project performance period. Substantial agency involvement may be necessary when an activity is technically and/or managerially complex and would require extensive or close coordination between NSF and the awardee. This, however, does not affect NSF's right to unilaterally suspend or terminate support for cause or consider termination in accordance with Chapter XII, if it is in the best interest of NSF or the Government. The doctrine of substantial involvement is set forth in the Federal Grant and Cooperative Agreement Act of 1977 (31 USC 6301-6308).

NSF utilizes two types of cooperative agreements:

- **Standalone Cooperative Agreement (CA)**, which consists of a cooperative agreement for a single, unified award where there is no need to provide separate, discrete funding and oversight for the projects or programs under that award.

- **Master Cooperative Agreement/Cooperative Support Agreement (CA/CSA),** which consists of a master or overall agreement having separate and specific awards (CSAs) that are funded individually under the umbrella of the master agreement. CSAs have their own terms and conditions in addition to those of the master agreement. The scope of CSAs falls within the scope

of the master agreement, but each CSA has its own distinct award number and funding based on its approved budget; no funding is attached to the master CA.

Examples of projects suitable for cooperative agreements include: management of research centers, large curriculum projects, multi-user facilities, projects which involve complex subcontracting, construction or operations of major in-house university facilities and major instrumentation development, and projects in which NSF participates with other stakeholder agencies or organizations that have influence over project direction and/or development.

Under a cooperative agreement, the awardee has primary responsibility for the conduct of the project. To the extent that NSF does not reserve responsibility for coordinating or integrating the project activities with other related activities or does not assume a degree of shared responsibility for certain aspects of the project, all such responsibilities remain with the awardee. While NSF will monitor the cooperative agreement in accordance with the terms and conditions of the award, the Foundation will not assume overall control of a project or unilaterally change or direct the project activities.

The cooperative agreement will specify the extent to which NSF will advise, review, approve or otherwise be involved with project activities, as well as NSF's right to require more clearly defined deliverables. NSF may provide advice, guidance or assistance of a technical, management, or coordinating nature and may require that the awardee obtain NSF prior approval of specific decisions, milestones, or project activities. Substantial involvement is incorporated in key areas of accountability in both financial and programmatic award terms; examples include prior agency approval requirements, type and frequency of project plans, special reporting requirements, and project and awardee reviews that NSF will conduct during the term of the award.

Cooperative agreements for construction are generally funded through a separate appropriation from Congress for Major Research Equipment and Facilities Construction (MREFC). NSF maintains the MREFC appropriations in a separate budget account, for major construction projects that successfully undergo a rigorous selection process. MREFC funds cannot be co-mingled with funds for activities other than construction; therefore, NSF issues a separate award for operations and other activities related to commissioning and management of the facility or major instrument. The awardee is required to maintain an accounting system capable of segregating MREFC and operating costs, and to ensure that such costs are applied accordingly.

Many large facility awards, including those for NSF-supported Federally Funded Research and Development Centers (FFRDCs), consist of a cooperative agreement as an umbrella award, establishing the overall basic provisions of the agreements, and separate cooperative support agreements with specific terms and conditions for construction activities, management and operations, research activities that are co-sponsored by other agencies, and any other focused activities that NSF needs to monitor separately from the overall objectives of the cooperative agreement.

E. NSF Organizations

The NSF organizations/offices described below are normally of most direct interest to the NSF proposer and awardee community. Consult the NSF website at: http://www.nsf.gov/staff/orglist.jsp for the most current listing of NSF offices/directorates and an organizational chart.

1. National Science Board (NSB)

The NSB was established by Congress in 1950, and along with the Director, constitutes the National Science Foundation. The Board provides oversight for, and establishes the policies of, the agency within the framework of applicable national policies set forth by the President and Congress. In this capacity, the Board identifies issues that are critical to NSF's future, approves NSF's strategic budget directions, approves annual budget submissions to the Office of Management and Budget (OMB), approves major awards and consults on certain programs, analyzes NSF's budget to ensure progress and consistency along the strategic direction set for NSF, and ensures balance between initiatives and core programs. In addition, the Board serves as an independent body of advisors to both the President and Congress on broad national policy issues and, together with the Director, recommends and encourages the pursuit of national policies related to science and engineering research and education. The Board is comprised of 24 members appointed by the President. The NSF Director also serves as an *ex officio* voting member of the Board. Members are selected on the basis of their distinguished service in science and engineering research and education, and are representative of scientific, engineering, and educational leadership throughout the Nation.

2. Program Divisions/Offices

Program Divisions/Offices are responsible for the scientific, technical and programmatic review and evaluation of proposals and for recommending that proposals be declined or awarded. The scientific, engineering and/or educational aspects of an award will be monitored by the NSF Program Officer identified in the award notice. (See Chapter III for a detailed description of the NSF Merit Review Process.) Integral staff in the program division/office relative to the NSF proposal and award process are:

a. NSF Program Officers. Program Officers are considered subject matter experts in both technical and programmatic areas. They conduct merit review of proposals and recommend which projects should be funded by the Foundation.

b. NSF Division Directors. Division Directors are NSF executives whose responsibilities include long-range planning, contributing to the achievement of the Foundation's strategic goals and objectives, and providing stewardship for budgetary and other resources. They are responsible for ensuring the integrity of the merit review and award process.

3. Division of Grants & Agreements (DGA)

DGA is responsible for the award and administration of the majority of NSF's assistance awards – i.e., grants, cooperative agreements, and fellowship awards, recommended for support by NSF program offices. From pre-award through closeout, DGA conducts a variety of business, financial, and administrative reviews to ensure compliance with award terms and conditions and consistency with applicable NSF policies and Federal rules and regulations. DGA provides stewardship and support to a diverse set of stakeholders including awardees, NSF Directorates/Offices, and others within the scientific research and education communities. DGA also maintains a leadership role in the Federal grants arena. In carrying out NSF's primary mission of promoting the progress of science, DGA continually interacts with academic and non-academic institutions, private industry, State and local governments, and other Federal agencies.

Grants & Agreements Officers (Grants Officers) have delegated warrant authority to issue awards on behalf of the Foundation and their approval constitutes a legal obligation of Federal funds for awardees to expend

to fulfill the scope of the approved proposal. In addition, Grants Officers are responsible for issuing all award amendments and certain post-award prior approvals, for monitoring awardee compliance with award terms and conditions, and for the administration and closeout of these awards.

4. Division of Institution & Award Support (DIAS)

DIAS is responsible for the development and implementation of proposal and award policies and procedures, clearance of NSF funding opportunities, advanced monitoring activities, cost analysis and award support, audit resolution, electronic award systems administration, and outreach to the external community. DIAS also advocates for the needs of the research community in NSF electronic research administration activities, including the modernization of NSF's externally-facing FastLane system via Research.gov. DIAS organizational units are as follows:

a. The Policy Office is responsible for the development, coordination, and issuance of NSF pre- and post-award policies for the assistance programs of NSF. The Policy Office provides guidance on the interpretation of NSF policies and procedures within NSF's electronic proposal and award systems, as well as official clearance for NSF funding opportunities.

The Policy Office coordinates outreach programs for external stakeholders across the broad research community and NSF staff. Through a variety of mechanisms, it releases timely information regarding NSF policies and procedures, proposal preparation, and award management. In addition to working closely with professional research administration associations, the Policy Office coordinates two major grants conferences held at various locations throughout the US, typically in the spring and fall of each year.

b. The Cost Analysis and Pre-award (CAP) Branch specializes in determinations with regard to the allowability, allocability and reasonableness of costs either budgeted or claimed under NSF awards. CAP evaluates accounting systems, internal controls, and policies and procedures of prospective and current NSF grantees. Its major functions include: pre-award reviews of new grantees, Phase II research projects involving small businesses; budgets of large-scale awards; and indirect cost rate negotiation. CAP provides guidance to NSF Program and Grants Officers, as well as grantees for questions related to its areas of responsibility.

c. The Resolution and Advanced Monitoring (RAM) Branch specializes in determining the allowability, allocability and reasonableness of costs claimed under NSF awards. RAM also evaluates the accounting systems, internal controls and policies and procedures of current NSF grantees. RAM's primary responsibilities include: audit resolution, advanced monitoring to assess grantees' administrative capability, performance, and compliance with award terms and conditions; and review of certain post-award adjustments to expenditures. RAM provides guidance to NSF program staff and grantees for questions related to its areas of responsibility.

d. The Systems Office plays a major role in the design, implementation, administration, and oversight of business rules for assistance awards across NSF electronic corporate systems. It is also responsible for systems analysis and requirements development necessary for the implementation of award business rules.

5. Division of Acquisition and Cooperative Support (DACS)

DACS provides acquisition and cooperative agreement award support for the Foundation. The Contracts Branch is responsible for planning, solicitation, negotiation, award and administration of professional, administrative, and research support contracts for NSF. The Cooperative Support Branch (CSB) is responsible for planning, solicitation, negotiation, award and administration of cooperative agreements for FFRDCs and major research facilities in various stages of construction and operations, including multi-institutional and international programs. This includes participation and input on NSF project advisory teams, business process reviews and redesign, risk assessments, and administrative assistance. The CSB Grants & Agreements Officers (Grants Officers) have delegated warrant authority to issue awards on behalf

of the Foundation and their approval constitutes a legal obligation of Federal funds for awardees to expend to fulfill the scope of the approved proposal. In addition, Grants Officers are responsible for issuing all award amendments and certain post-award prior approvals, for monitoring awardee compliance with award terms and conditions, and for the administration and closeout of these awards.

6. Division of Financial Management (DFM)

DFM is responsible for the financial policy and financial management of NSF. The Division is responsible for NSF's financial reporting, grantee business office relationships and payment of vendors. The Cash Management Branch of DFM is available to assist grantee financial and business officials in matters of payment and financial reporting discussed in Chapter VIII of the PAPPG.

7. Large Facilities Office (LFO)

LFO is the Foundation's primary resource for all oversight practices related to major facility projects, and is the NSF-wide resource on project management best practices. LFO has the institutional authority and resources to effectively develop mandatory policies, practices and procedures, which are approved by senior management, for all stages of the facility life-cycle. The Office provides: (1) expert assistance on non-scientific and non-technical aspects of project planning, budgeting, and implementation for major facilities; (2) assurance that all applicable requirements are followed in order to give credence to NSF's oversight capabilities; and (3) facilitates the use of best practices by fostering coordination and collaboration throughout NSF to share application of lessons learned from prior major facility projects.

8. Office of the General Counsel (OGC)

OGC is the legal advisor and advocate for the Foundation, providing legal advice and counsel on all aspects of the Foundation's programs, policies, and operations, as well as areas affecting science and technology more broadly. Advice is provided in a wide variety of areas, such as: grants and contracts; ethics and conflicts of interest; Freedom of Information Act; Privacy Act; labor and personnel law; environmental law; Federal fiscal and administrative law and procedure; and international law and agreements.

9. Office of Diversity & Inclusion (ODI)

ODI is responsible for responding to all civil rights matters pertaining to NSF programs or activities receiving Federal financial assistance. (See Chapter XI.A for additional information.)

10. Office of the Inspector General (OIG)

OIG is an independent oversight office that reports directly to the NSB and Congress. It is responsible for conducting audits, reviews, and investigations of NSF programs, and of organizations and individuals that apply for or receive NSF funding. OIG also investigates allegations of research misconduct, such as plagiarism, falsification, or fabrication, involving researchers who request or receive NSF funding (see Chapter XII.C.1). The OIG staff includes scientists, attorneys, auditors, law enforcement personnel, evaluators, and information technology specialists. OIG audits focus on NSF's internal agency programs, as well as grants, cooperative agreements and contracts funded by NSF. Their purpose is to ensure that the financial, administrative, and program activities of NSF are conducted efficiently and effectively, and that the NSF awardee organization's claimed costs are allowable, reasonable and properly allocated.

OIG investigations focus on program integrity and financial or nonfinancial wrongdoing by organizations and individuals who submit proposals to, receive awards from, conduct business with, or work for NSF, and can result in criminal, civil, or administrative sanctions. Statutory law enforcement authority was granted to OIG by the US Attorney General.

Anyone, including grantees, administrators, and NSF personnel, should contact the OIG (1-800-428-2189 or oig@nsf.gov) to report instances of possible misconduct, fraud, waste, or abuse.

F. NSF Electronic Capabilities Modernization Status

NSF has undertaken a multi-year effort to modernize and transition grantee electronic capabilities from FastLane to Research.gov. During this time, electronic capabilities will be developed and launched in Research.gov. These capabilities may simultaneously still be available in FastLane for a period of time prior to being ultimately retired and the functionality available exclusively through Research.gov. In order to assist grantees, NSF has developed a matrix that lists NSF's grantee electronic capabilities, and whether they can be found in FastLane, Research.gov or both. This matrix will be updated as appropriate, independent of the PAPPG revision cycle. The Electronic Capabilities Modernization Status website is available at: http://www.nsf.gov/bfa/dias/policy/estatus_matrix.jsp.

PART I: PROPOSAL PREPARATION AND SUBMISSION GUIDELINES

Part I sets forth NSF's proposal preparation and submission guidelines. The coverage provides guidance for the preparation and submission of proposals to NSF. Some NSF programs have program solicitations that modify the general provisions of the PAPPG, and, in such cases, the guidelines provided in the solicitation must be followed.

Chapter I: Pre-Submission Information

A. NSF Proposal Preparation and Submission

Unless specified in an NSF program solicitation, proposals submitted to NSF must be submitted via use of either the NSF FastLane System or Grants.gov. Further information on each system is provided below.

- **Proposal Preparation and Submission via the NSF FastLane System.** The policy and procedural guidance contained in Part I of the PAPPG relates specifically to proposals submitted via the NSF FastLane System. FastLane may be used for proposal preparation, submission, file updates, and select postaward administrative activities. (See Introduction, Section F.) Detailed information about the FastLane System is available from the FastLane website at: https://www.fastlane.nsf.gov.

- **Proposal Preparation and Submission via Grants.gov.** The policy and procedural guidance contained in the NSF *Grants.gov Application Guide* relates specifically to proposals submitted via Grants.gov. Grants.gov was established as a government-wide resource to electronically find grant opportunities, as well as to apply for Federal awards. Grants.gov is a central storehouse for information on over 1,000 grant programs from the 26 Federal grant-making agencies and provides access to approximately $550 billion annually in awards. Detailed information about Grants.gov is available from the Grants.gov website at: http://www.grants.gov.

B. NSF Programs and Funding Opportunities

The NSF website provides the most comprehensive source of information on NSF Directorates/Offices (including contact information), programs and funding opportunities. Use of this website by potential proposers is strongly encouraged. In addition, "NSF Update" is an information-delivery system designed to keep potential proposers and other interested parties apprised of new NSF funding opportunities and publications, important changes in proposal and award policies and procedures, and upcoming NSF Grants Conferences. Subscribers are informed each time new publications are issued that match their identified interests. "NSF Update" is available on NSF's website at: https://public.govdelivery.com/accounts/USNSF/subscriber/new?qsp=823.

C. Categories of Funding Opportunities

NSF utilizes a variety of mechanisms to communicate opportunities for research and education support, as well as to generate proposals. A brief description of each category of funding opportunity follows.

1. Program Descriptions

The term "program description" includes broad, general descriptions of programs and activities in NSF Directorates/Offices and Divisions. Program descriptions are posted on Directorate/Division websites to encourage the submission of proposals in specific program areas of interest to NSF.

Program descriptions utilize the generic eligibility and proposal preparation instructions specified in Part I of the PAPPG, as well as the NSB-approved merit review criteria. See Chapter III for additional information.

2. Program Announcements

The term "program announcement" refers to formal NSF publications that announce NSF programs. Program announcements utilize the generic eligibility and proposal preparation guidelines specified in Part I of the PAPPG and incorporate the NSB-approved merit review criteria.

3. Program Solicitations

The term "program solicitation" refers to formal NSF publications that encourage the submission of proposals in specific program areas of interest to NSF. They generally are more focused than program announcements, and normally apply for a limited period of time. Competition among proposals is more precisely defined than with program announcements, and proposals received compete directly with each other for NSF funding. Program solicitations are issued when the funding opportunity has one or more of the following features:

- provides supplemental proposal preparation guidance or deviates from the guidelines established in Part I of the PAPPG;
- contains additional review criteria relevant to the program;
- requires submission of a letter of intent (see Chapter I.D.1) or preliminary proposal (see Chapter I.D.2);
- deviates from (or restricts) the standard categories of proposers specified in Section E. below;
- limits the number of proposals that may be submitted by an organization and/or researcher/educator;[4]
- requires cost sharing;
- requires a limitation in indirect (Facilities & Administrative (F&A)) costs;
- specifies additional award conditions and/or reporting requirements;
- anticipates use of a cooperative agreement.

4. Dear Colleague Letters (DCLs)

DCLs are intended to provide general information to the community, clarify or amend an existing policy or document, or inform the NSF proposer community about upcoming opportunities or special competitions for supplements to existing awards. In addition, DCLs are often used to draw attention to an impending change in NSF policies or programs.

[4]Unless otherwise specified, the term “organization” refers to all categories of proposers.

D. Types of Submissions

1. Letters of Intent (LOI)

Some NSF program solicitations require or request submission of an LOI in advance of submission of a full proposal. An LOI is not a binding document. The predominant reason for its use is to help NSF program staff gauge the size and range of the competition, enabling earlier selection and better management of reviewers and panelists. In addition, the information contained in an LOI is used to help avoid potential conflicts of interest in the review process.

An LOI normally contains the Principal Investigator's (PI's) and co-PI's names, a proposed title, a list of possible participating organizations (if applicable), and a synopsis that describes the work in sufficient detail to permit an appropriate selection of reviewers. Proposers that plan to submit a collaborative proposal from multiple organizations should submit a single LOI for the entire project, given that NSF considers a collaborative proposal to be a unified research project. An LOI is not externally evaluated or used to decide on funding. The requirement to submit an LOI will be identified in the program solicitation, and such letters are submitted electronically to NSF. Failure to submit a required LOI identified in a program solicitation will result in a full proposal not being accepted or returned without review.

2. Preliminary Proposals

Some NSF program solicitations require or request submission of a preliminary proposal in advance of submission of a full proposal. The three predominant reasons for requiring submission of a preliminary proposal are to:

- reduce the proposers' unnecessary effort in proposal preparation when the chance of success is very small. This is particularly true of exploratory initiatives when the community senses that a major new direction is being identified, or competitions that will result in a small number of awards;
- increase the overall quality of the full submission; and
- assist NSF program staff in managing the review process and in the selection of reviewers.

The NSF program solicitation will specify content and submission requirements when preliminary proposals are to be used. Preliminary proposals are prepared by the PI using the Proposal Preparation Module in FastLane. On the Cover Sheet, the PI clicks on the "Preliminary Proposal" check box. The PI completes only the sections appropriate to the preliminary proposal. The PI then forwards the proposal to the appropriate office at his/her organization, and the Authorized Organizational Representative (AOR) signs and submits the preliminary proposal via use of NSF's electronic systems.

One of the following two types of decisions may be received from NSF upon submission of a preliminary proposal. The program solicitation will specify the type of decision to be rendered for a particular program.

a. Invite/Not Invite Decisions

This type of mechanism is used when the NSF decision made on the preliminary proposal is final, affecting the organization's eligibility to submit a full proposal. Only submitters of favorably reviewed preliminary proposals are invited and eligible to submit full proposals. The PI and the organization's Sponsored Projects Office (SPO) (or equivalent) will be electronically notified of NSF's decision to either invite submission of a full proposal or decline NSF support.

b. Encourage/Discourage Decisions

This type of mechanism is used when the NSF decision made on the preliminary proposal is advisory only. This means that submitters of both favorably and unfavorably reviewed preliminary proposals are eligible to submit full proposals. The PI and the organization's SPO will be notified of NSF's decision to either encourage or discourage submission of a full proposal.

3. Full Proposals

The full proposal should present the (1) objectives and scientific, engineering, or educational significance of the proposed work; (2) suitability of the methods to be employed; (3) qualifications of the investigator and the grantee organization; (4) effect of the activity on the infrastructure of science, engineering and education, if applicable; and (5) amount of funding required. It should present the intellectual merit and broader impacts of the proposed project clearly and should be prepared with the care and thoroughness of a paper submitted for publication. The requisite proposal preparation instructions are contained in Chapter II. Sufficient information should be provided to enable reviewers to evaluate the proposal in accordance with the two merit review criteria established by the NSB. (See Chapter III for additional information on NSF processing and review of proposals.)

NSF expects strict adherence to the rules of proper scholarship and attribution. The responsibility for proper scholarship and attribution rests with the authors of a proposal; all parts of the proposal should be prepared with equal care for this concern. Authors other than the PI (or any co-PI) should be named and acknowledged. Serious failure to adhere to such standards can result in findings of research misconduct. NSF policies and rules on research misconduct[5] are discussed in the Chapter XII.C, as well as 45 CFR Part 689.

The Metric Conversion Act of 1975, as amended, and E.O. 12770 of 1991 encourage Federal agencies to use the Metric System (SI) in procurement, grants and other business-related activities. Proposers are encouraged to use the Metric System of weights and measures in proposals submitted to the Foundation. Grantees also are encouraged to use metric units in reports, publications and correspondence relating to proposals and awards.

E. Who May Submit Proposals

NSF welcomes proposals on behalf of all qualified scientists, engineers and educators. The Foundation strongly encourages women, minorities and persons with disabilities to participate fully in its programs. In accordance with Federal statutes, regulations and NSF policies, no person on grounds of race, color, age, sex, national origin or disability shall be excluded from participation in, be denied the benefits of, or be subjected to discrimination under, any program or activity receiving financial assistance from NSF, although some programs may have special requirements that limit eligibility.

Scientists, engineers and educators usually initiate proposals that are officially submitted by their employing organization. Before formal submission, the proposal may be discussed with appropriate NSF program staff. Graduate students are not encouraged to submit research proposals, but should arrange to serve as research assistants to faculty members. Some NSF divisions accept proposals for Doctoral Dissertation Research Grants when submitted by a faculty member on behalf of the graduate student.

[5] Research misconduct refers to fabrication, falsification, or plagiarism in proposing or performing research funded by NSF, reviewing research proposals submitted to NSF, or in reporting research results funded by NSF. Organizations involved in international collaborations might find the following document provided by the Organisation for Economic Co-operation and Development (OECD) to be useful: "Best Practices for Ensuring Scientific Integrity and Preventing Misconduct"

Categories of Proposers

Except where a program solicitation establishes more restrictive eligibility criteria, individuals and organizations in the following categories may submit proposals:

1. Institutions of Higher Education (IHEs) — Two- and four-year IHEs (including community colleges) accredited in, and having a campus located in the US, acting on behalf of their faculty members. IHEs located outside the US fall under paragraph 6. below.

Special Instructions for International Branch Campuses of US IHEs

If the proposal includes funding to be provided to an international branch campus of a US institution of higher education (including through use of subawards and consultant arrangements), the proposer must explain the benefit(s) to the project of performance at the international branch campus, and justify why the project activities cannot be performed at the US campus.

2. Non-profit, Non-academic Organizations — Independent museums, observatories, research laboratories, professional societies and similar organizations located in the US that are directly associated with educational or research activities.

3. For-profit Organizations — US commercial organizations, especially small businesses with strong capabilities in scientific or engineering research or education. An unsolicited proposal from a commercial organization may be funded when the project is of special concern from a national point of view, special resources are available for the work, or the proposed project is especially meritorious. NSF is interested in supporting projects that couple industrial research resources and perspectives with those of universities; therefore, it especially welcomes proposals for cooperative projects involving both universities and the private commercial sector.

4. State and Local Governments — State educational offices or organizations and local school districts may submit proposals intended to broaden the impact, accelerate the pace, and increase the effectiveness of improvements in science, mathematics and engineering education in both K-12 and post-secondary levels.

5. Unaffiliated Individuals — Unaffiliated individuals in the US and US citizens rarely receive direct funding support from NSF. Recipients of Federal funds must be able to demonstrate their ability to fully comply with the requirements specified in 2 CFR § 200, *Uniform Administrative Requirements, Cost Principles, and Audit Requirements for Federal Awards.* As such, unaffiliated individuals are strongly encouraged to affiliate with an organization that is able to meet the requirements specified in 2 CFR § 200.

Unaffiliated individuals must contact the cognizant Program Officer prior to preparing and submitting a proposal to NSF.

6. Foreign Organizations — NSF rarely provides funding support to foreign organizations. NSF will consider proposals for cooperative projects involving US and foreign organizations, provided support is requested only for the US portion of the collaborative effort. In cases however, where the proposer considers the foreign organization's involvement to be essential to the project (e.g., through subawards or consultant arrangements), the proposer must explain why local support is not feasible and why the foreign organization can carry out the activity more effectively. In addition, the proposed activity must demonstrate how one or more of the following conditions have been met:

- The foreign organization contributes a unique organization, facilities, geographic location and/or access to unique data resources not generally available to US investigators (or which would require significant effort or time to duplicate) or other resources that are essential to the success of the proposed project; and/or

- The foreign organization to be supported offers significant science and engineering education, training or research opportunities to the US.

7. Other Federal Agencies — NSF does not normally support research or education activities by scientists, engineers or educators employed by Federal agencies or FFRDCs. Under unusual circumstances, other Federal agencies and FFRDCs may submit proposals directly to NSF. A proposed project is only eligible for support if it meets one or more of the following exceptions, as determined by a cognizant NSF Program Officer:

- Special Projects. Under exceptional circumstances, research or education projects at other Federal agencies or FFRDCs that can make unique contributions to the needs of researchers elsewhere or to other specific NSF objectives may receive NSF support.

- National and International Programs. The Foundation may fund research and logistical support activities of other Government agencies or FFRDCs directed at meeting the goals of special national and international research programs for which the Foundation bears special responsibility, such as the US Antarctic Research Program.

- International Travel Awards. In order to ensure appropriate representation or availability of a particular expertise at an international conference, staff researchers of other Federal agencies may receive NSF international travel awards.

Proposers who think their project may meet one of the exceptions listed above must contact a cognizant NSF Program Officer before preparing a proposal for submission. In addition, a scientist, engineer or educator who has a joint appointment with a university and a Federal agency (such as a Veterans Administration Hospital, or with a university and a FFRDC) may submit proposals through the university and may receive support if he/she is a faculty member (or equivalent) of the university, although part of his/her salary may be provided by the Federal agency. Preliminary inquiry must be made to the appropriate program before preparing a proposal for submission.

F. When to Submit Proposals

Proposers should allow adequate time for processing of proposals (see Chapter I.H for further information). Many NSF programs accept proposals at any time. Other programs, however, establish due dates for submission of proposals. The following types of due dates are utilized by NSF:

1. **Target Dates:** dates after which proposals will still be accepted, although they may miss a particular panel or committee meeting.

2. **Deadline Dates:** dates after which proposals will not be accepted or will be returned without review by NSF. The deadline date will be waived only in extenuating circumstances. Such a deviation may be authorized only in accordance with Chapter II.A.

3. **Submission Windows:** designated periods of time during which proposals will be accepted for review by NSF. It is NSF's policy that the end date of a submission window converts to, and is subject to, the same policies as a deadline date.

These target dates, deadlines, and submission windows are published in specific program descriptions, program announcements and solicitations that can be obtained through the NSF website.[6] Unless otherwise stated in a program announcement or solicitation, proposals must be received by the specified date. If the deadline date falls on a weekend, it will be extended to the following Monday; if the date falls

[6]A listing of upcoming target dates and deadlines, sorted by date and by program area is available on the NSF website at: http://nsf.gov/funding/pgm_list.jsp?org=NSF&ord=date.

on a Federal holiday, it will be extended to the following business day. Proposals must be received by 5 p.m. submitter's local time on the established deadline date. Failure to submit by 5.p.m. submitter's local time will result in the proposal not being accepted. See Chapter IV.B for additional information. Letters of intent or preliminary proposals also follow the 5 p.m. submitter's local time standard.

Special Exceptions to NSF's Deadline Date Policy

In the event of a natural or anthropogenic disaster, or when NSF is closed due to inclement weather or other reason that interferes with an organization's ability to meet a proposal submission deadline, NSF has developed the following guidelines for use by impacted organizations.

Natural or Anthropogenic Disasters - Flexibility in meeting announced deadline dates because of a natural or anthropogenic disaster that impacts a proposer's ability to submit a proposal to NSF may be granted with the approval of the cognizant NSF Program Officer. Where possible, such requests should be submitted in advance of the proposal deadline. Proposers should contact the cognizant NSF Program Officer in the Division/Office to which they intend to submit their proposal and request authorization to submit a proposal after the deadline date. Proposers should then follow the written or verbal guidance provided by the cognizant NSF Program Officer. The Foundation will work with each impacted organization on a case-by-case basis to address its specific issue(s). Generally, NSF permits extension of the deadline by up to five business days.

To submit the proposal after the deadline date, proposers must check the "Special Exception to the Deadline Date Policy" box on the NSF Cover Sheet, indicating NSF approval has been obtained. A statement identifying the nature of the event that impacted the ability to submit the proposal on time should be uploaded under Nature of Natural or Anthropogenic event in the Single Copy Document section in FastLane. If available, written approval from the cognizant NSF Program Officer also should be uploaded under the Additional Single Copy Documents in the Single Copy Document section in FastLane.

Closure of NSF – When NSF is closed due to inclement weather or other reason[7], deadline(s) that occurred during the closure automatically will be extended to the following business day after the closure ends.

G. How to Submit Proposals

1. Electronic Requirements

Proposals to NSF must be submitted via the NSF FastLane System or via use of Grants.gov. For proposals prepared and submitted via Grants.gov, the guidelines specified in the NSF *Grants.gov Application Guide* apply.

2. Submission Instructions

The same work/proposal cannot be funded twice. If the proposer envisions review by multiple programs, more than one program may be designated on the Cover Sheet. The submission of duplicate or substantially similar proposals concurrently for review by more than one program without prior NSF approval will result in the return of the redundant proposals. (See Chapter IV.B for further information.)

In submission of a proposal for funding, the AOR is required to provide certain proposal certifications. (See Chapter II.C.1.d for a listing.) This certification process will occur concurrently with submission of the proposal.

[7] This policy is not intended to cover NSF closures due to lapses in appropriation. In such cases, specific guidance will be issued, as appropriate.

3. Requirements Relating to Data Universal Numbering System (DUNS) Numbers and Registration in the System for Award Management (SAM)

Proposers must provide a Dun and Bradstreet (D&B) DUNS number when applying for a new or renewal award. NSF requires that organizations registering to use NSF's electronic systems have a valid and active SAM registration and have a valid DUNS number. NSF will validate that each proposer's DUNS number and SAM registration are active and valid prior to allowing submission of a proposal to NSF. Any subrecipients named in the proposal also are required to obtain a DUNS number and register in FastLane. Subrecipients named in the proposal, however, do not need to be registered in SAM.

The SAM is the primary registrant database for the US Government. SAM collects, validates, stores, and disseminates data in support of agency acquisition missions, including Federal agency contract and assistance awards. This SAM registration must be maintained with current information at all times during which the organization has an active award or a proposal under consideration by NSF. Failure to comply with the SAM registration requirement prior to proposal submission may impact the processing of the proposal. To register in the SAM, go to: https://www.sam.gov. Proposers are advised that entity registration will become active after three to five days when the Internal Revenue Service (IRS) validates the Tax ID Number.

The organization also is responsible for updating all SAM registration information as it changes. Once an award is made, failure to maintain current and complete information within SAM will impact receipt of funding. To maintain an active status in SAM, an organization's registration must be renewed and revalidated at least every 12 months from the date of the previous registration. If the registration is not renewed, it will expire. An expired registration will impact the organization's ability to submit proposals or receive grant payments.

SAM is the NSF system of record for organizational information, including financial and address information. The Legal Business Name and Physical Address information are automatically input into the proposer's SAM registration from D&B, and it is the organization's responsibility to keep this information updated.

4. NSF ID

The NSF ID is a unique numerical identifier assigned to users by NSF. The NSF ID may be used throughout NSF's electronic systems as a login ID and identification verification. Each individual user of NSF systems, (e.g., Fastlane and Research.gov) should not have more than one NSF ID. Users with more than one NSF ID should contact the Help Desk at (800) 673-6188 or (703) 292-8142 or by e-mail to fastlane@nsf.gov for assistance.

Submission of Social Security Numbers (SSNs) only will be requested where it is necessary for business purposes, e.g., financial reimbursement. An SSN is solicited under the NSF Act of 1950, as amended.

5. Proposal Receipt

Once the proposal is submitted, PIs can check the status of the proposal via use of NSF's electronic systems. If a proposal number is not reflected in the electronic systems, contact the Help Desk at (800) 673-6188 or (703) 292-8142 or by e-mail to fastlane@nsf.gov.

Communications about the proposal should be addressed to the cognizant NSF Program Officer with reference to the proposal number. Proposers are strongly encouraged to use NSF's electronic systems to verify the status of their submission to NSF.

H. Proposal Processing

Proposers should allow up to six months for programmatic review and processing (see Chapter III for additional information on the NSF merit review process). In addition, proposers should be aware that the NSF Division of Grants and Agreements generally makes awards within 30 days after the program division/office makes its recommendation. Grants being made to organizations that have not received an NSF award within the preceding five years, or involving special situations (such as coordination with another Federal agency or a private funding source), cooperative agreements, and other unusual arrangements may require additional review and processing time. Proposals that are time-sensitive (e.g., conference and group travel) will be accepted for review only if, in the opinion of the cognizant Program Officer, they are received in sufficient time to permit appropriate NSF review and processing to support an award in advance of the activity to be supported. Every effort is made to reach a decision and inform the proposer promptly. Until an award is made, NSF is not responsible for any costs incurred by the proposing organization.

Chapter II: Proposal Preparation Instructions

Each proposing organization that is new to NSF or has not had an active NSF assistance award within the previous five years should be prepared to submit basic organization and management information and certifications, when requested, to the applicable award-making division within the Office of Budget, Finance & Award Management (BFA). The requisite information is described in the *NSF Prospective New Awardee Guide*. The information contained in this Guide will assist the organization in preparing documents which NSF requires to conduct administrative and financial reviews of the organization. This Guide also serves as a means of highlighting the accountability requirements associated with Federal awards.

To facilitate proposal preparation, Frequently Asked Questions (FAQs) regarding proposal preparation and submission are available on the NSF website.[8]

Proposers should also be aware of core strategies that are essential to the fulfillment of NSF's mission, as articulated in *Investing in Science, Engineering, and Education for the Nation's Future: NSF Strategic Plan, 2014-2018*. These strategies are integrated in the program planning and implementation process, of which proposal review is one part. NSF's mission is particularly well-implemented through the integration of research and education and broadening participation in NSF programs, projects, and activities.

One of the strategic objectives in support of NSF's mission is to foster integration of research and education through the programs, projects, and activities it supports at NSF grantee organizations. These organizations recruit, train, and prepare a diverse science, technology, engineering, and mathematics (STEM) workforce to advance the frontiers of science and participate in the US technology-based economy. NSF's contribution to the national innovation ecosystem is to provide cutting-edge research under the guidance of the Nation's most creative scientists and engineers. NSF also supports development of a strong STEM workforce by investing in building the knowledge that informs improvements in STEM teaching and learning.

NSF's mission calls for the broadening of opportunities and expanding participation of groups, organizations, and geographic regions that are underrepresented in STEM disciplines, which is essential to the health and vitality of science and engineering. NSF is committed to this principle of diversity and deems it central to the programs, projects, and activities it considers and supports.

A. Conformance with Instructions for Proposal Preparation

It is important that all proposals conform to the proposal preparation instructions contained in Part I of the PAPPG or the NSF *Grants.gov Application Guide*. Conformance is required and will be strictly enforced unless an authorization to deviate from standard proposal preparation requirements has been approved. NSF will not accept or will return without review proposals that are not consistent with these instructions. See Chapter IV.B for additional information. NSF authorization to deviate from these instructions must be received prior to proposal submission. Deviations may be authorized in one of two ways:

1. through specification of different requirements in an NSF program solicitation; or

2. by the written approval of the cognizant NSF Assistant Director/Office Head or designee. These approvals to deviate from NSF proposal preparation instructions may cover a particular program or programs or, in rare instances, an individual deviation for a particular proposal.

Proposers may deviate from these instructions only to the extent authorized. Proposals must include an authorization to deviate from standard NSF proposal preparation instructions in one of the following ways, as appropriate: (a) by identifying the solicitation number that authorized the deviation in the appropriate block on the Cover Sheet; or (b) for individual deviations, by identifying the name, date and title of the NSF official authorizing the deviation.

[8]FAQs regarding FastLane proposal preparation and submission also are available in FastLane.

B. Format of the Proposal

Prior to submission, it is strongly recommended that proposers conduct an administrative review to ensure that proposals comply with the guidelines established in Part I of the PAPPG or the NSF *Grants.gov Application Guide*. The Proposal Preparation Checklist (Exhibit II-1) may be used to assist in this review. The checklist is not intended to be an all-inclusive repetition of the required proposal contents and associated proposal preparation guidelines. It is, however, meant to highlight certain critical items so they will not be overlooked when the proposal is prepared.

During completion of the proposal Cover Sheet (See Chapter II.C.2.a.), the PI will be prompted to select the applicable response that describes the nature and type of proposal being developed:

The type of proposal being developed:

- Research (see Chapter II, Sections A through C);
- Rapid Response Research (RAPID) (see Chapter II.E.1);
- Early-concept Grants for Exploratory Research (EAGER) (see Chapter II.E.2);
- Research Advanced by Interdisciplinary Science and Engineering (RAISE)(see Chapter II.E.3);
- Grant Opportunities for Academic Liaison with Industry (GOALI) (see Chapter II.E.4);
- Ideas Lab (see Chapter II.E.5);
- Facilitation Awards for Scientists and Engineers with Disabilities (FASED) (see Chapter II.E.6);
- Conference (see Chapter II.D.7);
- Equipment (see Chapter II.D.8);
- Travel (see Chapter II.D.9);
- Center/Research Infrastructure (see relevant funding opportunity); or
- Fellowship (see relevant funding opportunity).

Whether the proposal is:

- A collaborative proposal from one organization (see Chapter II.D.3.a);
- A collaborative proposal from multiple organizations (see Chapter II.D.3.b); or
- Not a collaborative proposal.

The requested proposal information noted above will be used to determine the applicable proposal preparation business rules that must be followed. Proposers are strongly advised to review the applicable sections of Part I of the PAPPG pertinent to the type of proposal being developed **PRIOR** to submission. Additional information on NSF auto-compliance checks run during the proposal preparation and submission process can be found at: http://www.nsf.gov/bfa/dias/policy/autocompliance.jsp.

1. Proposal Pagination Instructions

Proposers are advised that FastLane does not automatically paginate a proposal. Each section of the proposal that is uploaded as a file must be individually paginated prior to being uploaded to the electronic system.

2. Proposal Margin and Spacing Requirements

The proposal must conform to the following requirements:

a. Use one of the following typefaces identified below:

- Arial[9], Courier New, or Palatino Linotype at a font size of 10 points or larger;
- Times New Roman at a font size of 11 points or larger; or
- Computer Modern family of fonts at a font size of 11 points or larger.

A font size of less than 10 points may be used for mathematical formulas or equations, figures, table or diagram captions and when using a Symbol font to insert Greek letters or special characters. PIs are cautioned, however, that the text must still be readable.

b. No more than six lines of text within a vertical space of one inch.

c. Margins, in all directions, must be at least an inch.

These requirements apply to all uploaded sections of a proposal, including supplementary documentation.

3. Page Formatting

Proposers are strongly encouraged to use only a standard, single-column format for the text.

The guidelines specified above establish the minimum type size requirements; however, PIs are advised that readability is of paramount importance and should take precedence in selection of an appropriate font for use in the proposal. **Small type size makes it difficult for reviewers to read the proposal; consequently, the use of small type not in compliance with the above guidelines may be grounds for NSF to return the proposal without review.** Adherence to type size and line spacing requirements also is necessary to ensure that no proposer will have an unfair advantage, by using smaller type or line spacing to provide more text in the proposal.

C. Proposal Contents

1. Single-Copy Documents

Certain categories of information that are submitted in conjunction with a proposal are for "NSF Use Only." As such, the information is not provided to reviewers for use in the review of the proposal. With the exception of proposal certifications (which are submitted via the Authorized Organizational Representative function[10]), these documents should be submitted via the FastLane Proposal Preparation Module. A summary of each of these categories follows:

a. Authorization to Deviate from NSF Proposal Preparation Requirements (if applicable)

Instructions for obtaining authorization to deviate from NSF proposal preparation instructions are provided in Chapter II.A.

[9] Macintosh users also may use Helvetica and Palatino typefaces.
[10] Further instructions for this process are available in FastLane.

b. List of Suggested Reviewers or Reviewers Not to Include (optional)

Proposers may include a list of suggested reviewers (including email address and organizational affiliation) who they believe are especially well qualified to review the proposal. Proposers also may designate persons they would prefer not review the proposal, indicating why. These suggestions are optional. Exhibit II-2 contains information on conflicts of interest that may be useful in preparation of this list.

The cognizant Program Officer handling the proposal considers the suggestions and may contact the proposer for further information. The decision whether or not to use the suggestions, however, remains with the Program Officer.

c. Proprietary or Privileged Information (if applicable)

Instructions for submission of proprietary or privileged information are provided in Chapter II.D.1.

d. Proposal Certifications

With the exception of the *Disclosure of Lobbying Activities (SF LLL)* identified below, the procedures for submission of the proposal certifications differ from those used with other single-copy documents. The AOR must use the "Authorized Organizational Representative function" in FastLane to sign and submit the proposal, including the proposal certifications. It is the proposing organization's responsibility to assure that only properly authorized individuals perform this function.[11]

The required proposal certifications are as follows:

- **Certification for Authorized Organizational Representative (AOR) or Individual Proposer:** The AOR is required to complete certifications regarding the accuracy and completeness of statements contained in the proposal, as well as to certify that the organization (or individual) agrees to accept the obligation to comply with grant terms and conditions.

- **Certification Regarding Conflict of Interest:** The AOR is required to complete certifications stating that the organization has implemented and is enforcing a written policy on conflicts of interest (COI), consistent with the provisions of Chapter IX.A: that, to the best of his/her knowledge, all financial disclosures required by the conflict of interest policy were made; and that conflicts of interest, if any, were, or prior to the organization's expenditure of any funds under the grant, will be, satisfactorily managed, reduced or eliminated in accordance with the organization's conflict of interest policy. Conflicts that cannot be satisfactorily managed, reduced or eliminated, and research that proceeds without the imposition of conditions or restrictions when a conflict of interest exists, must be disclosed to NSF via use of NSF's electronic systems.

- **Drug-Free Workplace:** The AOR is required to complete a certification regarding the Drug-Free Workplace Act. See Exhibit II-3 for the full text of the Drug-Free Workplace Certification.

- **Debarment and Suspension:** The AOR is required to complete a certification regarding Debarment and Suspension. See Exhibit II-4for the full text of the Debarment and Suspension Certification.

- **Certification Regarding Lobbying:** When the proposal exceeds $100,000, the AOR is required to complete a certification regarding lobbying restrictions. The *Certification for Contracts, Grants, Loans and Cooperative Agreements* is included in full text on the FastLane submission screen as well as in Exhibit II-5. The box for "Disclosure of Lobbying Activities" must be checked on the Cover Sheet only if, pursuant to paragraph 2 of the certification, submission of the SF LLL is required.[12]

[11]Detailed instructions for completion of this process are available in FastLane.
[12]Detailed instructions for submission of the SF LLL are available in FastLane.

- **Certification Regarding Nondiscrimination:** The AOR is required to complete a certification regarding compliance with NSF nondiscrimination regulations and policies. See Exhibit II-6 for the full text of the Nondiscrimination Certification. This certification sets forth the nondiscrimination obligations with which all grantees must comply. These obligations also apply to subrecipients or contractors under the grant. The proposer, therefore, shall obtain the NSF Nondiscrimination Certification from each organization that applies to be, or serves as a subrecipient or contractor under the award (for other than the provision of commercially available supplies, materials, equipment or general support services) prior to entering into the subaward or contract arrangement.

- **Certification Regarding Flood Hazard Insurance:** Two sections of the National Flood Insurance Act of 1968 (42 USC § 4012a and § 4106) bar Federal agencies from giving financial assistance for acquisition or construction purposes in any area identified by the Federal Emergency Management Agency (FEMA) as having special flood hazards unless the:

  (1) community in which that area is located participates in the national flood insurance program; and

  (2) building (and any related equipment) is covered by adequate flood insurance.

  By signing the certification pages, AORs for prospective grantees located in FEMA-designated special flood hazard areas are certifying that adequate flood insurance has been or will be obtained in the following situations:

  (1) for NSF grants for the construction of a building or facility, regardless of the dollar amount of the grant; and

  (2) for other NSF grants when more than $25,000 has been budgeted in the proposal for repair, alteration or improvement (construction) of a building or facility.

  Prospective grantees should contact their local government or a Federally-insured financial institution to determine what areas are identified as having special flood hazards and the availability of flood insurance in their community.

- **Certification Regarding Responsible Conduct of Research (RCR)**[13]**:** The AOR is required to complete a certification that the institution has a plan to provide appropriate training and oversight in the responsible and ethical conduct of research to undergraduates, graduate students, and postdoctoral researchers who will be supported by NSF to conduct research.

  Additional information on NSF's RCR policy is available in the Chapter IX.B. While training plans are not required to be included in proposals submitted to NSF, institutions are advised that they are subject to review upon request.

- **Certification Regarding Organizational Support:** The AOR is required to complete a certification that there is organizational support for the proposal as required by Section 526 of the *America COMPETES Reauthorization Act of 2010.* This support extends to the portion of the proposal developed to satisfy the broader impacts review criterion as well as the intellectual merit review criterion, and any additional review criteria specified in the solicitation. Organizational support will be made available, as described in the proposal, in order to address the broader impacts and intellectual merit activities to be undertaken.

[13] A wide array of information exists to help inform development of an institution's RCR training plan. For example, many professional societies as well as governmental licensing authorities for professional scientists and engineers have adopted policies or best practices that might be usefully considered. In addition, research is illuminating existing practices surrounding ethical issues, and providing an evaluation of pedagogical innovations in ethics education.

- **Certification Regarding Federal Tax Obligations:** When the proposal exceeds $5,000,000, the AOR is required to complete a certification regarding Federal tax obligations. By signing the certification pages, the AOR certifies that, to the best of his/her knowledge and belief, the proposing organization:

  (1) has filed all Federal tax returns required during the three years preceding this certification;

  (2) has not been convicted of a criminal offense under the Internal Revenue Code of 1986; and

  (3) has not, more than 90 days prior to this certification, been notified of any unpaid Federal tax assessment for which the liability remains unsatisfied, unless the assessment is the subject of an installment agreement or offer in compromise that has been approved by the IRS and is not in default, or the assessment is the subject of a non-frivolous administrative or judicial proceeding.

- **Certification Regarding Unpaid Federal Tax Liability:** If the proposer is a corporation, the AOR (or equivalent) is required to complete a certification that the corporation has no unpaid Federal tax liability that has been assessed, for which all judicial and administrative remedies have been exhausted or lapsed, and that is not being paid in a timely manner pursuant to an agreement with the authority responsible for collecting the tax liability.

- **Certification Regarding Criminal Convictions:** If the proposer is a corporation, the AOR (or equivalent) is required to complete a certification that the corporation has not been convicted of a felony criminal violation under any Federal law within the 24 months preceding the date on which the certification is signed.

- **Certification Regarding Dual Use Research of Concern:** The AOR is required to complete a certification that the organization will be or is in compliance with all aspects of the *United States Government Policy for Institutional Oversight of Life Sciences Dual Use Research of Concern.*

e. Collaborators & Other Affiliations Information

The following information regarding collaborators and other affiliations (COA) must be separately provided for each individual identified as senior project personnel. The COA information must be provided through use of the COA template. If there are more than 10 individuals designated as senior project personnel on the proposal, or if there are print preview issues, each *completed* template must be saved as a .txt file [select the Text (Tab Delimited) option] rather than as an .xlsx or .xls file. This format will still enable preservation of searchable text and avoid delays in processing and review of the proposal.

Please note that some information requested in prior versions of the PAPPG is no longer requested. THIS IS PURPOSEFUL AND WE NO LONGER REQUIRE THIS INFORMATION TO BE REPORTED. Certain relationships will be reported in other sections (i.e., the names of postdoctoral scholar sponsors should not be reported, however if the individual collaborated on research with their postdoctoral scholar sponsor, then they would be reported as a collaborator). The information in the tables is not required to be sorted, alphabetically or otherwise.

There are five separate categories of information which correspond to the five tables in the COA template:

COA template Table 1:

List the individual's last name, first name, middle initial, and organizational affiliation (including considered affiliation) in the last 12 months.

COA template Table 2:

List names as last name, first name, middle initial, for whom a personal, family, or business relationship would otherwise preclude their service as a reviewer.

COA template Table 3:

List names as last name, first name, middle initial, and provide organizational affiliations, if known, for the following:[14]

- The individual's Ph.D. advisors; and
- All of the individual's Ph.D. thesis advisees.

COA template Table 4:

List names as last name, first name, middle initial, and provide organizational affiliations, if known, for the following:

- Co-authors on any book, article, report, abstract or paper with collaboration in the last 48 months (publication date may be later); and
- Collaborators on projects, such as funded grants, graduate research or others in the last 48 months.

COA template Table 5:

List editorial board, editor-in chief and co-editors with whom the individual interacts. An editor-in-chief must list the entire editorial board.

- Editorial Board:[15] List name(s) of editor-in-chief and journal in the past 24 months; and
- Other co-Editors of journal or collections with whom the individual has directly interacted in the last 24 months.

The template has been developed to be fillable, however, the content and format requirements must not be altered by the user. This template must be saved in .xlsx or .xls format, and directly uploaded into FastLane as a Collaborators and Other Affiliations Single Copy Document. FastLane will convert the uploaded .xlsx or .xls files to PDF. Using the .xlsx or .xls format will enable preservation of searchable text that otherwise would be lost. It is therefore imperative that this document be uploaded in .xlsx or .xls **only**. Uploading a document in any format other than .xlsx or .xls may delay the timely processing and review of the proposal.

This information is used to manage reviewer selection. See Exhibit II-2 for additional information on potential reviewer conflicts.

f. Submission of Proposals by Former NSF Staff

For one year following separation from the Foundation, any communication with NSF by a former employee or IPA must be done through use of a "substitute negotiator." Unless a substitute negotiator has been designated by the proposer/grantee, the Division of Grants and Agreements (DGA) or the Division of Acquisition and Cooperative Support (DACS) will not process a new proposal with a former employee or IPA as PI or co-PI. If it has been less than a year since a former employee separated from NSF or an IPA ended their appointment and they submit a proposal, documentation from the Authorized Organizational

[14] Note that graduate advisors are no longer required to be reported.

[15] Editorial Board does not include Editorial Advisory Board, International Advisory Board, Scientific Editorial Board, or any other subcategory of Editorial Board. It is limited to those individuals who perform editing duties or manage the editing process (i.e., editor in chief).

Representative (AOR) needs to be included which designates a substitute negotiator for that proposal. A co-PI on a new proposal should designate the PI as the substitute negotiator. This information should be submitted as a single copy document and uploaded in the "Additional Single Copy Documents" category.

2. Sections of the Proposal

The sections described below represent the body of a research proposal submitted to NSF. Failure to submit the required sections will result in the proposal not being accepted[16], or being returned without review. See Chapter IV.B for additional information.

A full research proposal must contain the following sections[17]. Note that the *NSF Grants.gov Application Guide* may use different naming conventions, and sections may appear in a different order than in FastLane, however, the content is the same:

a. Cover Sheet
b. Project Summary
c. Table of Contents
d. Project Description
e. References Cited
f. Biographical Sketch(es)
g. Budget and Budget Justification
h. Current and Pending Support
i. Facilities, Equipment and Other Resources
j. Special Information and Supplementary Documentation
   - Data Management Plan
   - Postdoctoral Mentoring Plan (if applicable)
k. Single Copy Documents
   - Collaborators & Other Affiliations Information

Proposal preparation instructions for RAPID, EAGER, RAISE, GOALI, Ideas Lab, FASED, conference, equipment, travel, center, research infrastructure, and fellowships may deviate from the above content requirements.

All proposals to NSF will be reviewed using the two NSB-approved merit review criteria described in greater length in Chapter III.

a. Cover Sheet

There are four major components of the Cover Sheet. A number of the boxes contained on the Cover Sheet are pre-filled as part of the FastLane login process. The information requested on the Cover Sheet is as follows:

(1) Awardee Organization/Primary Place of Performance

The information on the Awardee Organization is prefilled on the Cover Sheet based on the login information entered. If the project will be performed at the awardee organization, check the designated box. If the project, however, will be performed at a location other than the awardee, provide the following information (where applicable):

- Organization Name (identify the organization name of the primary site where the work will be performed, if different than the awardee);
- Street;

[16] Proposal Not Accepted is defined as FastLane will not permit submission of the proposal.
[17] See Chapter II.E for the proposal preparation requirements for other types of proposals submitted to NSF.

- City;
- State;
- Country; and
- 9-digit Zip Code.

(2) Program Announcement/Solicitation/Program Description Number

Proposers are required to select the applicable funding opportunity (i.e., program announcement, solicitation or description.) If the proposal is not submitted in response to a specific funding opportunity, proposers should select "Proposal and Award Policies and Procedures Guide." Proposers are advised to select "No Closing Date" when the proposal is not submitted in response to any relevant NSF funding opportunity.

(3) NSF Unit of Consideration

Proposers must follow instructions for selection of an applicable NSF Division/Office and Program(s) to which the proposal should be directed.

(4) Remainder of the Cover Sheet

(a) Title of Proposed Project

The title of the project must be brief, scientifically or technically valid, and suitable for use in the public press. NSF may edit the title of a project prior to making an award.

(b) Budget and Duration Information

The proposed duration for which support is requested should be consistent with the nature and complexity of the proposed activity. The Foundation encourages proposers to request funding for durations of three to five years when such durations are necessary for completion of the proposed work and are technically and managerially advantageous. The requested start date should allow at least six months for NSF review, processing and decision. The PI should consult his/her organization's SPO for unusual situations (e.g., a long lead time for procurement) that create problems regarding the proposed start date. Specification of a desired start date for the project is important and helpful to NSF staff; however, requests for specific start dates may not be met.

(c) Announcement and Consideration Information

This information is prefilled based on previously entered information.

(d) PI Information and co-PI Information

Information (including address information) regarding the PI is derived from login information and is not entered when preparing the Cover Sheet. The proposal also may identify up to four additional co-PIs.

Each individual's name and either NSF ID or primary registered e-mail address, must be entered in the boxes provided.

(e) Previous NSF Award

If the proposal is a renewal proposal, or an accomplishment-based renewal proposal, the applicable box must be checked. If yes, the proposer will be requested to select the applicable previous award number.

Some NSF program solicitations require submission of both a preliminary and full proposal as part of the proposal process. In such cases, the following instructions apply:

(i) During the preliminary proposal stage, the proposing organization should identify the submission as a preliminary proposal by checking the block entitled, “Preliminary Proposal” on the Cover Sheet;

(ii) During the full proposal submission stage, the proposing organization should identify in the block entitled, “Show Related Preliminary Proposal Number”, the related preliminary proposal number assigned by NSF.

For projects that support research infrastructure and tools, such as vessels, facilities, and telescopes, the project/performance site should correspond to the physical location of the research asset. For research assets or projects that are geographically distributed, the proposer should report information for the primary site, as defined by the proposer. For example, proposals for the operations and maintenance of research vessels may list the project/performance site as the vessel’s home port.

(f) Consideration by Other Federal Agencies

If the proposal is being submitted for consideration by another Federal agency, the abbreviated name(s) of the Federal agency(ies) must be identified in the spaces provided.

(g) Awardee Organization Information

The awardee organization name, address, NSF organization code, DUNS number and Employer Identification Number/Taxpayer Identification Number are derived from the profile information provided by the organization or pulled by NSF from the SAM database and are not entered when preparing the Cover Sheet.

Profit-making organizations must identify their status by checking the appropriate boxes on the Cover Sheet, using the following guidelines:

- A small business must be organized for profit, independently owned and operated (not a subsidiary of, or controlled by, another firm), have no more than 500 employees, and not be dominant in its field.

- A minority business must be: (i) at least 51 percent owned by one or more minority or disadvantaged individuals or, in the case of a publicly owned business, have at least 51 percent of the voting stock owned by one or more minority or disadvantaged individuals; and (ii) one whose management and daily business operations are controlled by one or more such individuals.

- A woman-owned business must be at least 51 percent owned by a woman or women, who also control and operate it. "Control" in this context means exercising the power to make policy decisions. "Operate" in this context means being actively involved in the day-to-day management.

(h) Primary Place of Performance

This information is prefilled based on previously entered information.

(i) Other Information

Should any of the following items on the Cover Sheet apply to a proposal, the applicable box(es) must be checked.

- Beginning Investigator (See Chapter II.D.2) (Note: this box is applicable only to proposals submitted to the Biological Sciences Directorate.)
- Disclosure of Lobbying Activities (See Chapter II.C.1.d)
- Proprietary or Privileged Information (See Chapter II.C.1.c and II.D.1)

- Historic Places (See Chapter II.C.2.j)
- Vertebrate Animals[18] (See Chapter II.D.4)
- Human Subjects[19] (See Chapter II.D.5)
- International Activities Country Name(s) -- For each proposal that describes an international activity, proposers should list the primary countries involved. A maximum of five countries may be listed. An international activity is defined as research, training, and/or education carried out in cooperation with international counterparts either overseas or in the US using virtual technologies. Proposers also should enter the country/countries with which project participants will engage and/or travel to attend international conferences. If the specific location of the international conference is not known at the time of the proposal submission, proposers should enter "Worldwide". (See Chapter II.C.2.j)

b. Project Summary

Each proposal must contain a summary of the proposed project not more than one page in length. The Project Summary consists of an overview, a statement on the intellectual merit of the proposed activity, and a statement on the broader impacts of the proposed activity.

The overview includes a description of the activity that would result if the proposal were funded and a statement of objectives and methods to be employed. The statement on intellectual merit should describe the potential of the proposed activity to advance knowledge. The statement on broader impacts should describe the potential of the proposed activity to benefit society and contribute to the achievement of specific, desired societal outcomes.

The Project Summary should be informative to other persons working in the same or related fields, and, insofar as possible, understandable to a broad audience within the scientific domain. It should not be an abstract of the proposal.

The Project Summary may **ONLY** be uploaded as a Supplementary Document if use of special characters is necessary. Such Project Summaries must be formatted with separate headings for Overview, Intellectual Merit and Broader Impacts. Failure to include these headings will result in the proposal being returned without review.

c. Table of Contents

A Table of Contents is automatically generated for the proposal. The proposer cannot edit this form.

d. Project Description (including Results from Prior NSF Support)

(i) Content

The Project Description must contain, as a separate section within the narrative, a section labeled "Intellectual Merit". The Project Description should provide a clear statement of the work to be undertaken and must include the objectives for the period of the proposed work and expected significance; the relationship of this work to the present state of knowledge in the field, as well as to work in progress by the PI under other support.

The Project Description should outline the general plan of work, including the broad design of activities to be undertaken, and, where appropriate, provide a clear description of experimental methods and procedures. Proposers should address what they want to do, why they want to do it, how they plan to do

[18]If the proposal includes use of vertebrate animals, supplemental information is required. See Chapter II.D.4 for additional information.

[19] If the proposal includes use of human subjects, supplemental information is required. See Chapter II.D.5 for additional information.

it, how they will know if they succeed, and what benefits could accrue if the project is successful. The project activities may be based on previously established and/or innovative methods and approaches, but in either case must be well justified. These issues apply to both the technical aspects of the proposal and the way in which the project may make broader contributions.

The Project Description also must contain, as a separate section within the narrative, a section labeled "Broader Impacts". This section should provide a discussion of the broader impacts of the proposed activities. Broader impacts may be accomplished through the research itself, through the activities that are directly related to specific research projects, or through activities that are supported by, but are complementary to the project. NSF values the advancement of scientific knowledge and activities that contribute to the achievement of societally relevant outcomes. Such outcomes include, but are not limited to: full participation of women, persons with disabilities, and underrepresented minorities in science, technology, engineering, and mathematics (STEM); improved STEM education and educator development at any level; increased public scientific literacy and public engagement with science and technology; improved well-being of individuals in society; development of a diverse, globally competitive STEM workforce; increased partnerships between academia, industry, and others; improved national security; increased economic competitiveness of the US; and enhanced infrastructure for research and education.

Plans for data management and sharing of the products of research, including preservation, documentation, and sharing of data, samples, physical collections, curriculum materials and other related research and education products should be described in the Special Information and Supplementary Documentation section of the proposal (see Chapter II.C.2.j for additional instructions for preparation of this section).

(ii) Page Limitations and Inclusion of Uniform Resource Locators (URLs) within the Project Description

Brevity will assist reviewers and Foundation staff in dealing effectively with proposals. Therefore, the Project Description (including Results from Prior NSF Support, which is limited to five pages) **may not exceed 15 pages.** Visual materials, including charts, graphs, maps, photographs and other pictorial presentations are included in the 15-page limitation. PIs are cautioned that the Project Description must be self-contained and that URLs **must not** be used because: 1) the information could circumvent page limitations; 2) the reviewers are under no obligation to view the sites; and 3) the sites could be altered or deleted between the time of submission and the time of review.

Conformance to the 15-page limit will be strictly enforced and may not be exceeded unless a deviation has been specifically authorized. (Chapter II.A contains information on deviations.)

(iii) Results from Prior NSF Support

The purpose of this section is to assist reviewers in assessing the quality of prior work conducted with prior or current NSF funding. If **any PI or co-PI** identified on the proposal has received prior NSF support including:

- an award with an end date in the past five years; or
- any current funding, including any no cost extensions,

information on the award is required **for each PI and co-PI**, regardless of whether the support was directly related to the proposal or not. In cases where the PI or any co-PI has received more than one award (excluding amendments to existing awards), they need only report on the one award that is most closely related to the proposal. Support means salary support, as well as any other funding awarded by NSF, including research, Graduate Research Fellowship, Major Research Instrumentation, conference, equipment, travel, and center awards, etc.

The following information must be provided:

(a) the NSF award number, amount and period of support;

(b) the title of the project;

(c) a summary of the results of the completed work, including accomplishments, supported by the award. The results must be separately described under two distinct headings: Intellectual Merit and Broader Impacts;

(d) a listing of the publications resulting from the NSF award (a complete bibliographic citation for each publication must be provided either in this section or in the References Cited section of the proposal); if none, state "No publications were produced under this award."

(e) evidence of research products and their availability, including, but not limited to: data, publications, samples, physical collections, software, and models, as described in any Data Management Plan; and

(f) if the proposal is for renewed support, a description of the relation of the completed work to the proposed work.

If the project was recently awarded and therefore no new results exist, describe the major goals and broader impacts of the project. Note that the proposal may contain up to five pages to describe the results. Results may be summarized in fewer than five pages, which would give the balance of the 15 pages for the Project Description.

(iv) Unfunded Collaborations

Any substantial collaboration with individuals not included in the budget should be described in the Facilities, Equipment and Other Resources section of the proposal (see Chapter II.C.2.i) and documented in a letter of collaboration from each collaborator. Such letters should be provided in the supplementary documentation section of the FastLane Proposal Preparation Module and follow the format instructions specified in Chapter II.C.2.j. Collaborative activities that are identified in the budget should follow the instructions in Chapter II.D.3.

(v) Group Proposals

NSF encourages submission of proposals by groups of investigators; often these are submitted to carry out interdisciplinary projects. Unless stipulated in a specific program solicitation, however, such proposals will be subject to the 15-page Project Description limitation established in Section (ii) above. PIs who wish to exceed the established page limitations for the Project Description must request and receive a deviation in advance of proposal submission. (Chapter II.A contains information on deviations.)

(vi) Proposals for Renewed Support

See Chapter V for guidance on preparation of renewal proposals.

e. References Cited

Reference information is required. Each reference must include the names of all authors (in the same sequence in which they appear in the publication), the article and journal title, book title, volume number, page numbers, and year of publication. (See also Chapter II.C.2.d.(iii)(d)) If the proposer has a website address readily available, that information should be included in the citation. It is not NSF's intent, however, to place an undue burden on proposers to search for the URL of every referenced publication. Therefore, inclusion of a website address is optional. A proposal that includes reference citation(s) that do not specify

a URL is not considered to be in violation of NSF proposal preparation guidelines and the proposal will still be reviewed.

Proposers must be especially careful to follow accepted scholarly practices in providing citations for source materials relied upon when preparing any section of the proposal. While there is no established page limitation for the references, this section must include bibliographic citations only and must not be used to provide parenthetical information outside of the 15-page Project Description.

f. Biographical Sketch(es)

(i) Senior Personnel

A biographical sketch (limited to two pages) is required for each individual identified as senior personnel. (See Exhibit II-7 for the definitions of Senior Personnel.) Proposers may elect to use third-party solutions, such as NIH's SciENcv to develop and maintain their biographical sketch. However, proposers are advised that they are still responsible for ensuring that biographical sketches created using third-party solutions are compliant with NSF proposal preparation requirements.

The following information must be provided in the order and format specified below. Inclusion of additional information beyond that specified below may result in the proposal being returned without review.

Do not submit any personal information in the biographical sketch. This includes items such as: home address; home telephone, fax, or cell phone numbers; home e-mail address; driver's license number; marital status; personal hobbies; and the like. Such personal information is not appropriate for the biographical sketch and is not relevant to the merits of the proposal. NSF is not responsible or in any way liable for the release of such material. (See also Chapter III.H).

(a) Professional Preparation

A list of the individual's undergraduate and graduate education and postdoctoral training (including location) as indicated below:

Undergraduate Institution(s)	Location	Major	Degree & Year
Graduate Institution(s)	Location	Major	Degree & Year
Postdoctoral Institution(s)	Location	Area	Inclusive Dates (Years)

(b) Appointments

A list, in reverse chronological order, of all the individual's academic/professional appointments beginning with the current appointment.

(c) Products

A list of: (i) up to five products most closely related to the proposed project; and (ii) up to five other significant products, whether or not related to the proposed project. Acceptable products must be citable and accessible including but not limited to publications, data sets, software, patents, and copyrights. Unacceptable products are unpublished documents not yet submitted for publication, invited lectures, and additional lists of products. Only the list of ten will be used in the review of the proposal.

Each product must include full citation information including (where applicable and practicable) names of all authors, date of publication or release, title, title of enclosing work such as journal or book, volume, issue, pages, website and URL, or other Persistent Identifier.

If only publications are included, the heading "Publications" may be used for this section of the Biographical Sketch.

(d) Synergistic Activities

A list of up to five examples that demonstrate the broader impact of the individual's professional and scholarly activities that focuses on the integration and transfer of knowledge as well as its creation. Examples could include, among others: innovations in teaching and training (e.g., development of curricular materials and pedagogical methods); contributions to the science of learning; development and/or refinement of research tools; computation methodologies and algorithms for problem-solving; development of databases to support research and education; broadening the participation of groups underrepresented in STEM; and service to the scientific and engineering community outside of the individual's immediate organization.

In FastLane, Biographical sketches for all senior project personnel must be uploaded as a single PDF file associated with that individual.

(ii) Other Personnel

For the personnel categories listed below, the proposal also may include information on exceptional qualifications that merit consideration in the evaluation of the proposal. Such information should be clearly identified as "Other Personnel" biographical information and uploaded as a single PDF file in the Other Supplementary Documents section of the proposal.

(a) Postdoctoral associates

(b) Other professionals

(c) Students (research assistants)

(iii) Equipment Proposals

For equipment proposals, the following must be provided for each auxiliary user:

(a) Short biographical sketch; and

(b) List of up to five publications most closely related to the proposed acquisition.

Such information should be clearly identified as "Equipment Proposal" biographical information and uploaded as a single PDF file in the Other Supplementary Documents section of the proposal.

g. Budget and Budget Justification

Each proposal must contain a budget for each year of support requested. The budget justification must be no more than five pages per proposal. The amounts for each budget line item requested must be documented and justified in the budget justification as specified below. For proposals that contain a subaward(s), **each subaward** must include a separate budget justification of no more than five pages. See Chapter II.C.2.g.(vi)(e) for further instructions on proposals that contain subawards.

The proposal may request funds under any of the categories listed so long as the item and amount are considered necessary, reasonable, allocable, and allowable under 2 CFR § 200, Subpart E, NSF policy, and/or the program solicitation. For-profit entities are subject to the cost principles contained in the Federal Acquisition Regulation, Part 31. Amounts and expenses budgeted also must be consistent with the proposing organization's policies and procedures and cost accounting practices used in accumulating and reporting costs.

Proposals for major facilities also should consult NSF's Large Facilities Manual for additional budgetary preparation guidelines.

(i) Salaries and Wages (Lines A and B on the Proposal Budget)

(a) Senior Personnel Salaries & Wages Policy

NSF regards research as one of the normal functions of faculty members at institutions of higher education. Compensation for time normally spent on research within the term of appointment is deemed to be included within the faculty member's regular organizational salary.

As a general policy, NSF limits the salary compensation requested in the proposal budget for senior personnel to no more than two months of their regular salary in any one year. (See Exhibit II-7 for the definitions of Senior Personnel.) It is the organization's responsibility to define and consistently apply the term "year", and to specify this definition in the budget justification. This limit includes salary compensation received **from all NSF-funded grants**. This effort must be documented in accordance with 2 CFR § 200, Subpart E, including 2 CFR § 200.430(i). If anticipated, any compensation for such personnel in excess of two months must be disclosed in the proposal budget, justified in the budget justification, and must be specifically approved by NSF in the award notice budget.[20]

Under normal rebudgeting authority, as described in Chapters VII and X, a grantee can internally approve an increase or decrease in person months devoted to the project after an award is made, even if doing so results in salary support for senior personnel exceeding the two month salary policy. No prior approval from NSF is necessary as long as that change would not cause the objectives or scope of the project to change. NSF prior approval is necessary if the objectives or scope of the project change.

These same general principles apply to other types of non-academic organizations.

(b) Administrative and Clerical Salaries & Wages Policy

In accordance with 2 CFR § 200.413, the salaries of administrative and clerical staff should normally be treated as indirect costs (F&A). Direct charging of these costs may be appropriate only if all the conditions identified below are met:

(i) Administrative or clerical services are integral to a project or activity;

(ii) Individuals involved can be specifically identified with the project or activity;

(iii) Such costs are explicitly included in the approved budget or have the prior written approval of the cognizant NSF Grants Officer; and

(iv) The costs are not also recovered as indirect costs.

Conditions (i) (ii) and (iv) above are particularly relevant for consideration at the budget preparation stage.

(c) Procedures

The names of the PI(s), faculty, and other senior personnel and the estimated number of full-time-equivalent person-months for which NSF funding is requested, and the total amount of salaries requested per year, must be listed. For consistency with the NSF cost sharing policy, if person months will be requested for senior personnel, a corresponding salary amount must be entered on the budget. If no person months and

[20]NSF grantees remain subject to the provisions of OMB M-01-06, "*Clarification of OMB A-21 Treatment of Voluntary Uncommitted Cost Sharing and Tuition Remission Costs*," regarding requirements for committing and tracking "some level" of faculty (or senior researcher) effort as part of the organized research base.

no salary are being requested for senior personnel, they should be removed from Section A of the budget. Their name(s) will remain on the Cover Sheet and the individual(s) role on the project should be described in the Facilities, Equipment and Other Resources section of the proposal.
For postdoctoral associates and other professionals, the total number of persons for each position must be listed, with the number of full-time-equivalent person-months and total amount of salaries requested per year. For graduate and undergraduate students, secretarial, clerical, technical, etc., whose time will be charged directly to the project, only the total number of persons and total amount of salaries requested per year in each category is required. Compensation classified as salary payments must be requested in the salaries and wages category. Salaries requested must be consistent with the organization's regular practices. The budget justification should detail the rates of pay by individual for senior personnel, postdoctoral associates, and other professionals.

(d) Confidential Budgetary Information

The proposing organization may request that salary data on senior personnel not be released to persons outside the Government during the review process. In such cases, the item for senior personnel salaries in the proposal may appear as a single figure and the person-months represented by that amount omitted. If this option is exercised, senior personnel salaries and person-months must be itemized in a separate statement, and forwarded to NSF in accordance with the instructions specified in Chapter II.D.1. This statement must include all of the information requested on the proposal budget for each person involved. NSF will not forward the detailed information to reviewers and will hold it privileged to the extent permitted by law. The information on senior personnel salaries will be used as the basis for determining the salary amounts shown in the budget. The box for "Proprietary or Privileged Information" must be checked on the Cover Sheet when the proposal contains confidential budgetary information.[21]

(ii) Fringe Benefits (Line C on the Proposal Budget)

If the proposer's usual accounting practices provide that its contributions to employee benefits (leave, employee insurance, social security, retirement, other payroll-related taxes, etc.) be treated as direct costs, NSF grant funds may be requested to fund fringe benefits as a direct cost. These are typically determined by application of a calculated fringe benefit rate for a particular class of employee (full time or part-time) applied to the salaries and wages requested. They also may be paid based on actual costs for individual employees, if that institutional policy has been approved by the cognizant Federal agency. See 2 CFR § 200.431 for the definition and allowability of inclusion of fringe benefits on a proposal budget.

(iii) Equipment (Line D on the Proposal Budget)

Equipment is defined as tangible personal property (including information technology systems) having a useful life of more than one year and a per-unit acquisition cost which equals or exceeds the lesser of the capitalization level established by the proposer for financial statement purposes, or $5,000. It is important to note that the acquisition cost of equipment includes modifications, attachments, and accessories necessary to make the property usable for the purpose for which it will be purchased. Items of needed equipment must be adequately justified, listed individually by description and estimated cost.

Allowable items ordinarily will be limited to research equipment and apparatus not already available for the conduct of the work. General purpose equipment such as office equipment and furnishings, and information technology equipment and systems are typically not eligible for direct cost support. Special purpose or scientific use computers or associated hardware and software, however, may be requested as items of equipment when necessary to accomplish the project objectives and not otherwise reasonably available. Any request to support such items must be clearly disclosed in the proposal budget, justified in the budget justification, and be included in the NSF award budget. See 2 CFR § 200.313 for additional information.

[21] Detailed instructions for submission of confidential budgetary information are available in FastLane.

(iv) Travel (Line E on the Proposal Budget)

(a) General

When anticipated, travel and its relation to the proposed activities must be specified, itemized and justified by destination and cost. Funds may be requested for field work, attendance at meetings and conferences, and other travel associated with the proposed work, including subsistence. In order to qualify for support, however, attendance at meetings or conferences must be necessary to accomplish proposal objectives, or disseminate its results. Travel support for dependents of key project personnel may be requested only when the travel is for a duration of six months or more either by inclusion in the approved budget or with the prior written approval of the cognizant NSF Grants Officer. Temporary dependent care costs above and beyond regular dependent care that directly result from travel to conferences are allowable costs provided that the conditions established in 2 CFR § 200.474 are met.

Allowance for air travel normally will not exceed the cost of round-trip, economy airfares. Persons traveling under NSF grants must travel by US-Flag Air carriers, if available.

(b) Domestic Travel

Domestic travel includes travel within and between the US, its territories and possessions.[22] Travel, meal and hotel expenses of grantee employees who are not on travel status are unallowable. Costs of employees on travel status are limited to those specifically authorized by 2 CFR § 200.474.

(c) Foreign Travel

Travel outside the areas specified above is considered foreign travel. When anticipated, the proposer must enter the names of countries and dates of visit on the proposal budget, if known.

(v) Participant Support (Line F on the Proposal Budget)

This budget category refers to direct costs for items such as stipends or subsistence allowances, travel allowances, and registration fees paid to or on behalf of participants or trainees (but not employees) in connection with NSF-sponsored conferences or training projects. Any additional categories of participant support costs other than those described in 2 CFR § 200.75 (such as incentives, gifts, souvenirs, t-shirts and memorabilia), must be justified in the budget justification, and such costs will be closely scrutinized by NSF. (See also Chapter II.E.7) For some educational projects conducted at local school districts, however, the participants being trained are employees. In such cases, the costs must be classified as participant support if payment is made through a stipend or training allowance method. The school district must have an accounting mechanism in place (i.e., sub-account code) to differentiate between regular salary and stipend payments.

To help defray the costs of participating in a conference or training activity, funds may be proposed for payment of stipends, per diem or subsistence allowances, based on the type and duration of the activity. Such allowances must be reasonable, in conformance with the policy of the proposing organization and limited to the days of attendance at the conference plus the actual travel time required to reach the conference location. Where meals or lodgings are furnished without charge or at a nominal cost (e.g., as part of the registration fee), the per diem or subsistence allowance should be correspondingly reduced. Although local participants may participate in conference meals and coffee breaks, funds may not be proposed to pay per diem or similar expenses for local participants in the conference.

[22] According to the IRS, US territories and possessions are as follows: Puerto Rico, US Virgin Islands, Guam, American Samoa, the Commonwealth of the Northern Mariana Islands, Midway Island, Wake Island, Palmyra Island, Howland Island, Johnston Island, Baker Island, Kingman Reef, Jarvis Island, and other US islands, cays, and reefs that are not part of any of the fifty States.

Funds may be requested for the travel costs of participants. If so, the restrictions regarding class of accommodations and use of US-Flag air carriers are applicable.[23] In training activities that involve field trips, costs of transportation of participants are allowable. The number of participants to be supported must be entered in the parentheses on the proposal budget. Participant support costs must be specified, itemized and justified in the budget justification section of the proposal. Indirect costs (F&A) are not allowed on participant support costs. Participant support costs must be accounted for separately should an award be made.

(vi) Other Direct Costs (Lines G1 through G6 on the Proposal Budget)

Any costs proposed to an NSF project must be allowable, reasonable and directly allocable to the supported activity. When anticipated, the budget must identify and itemize other anticipated direct costs not included under the headings above, including materials and supplies, publication costs, computer services and consultant services. Examples include aircraft rental, space rental at research establishments away from the proposing organization, minor building alterations, payments to human subjects, and service charges. Reference books and periodicals only may be included on the proposal budget if they are specifically allocable to the project being supported by NSF.

(a) Materials and Supplies (including Costs of Computing Devices) (Line G1 on the Proposal Budget)

When anticipated, the proposal budget justification must indicate the general types of expendable materials and supplies required. Supplies are defined as all tangible personal property other than those described in paragraph (d)(iii) above. A computing device is considered a supply if the acquisition cost is less than the lesser of the capitalization level established by the proposer or $5,000, regardless of the length of its useful life. In the specific case of computing devices, charging as a direct cost is allowable for devices that are essential and allocable, but not solely dedicated, to the performance of the NSF project. Details and justification must be included for items requested to support the project.

(b) Publication/Documentation/Dissemination (Line G2 on the Proposal Budget)

The proposal budget may request funds for the costs of documenting, preparing, publishing or otherwise making available to others the findings and products of the work conducted under the grant. This generally includes the following types of activities: reports, reprints, page charges or other journal costs (except costs for prior or early publication); necessary illustrations; cleanup, documentation, storage and indexing of data and databases; development, documentation and debugging of software; and storage, preservation, documentation, indexing, etc., of physical specimens, collections or fabricated items.

(c) Consultant Services (also referred to as Professional Service Costs) (Line G3 on the Proposal Budget)

The proposal budget may request costs for professional and consultant services. Professional and consultant services are services rendered by persons who are members of a particular profession or possess a special skill, and who are not officers or employees of the proposing organization. Costs of professional and consultant services are allowable when reasonable in relation to the services rendered and when not contingent upon recovery of costs from the Federal government. Anticipated services must be justified and information furnished on each individual's expertise, primary organizational affiliation, normal daily compensation rate, and number of days of expected service. Consultants' travel costs, including subsistence, may be included. If requested, the proposer must be able to justify that the proposed rate of pay is reasonable. Additional information on the allowability of consultant or professional service costs is available in 2 CFR § 200.459. In addition to other provisions required by the proposing organization,

[23] See Chapter XI.F, Grant General Conditions (GC-1) Article 10, and Article 14 in the NSF Agency Specific Requirements to the Research Terms and Conditions, as applicable, for additional information on travel restrictions.

all contracts made under the NSF award must contain the applicable provisions identified in 2 CFR § 200 Appendix II.

(d) Computer Services (Line G4 on the Proposal Budget)

The cost of computer services, including computer-based retrieval of scientific, technical and educational information, may be requested only where it is institutional policy to charge such costs as direct charges. A justification based on the established computer service rates at the proposing organization must be included. The proposal budget also may request costs for leasing of computer equipment. As noted in Chapter II.C.2.g(iii), general purpose (such as word processing, spreadsheets, communication) computer equipment should not be requested. Note: See paragraph (a) above for guidance on acquisition of computing devices.

(e) Subawards[24] (Line G5 on the Proposal Budget)

Except for the purchase of materials and supplies, equipment or general support services allowable under the grant, no portion of the proposed activity may be subawarded or transferred to another organization without prior written NSF authorization. Such authorization must be provided either through inclusion of the subaward(s) on an NSF award budget or by receiving written prior approval from the cognizant NSF Grants Officer after an award is issued.

If known at the time of proposal submission, the intent to enter into such arrangements must be disclosed in the proposal. A separate budget and a budget justification of no more than five pages, must be provided for each subrecipient, if already identified, along with a description of the work to be performed.

All proposing organizations are required to make a case-by-case determination regarding the role of a subrecipient versus contractor for each agreement it makes. 2 CFR § 200.330 provides characteristics of each type of arrangement to assist proposing organizations in making that determination. However, inclusion of a subaward or contract in the proposal budget or submission of a request after issuance of an NSF award to add a subaward or contract will document the organizational determination required.

It is NSF's expectation that, consistent with 2 CFR § 200.414, NSF grantees will use the domestic subrecipient's applicable US Federally negotiated indirect cost rate(s). If no such rate exists, the NSF grantee may either negotiate a rate or will fund the subrecipient using the *de minimis* indirect cost rate recovery of 10% of modified total direct costs.

It is also NSF's expectation that NSF grantees will use the foreign subrecipient's applicable US Federally negotiated indirect cost rate(s). However, if no such rate exists, the NSF grantee will fund the foreign subrecipient using the *de minimis* indirect cost rate recovery of 10% of modified total direct costs.

(f) Other (Line G6 on the Proposal Budget)

Any other direct costs not specified in Lines G1 through G5 must be identified on Line G6. Such costs must be itemized and detailed in the budget justification.

Incentive payments, for example, payments to human subjects or incentives to promote completion of a survey, should be included on line G6 of the NSF budget. Incentive payments should be proposed in accordance with organizational policies and procedures. Indirect costs should be calculated on incentive payments in accordance with the organization's approved US Federally negotiated indirect cost rate(s). Performance based incentive payments to employees as described in 2 CFR §200.430(f) should not be included in this section of the budget.

[24]A subaward may be provided through any form of legal agreement, including an agreement that the proposing organization considers a contract. The substance of the relationship is more important than the form of the agreement.

(vii) Total Direct Costs (Line H on the Proposal Budget)

The total amount of direct costs requested in the budget, to include Lines A through G, must be entered on Line H.

(viii) Indirect Costs (also known as Facilities and Administrative Costs (F&A) for Colleges and Universities) (Line I on the Proposal Budget)

Except where specifically identified in an NSF program solicitation, the applicable US Federally negotiated indirect cost rate(s) must be used in computing indirect costs (F&A) for a proposal. Use of an indirect cost rate lower than the organization's current negotiated indirect cost rate is considered a violation of NSF's cost sharing policy. See section (xii) below. The amount for indirect costs should be calculated by applying the current negotiated indirect cost rate(s) to the approved base(s), and such amounts should be specified in the budget justification. Indirect cost recovery for IHEs are additionally restricted by 2 CFR § 200, Appendix III, paragraph C.7. which specifies Federal agencies are required to use the negotiated F&A rate that is in effect at the time of the initial award throughout the life of the sponsored agreement. Additional information on the charging of indirect costs to an NSF award is available in Chapter X.D.

Domestic proposing organizations that do not have a current negotiated rate agreement with a cognizant Federal agency, and who are requesting more than a *de minimis* 10% recovery of modified total direct costs should prepare an indirect cost proposal based on expenditures for its most recently ended fiscal year. Based on the information provided in the indirect cost proposal, NSF may negotiate an award-specific rate to be used only on the award currently being considered for funding. No supporting documentation is required for proposed rates of 10% or less of modified total direct costs. The contents and financial data included in indirect cost proposals vary according to the make-up of the proposing organization. Instructions for preparing an indirect cost rate proposal can be found at: http://www.nsf.gov/bfa/dias/caar/docs/idcsubmissions.pdf. NSF formally negotiates indirect cost rates for the organizations for which NSF has rate cognizance. NSF does not negotiate rates for organizations that are not direct recipients of NSF funding (e.g., subrecipients). The prime grantee is responsible for ensuring that proposed subrecipient costs, including indirect costs, are reasonable and appropriate.

Foreign organizations that do not have a current US Federally negotiated indirect cost rate(s) are limited to a *de minimis* indirect cost rate recovery of 10% of modified total direct costs. Foreign grantees that have a US Federally negotiated indirect cost rate(s) may recover indirect costs at the current negotiated rate.

(ix) Total Direct and Indirect Costs (F&A) (Line J on the Proposal Budget)

The total amount of direct and indirect costs (F&A) (sum of Lines H and I) must be entered on Line J.

(x) Fees (Line K on the Proposal Budget)

This line is available for use only by the SBIR/STTR programs.

(xi) Amount of This Request (Line L on the Proposal Budget)

The total amount of funds requested by the proposer.

(xii) Cost Sharing (Line M on the Proposal Budget)

The National Science Board issued a report entitled "*Investing in the Future: NSF Cost Sharing Policies for a Robust Federal Research Enterprise"* (NSB 09-20, August 3, 2009), which contained eight recommendations for NSF regarding cost sharing. In implementation of the Board's recommendation, NSF's guidance[25] is as follows:

[25] See NSF's Revised Cost Sharing Policy Statement for the Foundation's overarching policies on cost sharing.

Voluntary Committed and Uncommitted Cost Sharing

As stipulated in 2 CFR § 200.99, **"***Voluntary committed cost sharing* means cost sharing specifically pledged on a voluntary basis in the proposal's budget or the Federal award on the part of the non-Federal entity and that becomes a binding requirement of Federal award." As such, to be considered voluntary committed cost sharing, the amount must appear on the NSF proposal budget and be specifically identified in the approved NSF budget.[26] Unless required by NSF (see the section on Mandatory Cost Sharing below), inclusion of voluntary committed cost sharing is prohibited and Line M on the proposal budget will not be available for use by the proposer. NSF Program Officers are not authorized to impose or encourage mandatory cost sharing unless such requirements are explicitly included in the program solicitation.

In order for NSF, and its reviewers, to assess the scope of a proposed project, all organizational resources necessary for, and available to, a project must be described in the Facilities, Equipment and Other Resources section of the proposal (see Chapter II.C.2.i for further information). While not required by NSF, the grantee may, at its own discretion, continue to contribute voluntary uncommitted cost sharing to NSF-sponsored projects. **As noted above, however, these resources are not auditable by NSF and should not be included in the proposal budget or budget justification.**

Mandatory Cost Sharing

Mandatory cost sharing will only be required for NSF programs when explicitly authorized by the NSF Director, the NSB, or legislation. A complete listing of NSF programs that require cost sharing is available on the NSF website at: http://www.nsf.gov/bfa/dias/policy/. In these programs, cost sharing requirements will be clearly identified in the solicitation and must be included on Line M of the proposal budget. For purposes of budget preparation, the cumulative cost sharing amount must be entered on Line M of the first year's budget. Should an award be made, the organization's cost sharing commitment, as specified on the first year's approved budget, must be met prior to the award end date.

Such cost sharing will be considered as an eligibility, rather than a review criterion. Proposers are advised not to exceed the mandatory cost sharing level or amount specified in the solicitation.[27]

When mandatory cost sharing is included on Line M, and accepted by the Foundation, the commitment of funds becomes legally binding and is subject to audit. When applicable, the estimated value of any in-kind contributions also should be included on Line M. An explanation of the source, nature, amount and availability of any proposed cost sharing must be provided in the budget justification[28]. It should be noted that contributions derived from other Federal funds or counted as cost sharing toward projects of another Federal agency must not be counted towards meeting the specific cost sharing requirements of the NSF award.

Failure to provide the level of cost sharing required by the NSF solicitation and reflected in the NSF award budget may result in termination of the NSF award, disallowance of award costs and/or refund of award funds to NSF by the grantee.

[26] Inclusion in the Budget Justification also meets this definition.

[27] For further information on procedures for inclusion of programmatic cost sharing in an NSF solicitation, see: http://www.nsf.gov/bfa/dias/policy/csdocs/principles.pdf.

[28] 2 CFR § 200.306 describes criteria and procedures for the allowability of cash and in-kind contributions in satisfying cost sharing and matching requirements.

(xiii) Allowable and Unallowable Costs

2 CFR § 200, Subpart E provides comprehensive information regarding costs allowable under Federal awards. The following categories of unallowable costs are highlighted because of their sensitivity:

(a) Entertainment

Costs of entertainment, amusement, diversion and social activities, and any costs directly associated with such activities (such as tickets to shows or sporting events, meals, lodging, rentals, transportation and gratuities) are unallowable. Travel, meal and hotel expenses of grantee employees who are not on travel status are unallowable. See also 2 CFR § 200.438.

(b) Meals and Coffee Breaks

No funds may be requested for meals or coffee breaks for intramural meetings of an organization or any of its components, including, but not limited to, laboratories, departments and centers. (See 2 CFR § 200.432, for additional information on the charging of certain types of costs generally associated with conferences supported by NSF.) Meal expenses of grantee employees who are not on travel status are unallowable. See also 2 CFR § 200.438.

(c) Alcoholic Beverages

No NSF funds may be requested or spent for alcoholic beverages.

h. Current and Pending Support

This section of the proposal calls for required information on all current and pending support for ongoing projects and proposals, **including this project**, and any subsequent funding in the case of continuing grants. All current project support from whatever source (e.g., Federal, State, local or foreign government agencies, public or private foundations, industrial or other commercial organizations, or internal funds allocated toward specific projects) must be listed. The proposed project and all other projects or activities requiring a portion of time of the PI and any other senior personnel must be included, even if they receive no salary support from the project(s). The total award amount for the entire award period covered (including indirect costs) must be shown as well as the number of person-months per year to be devoted to the project, regardless of source of support. Similar information must be provided for all proposals already submitted or submitted concurrently to other possible sponsors, including NSF. Concurrent submission of a proposal to other organizations will not prejudice its review by NSF. The Biological Sciences Directorate exception to this policy is delineated in Chapter II.D.2.

If the project now being submitted has been funded previously by a source other than NSF, the information requested in the paragraph above must be furnished for the last period of funding.

In FastLane, Current and Pending Support for all senior project personnel must be uploaded as a single PDF file or inserted as text associated with that individual.

i. Facilities, Equipment and Other Resources

This section of the proposal is used to assess the adequacy of the resources available to perform the effort proposed to satisfy both the Intellectual Merit and Broader Impacts review criteria. Proposers should describe only those resources that are directly applicable. Proposers should include an aggregated description of the internal and external resources (both physical and personnel) that the organization and its collaborators will provide to the project, should it be funded. Such information must be provided in this section, in lieu of other parts of the proposal (e.g., Budget Justification, Project Description). The description should be narrative in nature and must not include any quantifiable financial information. Reviewers will

evaluate the information during the merit review process and the cognizant NSF Program Officer will review it for programmatic and technical sufficiency.

Although these resources are not considered voluntary committed cost sharing as defined in 2 CFR § 200.99, the Foundation **does expect** that the resources identified in the Facilities, Equipment and Other Resources section will be provided, or made available, should the proposal be funded. Chapter VII.B.1 specifies procedures for use by the grantee when there are postaward changes to objectives, scope or methods/procedures.

j. Special Information and Supplementary Documentation

Except as specified below, special information and supplementary documentation must be included as part of the Project Description (or part of the budget justification), if it is relevant to determining the quality of the proposed work. Information submitted in the following areas is not considered part of the 15-page Project Description limitation. This Special Information and Supplementary Documentation section also is not considered an appendix. Specific guidance on the need for additional documentation may be obtained from the organization's SPO or in the references cited below.

- Postdoctoral Researcher Mentoring Plan. Each proposal[29] that requests funding to support **postdoctoral researchers**[30] must upload under "Mentoring Plan" in the supplementary documentation section of FastLane, a description of the mentoring activities that will be provided for such individuals. In no more than one page, the mentoring plan must describe the mentoring that will be provided to all postdoctoral researchers supported by the project, regardless of whether they reside at the submitting organization, any subrecipient organization, or at any organization participating in a simultaneously submitted collaborative proposal. Proposers are advised that the mentoring plan must not be used to circumvent the 15-page Project Description limitation. See Chapter II.D.3 for additional information on collaborative proposals. Mentoring activities provided to postdoctoral researchers supported on the project will be evaluated under the Broader Impacts review criterion.

  Examples of mentoring activities include, but are not limited to: career counseling; training in preparation of grant proposals, publications and presentations; guidance on ways to improve teaching and mentoring skills; guidance on how to effectively collaborate with researchers from diverse backgrounds and disciplinary areas; and training in responsible professional practices.

- Plans for data management and sharing of the products of research. Proposals must include a document of no more than two pages uploaded under "Data Management Plan" in the supplementary documentation section of FastLane. This supplementary document should describe how the proposal will conform to NSF policy on the dissemination and sharing of research results (see Chapter XI.D.4), and may include:

  1. the types of data, samples, physical collections, software, curriculum materials, and other materials to be produced in the course of the project;

[29] For purposes of meeting the mentoring requirement, simultaneously submitted collaborative proposals, and collaborative proposals that include subawards, constitute a single unified project. Therefore, only one mentoring plan may be submitted for the entire project.

[30] In situations where a postdoctoral researcher is listed in Section A of the NSF Budget, and is functioning in a Senior Personnel capacity (i.e., responsible for the scientific or technical direction of the project), a mentoring plan is not required.

2. the standards to be used for data and metadata format and content (where existing standards are absent or deemed inadequate, this should be documented along with any proposed solutions or remedies);

3. policies for access and sharing including provisions for appropriate protection of privacy, confidentiality, security, intellectual property, or other rights or requirements;

4. policies and provisions for re-use, re-distribution, and the production of derivatives; and
5. plans for archiving data, samples, and other research products, and for preservation of access to them.

Data management requirements and plans specific to the Directorate, Office, Division, Program, or other NSF unit, relevant to a proposal are available at: http://www.nsf.gov/bfa/dias/policy/dmp.jsp. If guidance specific to the program is not available, then the requirements established in this section apply.

Simultaneously submitted collaborative proposals and proposals that include subawards are a single unified project and should include only one supplemental combined Data Management Plan, regardless of the number of non-lead collaborative proposals or subawards included. In such collaborative proposals, the data management plan should discuss the relevant data issues in the context of the collaboration.

A valid Data Management Plan may include only the statement that no detailed plan is needed, as long as the statement is accompanied by a clear justification. Proposers who feel that the plan cannot fit within the limit of two pages may use part of the 15-page Project Description for additional data management information. Proposers are advised that the Data Management Plan must not be used to circumvent the 15-page Project Description limitation. The Data Management Plan will be reviewed as an integral part of the proposal, considered under Intellectual Merit or Broader Impacts or both, as appropriate for the scientific community of relevance.

- Rationale for performance of all or part of the project off-campus or away from organizational headquarters.

- Documentation of collaborative arrangements of significance to the proposal through letters of collaboration. (See Chapter II.C.2.d.(iv).) Letters of collaboration should be limited to stating the intent to collaborate and should not contain endorsements or evaluation of the proposed project. The recommended format for letters of collaboration is as follows:

  "If the proposal submitted by Dr. [insert the full name of the Principal Investigator] entitled [insert the proposal title] is selected for funding by NSF, it is my intent to collaborate and/or commit resources as detailed in the Project Description or the Facilities, Equipment and Other Resources section of the proposal."

  While letters of collaboration are permitted, unless required by a specific program solicitation, letters of support should not be submitted as they are not a standard component of an NSF proposal. A letter of support is typically from a key stakeholder such as an organization, collaborator or Congressional Representative, and is used to convey a sense of enthusiasm for the project and/or to highlight the qualifications of the PI or co-PI. A letter of support submitted in response to a program solicitation requirement must be unique to the specific proposal submitted and cannot be altered without the author's explicit prior approval. Proposals that contain letters of support not authorized by the program solicitation may be returned without review.

- In order for NSF to comply with Federal environmental statutes (including, but not limited to, the National Environmental Policy Act (42 USC. §§ 4321, et seq.), the National Historic Preservation Act (54 USC § 306108 [previously codified at 16 USC § § 470, et seq.], and the Endangered

Species Act (16 USC. §§ 1531, et seq.), the proposer may be requested to submit supplemental post-proposal submission information to NSF in order that a reasonable and accurate assessment of environmental impacts by NSF may be made. The types of information that may be requested is shown in the Organization Environmental Impacts Checklist.

- International Activities

  1. International Research/Education/Training Activities. For each proposal that describes an international activity, PIs should list the primary countries involved on the Cover Sheet. An international activity is defined as research, training, and/or education carried out in cooperation with foreign counterparts either overseas or in the US using virtual technologies.

  2. International Conferences. Proposers also should enter on the Cover Sheet the country/countries with which project participants will engage and/or travel to attend international conferences. If the specific location of the international conference is not known at the time of the proposal submission, proposers should enter "Worldwide" on the Cover Sheet.

  3. Work in foreign countries. Some governments require nonresidents to obtain official approval to carry out investigations within their borders and coastal waters under their jurisdiction. PIs are responsible for obtaining the required authorizations. Advance coordination should minimize disruption of the research. (See Chapter XI.B.4.)

- Antarctic proposals to *any* NSF program require "Logistical Requirements and Field Plan" supplementary documents to be submitted with the proposal. See "proposal with fieldwork" in Chapter V.A of the Antarctic Research solicitation. Special budgetary considerations also apply. See also Chapter V.B of the Antarctic Research solicitation.

- Research in a location designated, or eligible to be designated, a registered historic place. (See Chapter XI.J). Where applicable, the box for "Historic Places" must be checked on the Cover Sheet.

- Research involving field experiments with genetically engineered organisms. (See Chapter XI.B.2)

- Documentation regarding research involving the use of human subjects, hazardous materials, vertebrate animals, or endangered species. (See Chapter XI.B, Chapter II.D.4 and II.D.5).

- Special components in new proposals or in requests for supplemental funding, such *as Facilitation Awards for Scientists and Engineers with Disabilities (FASED), Research Opportunity Awards (ROAs), Research Experiences for Undergraduates (REUs), and Facilitating Research at Primarily Undergraduate Institutions (RUIs).* See Chapter II.E.6 for information on FASED, and, for the other programs identified, consult the relevant solicitation).

In addition, the supplementary documentation section should alert NSF officials to unusual circumstances that require special handling, including, for example, proprietary or other privileged information in the proposal, matters affecting individual privacy, required intergovernmental review under E.O. 12372 (Intergovernmental Review of Federal Programs) for activities that directly affect State or local governments, or possible national security implications.

k. Appendices

All information necessary for the review of a proposal must be contained in Sections a through i of the proposal. **Appendices may not be included unless a deviation has been authorized.** Chapter II.A contains further information.

D. Special Processing Instructions

1. Proprietary or Privileged Information

Patentable ideas, trade secrets, privileged or confidential commercial or financial information, disclosure of which may harm the proposer, should be included in proposals only when such information is necessary to convey an understanding of the proposed project. Such information must be clearly marked in the proposal and be appropriately labeled with a legend such as,

> "The following is (proprietary or confidential) information that (name of proposing organization) requests not be released to persons outside the Government, except for purposes of review and evaluation."

Such information also may be included as a separate statement. If this method is used, the statement must be submitted as a single-copy document in the Proposal Preparation Module in FastLane. (See also Chapter II.C.1 for further information regarding submission of single-copy documents.)[31]

The box for "Proprietary or Privileged Information" must be checked on the Cover Sheet when the proposal contains such information. While NSF will make every effort to prevent unauthorized access to such material, the Foundation is not responsible or in any way liable for the release of such material.

2. Beginning Investigators (applies to proposals submitted to the Biological Sciences Directorate only)

Research proposals to the Biological Sciences Directorate ONLY (not proposals for conferences) cannot be duplicates of proposals to any other Federal agency for simultaneous consideration. The only exceptions to this rule are: (1) when the Program Officers at the relevant Federal agencies have previously agreed to joint review and possible joint funding of the proposal; or (2) proposals for PIs who are beginning investigators (individuals who have not been a PI or co-PI on a Federally funded award with the exception of doctoral dissertation, postdoctoral fellowship or research planning grants). For proposers who qualify under this latter exception, the box for "Beginning Investigator" must be checked on the Cover Sheet.

3. Collaborative Proposals

A collaborative proposal is one in which investigators from two or more organizations wish to collaborate on a unified research project. Collaborative proposals may be submitted to NSF in one of two methods: as a single proposal, in which a single award is being requested (with subawards administered by the lead organization); or by simultaneous submission of proposals from different organizations, with each organization requesting a separate award. In either case, the lead organization's proposal must contain all of the requisite sections as a single package to be provided to reviewers (that will happen automatically when procedures below are followed). All collaborative proposals must clearly describe the roles to be played by the other organizations, specify the managerial arrangements, and explain the advantages of the multi-organizational effort within the Project Description.

a. Submission of a collaborative proposal from one organization

The single proposal method allows investigators from two or more organizations who have developed an integrated research project to submit a single, focused proposal. A single investigator bears primary responsibility for the administration of the grant and discussions with NSF, and, at the discretion of the organizations involved, investigators from any of the participating organizations may be designated as co-PIs. Note, however, that if awarded, a single award would be made to the submitting organization, with

[31]Detailed instructions for submission of proprietary or privileged information are available in FastLane at: http://www.fastlane.nsf.gov/help/proprietary.htm.

any collaborators listed as subawards. (See Chapter II.C.2.g(vi)(e) for additional instructions on preparation of this type of proposal.)

If a proposed subaward includes funding to support postdoctoral researchers, the mentoring activities to be provided for such individuals must be incorporated in the supplemental mentoring plan outlined in Chapter II.C.2.j.

b. Submission of a collaborative proposal from multiple organizations

Simultaneous submission of proposals allows multiple organizations to submit a unified set of certain proposal sections, as well as information unique to each organization as specified below. All collaborative proposals arranged as separate submissions from multiple organizations must be submitted via FastLane. For these proposals, the project title must begin with the words "Collaborative Research:" If funded, each organization bears responsibility for a separate award.

Required sections of the proposal differ based on the organization's role. The following sections are required for a collaborative proposal submitted by:

Lead Organization

- Cover Sheet
- Project Summary
- Table of Contents (automatically generated)
- Project Description
- References Cited
- Biographical Sketch(es)
- Budget and Budget Justification
- Current and Pending Support
- Facilities, Equipment and Other Resources
- Data Management Plan
- Postdoctoral Mentoring Plan (if applicable)
- Collaborators & Other Affiliations Information

Non-Lead Organization

- Cover Sheet
- Table of Contents (automatically generated)
- Biographical Sketch(es)
- Budget and Budget Justification
- Current and Pending Support
- Facilities, Equipment and Other Resources
- Collaborators & Other Affiliations Information

See Chapter II.C.2.j for additional guidance on the mentoring and data management plan requirements for collaborative proposals. NSF will combine the proposal submission for printing or electronic viewing.

To submit the collaborative proposal, the following process must be completed:[32]

(i) Each non-lead organization must assign their proposal a proposal PIN. This proposal PIN and the temporary proposal ID generated by FastLane when the non-lead proposal is created must be provided to the lead organization before the lead organization submits its proposal to NSF.

[32]Detailed technical instructions for the preparation and submission of collaborative proposals are available in FastLane.

(ii) The lead organization must then enter each non-lead organization(s) proposal PIN and temporary proposal ID into the FastLane lead proposal by using the "Link Collaborative Proposals" option found on the FastLane "Form Preparation" screen.

(iii) **All components** of the collaborative proposal must meet any established deadline date, and failure to do so may result in the entire collaborative proposal being returned without review.

(iv) If funded, both lead and non-lead organizations are required to submit separate annual and final project reports. These reports should reference the work of the collaborative, while focusing on the distinct work conducted at each funded organization.

4. Proposals Involving Vertebrate Animals

a. Any project proposing use of vertebrate animals for research or education shall comply with the Animal Welfare Act (7 USC 2131, *et seq*.) and the regulations promulgated thereunder by the Secretary of Agriculture (9 CFR 1.1-4.11) pertaining to the humane care, handling, and treatment of vertebrate animals held or used for research, teaching, or other activities supported by Federal awards. In accordance with these requirements, proposed projects involving use of any vertebrate animal for research or education must be approved by the submitting organization's Institutional Animal Care and Use Committee (IACUC) before an award can be made. For this approval to be accepted by NSF, the organization must have a current Public Health Service (PHS) Approved Assurance. See also Chapter XI.B.3 for additional information on the administration of awards that utilize vertebrate animals. Note that for some types of vertebrate animals, additional review may be required.

Any project proposing use of vertebrate animals for research or education must comply with the provision in the PHS Assurance for Institutional Commitment (Section II) that requires the submitting organization to establish and maintain a program for activities involving animals in accordance with the *Guide for the Care and Use of Laboratory Animals* (Guide). Taxon-specific guidelines may be used as supplemental references.[33] Departures from the Guide must be approved by the IACUC and based on scientific, veterinary, medical, or animal welfare issues (for more information, see Office of Laboratory Animal Welfare (OLAW) Departures from the Guide).

b. Sufficient information must be provided within the 15-page Project Description to enable reviewers to evaluate the:

(i) rationale for involving animals;

(ii) choice of species and number of animals to be used;

(iii) description of the proposed use of the animals;

(iv) exposure of animals to discomfort, pain, or injury; and

(v) description of any euthanasia methods to be used.

c. Research facilities subject to the Animal Welfare Act using or intending to use live animals in research and who receive Federal funding are required to register the facility with the Animal and Plant Health Inspection Service (APHIS), US Department of Agriculture. A current listing of licensed animal dealers also may be obtained from APHIS. The location of the nearest APHIS Regional Office, as well as information concerning this and other APHIS activities, may be obtained at: http://www.aphis.usda.gov/.

[33] Guidelines to the Use of Wild Birds in Research; Guidelines of the American Society of Mammalogists for the Use of Wild Mammals in Research; Guidelines for the Use of Fishes in Research; and Guidelines for the Use of Live Amphibians and Reptiles in Field and Laboratory Research.

d. Projects involving the care or use of vertebrate animals at an international organization or international field site also require approval of research protocols by the US grantee's IACUC. If the project is to be funded through an award to an international organization or through an individual fellowship award that will support activities at an international organization, NSF will require a statement from the international organization explicitly listing the proposer's name and referencing the title of the award to confirm that the activities will be conducted in accordance with all applicable laws in the international country and that the *International Guiding Principles for Biomedical Research Involving Animals* (see: http://www.cioms.ch/) will be followed.

e. The following information regarding the organization's intention to utilize vertebrate animals as part of the project should be provided on the Cover Sheet:
(i) The box for "Vertebrate Animals" must be checked on the Cover Sheet if care and use of vertebrate animals is envisioned.

(ii) The date of IACUC approval of the animal-use protocol covering the proposed work, if such approval has been granted prior to proposal submission, must be identified in the space provided. If IACUC approval has not been obtained prior to submission, the proposer should indicate "Pending" in the space provided for the approval date. If a decision is made to fund the proposal, the organization must provide a copy of the approval letter from the IACUC. The approval letter must affirm that an animal-use protocol covering the proposed activities has been approved, and should explicitly list the organization's PHS Assurance Number, the proposer's name, the title and number of the NSF proposal, and the date of IACUC approval, as well as show an organizational signature. The approval letter must be provided to the cognizant NSF Program Officer before an award can be issued.

(iii) The PHS Approved Animal Welfare Assurance Number must be entered in the space provided.

f. For fellowship proposals submitted by individuals that involve the care and use of vertebrate animals, the proposal should contain the information specified in paragraph b. above. In addition, a copy of the approval letter from the IACUC of the organization that provides oversight of the proposed work should be included as an Other Supplementary Document in FastLane. The approval letter must affirm that an animal-use protocol covering the proposed activities has been approved, and should explicitly list the organization's PHS Assurance Number, the proposer's name, the title and number of the NSF proposal, and the date of IACUC approval, as well as show an organizational signature. If IACUC approval has not been obtained prior to submission, the individual should indicate "Pending" in the space provided for the approval date. If a decision is made to fund the proposal, the individual must provide a signed copy of the official IACUC approval letter (which includes the items specified above) to the cognizant NSF Program Officer before an award can be issued.

See also Chapter XI.B.3 for additional information on the administration of awards that include use of vertebrate animals.

5. Proposals Involving Human Subjects

a. Projects involving research with human subjects must ensure that subjects are protected from research risks in conformance with the relevant Federal policy known as the Common Rule (Federal Policy for the Protection of Human Subjects, 45 CFR § 690). All projects involving human subjects must either (1) have approval from an Institutional Review Board (IRB) before issuance of an NSF award; or, (2) must affirm that the IRB has declared the research exempt from IRB review, in accordance with the applicable subsection, as established in 45 CFR § 690.104(d) of the Common Rule. If certification of exemption is provided after submission of the proposal and before the award is issued, the exemption number corresponding to one or more of the exemption categories also must be included in the documentation provided to NSF.

NSF cannot accept any IRB document that requires continued monitoring of the award activities involving human subjects by NSF. For projects lacking definite plans for the use of human subjects, their data or their specimens, pursuant to 45 CFR § 690.118, NSF can accept a determination notice[34] that establishes a limited time period under which the PI may conduct preliminary or conceptual work that does not involve human subjects. Further instructions are provided in paragraph (iv) below.

If the project involves human subjects and is to be performed outside of the US, evidence of IRB approval also is required. If there is no IRB approval provided, nor is a Federal Wide Assurance (FWA) on file with the Department of Health and Human Services, Office for Human Research Protections (OHRP) (http://ohrp.cit.nih.gov/search/search.aspx?styp=bsc), NSF may decline to support the project. Pursuant to 45 CFR §690.101(g), the Common Rule is not intended to supersede any additional protections that may be afforded to human subjects under foreign laws or regulations. OHRP keeps a list of foreign laws, regulations, and guidelines governing human subjects research.

b. The following information regarding the organization's intention to use human subjects as part of the project should be provided on the Cover Sheet:

(i) The box for "Human Subjects" must be checked on the Cover Sheet if use of human subjects is envisioned.

(ii) If human subject activities are exempt from IRB review, provide the exemption number(s) corresponding to one or more of the exemption categories. The six categories of research that qualify for exemption from coverage by the regulations are defined in the *Common Rule for Protection of Human Subjects.*

(iii) If the research is not designated as exempt, the IRB approval date should be identified in the space provided. This date, at minimum, should cover the period at which the project is initiated. If IRB approval has not been obtained prior to submission, the proposer should indicate "Pending" in the space provided for the approval date. If a decision is made to fund the proposal, the organization must provide a signed copy of the IRB approval letter to the cognizant program prior to award. The letter should indicate approval of the proposed activities and must be submitted prior to an award being issued.

(iv) If the project lacks definite plans regarding use of human subjects, their data or their specimens, pursuant to 45 CFR §690.118, the proposer must check the box for "Human Subjects" on the Cover Sheet and enter "Pending" in the space provided for the approval date. If available at the time of proposal submission, the determination notice should be uploaded as an Other Supplementary Document in FastLane. If the determination notice is not available, and, the decision is made to fund the proposal, the organization must provide a signed copy of the determination notice to the cognizant program prior to award.

Prior to the expiration date specified in the determination notice, the AOR is required to provide to the cognizant NSF Program Officer:

1. verification that the project continues to lack definite plans for the involvement of human subjects, their data, or their specimens; or

2. documentation that demonstrates that IRB approval has been obtained.

The determination notice must indicate that no work with human subjects, including recruitment, will be conducted until full IRB approval is obtained. NSF will add conditions to the grant that prevent any research involving human subjects from being carried out, or otherwise restrict the drawing down of funds, until IRB approval has been obtained.

[34] An NSF-approved format for submission of these determination notices is available on the NSF website.

(v) The FWA Number that the proposer has on file with OHRP should be entered, if available.

See also Chapter XI.B.1 for additional information on the administration of awards that include use of human subjects.

6. Life Sciences Dual Use Research of Concern (DURC)

a. Applicability

This section applies to all research, for which NSF grant funds may be used, that potentially falls within the scope of the *US Government Policy for Institutional Oversight of Life Sciences Dual Use Research of Concern* (http://www.phe.gov/s3/dualuse/Pages/default.aspx) as published in September, 2014, hereafter referred to as the "Policy".

b. NSF Implementation of the Policy

NSF is committed to preserving the benefits of life sciences research while minimizing the risk of misuse of the knowledge, information, products, or technologies provided by such research. The purpose of NSF's implementation of the Policy is to clarify proposer expectations about NSF-funded research with certain high-consequence pathogens and toxins with potential to be considered DURC.

Proposing organizations are responsible for identifying NSF-funded life sciences proposals that could potentially be considered DURC as defined in the Policy and for compliance with the requirements established in that Policy therein. NSF will not fund research that would be considered to lead to a gain of function of agents associated with the US Government Policy on DURC (See also Chapter XI.B.5 for additional information.)

7. Projects Requiring High-Performance Computing Resources, Large Amounts of Data Storage, or Advanced Visualization Resources

Many research projects require access to computational, data storage or visualization resources in order to complete the work proposed. Typically such resources will be noted in the proposal under Facilities, Equipment and Other Resources. For those projects that require such resources at a scale that is beyond that available locally, NSF supports a number of national resources. For the most computationally massive projects, the Blue Waters system at University of Illinois, Urbana/Champaign, is the most suitable. Blue Waters is designed to support a small number (~50) of research teams involved with projects requiring the most advanced computational and data resources. The allocation review process is through proposal submission to the cognizant Program Officer in the Office of Advanced CyberInfrastructure within the Directorate for Computer & Information Science & Engineering. Proposals are reviewed for both their scientific and computational needs. The Blue Waters supercomputer provides sustained performance of 1 petaflop on a range of real-world science and engineering applications. It is one of the most powerful supercomputers in the world. Those interested should visit the Blue Waters portal (https://bluewaters.ncsa.illinois.edu/) for more details of the system's hardware and capabilities.

The National Center for Atmospheric Research (NCAR)-Wyoming Supercomputing Center (NWSC) is a significant resource, with current capabilities of 1.5 petaflops peak speed. The NWSC is designed to meet the needs of the atmospheric and related-sciences communities. NWSC operates its own allocations process and those interested in obtaining time and/or storage should consult the cognizant Program Officer in the Division of Atmospheric and Geospace Sciences within the Geosciences Directorate.

The most general set of large computational and data resources funded by NSF are accessible through the XSEDE project. XSEDE provides the integrating fabric for a collection of very powerful supercomputers, a high-throughput computing environment, high-volume data storage facilities, advanced visualization services, connected by a high-bandwidth private network, a training education and outreach program in how to use its services, and an extended collaborative support program to assist researchers in using the

advanced computational resources. The physical resources themselves are provided by Service Providers (SP) via separate awards from NSF. Allocations of those resources for large projects are determined by the XSEDE Resource Allocation Committee, which meets quarterly, using an external set of experts. Smaller requests do not require a proposal or review and a simple on-line process may be used to request such an allocation. NSF encourages prospective users to seek more information at: https://www.xsede.org/allocations.

E. Types of Proposals

In addition to standard research proposals that follow the proposal preparation instructions contained in sections A through C of this chapter, there are other types of proposals that may be submitted to NSF. Each of them is described below, along with instructions that may supplement or deviate from NSF's standard proposal preparation instructions.

1. Rapid Response Research (RAPID) Proposal

RAPID is a type of proposal used when there is a severe urgency with regard to availability of, or access to, data, facilities or specialized equipment, including quick-response research on natural or anthropogenic disasters and similar unanticipated events. PI(s) must contact the NSF Program Officer(s) whose expertise is most germane to the proposal topic before submitting a RAPID proposal. This will facilitate determining whether the proposed work is appropriate for RAPID funding.

- The Project Description is expected to be brief and must be no more than five pages. It must include clear statements as to why the proposed research is of an urgent nature and why RAPID is the most appropriate type of proposal for supporting the proposed work. Note this proposal preparation instruction deviates from the standard proposal preparation instructions contained in this Guide; RAPID proposals must otherwise be compliant with the proposal preparation requirements specified in Part I of the PAPPG.

- The "RAPID" proposal type must be selected in the proposal preparation module in FastLane.

- Only internal merit review is required for RAPID proposals. Under rare circumstances, Program Officers may elect to obtain external reviews to inform their decision. If external review is to be obtained, then the PI will be informed in the interest of maintaining the transparency of the review and recommendation process. The two standard NSB-approved merit review criteria will apply.

- Requests may be for up to $200K and up to one year in duration. The award size, however, will be consistent with the project scope and of a size comparable to grants in similar areas.

- No-cost extensions and requests for supplemental funding will be processed in accordance with standard NSF policies and procedures.

- Renewed funding of RAPID awards may be requested only through submission of a proposal that will be subject to full external merit review. Such proposals would be designated as "RAPID renewals."

2. EArly-concept Grants for Exploratory Research (EAGER) Proposal

EAGER is a type of proposal used to support exploratory work in its early stages on untested, but potentially transformative, research ideas or approaches. This work may be considered especially "high risk-high payoff" in the sense that it, for example, involves radically different approaches, applies new expertise, or engages novel disciplinary or interdisciplinary perspectives. These exploratory proposals also may be submitted directly to an NSF program, but the EAGER proposal type should not be used for projects that are appropriate for submission as "regular" (i.e., non-EAGER) NSF proposals. PI(s) must contact the NSF Program Officer(s) whose expertise is most germane to the proposal topic prior to submission of an EAGER

proposal. This will aid in determining the appropriateness of the work for consideration under the EAGER proposal type; this suitability must be assessed early in the process.

- The Project Description is expected to be brief and must be no more than eight pages. It must include clear statements as to why this project is appropriate for EAGER funding, including why it does not fit into existing programs and why it is a good fit for EAGER. Note this proposal preparation instruction deviates from the standard proposal preparation instructions contained in this Guide; EAGER proposals must otherwise be compliant with the proposal preparation requirements specified in Part I of the PAPPG.

- The "EAGER" proposal type must be selected in the proposal preparation module in FastLane.
- Only internal merit review is required for EAGER proposals. Under rare circumstances, Program Officers may elect to obtain external reviews to inform their decision. If external review is to be obtained, then the PI will be informed in the interest of maintaining the transparency of the review and recommendation process. The two standard NSB-approved merit review criteria will apply.

- Requests may be for up to $300K and up to two years in duration. The award size, however, will be consistent with the project scope and of a size comparable to grants in similar areas.

- No-cost extensions and requests for supplemental funding will be processed in accordance with standard NSF policies and procedures.

- Renewed funding of EAGER awards may be requested only through submission of a proposal that will be subject to full external merit review. Such proposals would be designated as "EAGER renewals."

3. Research Advanced by Interdisciplinary Science and Engineering (RAISE) Proposal

RAISE is a type of proposal that may be used to support bold, interdisciplinary projects whose:

- Scientific advances lie in great part outside the scope of a single program or discipline, such that substantial funding support from more than one program or discipline is necessary.

- Lines of research promise transformational advances.

- Prospective discoveries reside at the interfaces of disciplinary boundaries that may not be recognized through traditional review or co-review.

To receive funding as a RAISE-appropriate project, all three criteria must be met. RAISE is not intended to be used for projects that can be accommodated within other types of proposals or that continue well established practices. Prospective PIs must receive approval to submit a proposal from at least two NSF Program Officers, in intellectually distinct programs, whose expertise is most germane to the proposal topics.

Contingent on Program Officers' approval to submit a proposal:

- RAISE proposals must be compliant with Part I of the PAPPG unless a deviation from the standard proposal preparation instructions is indicated below.

- NSF will not accept collaborative RAISE proposals for a single project submitted separately from multiple organizations. A multi-organization RAISE project must be submitted as a single proposal requesting a single award with subawards administered by the lead organization.

- The RAISE proposal type must be selected in the proposal preparation module in FastLane.

- The project title will be preceded by the prefix "RAISE:"

- Email documentation from at least two NSF Program Officers confirming approval to submit a proposal must be uploaded under "RAISE – Program Officer Concurrence Emails" in the Supplementary Documentation section of FastLane.

- Requests may be for up to $1,000,000 and up to five years in duration. The award size and duration will be consistent with the project scope.

- The proposal must explicitly address how the project is better suited for RAISE than for a regular NSF review process.

- Only internal merit review is required for RAISE proposals. Program Officers may elect to obtain external reviews to inform their decision. If external review is to be obtained, then the PI will be informed in the interest of maintaining the transparency of the review and recommendation process.

- The two standard NSB-approved merit review criteria will apply. The interdisciplinary and transformative potential of the project will be evaluated within the intellectual merit of the proposal.

- On the basis of the review criteria, the cognizant Program Officers will decide whether to recommend a RAISE proposal for co-funding from their programs.

- No-cost extensions and requests for supplemental funding will be processed in accordance with standard NSF policies and procedures.

- There are no renewals for RAISE awards.

4. Grant Opportunities for Academic Liaison with Industry (GOALI) Proposal

GOALI is a type of proposal that seeks to stimulate collaboration between academic research institutions and industry. Under this proposal type, academic scientists and engineers request funding either in conjunction with a regular proposal submitted to a standing NSF program or as a supplemental funding request to an existing NSF-funded award. GOALI is not a separate program; GOALI proposals must be submitted to an active NSF funding opportunity and must be submitted in accordance with the deadlines specified therein. A proposer interested in submitting a GOALI proposal or a GOALI supplemental funding request to an existing NSF-funded award must contact the cognizant NSF Program Officer listed in the relevant funding opportunity prior to submission. Special interest is focused on affording opportunities for:

- Interdisciplinary university-industry teams to conduct collaborative research projects, in which the industry research participant provides critical research expertise, without which the likelihood for success of the project would be diminished;

- Faculty, postdoctoral fellows, and students to conduct research and gain experience in an industrial setting; and

- Industrial scientists and engineers to bring industry's perspective and integrative skills to academe.

GOALI proposals should focus on research that addresses shared interests by academic researchers and industrial partners. The research should further scientific and engineering foundations to enable future breakthrough technologies with the potential to address critical industry needs. Industry involvement assures that the research is industrially relevant. Principal Investigators are expected to integrate their research objectives with educational and industrial needs.

Interdisciplinary research and education projects that enable faculty from different academic departments or institutions to interact with one or more industrial partners in industry-university groups or networks are encouraged. Proposals may include the participation of a "third partner" such as a National Laboratory or a non-profit organization. NSF funding can be used for university research/education activities and may support activities of faculty and their students and research associates in the industrial setting. NSF funds are not permitted to be used to support the industrial research partner.

GOALI proposals and supplemental funding requests are reviewed by the program to which the proposal is submitted. In addition to any program-specific review criteria defined in the solicitation, reviewers may be asked to evaluate the degree and extent to which industry will be involved with the proposed research and the extent to which students and/or post-doctoral researchers will benefit from the interaction. The proposed research should be transformative, beneficial to industry, and further collaboration between the academic and industrial partners.

Specific instructions for each type of request are provided below.

a. Requests as part of a competitive proposal submission

(i) GOALI proposals must follow the deadlines applicable to an existing funding opportunity as well as the following GOALI-specific requirements: The title of a GOALI proposal should start with "GOALI:" (after any other title requirements specified by the funding opportunity to which the proposal is being submitted);

(ii) At least one industrial co-PI must be listed on the Cover Sheet at the time of submission although the industrial participant cannot use or receive any NSF funds;

(iii) The university-industry interaction should be described in the Project Description;

(iv) A GOALI-Industrial PI Confirmation Letter from the industrial partner that confirms the participation of a co-PI from industry **must be submitted with the proposal** (if applicable, the letter also must state the degree of industrial participation as well as detail any support that the industry is providing to the academic partner). All GOALI-related confirmation must be uploaded under “GOALI-Industrial PI Confirmation Letter” in the supplementary documentation section of FastLane. This supplementary documentation will not be counted towards the 15-page Project Description limitation; and

(v) Academic and industry partners should agree in advance as to how intellectual property (IP) rights will be handled. A signed university-industry agreement on IP (including publication and patent rights) must be submitted prior to issuance of an award. NSF will review this agreement to ensure that the graduation of students will not be unduly affected. NSF is responsible neither for the agreement reached nor the IP information exchanged between the academic institution and the industrial partner.

b. Supplemental funding requests to existing NSF awards

Supplemental funding requests to add GOALI elements to a currently funded NSF research project should be submitted by using the “Supplemental Funding Request” function in FastLane. Such requests should include a brief description of the proposed activity, a budget and a budget justification, in addition to items (iii)-(v) above. At least one industrial participant must be included in the GOALI activity and must be specified in the GOALI-Industrial PI Confirmation Letter. The industrial participant cannot use or receive any NSF funds.

5. Ideas Lab Proposal

"Ideas Lab" is a type of proposal to support the development and implementation of creative and innovative project ideas that have the potential to transform research paradigms and/or solve intractable problems. An Ideas Lab may be run independently, or in parallel, with the issuance of an NSF funding opportunity on the same topic. These project ideas typically will be high-risk/high-impact, as they represent new and

unproven ideas, approaches and/or technologies. This mechanism was developed collaboratively within NSF, modeled on the "sandpit" workshops that are a key component of the United Kingdom Research Council's "IDEAs Factory" program.

The Ideas Lab type of proposal is implemented using the four-stage process described below:

a. Stage 1: Selection of Panelists

There are two separate panels convened for an Ideas Lab: a selection panel and an Ideas Lab panel. The role of the selection panel is to provide advice on the selection of participants. The role of the Ideas Lab panel is to provide an assessment of the project ideas developed during the Ideas Lab. The individuals selected to participate in each of these panels are subject matter experts for the specific topic of the Ideas Lab. All panelists are barred from receiving any research funding through, or in any other way collaborating on, the particular Ideas Lab in which they are involved.

b. Stage 2: Selection of Participants

A "call for participants" solicitation that describes the specific focus of the Ideas Lab will be issued. The solicitation will specify the content and submission instructions for such applications.

The Project Description is limited to two pages and should include information regarding the applicant's specific expertise and interest in the topic area, as well as certain personal attributes that enhance the success of the Ideas Lab workshop (e.g., experience and interest in working in teams, communication skills, level of creativity, willingness to take risks). Applicants also must include a Biographical Sketch and Current and Pending Support information (both of which must be prepared in accordance with standard NSF formatting guidelines). All other elements of a "full proposal" are waived (i.e., Project Summary, References Cited, Budget and Budget Justification, Facilities, Equipment and Other Resources). The application must be submitted as a preliminary proposal in FastLane. No appendices or supplementary documents may be submitted.

Applicants are notified electronically of NSF's decision regarding whether they are invited or not invited to participate in the Ideas Lab. Applicants will be informed about the context of the review and the criteria that were used to assess the applications in the form of a panel summary, but will not receive individual reviews or other review-related feedback.

c. Stage 3: Ideas Lab

The agenda and duration[35] of the Ideas Lab are communicated to meeting participants by the cognizant NSF Program Officer. Typically, Anonymous real-time peer review involving the participants and the Ideas Lab panel is incorporated into the workshop format, providing iterative constructive feedback during the development of project ideas. The Ideas Lab concept incorporates a "guided creativity" process, thus the use of a facilitator(s) is included, both to guide the creation of interdisciplinary teams and the creative development of ideas, and to ensure that the workshop progresses in a productive manner. At the end of the Ideas Lab, the Ideas Lab panel will provide a consensus report summarizing their evaluation of each project idea. The recommendations of the Ideas Lab panel are advisory to NSF. Within seven to fourteen days following the Ideas Lab, the NSF Program Officers will determine which project ideas are meritorious and should be invited as full proposals. At the NSF Program Officers' discretion (subject to Division Director concurrence), they may invite none, some, or all of the project ideas as full proposals, with the final funding decision to occur after the full proposals have been received and reviewed. Invited full proposals (which are prepared in accordance with standard research proposal formatting guidelines) must be submitted within two months of receiving NSF notification after the Ideas Lab.

[35] Ideas Labs are generally one to five days in duration.

d. Stage 4: Review and recommendation of full proposals

Invited proposals will be reviewed internally by the cognizant NSF Program Officers, the Ideas Lab panelists, and other external reviewers, as appropriate. Resulting awards will be administered in accordance with standard NSF policies and procedures, including no-cost extensions and supplemental funding requests. Renewed funding of an Ideas Lab award may be requested only through submission of a full proposal that will be subject to external merit review. Such proposals would be designated as an "Ideas Lab renewal."

6. Facilitation Awards for Scientists and Engineers with Disabilities (FASED) Proposal

As part of its effort to promote full utilization of highly qualified scientists, mathematicians, and engineers, and to develop scientific and technical talent, the Foundation has the following goals:

- to reduce or remove barriers to participation in research and training by persons with physical disabilities by providing special equipment and assistance under awards made by NSF; and

- to encourage persons with disabilities to pursue careers in science and engineering by stimulating the development and demonstration of special equipment that facilitates their work performance.

Persons with disabilities eligible for facilitation awards include PIs, other senior personnel, and graduate and undergraduate students. The cognizant NSF Program Officer will make decisions regarding what constitutes appropriate support on a case-by-case basis. The specific nature, purpose, and need for equipment or assistance should be described in sufficient detail in the proposal to permit evaluation by knowledgeable reviewers.

There is no separate program for funding of special equipment or assistance. Requests are made in conjunction with regular competitive proposals, or as a supplemental funding request to an existing NSF award. Specific instructions for each type of request are provided below.

a. Requests as part of a competitive proposal submission

Funds may be requested to purchase special equipment, modify equipment or provide services required specifically for the work to be undertaken. Requests for funds for equipment or assistance that compensate in a general way for the disabling condition are not permitted. For example, funds may be requested to provide: prosthetic devices to manipulate a particular apparatus; equipment to convert sound to visual signals, or vice versa, for a particular experiment; access to a special site or to a mode of transportation (except as defined below); a reader or interpreter with special technical competence related to the project; or other special-purpose equipment or assistance needed to conduct a particular project. Items, however, such as standard wheel chairs, prosthetics, hearing aids, TDD/text-phones, or general readers for the blind would not be supported because the need for them is not specific to the proposed project. Similarly, ramps, elevators, or other structural modifications of research facilities are not eligible for direct support under this program.

No maximum funding amount has been established for such requests. It is expected, however, that the cost (including equipment adaptation and installation) will not be a major component of the total proposed budget for the project. Requests for funds for special equipment or assistance to facilitate the participation of individuals with disabilities should be included in the proposed budget for the project and documented in the budget justification. The specific nature, purpose and need for such equipment or assistance should be described in sufficient detail in the Project Description to permit evaluation of the request by knowledgeable reviewers.

b. Supplemental funding requests to existing NSF grants

Supplemental funds for special equipment or assistance to facilitate participation in NSF-supported projects by persons with disabilities may be requested under existing NSF grants. Normally, title is vested in the grantee organization for equipment purchased in conjunction with NSF-supported activities. In accordance with the applicable grant terms and conditions, the grantee organization guarantees use of the equipment for the specific project during the period of work funded by the Foundation, and assures its use in an appropriate manner after project completion. In instances involving special equipment for persons with disabilities, the need for such may be unique to the individual. In such cases, the grantee organization may elect to transfer title to the individual to assure appropriate use after project completion.

Supplemental funding requests should be submitted by using the "Supplemental Funding Request" function in FastLane and should include a brief description of the request, a budget and a budget justification. Requests must be submitted at least two months before funds are needed. Funding decisions will be made on the basis of the justification and availability of program funds with any resultant funding provided through a formal amendment of the existing NSF grant.

7. Conference Proposal[36]

NSF supports conferences in special areas of science and engineering that bring experts together to discuss recent research or education findings or to expose other researchers or students to new research and education techniques. NSF encourages the convening in the US of major international conferences.

A conference proposal will be evaluated through use of the two National Science Board (NSB)-approved merit review criteria of Intellectual Merit and Broader Impacts, and, will be supported only if equivalent results cannot be obtained by attendance at regular meetings of professional societies. Although requests for support of a conference proposal ordinarily originates with educational institutions or scientific and engineering societies, they also may come from other groups. Shared support by several Federal agencies, States or private organizations is encouraged. A conference proposal should generally be submitted at least a year in advance of the scheduled date. Conferences, including the facilities in which they are held, funded in whole or in part with NSF funds, must be accessible to participants with disabilities.

A conference proposal must contain the elements identified below:

- Cover Sheet
- Project Summary (Chapter II.C.2.b) should be consulted to prepare this portion of the proposal)
- Project Description (not to exceed 15 pages) that includes:

a. A statement of the need for such a gathering and a list of topics;

b. Separate statements on the intellectual merit and broader impacts of the proposed activity;

c. A listing of recent meetings on the same subject, including dates and locations;

d. The names of the chairperson and members of organizing committees and their organizational affiliations;

e. Information on the location and probable date(s) of the meeting and the method of announcement or invitation;

[36] This coverage also applies to symposia and workshop proposals.

f. A statement of how the meeting will be organized and conducted, how the results of the meeting will be disseminated and how the meeting will contribute to the enhancement and improvement of scientific, engineering and/or educational activities; and

g. Results from Prior NSF Support (up to five pages): If **any PI or co-PI** identified on the proposal has received prior NSF support including:

- an award with an end date in the past five years; or
- any current funding, including any no cost extensions,

information on the award is required **for each PI and co-PI**, regardless of whether the support was directly related to the proposal or not. See Chapter II.C.2.d.(iii) for additional instructions on preparation of this section.

- Proposal Budget and Budget Justification: A budget, and budget justification for the conference prepared in accordance with Chapter II.C.2.g. The following provides a listing of the types of costs that may be included on a conference budget. Such costs may be included only if they are specifically and clearly identified in the proposed scope of work and budget. Note that registration fees under NSF-supported conferences are considered program income. For additional information on program income generated from conferences, see Chapter VIII.D.4.

a. Conference Facilities. Rental of facilities and necessary equipment.

b. Supplies. Expendable materials and supplies necessary for the meeting.

c. Conference Services. Costs of translation services, audio visual, webcast, and computer services for recording, transmitting and transcribing the proceedings.

d. Publication Costs. Costs of publishing the proceedings.

e. Salaries. Salaries of professional personnel, editorial and clerical assistants and other staff members in proportion to the time or effort devoted to the preparation and conduct of the conference and summarizing its results.

f. Consultant Services and Speaker Fees. Reasonable fees and travel allowances and per diem (or meals provided in lieu of per diem). Consultants' travel costs, including subsistence, may be included. If requested, the proposer must be able to justify that the proposed rate of pay is reasonable. Additional information on the allowability of consultant or professional service costs is available in 2 CFR § 200.459. In addition to other provisions required by the proposing organization, all contracts made under the NSF award must contain the applicable provisions identified in 2 CFR § 200, Appendix II.

g. Meals and Coffee Breaks. Meals that are an integral and necessary part of a conference (e.g., working meals where business is transacted). Funds may be included for furnishing a reasonable amount of hot beverages or soft drinks to conference participants and attendees during periodic coffee breaks. Proposed costs for meals must be reasonable and otherwise allowable to the extent such costs do not exceed charges normally allowed by the grantee organization in its regular operations as the result of the grantee organizations written policies. In the absence of an acceptable, written grantee organizational policy regarding meal costs, 2 CFR §200.474(b)(3) will apply.

h. Participant Support Costs. See Chapter II.C.2.g.(v).

i. Dependent Care Costs. As needed, the costs of identifying, but not providing, locally available dependent care resources may be included.

The following provides a listing of the types of costs that are not allowable for inclusion on a conference budget.

(i) Meals and Coffee Breaks for Intramural Meetings. NSF funds may not be included or spent for meals or coffee breaks for intramural meetings of an organization or any of its components, including, but not limited to, laboratories, departments and centers, as a direct cost.

(ii) Entertainment. Costs of entertainment, amusement, diversion and social activities (such as tickets to shows or sporting events, meals, lodging, rentals, transportation and gratuities) are unallowable and may not be requested. Travel, meal, and hotel expenses of awardee employees who are not on travel status also are not permitted. See also 2 CFR § 200.438.

(iii) Alcoholic Beverages. No NSF funds may be requested or spent for alcoholic beverages.

- Current and Pending Support: The support requested or available from other Federal agencies and other sources. Chapter II.C.2.h should be consulted to prepare this portion of the proposal.

- Facilities, Equipment and Other Resources: If there will be support from other sources for the conference, such information should be included in the Facilities, Equipment and Other Resources section of the proposal. The description should be narrative in nature and must not include any quantifiable financial information Chapter II.C.2.i should be consulted to prepare this portion of the proposal. If included, these resources will not be auditable and must not be included in the proposal budget or budget justification. A description of such support should be included in the Facilities, Equipment and Other Resources section of the proposal.

- Data Management Plan: Plans for management and sharing of any data products resulting from the activity. Chapter II.C.2.j should be consulted to prepare this portion of the proposal.

8. Equipment Proposal

A proposal for specialized equipment may be submitted by an organization for: individual investigators; groups of investigators within the same department; several departments; organization(s) participating in a collaborative or joint arrangement; any components of an organization; or a region. One individual must be designated as PI. Investigators may be working in closely related areas or their research may be multidisciplinary.

An equipment proposal must contain all of the following proposal sections:

- Cover Sheet

- Project Summary: Chapter II.C.2.b should be consulted to prepare this portion of the proposal.

- Project Description (not to exceed 15 pages) that includes:

a. an overall acquisition plan which discusses arrangements for acquisition, maintenance and operation. Equipment to be purchased, modified or constructed must be described in sufficient detail to allow comparison of its capabilities with the needs of the proposed activities;

b. a description, from each potential major user, of the project(s) for which the equipment will be used. This description must be succinct, not necessarily as detailed as in a full research proposal, and must emphasize the intrinsic merit of the activity and the importance of the equipment to it. A brief summary will suffice for auxiliary users; and

c. a description of comparable equipment already at the proposing organization(s), if applicable, and an explanation of why it cannot be used. This includes comparable government-owned equipment that is on-site.

d. Results from Prior NSF Support (up to five pages): If **any PI or co-PI** identified on the proposal has received prior NSF support including:

- an award with an end date in the past five years; or
- any current funding, including any no cost extensions,

information on the award is required **for each PI and co-PI**, regardless of whether the support was directly related to the proposal or not. See Chapter II.C.2.d.(iii) for additional instructions on preparation of this section.

- Biographical Sketch(es) of the person(s) who will have overall responsibility for maintenance and operation of the equipment and a brief statement of qualifications. (Chapter II.C.2.f should be consulted to prepare this portion of the proposal; also see Chapter II.C.2.f.(iii).

- Proposal Budget and Budget Justification: An annual budget and budget justification for the operation, maintenance and administration of the proposed equipment (Chapter II.C.2.g should be consulted to prepare this portion of the proposal).

- Current and Pending Support: Chapter II.C.2.h should be consulted to prepare this portion of the proposal.

- Facilities, Equipment and Other Resources that includes a description of the physical facility, including floor plans or other appropriate information, where the equipment will be located; a narrative description of the source of funds available for operation and maintenance of the proposed equipment; a brief description of other support services available, and a statement of why the equipment is severable or non-severable from the physical facility (Chapter II.C.2.i should be consulted to prepare this portion of the proposal).

- Data Management Plan: Chapter II.C.2.j should be consulted to prepare this portion of the proposal.

- Postdoctoral Mentoring Plan (if applicable): Chapter II.C.2.j should be consulted to prepare this portion of the proposal.

This type of proposal normally competes with proposals for research or education projects.[37]

9. Travel Proposal

A proposal for travel support, either domestic and/or international, for participation in scientific and engineering meetings are handled by the NSF organizational unit with program responsibility for the area of interest.

A group travel proposal is encouraged as the primary means of support for travel. A university, professional society or other non-profit organization may apply for funds to enable it to coordinate and support participation in one or more scientific meeting(s). A proposal submitted for this purpose must contain the elements identified below, with particular attention to plans for composition and recruitment of the travel group. Information on planned speakers should be provided, where available, from the conference organizer.

[37]See Chapter IX.D for additional information on the administration of equipment awards.

- Cover Sheet

- Project Summary (Chapter II.C.2.b should be consulted to prepare this portion of the proposal).

- Project Description (not to exceed 15 pages) that includes:

a. A statement of the need for attending such a gathering and a list of topics;

b. A listing of recent meetings on the same subject, including dates and locations;

c. Information on the location and probable date(s) of the meeting;

d. A statement of how the meeting will be organized and conducted, how the results of the meeting will be disseminated and how the meeting will contribute to the enhancement and improvement of scientific, engineering and/or educational activities; and

e. Results from Prior NSF Support (up to five pages): If **any PI or co-PI** identified on the proposal has received prior NSF support including:

- an award with an end date in the past five years; or
- any current funding, including any no cost extensions,

information on the award is required **for each PI and co-PI**, regardless of whether the support was directly related to the proposal or not. See Chapter II.C.2.d.(iii) for additional instructions on preparation of this section.

- Proposal Budget and Budget Justification: A budget, and budget justification for the travel prepared in accordance with Chapter II.C.2.g. For proposals to support travel to international destinations, in accordance with the Fly America Act (49 USC 40118), any air transportation to, from, between, or within a country other than the US of persons or property, the expense of which will be assisted by NSF funding, must be performed by or under a code-sharing arrangement with a US-flag air carrier if service provided by such a carrier is available (see Comptroller General Decision B-240956, dated September 25, 1991). Tickets (or documentation for electronic tickets) must identify the US flag air carrier's designator code and flight number. See Chapter XI.F for additional information.

- Current and Pending Support: The support requested or available from other Federal agencies and other sources. Chapter II.C.2.h should be consulted to prepare this portion of the proposal.

- Facilities, Equipment and Other Resources: If there will be support from other sources for the travel, such information should be included in the Facilities, Equipment and Other Resources section of the proposal. The description should be narrative in nature and must not include any quantifiable financial information. Chapter II.C.2.i should be consulted to prepare this portion of the proposal. If included, these resources will not be auditable and must not be included in the proposal budget or budget justification. A description of such support should be included in the Facilities, Equipment and Other Resources section of the proposal.

- Data Management Plan: Plans for management and sharing of any data products resulting from the activity. Chapter II.C.2.j should be consulted to prepare this portion of the proposal.

A group travel proposal may request support only for the travel costs of the proposed activity. Group travel grantees are required to retain supporting documentation that funds were spent in accordance with the original intent of the proposal. Such documentation may be required in final reports and is subject to audit.

10. Center Proposal

NSF provides support for a variety of individual Centers and Centers programs that contribute to the Foundation's vision as outlined in the NSF Strategic Plan. Centers exploit opportunities in science, engineering and technology in which the complexity of the research problem(s) or the resources needed to solve the(se) problem(s) require the advantages of scope, scale, change, duration, equipment, facilities, and students that can only be provided by an academic research center. They focus on investigations at the frontiers of knowledge not normally attainable through individual investigations, at the interfaces of disciplines and/or by incorporating fresh approaches to the core of disciplines. Centers focus on integrative learning and discovery and demonstrate leadership in broadening participation through focused investments in a diverse set of partner organizations and individuals. In doing so, they draw upon, and contribute to, the development of the Nation's full intellectual talent. Most Center awards are limited to a maximum duration of ten years and are often subject to mid-course external merit review. Proposers interested in learning more about current or future NSF Centers are encouraged to contact the appropriate disciplinary NSF Program Officer. Centers are not considered research infrastructure, but will often use research infrastructure to meet their objectives.

11. Research Infrastructure Proposal

As an integral part of its responsibility for strengthening the science and engineering capacity of the country, NSF provides support for the design, construction, operation and upgrade of research infrastructure including instrumentation, mid-scale projects and major facilities. NSF depends on the research communities to provide the justification as well as the capabilities to manage the development and implementation of research infrastructure projects. Justification normally occurs through National Academies studies, workshop reports, professional society activities, and other community-based mechanisms, including engineering studies and research projects related to the development of new technologies. Many of these mechanisms are funded by interested NSF Programs on the basis of merit-reviewed proposals. The NSF process and funding mechanisms for development and implementation of research infrastructure projects depends, in part, on the scale of the project. The largest projects, major facilities, are typically supported through the Major Research Equipment and Facilities Construction (MREFC) account. Proposers are strongly encouraged to contact the appropriate NSF Program to discuss the availability of funding and the appropriate funding mechanisms in advance of proposal submission. The Large Facilities Manual (LFM), a public document managed by the Large Facilities Office, contains policies and procedures related to NSF oversight and Recipient management of research infrastructure projects funded by NSF. The purpose of the LFM is to: (1) provide guidance to NSF staff on conducting appropriate oversight and to recipients in carrying out effective project planning and management; and (2) clearly state the required policies and procedures as well as pertinent good practices for each life-cycle stage.

Exhibit II-1: Proposal Preparation Checklist

It is imperative that all proposals conform to the proposal preparation and submission instructions specified in Part I of the *Proposal and Award Policies and Procedures Guide*. Conformance with all preparation and submission instructions is required and will be strictly enforced unless a deviation has been approved in advance of proposal submission. Note that some NSF program solicitations modify standard NSF proposal preparation guidelines, and, in such cases, the guidelines provided in the solicitation must be followed. FastLane uses the rules specified for each type of proposal, (e.g., Research, RAPID, EAGER, RAISE, GOALI, Ideas Lab, FASED, Conference, Equipment, or Travel) to check for compliance prior to submission to NSF. Proposers are strongly advised to review the applicable sections of Chapter II.E. relevant to the type of proposal being developed PRIOR to submission. NSF will not accept[38] or will return without review proposals that are not consistent with these instructions. See Chapter IV.B and visit: http://www.nsf.gov/bfa/dias/policy/autocompliance.jsp for additional information.

Prior to submission, it is strongly recommended that an administrative review be conducted to ensure that proposals comply with the instructions, and the format specified. This checklist is not intended to be an all-inclusive repetition of the required proposal contents and associated proposal preparation guidelines. It is, however, meant to highlight certain critical items so they will not be overlooked when the proposal is prepared.

[ ] General:

[ ] The proposal is compliant with the provisions in the PAPPG and/or the relevant program solicitation.

[ ] The proposal is responsive to the relevant program description or announcement (if applicable).

[ ] If the proposal has been previously declined and is being resubmitted, the proposal has been substantively revised to take into account the major comments from the prior NSF review.

[ ] The proposed work is appropriate for funding by NSF, and is not a duplicate of, or substantially similar to, a proposal already under consideration by NSF from the same submitter.

[ ] The proposal must be submitted by 5 p.m. submitter's local time on the established deadline date.

[ ] Single Copy Documents:

[ ] Authorization to Deviate from NSF Proposal Preparation Requirements is included (if applicable).

[ ] List of Suggested Reviewers, or Reviewers Not To Include has been provided (if applicable).

[ ] SF LLL, *Disclosure of Lobbying Activities* has been provided (if applicable).

[ ] Collaborators and Other Affiliations (COA) Information has been separately provided for each individual identified as senior project personnel through use of the COA template available at: https://nsf.gov/bfa/dias/policy/coa.jsp.

[38] Proposal Not Accepted is defined as FastLane will not permit submission of the proposal.

[ ] Cover Sheet:

[ ] For interdisciplinary proposals, ensure all relevant programs are identified.

[ ] Title includes any necessary prefix, e.g., "Collaborative Proposal:."

[ ] For renewal proposals, previous award numbers have been entered.

[ ] Related preliminary proposal number has been entered (if applicable).

[ ] The "Special Exception to the Deadline Date Policy" box has been checked on the NSF Cover Sheet and the requisite Single Copy Document has been provided (if applicable).

[ ] Appropriate box(es) have been checked, and requisite information has been provided.

[ ] Project Summary:

[ ] The Project Summary may ONLY be uploaded as a Supplementary Document if use of special characters is necessary. Such Project Summaries must be formatted with separate headings for Overview, Intellectual Merit and Broader Impacts.

[ ] The Project Summary must not exceed one page.

[ ] Project Description:

[ ] The Project Description must not exceed the 15-page limitation, the limit specified in a specific program solicitation, or the limit provided in the instructions for types of proposals (e.g., RAPID, EAGER and Ideas Lab).

[ ] Project Description contains, as a separate section within the narrative, a section labeled "Intellectual Merit."

[ ] Project Description contains, as a separate section within the narrative, a section labeled "Broader Impacts".

[ ] Project Description is self-contained, and Uniform Resource Locators (URLs) have not been included.

[ ] Results from Prior NSF Support have been provided for **any PI or co-PI** identified on the proposal that has received prior NSF support including:

- an award with an end date in the past five years; or
- any current funding, including any no cost extensions.

[ ] Results related to Intellectual Merit and Broader Impacts are described under two separate, distinct headings, and are limited to five pages of the Project Description.

[ ] References Cited:

[ ] This section includes bibliographic citations only and does not provide parenthetical information outside of the 15-page Project Description.

[ ] Each reference is in the required format, which may vary according to the norms of the scientific discipline.

[ ] Biographical Sketch(es):

[ ] The content described is in accordance with the instructions, and does not contain additional information beyond that specified.

[ ] Each biographical sketch must not exceed two pages.

[ ] Each individual's biographical sketch must be uploaded as a single PDF file associated with that individual.

[ ] Proposal Budget:

[ ] Each budget line item is documented and justified in the budget justification.

[ ] Any compensation for senior personnel in excess of two months is disclosed in the proposal budget and justified in the budget justification.

[ ] A budget justification must be provided for the proposer AND any proposed subawardee.

[ ] The amount for indirect costs was be calculated by applying the current negotiated indirect cost rate(s) to the approved base(s) and amount is specified in the budget justification.

[ ] Each budget justification must not exceed five pages or the page limitation specified in a specific program solicitation. For proposals that contain a subaward(s), **each subaward** must include a separate budget justification that must not exceed five pages.

[ ] Cost Sharing:

[ ] Unless required by an NSF program solicitation, voluntary committed cost sharing has not been included. Note that voluntary committed cost sharing is prohibited and Line M on the proposal budget will not be available for use by the proposer. While not required by NSF, proposing organizations may, at their own discretion, continue to contribute voluntary uncommitted cost sharing to NSF-sponsored projects. These resources are not auditable by NSF and should not be included in the proposal budget or budget justification.

[ ] Current and Pending Support:

[ ] All current and pending support from whatever source (e.g., Federal, state, local or foreign government agencies, public or private foundations, industrial or other commercial organizations, or internal funds allocated toward specific projects) must be listed. The proposed project and all other projects or activities requiring a portion of time of the PI and other senior personnel must be included, even if they receive no salary support from the project(s).

[ ] Information on this proposal is included.

[ ] Each individual's current and pending support must be uploaded as a single PDF file or inserted as text associated with that individual.

[ ] Facilities, Equipment and Other Resources:

[ ] An aggregated description of the internal and external resources (both physical and personnel) that the organization and its collaborators will provide to the project, should it be funded, has been included.

[ ] No quantifiable financial information has been provided.

[ ] If there are no facilities, equipment or other resources identified, a statement to that effect has been included in this section of the proposal and uploaded into FastLane.

[ ] Special Information and Supplementary Documentation:

[ ] A postdoctoral mentoring plan, limited to one page, has been included, if required.

[ ] A data management plan, limited to two pages, has been included.

[ ] Letters of collaboration documenting collaborative arrangements of significance to the proposal have been included (if applicable).

[ ] Other types of information identified in Chapter II.C.2.j have been included, as appropriate.

[ ] Any additional items specified in a relevant program solicitation have been included.

[ ] Appendices:

[ ] Appendices may not be included unless a deviation has been authorized.

Exhibit II-2: Potentially Disqualifying Conflicts of Interest

Unless a waiver has been granted by NSF, a reviewer cannot review a proposal if:

- the reviewer, the reviewer's spouse, minor child, or business partner;
- an organization where the reviewer is employed, serves as a consultant, has an arrangement for future employment or is negotiating for employment; or
- the organization where the reviewer is an officer, director, trustee, or partner;

has a financial interest in the outcome of the proposal.

Unless a waiver has been granted by NSF, a potential reviewer also may be barred from reviewing a proposal, if it involves individuals with whom he/she has a personal relationship, such as a close relative, current or former collaborator, or former Ph.D. student/advisor.

Unless a waiver has been granted by NSF, a disqualifying conflict may exist, if a proposal involves an organization or other entity with which the potential reviewer has a connection. Such potentially disqualifying connections include:

- a reviewer's recent former employer;
- an organization in which the reviewer is an active participant;
- an institution at which the reviewer is currently enrolled as a student, or at which he/she serves as a visiting committee member; or
- an entity with which the reviewer has or seeks some other business or financial relationship (including receipt of an honorarium).

Exhibit II-3: Drug-Free Workplace Certification

Instructions for Certification

1. By signing the NSF Cover Sheet and submitting this proposal, the Authorized Organizational Representative is providing the certifications set out below.

2. The certification set out below is a material representation of fact upon which reliance was placed when the agency determined to award the grant. If it is later determined that the grantee knowingly rendered a false certification, or otherwise violates the requirements of the Drug-Free Workplace Act, the agency, in addition to any other remedies available to the Federal Government, may take action authorized under the Drug-Free Workplace Act.

3. For grantees other than individuals, Alternate I applies.

4. For grantees who are individuals, Alternate II applies.

Certification Regarding Drug-Free Workplace Requirements

Alternate I (Grantees Other Than Individuals)

The grantee certifies that it will or will continue to provide a drug-free workplace by:

(a) Publishing a statement notifying employees that the unlawful manufacture, distribution, dispensing, possession or use of a controlled substance is prohibited in the grantee's workplace and specifying the actions that will be taken against employees for violation of such prohibition;

(b) Establishing an ongoing drug-free awareness program to inform employees about --

(1) The dangers of drug abuse in the workplace;

(2) The grantee's policy of maintaining a drug-free workplace;

(3) Any available drug counseling, rehabilitation and employee assistance programs; and

(4) The penalties that may be imposed upon employees for drug abuse violations occurring in the workplace;

(c) Making it a requirement that each employee to be engaged in the performance of the grant be given a copy of the statement required by paragraph (a);

(d) Notifying the employee in the statement required by paragraph (a) that, as a condition of employment under the grant, the employee will --

(1) Abide by the terms of the statement; and

(2) Notify the employer in writing of his or her conviction for a violation of a criminal drug statute occurring in the workplace, no later than five calendar days after such conviction;

(e) Notifying the agency in writing, within 10 calendar days after receiving notice under subparagraph (d)(2) from an employee or otherwise receiving actual notice of such conviction.

Employers of convicted employees must provide notice, including position title, to every grant officer or other designee on whose grant activity the convicted employee was working, unless the

Federal agency has designated a central point for the receipt of such notices. Notice shall include the identification number(s) of each affected grant;

(f) Taking one of the following actions, within 30 calendar days of receiving notice under subparagraph (d)(2), with respect to any employee who is so convicted--

(1) Taking appropriate personnel action against such an employee, up to and including termination, consistent with the requirements of the Rehabilitation Act of 1973, as amended; or

(2) Requiring such employee to participate satisfactorily in a drug abuse assistance or rehabilitation program approved for such purposes by a Federal, State, or local health, law enforcement, or other appropriate agency;

(g) Making a good faith effort to continue to maintain a drug-free workplace through implementation of paragraphs (a), (b), (c), (d), (e) and (f).

Alternate II (Grantees Who Are Individuals)

(a) The grantee certifies that, as a condition of the grant, he or she will not engage in the unlawful manufacture, distribution, dispensing, possession or use of a controlled substance in conducting any activity with the grant.

(b) If convicted of a criminal drug offense resulting from a violation occurring during the conduct of any grant activity, he or she will report the conviction, in writing, within 10 calendar days of the conviction, to every grant officer or other designee, unless the Federal agency designates a central point for the receipt of such notices. When notice is made to such a central point, it shall include the identification number(s) of each affected grant.

For NSF, grantee notification should be made to the Cost Analysis & Audit Resolution Branch, Division of Institution & Award Support, NSF, Arlington, VA 22230.

Exhibit II-4: Debarment and Suspension Certification

Instruction on Certification Regarding Debarment and Suspension

1. By signing and submitting this proposal, the prospective primary participant is providing the certification set out below.

2. The inability of a person to provide the certification required below will not necessarily result in denial of participation in this covered transaction. The prospective participant shall submit an explanation of why it cannot provide the certification set out below. The certification or explanation will be considered in connection with the department or agency's determination whether to enter into this transaction. However, failure of the prospective primary participant to furnish a certification or an explanation shall disqualify such person from participation in this transaction.

3. The certification in this clause is any material representation of fact upon which reliance was placed when the department or agency determined to enter into this transaction. If it is later determined that the prospective primary participant knowingly rendered an erroneous certification, in addition to other remedies available to the Federal Government, the department or agency may terminate this transaction for cause or default.

4. The prospective primary participant shall provide immediate written notice to the department or agency to whom this proposal is submitted if at any time the prospective primary participant learns that its certification was erroneous when submitted or has become erroneous by reason of changed circumstances.

5. The terms covered transaction, debarred, suspended, ineligible, lower tier covered transaction, participant, person, primary covered transaction, principal, proposal, and voluntarily excluded, as used in this clause, have the meanings set out in the Definitions and Coverage sections of the rules implementing Executive Order 12549. You may contact the department or agency to which this proposal is being submitted for assistance in obtaining a copy of those regulations.

6. The prospective primary participant agrees by submitting this proposal that, should the proposed covered transaction be entered into, it shall not knowingly enter into any lower tier covered transaction with a person who is debarred, suspended, declared ineligible, or voluntarily excluded from participation in this covered transaction, unless authorized by the department or agency entering into this transaction.

7. The prospective primary participant further agrees by submitting this proposal that it will include the clause titled "Certification Regarding Debarment, Suspension, Ineligibility and Voluntary Exclusion - Lower Tier Covered Transaction", provided by the department or agency entering into this covered transaction, without modification, in all lower tier covered transactions.

8. A participant in a covered transaction may rely upon a certification of a prospective participant in a lower tier covered transaction that it is not debarred, suspended, ineligible, or voluntarily excluded from the covered transaction, unless it knows that the certification is erroneous. A participant may decide the method and frequency by which it determines the eligibility of its principals. Each participant may, but is not required to, check the Nonprocurement List.

9. Nothing contained in the foregoing shall be construed to require establishment of a system of records in order to render in good faith the certification required by this clause. The knowledge and information of a participant is not required to exceed that which is normally possessed by a prudent person in the ordinary course of business dealings.

10. Except for transactions authorized under paragraph 6 of these instructions, if a participant in a covered transaction knowingly enters into a lower tier covered transaction with a person who is suspended, debarred, ineligible, or voluntarily excluded from participation in this transaction, in addition to other remedies available to the Federal Government, the department or agency may terminate this transaction for cause or default.

Certification

(1) The prospective primary participant certifies to the best of its knowledge and belief, that it and its principals: (a) Are not presently debarred, suspended, proposed for debarment, declared ineligible, or voluntarily excluded from a covered transaction by any Federal department or agency; (b) Have not within a three-year period preceding this proposal been convicted of or had a civil judgment rendered against them for commission of fraud or a criminal offense in connection with obtaining, attempting to obtain, or performing a public (Federal, State or local) transaction or contract under a public transaction; violation of Federal or State antitrust statutes or commission of embezzlement, theft, forgery, bribery, falsification or destruction of records, making false statements, or receiving stolen property; (c) Are not presently indicted for or otherwise criminally or civilly charged by a governmental entity (Federal, State or local) with commission of any of the offenses enumerated in paragraph (1)(b) of this certification; and (d) Have not within a three-year period preceding this application/proposal had one or more public transactions (Federal, State or local) terminated for cause or default.

(2) Where the prospective primary participant is unable to certify to any of the statements in this certification, such prospective participant shall include an explanation with this proposal.

Exhibit II-5: Lobbying Certification

Instructions on Certification Regarding Lobbying

This certification is required for an award of a Federal contract, grant or cooperative agreement exceeding $100,000 and for an award of a Federal loan or a commitment providing for the United States to insure or guarantee a loan exceeding $150,000. The *Certification for Contracts, Grants, Loans and Cooperative Agreements* also is included in full text on the FastLane submission screen.

Certification for Contracts, Grants, Loans and Cooperative Agreements

The undersigned certifies, to the best of his or her knowledge and belief, that:

(1) No Federal appropriated funds have been paid or will be paid, by or on behalf of the undersigned, to any person for influencing or attempting to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with the awarding of any federal contract, the making of any Federal grant, the making of any Federal loan, the entering into of any cooperative agreement, and the extension, continuation, renewal, amendment, or modification of any Federal contract, grant, loan, or cooperative agreement.

(2) If any funds other than Federal appropriated funds have been paid or will be paid to any person for influencing or attempting to influence an officer or employee of any agency, a Member of Congress, an officer or employee of Congress, or an employee of a Member of Congress in connection with this Federal contract, grant, loan, or cooperative agreement, the undersigned shall complete and submit Standard Form LLL, “Disclosure of Lobbying Activities,” in accordance with its instructions.

(3) The undersigned shall require that the language of this certification be included in the award documents for all subawards at all tiers including subcontracts, subgrants, and contracts under grants, loans, and cooperative agreements and that all subrecipients shall certify and disclose accordingly.

This certification is a material representation of fact upon which reliance was placed when this transaction was made or entered into. Submission of this certification is a prerequisite for making or entering into this transaction imposed by Section 1352, Title 31, US Code. Any person who fails to file the required certification shall be subject to a civil penalty of not less than $10,000 and not more than $100,000 for each such failure.

Exhibit II-6: Nondiscrimination Certification

Instructions for Nondiscrimination Certification

1. In accordance with NSF policy, by signing the proposal, the Authorized Organizational Representative is providing the requisite Certification of Compliance with National Science Foundation Nondiscrimination Regulations and Policies. This Certification sets forth the nondiscrimination obligations with which all awardees must comply. These obligations also apply to subrecipients, and contractors under the award. The proposer therefore, shall obtain the NSF Nondiscrimination Certification from each organization that applies to be, or serves as a subrecipient, or contractor under the award (for other than the provision of commercially available supplies, materials, equipment or general support services) prior to entering into the subaward or contract arrangement.

2. The proposer shall provide immediate notice to the Foundation if at any time the proposer learns that its certification was erroneous when submitted, or has become erroneous by reason of changed circumstances.

Certification of Compliance with National Science Foundation Nondiscrimination Regulations and Policies

By signing the proposal, the Authorized Organizational Representative hereby certifies that the organization will comply with Title VI of the Civil Rights Act of 1964 (42 USC § 2000d), Title IX of the Education Amendments of 1972 (20 USC §§ 1681 *et seq.*), the Rehabilitation Act of 1973 (29 USC § 794), the Age Discrimination Act of 1975 (42 USC §§ 6101 *et seq.*) and all regulations and policies issued by NSF pursuant to these statutes.

To that end, in accordance with the above-referenced nondiscrimination statutes, and NSF's implementing regulations and policies, no person in the United States shall, on the ground of race, color, national origin, sex, disability, or age, be excluded from participation in, be denied the benefits of, or be otherwise subjected to discrimination under any program or activity for which the Proposer receives Federal financial assistance from the Foundation; and HEREBY CERTIFIES THAT it will immediately take any measures necessary to effectuate this agreement.

If any real property or structure thereon is provided or improved with the aid of Federal financial assistance extended to the Proposer by the Foundation, this Certification shall obligate the Proposer, or in the case of any transfer of such property, the transferee, for the period during which the real property or structure is used for a purpose for which the Federal financial assistance is extended or for another purpose involving the provision of similar services or benefits. If any personal property is so provided, this Certification shall obligate the Proposer for the period during which it retains ownership or possession of the property. In all other cases, this Certification shall obligate the Proposer for the period during which the Federal financial assistance is extended to it by the Foundation.

THIS CERTIFICATION is given in consideration of and for the purpose of obtaining any and all Federal grants, cooperative agreements, loans, contracts, property, discounts or other Federal financial assistance extended after the date hereof to the Proposer by the Foundation, including installment payments after such date on account of applications for Federal financial assistance which were approved before such date. The Proposer recognizes and agrees that such Federal financial assistance will be extended in reliance on the representations and agreements made in this Certification, and that the United States shall have the right to seek judicial enforcement of this Certification. This Certification is binding on the Proposer, its successors, transferees, and assignees.

Exhibit II-7: Definitions of Categories of Personnel

The personnel categories listed on parts A and B of the Proposal Budget are defined as follows:

A. Senior Personnel

1. (co) Principal Investigator/Project Director (PI/PD) -- the individual(s) designated by the proposer, and approved by NSF, who will be responsible for the scientific or technical direction of the project. NSF does not infer any distinction in scientific stature among multiple PIs, whether referred to as PI or co-PI. If more than one, the first one listed will serve as the contact PI, with whom all communications between NSF program officials and the project relating to the scientific, technical, and budgetary aspects of the project should take place. The PI and any identified co-PIs, however, will be jointly responsible for submission of the requisite project reports. The term "Principal Investigator" generally is used in research projects, while the term "Project Director" generally is used in centers, major facilities, and other projects. For purposes of this Guide, PI/co-PI is interchangeable with PD/co-PD.

2. Faculty Associate (faculty member) (or equivalent) -- an individual other than the Principal Investigator(s) considered by the performing institution to be a member of its faculty (or equivalent) or who holds an appointment as a faculty member at another institution, and who will participate in the project being supported.

B. Other Personnel

1. Postdoctoral (Scholar, Fellow, or Other Postdoctoral Position) -- an individual who has received a doctoral degree (or equivalent) and is engaged in a temporary and defined period of mentored advanced training to enhance the professional skills and research independence needed to pursue his or her chosen career path. Postdoctoral scholars not identified under Senior Personnel above should be listed as Other Personnel.

2. Other Professional -- a person who may or may not hold a doctoral degree or its equivalent, who is considered a professional and is not reported as a Principal Investigator, faculty associate, postdoctoral scholar or student. Examples of persons included in this category are doctoral associates not reported under B1, professional technicians, physicians, veterinarians, system experts, computer programmers and design engineers.

3. Graduate Student (research assistant) -- a part-time or full-time student working on the project in a research capacity who holds at least a bachelor’s degree and is enrolled in a degree program leading to an advanced degree.

4. Undergraduate Student -- a student who is enrolled in a degree program (part-time or full-time) leading to a bachelor’s or associate’s degree.

5. & 6. These categories include persons working on the project in a non-research capacity, such as secretaries, clerk-typists, draftsmen, animal caretakers, electricians and custodial personnel regardless of whether they hold a degree or are involved in degree work.

Any personnel category for which NSF funds are requested must indicate, in the parentheses provided on the Proposal Budget, the number of persons expected to receive some support from those funds.

Chapter III: NSF Proposal Processing and Review

Proposals received by NSF are assigned to the appropriate NSF program and are assessed to ensure that they meet NSF compliance requirements. All compliant proposals are then carefully reviewed by a scientist, engineer, or educator serving as an NSF Program Officer, and usually by three to ten other persons outside NSF either as *ad hoc* reviewers, panelists, or both, who are experts in the particular fields represented by the proposal. Proposers are invited to suggest names of persons they believe are especially well qualified to review the proposal and/or persons they would prefer not review the proposal. These suggestions may serve as one source in the reviewer selection process at the Program Officer's discretion. In addition, Program Officers may obtain comments from site visits before recommending final action on proposals. Senior NSF staff further review recommendations for awards. A flowchart that depicts the entire NSF proposal and award process (and associated timeline) is included as Exhibit III-1.

A comprehensive description of the Foundation's merit review process is available on the NSF website at: http://www.nsf.gov/bfa/dias/policy/merit_review/.

Proposal review is one step in the NSF program planning and implementation process. Embedded in this process are core strategies that are fundamental to the fulfillment of NSF's mission. More information about NSF's mission and strategies can be found in *Investing in Science, Engineering, and Education for the Nation's Future: NSF Strategic Plan for 2014-2018*. NSF's mission is particularly well-implemented through the integration of research and education and broadening participation in NSF programs, projects, and activities.

A. Merit Review Principles and Criteria

The National Science Foundation strives to invest in a robust and diverse portfolio of projects that creates new knowledge and enables breakthroughs in understanding across all areas of science and engineering research and education. To identify which projects to support, NSF relies on a merit review process that incorporates consideration of both the technical aspects of a proposed project and its potential to contribute more broadly to advancing NSF's mission "to promote the progress of science; to advance the national health, prosperity, and welfare; to secure the national defense; and for other purposes." NSF makes every effort to conduct a fair, competitive, transparent merit review process for the selection of projects.

1. Merit Review Principles

These principles are to be given due diligence by PIs and organizations when preparing proposals and managing projects, by reviewers when reading and evaluating proposals, and by NSF program staff when determining whether or not to recommend proposals for funding and while overseeing awards. Given that NSF is the primary Federal agency charged with nurturing and supporting excellence in basic research and education, the following three principles apply:

- All NSF projects should be of the highest quality and have the potential to advance, if not transform, the frontiers of knowledge.

- NSF projects, in the aggregate, should contribute more broadly to achieving societal goals. These broader impacts may be accomplished through the research itself, through activities that are directly related to specific research projects, or through activities that are supported by, but are complementary to, the project. The project activities may be based on previously established and/or innovative methods and approaches, but in either case must be well justified.

- Meaningful assessment and evaluation of NSF funded projects should be based on appropriate metrics, keeping in mind the likely correlation between the effect of broader impacts and the resources provided to implement projects. If the size of the activity is limited, evaluation of that

activity in isolation is not likely to be meaningful. Thus, assessing the effectiveness of these activities may best be done at a higher, more aggregated, level than the individual project.

With respect to the third principle, even if assessment of Broader Impacts outcomes for particular projects is done at an aggregated level, PIs are expected to be accountable for carrying out the activities described in the funded project. Thus, individual projects should include clearly stated goals, specific descriptions of the activities that the PI intends to do, and a plan in place to document the outputs of those activities.

These three merit review principles provide the basis for the merit review criteria, as well as a context within which the users of the criteria can better understand their intent.

2. Merit Review Criteria

All NSF proposals are evaluated through use of two National Science Board approved merit review criteria. In some instances, however, NSF will employ additional criteria as required to highlight the specific objectives of certain programs and activities.

The two merit review criteria are listed below. Both criteria are to be given full consideration during the review and decision-making processes; each criterion is necessary but neither, by itself, is sufficient. Therefore, proposers must fully address both criteria. (Chapter II.C.2.d(i) contains additional information for use by proposers in development of the Project Description section of the proposal.) Reviewers are strongly encouraged to review the criteria, including Chapter II.C.2.d(i), prior to the review of a proposal.

When evaluating NSF proposals, reviewers will be asked to consider what the proposers want to do, why they want to do it, how they plan to do it, how they will know if they succeed, and what benefits could accrue if the project is successful. These issues apply both to the technical aspects of the proposal and the way in which the project may make broader contributions. To that end, reviewers will be asked to evaluate all proposals against two criteria:

- **Intellectual Merit:** The Intellectual Merit criterion encompasses the potential to advance knowledge; and

- **Broader Impacts:** The Broader Impacts criterion encompasses the potential to benefit society and contribute to the achievement of specific, desired societal outcomes.

The following elements should be considered in the review for both criteria:

1. What is the potential for the proposed activity to:

a. Advance knowledge and understanding within its own field or across different fields (Intellectual Merit); and

b. Benefit society or advance desired societal outcomes (Broader Impacts)?

2. To what extent do the proposed activities suggest and explore creative, original, or potentially transformative concepts?

3. Is the plan for carrying out the proposed activities well-reasoned, well-organized, and based on a sound rationale? Does the plan incorporate a mechanism to assess success?

4. How well qualified is the individual, team, or organization to conduct the proposed activities?

5. Are there adequate resources available to the PI (either at the home organization or through collaborations) to carry out the proposed activities?

B. Selection of Reviewers

The NSF guidelines for the selection of reviewers are designed to ensure selection of experts who can give Program Officers the proper information needed to make a recommendation in accordance with the NSB-approved criteria for selection of projects. Optimally, reviewers should have:

1. Special knowledge of the science and engineering subfields involved in the proposals to be reviewed to evaluate competence, intellectual merit, and utility of the proposed activity. Within reasonable limits, reviewers' fields of specialty should be complementary within a reviewer group.

2. Broader or more generalized knowledge of the science and engineering subfields involved in the proposals to be reviewed to evaluate the broader impacts of the proposed activity. Reviewers with broad expertise are required for proposals involving substantial size or complexity, broad disciplinary or multidisciplinary content, or significant national or international implications.

3. Broad knowledge of the infrastructure of the science and engineering enterprise, and its educational activities, to evaluate contributions to societal goals, scientific and engineering personnel, and distribution of resources to organizations and geographical areas.

4. To the extent possible, diverse representation within the review group. The goal is to achieve a balance among various characteristics. Important factors to consider include: type of organization represented, reviewer diversity, age distribution and geographic balance.

C. Proposal File Updates

It is the responsibility of the proposing organization to thoroughly review each proposal prior to submission. On occasion, however, a problem is identified with a portion of the proposal after the proposal has been submitted electronically to NSF.

The FastLane Proposal File Update Module allows the organization to request the replacement of files or revision of other Proposal Attributes, associated with a previously submitted proposal. (Note: The FastLane Proposal File Update module must not be used for submission of revised budgets. All budgetary revisions must be submitted through use of the FastLane Revised Proposal Budget Module. See Section D. below for further information.) A request for a proposal file update must be signed and submitted by the AOR. An update request must contain a justification that addresses:

1. why the changes or file replacements are being requested; and

2. any differences between the original and proposed replacement files.

A request for a proposal file update automatically will be accepted if submitted **prior to:**

- the deadline date;
- initiation of external peer review in cases when a target date is utilized; [39] and
- initiation of external peer review in the case of an unsolicited proposal.

A request for a proposal file update **after** the timeframes specified above will require acceptance by the cognizant NSF Program Officer. Such requests shall be submitted only to correct a technical problem with the proposal (i.e., formatting or print problems). Changes in the content of the proposal should not be requested after the timeframes specified above. When a request is accepted, the proposed files or

[39] The status of a proposal may be found in Research.gov.

revisions to proposal attributes will immediately replace the existing files and become part of the official proposal.

PIs can access the Proposal File Update Module via the "Proposal Functions" section of FastLane. Authorized individuals in the organization's SPO can initiate or review requests for proposal file updates using the "Submit Proposals/Supplements/File Updates/Withdrawals" Module via the FastLane "Research Administration Functions."[40]

NSF will consider only one request for a proposal file update per proposal at a time. It is anticipated that it will be a rare occurrence for more than one file update request to be submitted for a proposal.

D. Revisions to Proposals Made During the Review Process

In the event of a significant development (e.g., research findings, changed circumstances, unavailability of PI or other senior personnel, etc.) that might materially affect the outcome of the review of a pending proposal, the proposer must contact the cognizant NSF Program Officer to discuss the issue. Submitting additional information must not be used as a means of circumventing page limitations or stated deadlines.

Before recommending whether or not NSF should support a particular project, the cognizant NSF Program Officer may, subject to certain constraints outlined below, engage in discussions with the proposing PI(s).

Negotiating budgets generally involves discussing a lower or higher amount of total support for the proposed project. The cognizant NSF Program Officer may suggest reducing or eliminating costs for specific budget items that are clearly unnecessary or unreasonable for the activities to be undertaken, especially when the review process supports such changes; however, this would generally not include faculty salaries, salary rates, fringe benefits, or tuition. Note: indirect cost (F&A) rates are not subject to negotiation. The NSF Program Officer may discuss with PIs the "bottom line" award amount, i.e., the total NSF funding that will be recommended for a project. NSF Program Officers may not renegotiate cost sharing or other organizational commitments.

When such discussions result in a budget reduction of 10% or more from the amount originally proposed, a corresponding reduction should be made in the scope of the project. Proposers must use the FastLane Revised Proposal Budget Module to submit this information.[41] A revised proposal budget also must include a Budget Impact Statement that describes the impact of the budget reduction on the scope of the project.

Revised proposal budgets must be signed and submitted by the AOR.

E. Funding Recommendation

After scientific, technical and programmatic review and consideration of appropriate factors, the NSF Program Officer recommends to the cognizant NSF Division Director whether the proposal should be declined or recommended for award. Normally, final programmatic approval is at the Division/Office level. Because of the large volume of proposals, this review and consideration process may take up to six months. Large or particularly complex proposals may require additional review and processing time.

Should a proposal be recommended for award, the PI may be contacted by the NSF Program Officer for assistance in preparation of the public award abstract and its title. An NSF award abstract, with its title, is an NSF document that describes the project and justifies the expenditure of Federal funds by articulating how the project serves the national interest, as stated by NSF's mission: "to promote the progress of science; to advance the national health, prosperity and welfare; or to secure the national defense."

[40] Detailed instructions on submitting proposer-initiated proposal file updates are available on the FastLane website at: https://www.fastlane.nsf.gov/documents/pfu/pfu.jsp.

[41] Note: All preaward budgetary revisions must be submitted through use of the Revised Budget Module in Fastlane.

Note that a recommendation for an award by an NSF Program Officer does not constitute approval or obligation of Federal funds. Proposers are cautioned that only an appointed NSF Grants Officer may make commitments, obligations or awards on behalf of NSF or authorize the expenditure of funds. No commitment on the part of NSF or the Government should be inferred from technical or budgetary discussions with an NSF Program Officer. A PI or organization that makes financial or personnel commitments in the absence of a grant or cooperative agreement signed by a NSF Grants Officer does so at its own risk.

F. NSF's Risk Management Framework and the Decision to Award or Decline Proposals

If the program recommendation is for an award and final Division/Office or other programmatic approval is obtained, then the recommendation goes to the Division of Grants and Agreements (DGA) or the Division of Acquisition and Cooperative Support (DACS) for review of business, financial and policy implications. After the completion of this review, a final decision will be made to fund or decline the proposal.

1. NSF Risk Management Framework. Consistent with 2 CFR §200.205, NSF's risk-based framework evaluates the risks posed by proposers prior to issuance of an NSF award. This framework includes, but is not limited to, the following:

- conducting pre-award financial and administrative reviews for all proposers recommended for award that have not managed NSF funding in the last five years and whose NSF funding would exceed $225,000;

- conducting pre-award financial and administrative reviews for organizations who have received prior NSF awards whose cumulative NSF funding amount would exceed $225,000 should the proposal recommended for award be funded;

- conducting pre-award financial and administrative reviews for all proposers recommended for Phase II funding under the Small Business Innovation Research (SBIR) or Small Business Technology Transfer (STTR) program;

- considering the proposer's record of how it has managed past and current Federal awards, and leveraging NSF systems and to identify any ongoing issues that need to be considered before proceeding with future awards;

- considering the status of corrective actions necessary to address findings or concerns noted in audits, desk reviews, site visits, or other monitoring activities of the proposer's past and current Federal awards; and

- ensuring that NSF conducts review of information available through any OMB-designated repositories and that no awards are made to proposers that are currently suspended or debarred or otherwise ineligible for participation in Federal programs or activities.

DGA generally makes the decision to award or decline proposals within 30 days after the program Division/Office makes its recommendation. Proposals from organizations that have not received an NSF award within the preceding five years, involve special situations (such as coordination with another Federal agency or a private funding source), cooperative agreements, or unusual arrangements, may require additional review and processing time. NSF will report proposals that are declined for reasons that meet the guidelines set forth by OMB to the OMB-designated integrity and performance system in accordance with Federal regulation, but only after the proposer has had an opportunity to exhaust the review procedures contained in Chapter III.F.2 below.

2. Process to Appeal NSF's Decision to Decline a Proposal for Financial or Administrative Reasons

a. Background

A proposer who has been declined for an NSF award for reasons related to NSF's pre-award financial and administrative reviews will be afforded the opportunity to discuss the decline decision with the cognizant NSF Grants Officer or Branch Chief in DGA or DACS. If, after obtaining further clarification from the cognizant NSF Grants Officer or Branch Chief in DGA or DACS, the proposer believes that NSF made a substantive or procedural error in arriving at its decision to decline an award, the proposer may submit a request for review to the cognizant Division Director of DGA or DACS. The decision made by the cognizant Division Director of DGA or DACS is final.

Award of NSF assistance is discretionary. A formal hearing, therefore, is not provided.

b. Applicability

Chapter III.F.2.c contains the process by which proposers may appeal a DGA or DACS Branch Chief's decision to decline an NSF award arising from NSF's pre-award financial and administrative reviews. This process does not apply to decisions to return or decline a proposal for any other reason.

Proposals declined for administrative or financial reasons are not eligible for reconsideration under Chapter IV.D.

c. Procedures

1. Proposers who are declined for an NSF award for financial or administrative reasons will be identified as such in the declination notice. A proposer who disagrees with NSF's decision should first contact the cognizant NSF Grants Officer or Branch Chief in DGA or DACS, who will afford the proposer an informal opportunity to obtain further clarification.

2. If dissatisfied with the explanation provided by the cognizant NSF Grants Officer or Branch Chief in DGA or DACS, the proposing organization's AOR may submit a request for review to the cognizant Division Director of DGA or DACS. The letter must be addressed to the Division Director, Division of Grants and Agreements (DGA), or the Division Director, Division of Acquisition and Cooperative Support (DACS) as appropriate, and must be received by the Foundation within 30 days after the date of the declination notice. The time for filing a request for review is strictly enforced and no extensions for the purpose of preparing it will be granted.

3. The request for review need not follow any prescribed format. However, it must contain a full statement of the proposer's position with respect to the disputed matter, as well as the facts and reasons supporting the proposer's position that the declination was unwarranted. The request may address any errors made in the financial and administrative review process, and it may contain supporting documentation that was not originally presented as part of the financial and administrative review process. However, NSF will not consider any new information that would not have been available at the time the decision to decline was made. Therefore, new information presented in relation to the proposer's financial stability or the quality of its management systems will not be considered.

4. The Division Director, DGA or DACS, will review or designate one or more individuals to review the matter. In no case will the review be undertaken by any individual involved with the decline decision. The reviewing official(s) may request additional information from the proposer, but only information that would have been available at the time the decision to decline was made will be considered.

5. The designated reviewing official(s) will, within 30 days of NSF's receipt of the request for review, forward a report to the Division Director, DGA or DACS or his/her designee for a final written decision for the agency. The Division Director, DGA or DACS or his/her designee will communicate the decision in

writing to the proposer, normally within 15 days of receipt of the report, unless otherwise specified by NSF. The decision made by the Division Director, DGA or DACS, is final.

G. Review Information Provided to PI

When a decision has been made (whether an award or a declination), the following information is released electronically to the PI:

- description of the context in which the proposal was reviewed;
- copies of all reviews used in the decision (with any reviewer-identifying information redacted);
- copy of panel summary, if the proposal was reviewed by a panel at any point in the process; and/or
- site-visit reports, if applicable.

In addition, if not otherwise provided in the panel summary, the PI is provided an explanation (written or telephoned) of the basis for the declination. A PI also may request and obtain any other releasable material in NSF's file on his/her proposal. Everything in the file, except information that identifies either reviewers or other pending or declined proposals is usually releasable to the PI.

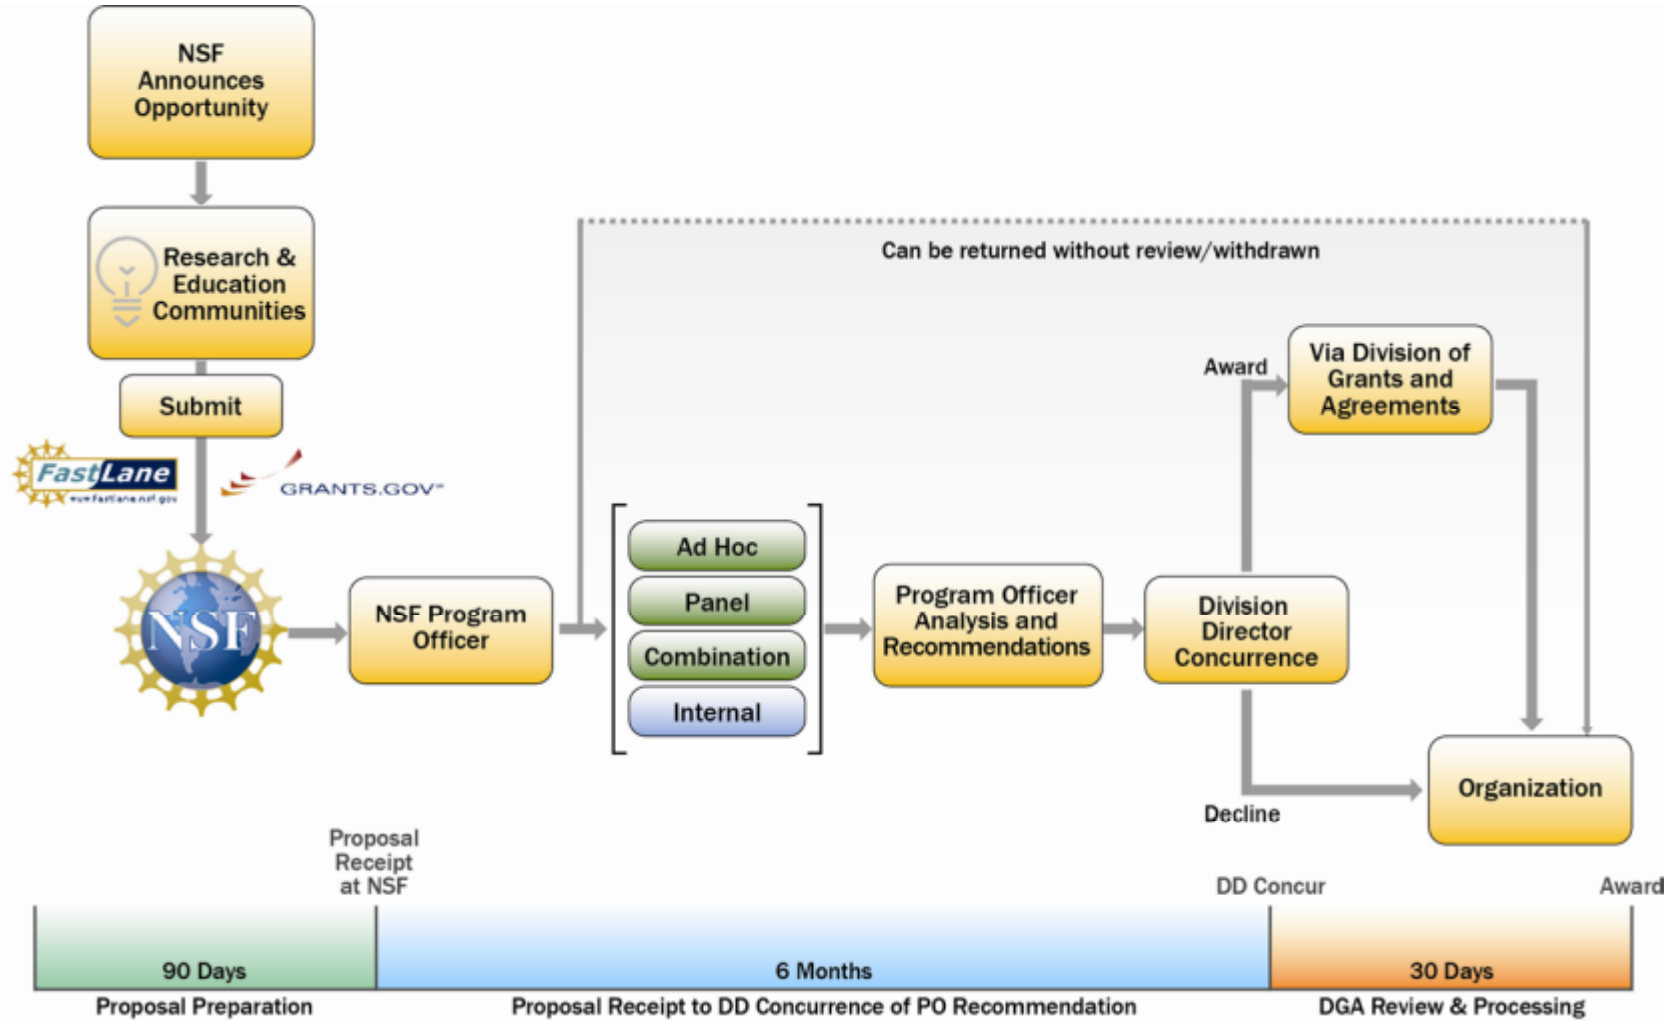
Reviews are made available directly to the PI, to provide feedback for the purpose of improving proposed research and research methods, and to assist in preparation of future proposals. They are not intended for any other purpose.

H. Release of Grantee Proposal Information

A proposal that results in an NSF award will be available to the public on request, except for privileged information or material that is personal, proprietary or otherwise exempt from disclosure under law. Appropriate labeling in the proposal aids identification of what may be specifically exempt. (See Chapter II.D.1) Such information will be withheld from public disclosure to the extent permitted by law, including the Freedom of Information Act. Without assuming any liability for inadvertent disclosure, NSF will seek to limit disclosure of such information to its employees and to outside reviewers when necessary for merit review of the proposal, or as otherwise authorized by law.

Portions of proposals resulting in grants that contain descriptions of inventions in which either the Government or the grantee owns a right, title, or interest (including a non-exclusive license) will not normally be made available to the public until a reasonable time has been allowed for filing patent applications. NSF will notify the grantee of receipt of requests for copies of funded proposals so the grantee may advise NSF of such inventions described, or other confidential, commercial or proprietary information contained in the proposal.

Exhibit III-1: NSF Proposal & Award Process & Timeline



Chapter IV: Non-Award Decisions and Transactions

A. Proposal Withdrawal

A proposal may be withdrawn at any time before a funding recommendation is made by the cognizant NSF Program Officer. FastLane automates the proposal withdrawal process and provides a mechanism that will help organizations to more effectively manage their proposal portfolio, as well as to help eliminate the submission of duplicate proposals to NSF. The Withdrawals Module includes three processes:

- *Principal Investigator's Proposal Withdrawal* allows a PI to initiate a proposal withdrawal and forward it to the organization's AOR for submission to NSF.

- *Sponsored Projects Office (SPO) Proposal Withdrawal* allows an authorized individual in the organization's SPO to initiate a proposal withdrawal and forward it to the AOR for submission to NSF.

- *Proposal Submission Duplicate Withdrawal* prevents the AOR from submitting a new proposal if a duplicate (a proposal from the same organization with the same title and same PI and co-PIs) already has been submitted to NSF within the last two weeks prior to the current submission. If these conditions are met, the system will allow the AOR to either withdraw the previous duplicate proposal, and then proceed with the submission of the new proposal, or to modify the new proposal so it is different from the previous proposal.

Authorized individuals[42] can initiate or review a proposal withdrawal using the " Proposals/File Updates/Supplements/Withdrawals" Module via the FastLane "Research Administration Functions".[43]

In cases where NSF already has made a funding decision, proposals will not be permitted to be withdrawn via the electronic proposal withdrawal system. When a PI or other authorized official attempts to prepare a proposal withdrawal for such a proposal, a message will be displayed to contact the cognizant NSF Program Officer for further assistance.

NSF must be notified if any funding for the proposed project is received from another source or sponsor. If it is brought to NSF's attention that funding for a proposal to NSF has been accepted from another sponsor, NSF will send a withdrawal confirmation to the PI and the SPO without waiting for the official withdrawal notification.

If a proposal withdrawal is submitted for a proposal that is part of a collaborative effort, regardless of whether the organization is the lead or non-lead, the electronic proposal withdrawal system will withdraw that proposal along with the other remaining proposals that are identified as part of the collaborative effort. If the remaining organizations in the collaborative determine that the project can still proceed, a new collaborative proposal must be submitted.

Copies of reviews received by NSF before a proposal is withdrawn will be provided to the PI. NSF provides notice of a withdrawal, return, declination, or reconsideration to both the PI and the SPO.

[42] AORs also can initiate a proposal withdrawal.
[43] Detailed instructions are available in FastLane at: https://www.fastlane.nsf.gov/documents/epw/epw.jsp.

B. Proposal Not Accepted or Returned Without Review

A proposal will not be accepted[44] or will be returned without review by NSF for the following reasons.

The proposal:

1. is inappropriate for funding by the National Science Foundation (see Chapter I.B);
2. is submitted with insufficient lead-time before the activity is scheduled to begin;
3. is a full proposal that was submitted by a proposer that has received a "not invited" response to the submission of a preliminary proposal (see Chapter I.D.2. and Chapter I.D.2.a);
4. is a duplicate of, or substantially similar to, a proposal already under consideration by NSF from the same submitter (see Chapter I.G.2);
5. does not meet NSF proposal preparation requirements, such as page limitations, formatting instructions, and electronic submission, as specified in Part I of the *Proposal and Award Policies and Procedures Guide* (see Chapters II.A, II.B, and II.C), the NSF *Grants.gov Application Guide,* or program solicitation;
6. is not responsive to the NSF funding opportunity;
7. does not meet an announced proposal deadline date;
8. was previously reviewed and declined and has not been substantially revised (see Chapter IV.E);
9. duplicates another proposal that was already awarded; and/or
10. does not contain each of the required sections of the proposal, as described in Chapter II.C.2.

C. Declinations

A PI whose proposal for NSF support has been declined will receive information and an explanation of the reason(s) for declination along with copies of the reviews considered in making the decision. If that explanation does not satisfy the PI, he/she may request additional information from the cognizant NSF Program Officer or Division Director. See Chapter III.G for additional information.

PIs and co-PIs may access review information from NSF after the decision has received the concurrence of the cognizant NSF Division Director, when all the review information has been released for their proposal.

D. Reconsideration

1. Overview

a. A proposer whose proposal has been declined may ask the cognizant NSF Program Officer or the cognizant NSF Division Director for information over and above the explanatory materials received with the declination notice. If the PI/PD is not satisfied that the proposal was fairly handled and reasonably reviewed, he/she may request reconsideration by the cognizant Assistant Director (AD) or Office Head. An organization (or an unaffiliated PI/PD) still not satisfied after reconsideration by the cognizant AD/Office Head may request further reconsideration by the Deputy Director of the Foundation. The decision made by the Deputy Director is final.

b. If a proposal has been declined after review by the NSB, only an explanation will be available.

c. The aim of any reconsideration is to ensure that NSF's review has been fair and reasonable, both substantively and procedurally. The scientific and technical merits may be examined within the context of budget availability and program priorities. Reconsideration also may address any procedural errors in peer review or other aspects of proposal review, including unaccounted-for conflict of interests or inappropriate consideration of records, information or rumor.

[44] Proposal Not Accepted is defined as FastLane will not permit submission of the proposal.

d. Award of NSF assistance is discretionary and reconsideration is not an adversarial process. A formal hearing, therefore, is not provided. Because factors such as program budget and priorities factor into the decision on a proposal, NSF cannot ensure proposers that reconsideration will result in an award even if error is established in connection with the initial review.

e. No revisions made to the proposal after declination will be considered in connection with the original proposal. A substantially revised proposal, however, may be submitted for review as a new proposal under standard procedures. NSF reserves the right to return without review a proposal that is substantially the same as one that was previously reviewed and declined whether or not a request for reconsideration was made.

2. Applicability

NSF's reconsideration process is available to individuals and organizations concerning proposals for grant funding. It does not apply to:

a. "discourage" (i.e., non-binding) decisions resulting from submission of a preliminary proposal;

b. proposals for:

(1) fellowships;
(2) travel grants;
(3) Rapid Response Grants (RAPID);
(4) EArly-concept Grants for Exploratory Research (EAGER);
(5) Research Advanced by Interdisciplinary Science and Engineering (RAISE); or
(6) Phase I proposals submitted under the Small Business Innovation Research (SBIR) program.

c. proposals returned without review by NSF for failure to:

(1) be submitted with sufficient lead time before the activity is to begin;
(2) meet an announced proposal deadline date; or
(3) meet NSF proposal preparation requirements, such as page limitations, formatting instructions, and electronic submission, as specified in Part I of the PAPPG*,* the NSF *Grants.gov Application Guide,* or program solicitation.

3. Reconsideration Process

The following paragraphs highlight the various stages of the NSF Reconsideration Process, including the necessary procedural aspects of each stage of the process.

a. Explanations by the NSF Program Officer or Division Director

When a proposal is declined, the PI/PD receives verbatim but unattributed copies of any *ad hoc* reviews and the panel summary (if applicable), a description of how the proposal was reviewed, and, if not otherwise provided in the panel summary, an explanation (written or telephoned) of the basis for the declination. A returned proposal also will be accompanied by an explanation. A PI/PD who is considering asking for reconsideration should first contact the cognizant NSF Program Officer or Division Director, who will afford the PI/PD an informal opportunity to seek further clarification.

b. Reconsideration by the Cognizant NSF Assistant Director

(1) If dissatisfied with the explanation provided by the NSF Program Officer or Division Director, the PI/PD may request in writing that NSF reconsider its action. Such a request will be considered only if the PI/PD has first sought and obtained further clarification from the cognizant NSF Program Officer or Division Director, and only if the request is received by the Foundation within 90 days after the declination or the

return. The request should be addressed to the AD/Office Head for the Directorate or Office that handled the proposal and should explain why the PI/PD believes that the declination or return was unwarranted.

(2) The AD/Office Head will reconsider the record to determine whether NSF's review of the declined proposal was fair and reasonable, substantively and procedurally, taking into account availability of funds and the policies and priorities of the program and NSF. In the case of a returned proposal, the record will be reviewed to determine whether the proposed project was inappropriate for NSF consideration. The AD/Office Head may request additional information from the PI/PD and may obtain additional reviews. If additional reviews are sought, they are subject to standard review procedures (e.g., instructions must be provided to reviewers and conflicts-of-interest policies must be followed). The AD/Office Head may conduct the reconsideration personally or may designate another NSF official who had no part in the initial review to do so. As used here, "AD/Office Head" includes such a designated official.

(3) Within 45 days after the date of the request, the AD/Office Head will furnish the results of the reconsideration, in writing, to the PI/PD. If results cannot be furnished within 45 days, the AD/Office Head will send the PI/PD a written explanation of the need for more time, indicating the date when the results can be expected. If the AD/Office Head reaffirms the declination or return, he/she will inform the PI/PD that the PI/PD's organization may obtain further reconsideration by the Deputy Director of NSF as provided below.

c. Further Reconsideration by the NSF Deputy Director

(1) Within 60 days after the AD/Office Head has notified the PI/PD of the results of the reconsideration, the proposing organization or an unaffiliated PI/PD may request further reconsideration by the Deputy Director of NSF.

(2) A request for further reconsideration need not be in any particular format, but it must be in writing, and must be signed by the organization's president or other chief executive officer and by the PI/PD. For declinations, it should explain why the organization believes that an error may have occurred in the initial evaluation and why it is not entirely satisfied with the reconsideration by the cognizant AD/Office Head. For returned proposals, it should explain why the organization believes that an error may have occurred in the initial determination that the proposal was inappropriate for NSF consideration.

(3) The Deputy Director will review the request for further reconsideration and the record of earlier NSF actions, including the original review and the reconsideration by the AD/Office Head, to determine whether NSF's review of the declined proposal was fair and reasonable, or, in the case of a returned proposal, whether the proposed project was inappropriate for NSF consideration. The Deputy Director may request additional information from the PI/PD or the proposing organization and may obtain additional reviews. If additional reviews are sought, they are subject to standard review procedures (e.g., instructions must be provided to reviewers and conflicts-of-interest policies must be followed).

(4) The Deputy Director may conduct the further reconsideration personally or may designate another NSF official who had no part in the initial evaluation of the proposal or the earlier reconsideration to do so. As used here, "Deputy Director" includes such a designated official.

(5) Within 30 days after a request for further reconsideration is received at NSF, the Deputy Director will furnish the results of the further reconsideration, in writing, to the organization. If results cannot be furnished within 30 days, the Deputy Director will send the organization a written explanation of the need for more time, indicating the date when the results can be expected.

(6) The decision made by the Deputy Director is final.

E. Resubmission

A declined proposal may be resubmitted, but only after it has undergone substantial revision. A resubmitted proposal that has not clearly taken into account the major comments or concerns resulting from the prior NSF review may be returned without review. The Foundation will treat the revised proposal as a new proposal, subject to the standard review procedures.

Chapter V: Renewal Proposals

A renewal proposal is a request for additional funding for a support period subsequent to that provided by a standard or continuing grant. A renewal proposal competes with all other proposals and must be developed as fully as though the proposer is applying for the first time. Renewal proposals must be submitted at least six months before additional funding is required or consistent with an established deadline, target date or submission window. In preparing a renewal proposal, proposers should assume that reviewers will not have access to previously submitted versions of the proposal. Please note the National Science Board strongly endorses the principle that all expiring awards are to be recompeted.[45]

All proposals for renewed support of research projects, from academic institutions *only*, must include information on human resources development at the postdoctoral, graduate and undergraduate levels as part of Results from Prior NSF Support.[46] This may involve, but is not limited to, the role of research in student training, course preparation and seminars (particularly for undergraduates). Special accomplishments in the development of professional scientists and engineers from underrepresented groups should be described. Graduate students who participated in the research should be identified by name. This requirement does not apply to non-academic organizations.

PIs are encouraged to discuss renewal proposals with the program prior to submission of a proposal. Unless precluded by individual program requirements, PIs may choose either of the following two formats for preparation of a renewal proposal.

A. Traditional Renewal. The “traditional” renewal proposal is developed as fully as though the proposer were applying for the first time. It covers all the information required in a proposal for a new project, including Results from Prior NSF Support. The 15-page limitation on the Project Description applies.

B. Accomplishment-Based Renewal. In an "Accomplishment-Based Renewal" (ABR) proposal, the Project Description (including the Results from Prior NSF Support) is replaced with the following items:

1. copies of no more than six reprints[47] of publications resulting from the research supported by NSF (including research supported by other sources that is closely related to the NSF-supported research) during the preceding period of NSF support. Of the six publications, two preprints (accepted for publication) may be included;

2. information on human resources development at the postdoctoral, graduate and undergraduate levels; and

3. a brief summary (not to exceed four pages) of plans for the proposed support period.

All other information required for NSF proposal submission remains the same.

---

[45]Reference National Science Board Resolution (NSB-2015-45) entitled, *National Science Board Statement on Recompetition of Major Facilities.* For the operation of a major facility, the National Science Board has endorsed the principle that NSF should perform a rigorous review prior to the end date of the award to determine whether it is in the best interest of US science and engineering to recompete that award (Reference NSB-2015-46).

[46]This requirement applies to both types of renewal proposals: Traditional Renewal and Accomplishment-Based Renewal.

[47]Reprints should be provided as supplementary documentation and should be submitted via the Proposal Preparation Module in FastLane.

It must be clearly indicated in the proposal that it is an ABR submission and the box for "Accomplishment-Based Renewal" must be checked on the Cover Sheet. ABR proposals may not be submitted for consecutive renewals.

PIs are advised that the ABR is a special type of renewal proposal appropriate only for an investigator who has made significant contributions, over a number of years, in the area of research addressed by the proposal. Investigators are strongly urged to contact the cognizant NSF Program Officer prior to developing a proposal using this format.

Descriptions of other forms of additional funding support, including continuing grants and supplemental funding requests, are contained in Chapter VI.

PART II: AWARD, ADMINISTRATION AND MONITORING OF GRANTS AND COOPERATIVE AGREEMENTS

Part II of the NSF *Proposal & Award Policies & Procedures Guide* sets forth NSF policies and procedures regarding the award, administration, and monitoring of grants and cooperative agreements. Coverage includes the NSF award process, from issuance and administration of an NSF award through closeout. Guidance is provided regarding other grant requirements or considerations that either are not universally applicable or do not follow the award cycle. Part II also implements other Public Laws, Executive Orders (E.O.) and other directives insofar as they apply to grants, and is issued pursuant to the authority of Section 11(a) of the NSF Act (42 USC §1870). When NSF Grant General Conditions or an award notice reference a particular section of the PAPPG, then that section becomes part of the award requirements through incorporation by reference.

Chapter VI: NSF Awards

A. Acceptance of Assistance Agreements

Grantees[48] are free to accept or reject the grant as awarded. Normally, a request to drawdown NSF funds constitutes acceptance, however, in limited circumstances, NSF may require formal acceptance of a grant. If the grantee chooses not to accept the award, then a written request should be sent to the cognizant NSF Program Officer to withdraw (or terminate) the grant.

B. Award Instrument

1. Composition of an NSF Award

Composition of an NSF award includes:

a. the award notice, including any special conditions applicable to the award and any numbered amendments thereto;

b. general Federal award information as required by 2 CFR § 200.210;

c. the budget, which indicates the amounts, by categories of expense, on which NSF has based its support;

d. the applicable NSF general conditions referenced in the award notice;

e. the proposal referenced in the award notice; and

f. any NSF program announcement, program solicitation or other documents or special requirements incorporated by reference in the award notice.

2. Award Transmission

NSF transmits award notices to organizations via e-mail. In addition to the e-mail notification, grantees and PIs also may access NSF award notices via use of NSF's electronic systems. SPOs are able to view, print and/or download NSF award notices for their organizations. PIs also may access their award notices via FastLane.

[48] For purposes of this Guide, except where explicitly noted, the term "grant" is interchangeable with the term "cooperative agreement", and the term "grantee" is interchangeable with the "awardee" of a cooperative agreement.

C. NSF Award Conditions

Each NSF award notice specifically identifies certain conditions that are applicable to, and become part of, that award. The award conditions are available electronically on NSF's website at: http://www.nsf.gov/awards/managing/. When these conditions reference a particular PAPPG section, that section becomes part of the award requirements through incorporation by reference.

D. NSF Grant Periods

1. Definitions

a. START DATE is the date specified in the award notice on or after which, except for fixed amount awards, expenditures may be charged to the grant. With the exception of PI transfers, the start date used by NSF is either the 1st or the 15th day of the month. If no start date is specified, then the date of the award notice is the start date. (For preaward expenditures, Chapter X.A.2.b.)

b. END DATE is the date specified in the award notice after which expenditures may not be charged against the grant except to satisfy obligations to pay allowable project costs committed on or before that date. The end date is the last day of a month.

c. AWARD DATE is the date when the NSF award is signed by the cognizant NSF Grants Officer.

d. GRANT PERIOD is the period of time between the start date and the end date of an NSF award shown as the duration.

2. Significance of Grant Period

a. Except in fixed amount awards, an NSF grant gives authority to the grantee to commit and expend funds for allowable costs (see Chapter X) in support of the project up to the grant amount specified in the award notice at any time during the grant period.

b. Except as provided in Chapter X.A.2.b or Chapter X.A.2.c, expenditures may not be charged prior to the start date or subsequent to the end date under an NSF cost reimbursement grant.

3. Changes in a Grant Period

a. Start Date

Once an award is made, the start date cannot be changed; however, grantees have the authority to incur pre-award costs as outlined in Chapter X.A.2.b.

b. End Date

The end date may be changed as a result of approval of a request for continued support of a continuing grant, for a no-cost grant extension, or by approval of a request for supplemental support. When appropriate, the NSF Grants Officer will issue an amendment to the grant.

c. No-Cost Extension

(i) Grantee-Approved Extension. Grantees may authorize a one-time extension of the end date of the grant of up to 12 months if additional time beyond the established end date is required to assure adequate completion of the original scope of work within the funds already made available. This one-time extension may not be exercised merely for the purpose of using the unliquidated balances. Grantees are not authorized to extend an award that contains a zero balance. The grantee shall notify NSF, providing supporting reasons for the extension and the revised period of performance, at least ten calendar days prior

to the end date specified in the grant to ensure accuracy of NSF's grant data. All grantee-approved extension notifications must be signed and submitted by the AOR via use of NSF's electronic systems.[49] For grantee-approved extensions, no amendment will be issued. The revised end date can be viewed via NSF's electronic systems.

(ii) NSF-Approved Extension

(a) If additional time beyond the extension provided by the grantee is required and exceptional circumstances warrant, a formal request must be signed and submitted by the AOR via use of NSF's electronic systems. The request should be submitted to NSF at least 45 days prior to the end date of the grant. All late requests must include a strong justification as to why it was not submitted earlier. The request must explain the need for the extension and include an estimate of the unobligated funds remaining and a plan for their use. As indicated above, that unobligated funds may remain at the end of the grant is not in itself sufficient justification for an extension. The plan must adhere to the previously approved objectives of the project. Such requests must be signed and submitted by the AOR via use of NSF's electronic systems.

(b) The first no-cost extension request will be considered for approval by the cognizant NSF Program Officer. The grantee and the PI will be electronically notified of the disposition of this request by the cognizant NSF Program Officer (an amendment to the grant will not be issued). The second (or any subsequent) no-cost extension request will be subject to the approval of an NSF Grants Officer, and, if approved, will be in the form of an amendment to the grant specifying a new end date. Grantees are cautioned not to make new commitments or incur new expenditures after the end date of the award in anticipation of a no-cost extension. In addition, grantees must be aware that most NSF appropriated funds have a limited period of availability for expenditure before the appropriation cancels. No-cost extensions do not extend the period of availability for canceling funds[50].

d. Two-Year Extensions for Special Creativity

A Program Officer may recommend the extension of funding for certain research grants beyond the initial period for which the grant was awarded for a period of up to two years. The objective of such extensions is to offer the most creative investigators an extended opportunity to attack adventurous, "high-risk" opportunities in the same general research area, but not necessarily covered by the original/current award. Awards eligible for such an extension are generally continuing grants. Special Creativity Extensions are normally initiated by the NSF Program Officer based on progress during the first two years of the grant; PIs will be informed of such action a year in advance of the end date of the grant. In response to the Program Officer's recommendation, the required information must be signed and submitted by the AOR via use of NSF's electronic systems.

E. Additional Funding Support

1. Types of Additional Funding Support

Additional funding of a project beyond the original grant period will be in the form of renewed support, continued support or supplemental support. A description of each of these additional funding mechanisms is provided below.

---

[49] NSF has developed a matrix that lists NSF's electronic capabilities, and whether they can be found in FastLane, Research.gov or both. This matrix will be updated as appropriate, independent of the *Proposal & Award Policies & Procedures Guide* revision cycle. The current version is located at: http://www.nsf.gov/bfa/dias/policy/estatus_matrix.jsp.

[50] In accordance with 31 USC 1552(a), funds will no longer be available for expenditure for any purpose beyond September 30th of the fifth fiscal year after the expiration of a fixed appropriation's period of availability for incurring new obligations – see also Chapter VIII.E for Financial Requirements and Payments.)

2. Renewed Support

Renewed support is defined as additional funding for a support period subsequent to that provided by the original grant. Renewals to grants, if any, will be in the form of a new grant with a new grant number. Costs incurred under the old grant cannot be transferred to the new grant. Residual funds remaining in the old grant cannot be transferred to the new grant.

Instructions for preparation of renewal proposals are contained in Chapters II and V.

3. Support under Continuing Grants

a. Funding increments for projects being supported under continuing grants receive high priority within NSF and normally are not considered in competition with proposals for new grants or for grants for renewed support.

b. Unless otherwise provided for in the original award notice, each increment of a continuing grant will be funded at the level indicated in the original award notice without a formal request, subject to NSF's judgment of satisfactory progress, availability of funds, and receipt and approval of the required annual report. NSF makes every attempt to honor continuing grant commitments. In order to adjust to changes in the general level of funds for a particular field of science or engineering or to major new opportunities in that field, however, NSF may reduce continuing grant increments below the levels indicated in original award notice. This requires full written justification by program staff and management review and approval. In the absence of major unanticipated fiscal year constraints, reductions are rare. Continuing grant increments will be released by the cognizant NSF Program Officer upon approval of the annual report. The SPO and PI will be notified by the cognizant NSF Program Officer of NSF's approval via email.

c. In order to obtain a committed funding increment and ensure continuity of funding, an annual project report must be submitted by the PI electronically via use of Research.gov no later than 90 days prior to the end of the current budget period. (See Chapter VII.D for additional information on submission of project reports.)

4. Supplemental Support

a. In unusual circumstances, small amounts of supplemental funding and up to six months of additional support may be requested to assure adequate completion of the original scope of work. Such requests for supplemental funding support must be signed and submitted by the AOR via use of NSF's electronic systems at least two months prior to the need for the additional funds and must be adequately justified. Program Officers may make decisions regarding whether or not to recommend a small supplement without merit review of the supplemental request. Requests for larger supplements may require external merit review.

b. A request for supplemental support must be submitted electronically via FastLane and must include:

(i) A summary of the proposed work;

(ii) A justification of the need for the supplemental funds; and

(iii) A budget and budget justification, highlighting the use by budget category of the additional funding as distinguished from the original funding provided in those categories of cost. AORs are required to electronically sign the supplemental funding request via the Authorized Organizational Representative Functions in FastLane.

c. NSF will not approve requests for supplemental support for such purposes as defraying the costs of increases in salaries, wages or staff benefits or for additional indirect cost (F&A) reimbursement, whether

caused by a change in the indirect cost rate or by changes in direct cost expenditures which affect the indirect cost base. (See Chapter X.A.2.a.)

d. If approved, the NSF Grants Officer will amend the grant to provide additional funding for the current support period. The amendment notice will specify both the amount of supplemental funding and the cumulative amount awarded through the end date, which normally will remain unchanged.

e. Special NSF programs such as *Research Experiences for Undergraduates* may provide their funding through supplements to other NSF grants. In such instances, the guidance in this section may not be applicable. Please see the applicable NSF funding opportunity for the relevant guidance.

Chapter VII: Grant Administration

A. Monitoring Project Performance

1. Grantee Responsibilities

a. The grantee has full responsibility for the conduct of the project or activity supported under an NSF grant and for the results achieved. The grantee should monitor the performance of the project to assure adherence to performance goals, time schedules or other requirements as appropriate to the project or the terms and conditions of the grant. In order to carry out these responsibilities, each grantee organization shall agree to comply with the applicable Federal requirements for grants and to the prudent management of all expenditures and actions affecting the grant. Documentation for each expenditure or action affecting the grant shall reflect appropriate organizational reviews or approvals, which should be made in advance of the action. Organizational reviews are intended to help assure that expenditures are allowable, necessary and reasonable for the conduct of the project, and that the proposed action:

(i) is consistent with grant terms and conditions;

(ii) is consistent with NSF and grantee policies;

(iii) represents effective utilization of resources; and

(iv) does not constitute changes in objectives or scope.

b. Notwithstanding these responsibilities, NSF continues to encourage communication between NSF Program Officers and PI/PDs on the progress of projects supported by NSF as well as on project changes.

c. NSF, through authorized representatives, has the right, at all reasonable times, to make site visits to review project accomplishments, grantee management control systems and administration and management of the grant and to provide technical assistance as may be required. If any site visit is made by the Foundation on the premises of the grantee or a subrecipient under a grant, the grantee shall provide and shall require its subrecipients to provide all reasonable facilities and assistance for the safety and convenience of the NSF representatives.

2. Grantee Notifications to NSF

The following is a listing of grantee notifications to NSF, including a reference to where additional guidance is provided. All notifications must be submitted via use of NSF's electronic systems. With the exception of significant changes in methods or procedures and significant changes, delays or events of unusual interest, all notifications must be signed and submitted by the AOR via use of NSF's electronic systems.

• Grantee-Approved No-Cost Extension	VI.D.3.c(i)
• Significant Changes in Methods or Procedures (Other than Changes in Objectives or Scope)	VII.B.1.b
• Significant Changes, Delays or Events of Unusual Interest (Other than Changes in Objectives or Scope)	VII.B.1.c
• Annual and Final Cost Share Notification by Recipient	VII.C.3
• Conflicts of Interest that cannot be satisfactorily managed, reduced or eliminated and research that proceeds without the imposition of conditions or restrictions when a conflict of interest exists	IX.A

Certain actions require prior approval from NSF. Guidance regarding prior approval requirements is covered in Chapter X.A.3, and the NSF column of the Research Terms and Conditions, Appendix A.

B. Changes in Project Direction or Management

1. Changes in Objectives, Scope or Methods/Procedures

a. Changes in Objectives or Scope

The objectives or scope of the project may not be changed without prior NSF approval. Such change requests must be signed and submitted by the AOR via use of NSF's electronic systems. If approved by NSF, the Grants Officer will amend the grant. Prior written NSF approval also is required for changes to the Facilities, Equipment and Other Resources section of the approved proposal that would constitute changes in objectives or scope (see Chapter II.C.2.i for further information).

b. Significant Changes in Methods or Procedures

NSF believes that the PI/PD and co-PI/co-PD, operating within the established policies of the grantee organization, should feel free to pursue interesting and important leads that may arise during the conduct of a research (or other grant-supported) project or to adopt an alternative approach which appears to be a more promising means of achieving the objectives of the project. Significant changes in methods or procedures should be reported to appropriate grantee official(s). The PI/PD also must notify NSF via use of NSF's electronic systems.

c. Significant Changes, Delays or Events of Unusual Interest

In the event there are problems, delays or adverse conditions that will materially impact the ability to attain the objectives of the project or to meet such time schedules as may have been proposed, the PI/PD should notify the appropriate grantee official(s). The PI/PD also must notify NSF via use of NSF's electronic systems.

NSF should be informed of any events of unusual interest that occur during the course of the project. Reports, communications or photographs should be submitted via the interim report capability in Research.gov.

2. Changes in PI/PD, co-PI/co-PD or Person-Months Devoted to the Project

The NSF decision to support a proposed project is based to a considerable extent upon its evaluation of the proposed PI/PD and any identified co-PI/co-PD's knowledge of the field of study and his/her capabilities to conduct the project in an efficient and productive manner. This is reflected in the NSF merit review criteria (see Chapter III). The named PI/PD (and co-PI/co-PD) should be continuously responsible for the conduct of the project and be closely involved with the effort.

If the grantee determines that there is a need for the addition of a new co-PI/co-PD, or the current PI/PD or co-PI/co-PD plans to, or becomes aware that he/she will: (i) devote substantially less effort to the project than anticipated in the approved proposal; (ii) sever his/her connection with the grantee organization; or (iii) otherwise relinquish active direction of the project, he/she shall advise the appropriate official at the grantee organization, who shall initiate action appropriate to the situation under the guidelines that follow.

a. Long-Term Disengagement of PI/PD or co-PI/co-PD

(i) In the event the PI/PD or co-PI/co-PD will be disengaged from the project for a period greater than three months (e.g. sabbatical leave) but intends to return, arrangements for oversight of the project must be signed and submitted by the AOR via use of NSF's electronic systems. This information must be provided at least 30 days before departure or as soon as practicable after the prospective disengagement is known. The cognizant NSF Program Officer will provide written approval to the grantee if the arrangements are satisfactory, but no formal amendment to the grant will be made. If the arrangements are not satisfactory to NSF, the grant may be terminated as prescribed in Chapter XII.A.

(ii) In the event the PI/PD or co-PI/co-PD will temporarily be working for NSF as an IPA (Intergovernmental Personnel Act employee) or VSEE (Visiting Scientist, Engineer or Educator), the appropriate officials at the

grantee organization **must** contact the cognizant NSF Program Officer for procedural guidance regarding any existing grants or pending proposals of the PI/PD or co-PI/PD.

b. Changes in Person-Months Devoted to the Project

If the PI/PD or co-PI/co-PD will devote substantially less time to the project than anticipated in the approved proposal, (defined in the applicable grant terms and conditions as a reduction of 25% or more in time) he/she should consult with the appropriate officials of the grantee organization. Requests for changes to the person-months devoted to the project must be signed and submitted by the AOR via use of NSF's electronic systems. If the grantee organization or NSF determines that the reduction of effort will substantially impair the successful execution of the project, the NSF Program Officer will consult the NSF Grants Officer. The NSF Grants Officer may:

(i) request the grantee to nominate a replacement PI/PD or co-PI/co-PD acceptable to the cognizant NSF Program Officer;

(ii) initiate the termination procedures described in Chapter XII.A.; or

(iii) negotiate an appropriate modification to the grant.

c. Addition of co-PI/co-PD

In the event the grantee desires to add a new co-PI/co-PD to a project[51], the AOR must sign and submit the request via use of NSF's electronic systems. The new co-PI/co-PD's name, biographical sketch, current and pending support from all ongoing projects and proposals, as well as a justification for the addition must also be included in the request. The contact information for the new co-PI/co-PD also should be included. If approved by NSF, the Grants Officer will amend the grant.

d. Withdrawal of PI/PD or co-PI/co-PD

In the event the PI/PD or co-PI/co-PD severs his/her connection with the grantee organization or otherwise relinquishes active direction of the project, the AOR must sign and submit a notification of the withdrawal of the PI/PD or co-PI/co-PD via use of NSF's electronic systems. The grantee also must:

(i) initiate transfer of the grant as described in Chapter VII.B.2.f;

(ii) nominate a substitute as described in Chapter VII.B.2.e; or

(iii) initiate grant closeout procedures through submission of final reports as described in Chapter VII.D.2.

e. Substitute (Change) PI/PD or co-PI/co-PD

In the event the grantee desires to continue the project with a substitute PI/PD or co-PI/co-PD, the AOR must sign and submit the request via use of NSF's electronic systems. The substitute PI/PD's name or co-PI/PD's name, biographical sketch, current and pending support from all ongoing projects and proposals, as well as a justification for the substitution must also be included in the request. The contact information for the substitute PI/PD or co-PI/co-PD also should be included. If approved by NSF, the Grants Officer will amend the grant. If not approved, NSF may take steps, pursuant to Chapter XII.A to suspend or terminate the grant.

In cases where a former NSF employee or IPA is being reappointed as PI or co-PI to an award they were previously involved with, the grantee must submit a "Change of PI" request using the FastLane Notifications and Requests module. The change in PI request should include documentation from the AOR designating a substitute negotiator for that award under the Associated Documents section. A co-PI request should designate the PI as the substitute negotiator.

[51] NSF's policy limits the number of co-PIs/co-PDs to four per award.

f. Disposition of a Grant When a PI/PD Transfers from One Organization to Another Organization

(i) Policy. When a PI/PD plans to leave an organization during the course of a grant, the organization has the prerogative to nominate a substitute PI/PD or request that the grant be terminated and closed out. In those cases where the PI/PD's original and new organizations agree, NSF will facilitate a transfer of the grant and the assignment of remaining unobligated funds to the PI/PD's new organization. This should normally be done with a tripartite agreement (involving NSF, the PI/PD's original organization and new organization), or by a subaward arrangement between the PI/PD's original and new organizations, subject to NSF's consent. (See Chapter VII.B.3)

(ii) Procedures. When a PI/PD plans to leave an organization during the course of a grant, the PI/PD or the SPO, shall notify the cognizant NSF Program Officer. If the project is to continue with the original organization, the cognizant NSF Program Officer should advise the grantee to nominate a substitute PI/PD (see Chapter VII.B.2.e). If the project is to be continued at the PI/PD's new organization, and if NSF and both organizations agree, formal notification of the impending transfer can be electronically initiated by either the PI/PD or the PI/PD's organization. The amount transferred has to be equal to or less than the unobligated balance. The request shall include a:

(a) brief summary of progress to date;

(b) description of work yet to be accomplished;

(c) completed on-line transfer request, including total disbursements and unpaid obligations to date (transfer amount will be automatically calculated, based on the amount entered in total disbursements). The original organization is responsible for including in the total estimated disbursements, any anticipated costs yet to be incurred against the original grant;

(d) detailed line item budget for the transfer amount and any outstanding continuing grant increments; and

(e) If funding is requested to support a postdoctoral researcher, then the request must include the requisite mentoring plan as described in Chapter II.C.2.j. The plan must be uploaded under "Mentoring Plan" in the Supplementary Documentation section of Fastlane. The PI must report on the mentoring activities provided to the individual(s) in annual and final project reports.

The original organization concurs with the transfer of the award by electronically forwarding the request to the new organization.

The new organization completes the request by providing a detailed budget for the transfer amount agreed to by both organizations. The AOR of the new organization must sign and submit the request via use of NSF's electronic systems. Submission of the request constitutes agreement by the new organization to assume responsibility for completion of the project effort and to administer the grant (as originally awarded) from the transfer date to completion in accordance with any special terms and conditions and the applicable general terms and conditions that normally govern NSF grants made to the new organization. Special terms and conditions, as appropriate, cited in the original award will convey to the new grantee organization.

NSF will assign a proposal number at the time of submission. This proposal number will become the new grant number when the transfer is approved by an NSF Grants Officer.

(iii) Fund Transfer. Upon receipt of the above material, NSF will review the request and, if approved, deduct the specified transfer amount from the original grant and re-establish it under a new grant number at the new organization. Award notification by the NSF Grants Officer will constitute NSF approval of the grant transfer. The award notification also will specify the applicable general terms and conditions that govern the grant.

(iv) Monetary Discrepancies. Upon transfer of the grant to the new organization, any monetary discrepancies must be resolved between the original and the new grantee. NSF will not intervene in any disputes between the two organizations regarding the transferred amount.

(v) Equipment Transfers. Equipment purchased with NSF funds for use in a specific project should remain available for use for the duration of the project. PI/PDs who are in the midst of projects that included funding for equipment and who will continue the project at a new organization with NSF support, should arrange with their original organization to have the equipment transferred with them. Shipping costs for such equipment may be charged to the original or transferred grant as an allowable cost. Budgets should not include funds to "buy" equipment that had been previously obtained with Federal funds.

(vi) Possible Alternatives to the Transfer Process. When the amount of time and funds remaining in a project are modest, and if both the original and new organizations are in agreement, the original organization may issue a subaward to the new organization for completion of the project. This and other possible alternatives should be discussed with the NSF Grants Officer.

3. Subawarding or Transferring Part of an NSF Award (Subaward)

Excluding the purchase of items such as commercially available materials and supplies, equipment or general support services allowable under the grant, no part of an NSF award may be subawarded or transferred to another organization without prior NSF authorization. The intent to enter into such arrangements should be disclosed in the proposal.

If it becomes necessary to subaward or transfer part of an NSF award after a grant has been made, the grantee shall submit, at a minimum:

a. a clear description of the work to be performed by each subrecipient;

b. a separate budget for each subaward; and

c. If funding is requested to support a postdoctoral researcher, and the original proposal did not include a mentoring plan, then the request must include the requisite mentoring plan as described in Chapter II.C.2.j. The plan must be uploaded under "Mentoring Plan" in the Supplementary Documentation section of Fastlane.

The request must be signed and submitted by the AOR via use of NSF's electronic systems, and NSF authorization will be indicated by an amendment to the grant signed by the Grants Officer. The NSF grant terms and conditions will identify which articles flow-down to subrecipients.

Procurements under NSF grants are subject to Chapter X.C as well as 2 CFR § 200.317-326.

4. Postaward Additions of Postdoctoral Scholars

If a grantee rebudgets funds to support a postdoctoral researcher and the original proposal included a mentoring plan, no further documentation is necessary. If the original proposal did not include a mentoring plan, then the grantee must send the cognizant NSF Program Officer the requisite mentoring plan, as described in Chapter II.C.2.j.

If supplemental funding is requested to support a postdoctoral researcher and the original proposal did not include a mentoring plan, then the supplemental funding request must include the requisite mentoring plan, as described in Chapter II.C.2.j. The plan should be uploaded to the "Other Supplementary Documents" section of the FastLane Supplemental Funding Request module.

In all cases, the PI must report on the mentoring activities provided to the individual in the annual and final project reports.

C. Cost Sharing

1. General

The National Science Board issued a report entitled "*Investing in the Future: NSF Cost Sharing Policies for a Robust Federal Research Enterprise"* (NSB 09-20), which contained eight recommendations for NSF regarding cost sharing. In implementation of the Board's recommendations, NSF's revised guidance[52] (see Chapter II.C.2.g(xii)) is as follows:

- inclusion of voluntary committed cost sharing is prohibited. It should be noted that foregoing full indirect cost rate (F&A) recovery is considered voluntary committed cost sharing; and

- when mandatory cost sharing is included on Line M and accepted by NSF, the commitment of funds becomes legally binding and is subject to audit. Failure to provide the level of cost sharing required by the NSF solicitation and reflected in the NSF award budget may result in termination of the NSF award, disallowance of award costs and/or refund of award funds to NSF by the grantee.

2. Mandatory Cost Sharing Commitments

2 CFR § 200.306 prescribes criteria and procedures for the allowability of cash and in-kind contributions. Grantees should be aware that mandatory cost sharing commitments are subject to audit. Audit findings involving cost sharing have pertained to: a) failure to keep adequate source documentation for claimed cost sharing; b) unclear valuation of in-kind donated contributions; c) lack of support for cost sharing contributions by subrecipients; and d) failure to complete annual certifications for awards with mandatory cost sharing requirements. Additional guidance on cost sharing may be obtained at: http://www.nsf.gov/bfa/dias/caar/costrev.jsp.

3. Mandatory Cost Sharing Records and Reports

a. Grantee Records

Grantees shall maintain records of all project costs that are claimed by the grantee to meet mandatory cost sharing requirements specified in an NSF program solicitation. Records for cost share contributed to NSF awards must be compliant with the requirements of 2 CFR § 200.306, and are subject to audit.

b. Grantee Reports

The amount of mandatory cost sharing must be documented (on an annual and final basis), certified by the AOR, and reported to the cognizant NSF Program Officer via use of NSF's electronic systems. Such notifications must be submitted no later than 90 days prior to the end of the current budget period to meet the annual notification requirement, and no later than 120 days following the end date of the of the grant to meet the final notification requirement. The cost share notification is considered due during the 90 or 120 day period respectively. The notification becomes overdue the day after the respective 90 or 120 day period ends.

c. Changes to the Cost Sharing Amount Specified on Line M of the NSF Award Budget

Should the grantee become aware that it may be unable to provide the cost sharing of at least the amount identified on Line M of the NSF award budget, it must immediately provide written notification to the Grants Officer of the situation; and either: indicate steps it plans to take to secure replacement cost sharing; or indicate the plans it has to either continue or phase out the project in the absence of the approved level of cost sharing.

Should NSF agree to the organization's proposed plans, the NSF Grants Officer will modify the award accordingly, including, if appropriate, reducing the amount of NSF support. Should the organization's plans be unacceptable

[52] See NSF's Revised Cost Sharing Policy Statement for the Foundation's overarching policies on cost sharing.

to NSF, the award may be subject to termination. NSF modifications to proposed cost sharing revisions are made on a case-by-case basis.

Failure by the organization to notify NSF, in accordance with the paragraph above, may result in the disallowance of some or all of the costs charged to the grant; the subsequent recovery by NSF of some or all of the NSF funds provided under the grant; possible termination of the grant; and may constitute a violation of the terms of the award so serious as to provide grounds for subsequent suspension or debarment.

D. Technical Reporting Requirements

NSF requires project reports for all assistance awards. Information from these reports is used in annual reports to Congress to demonstrate the Foundation's performance as mandated by the Government Performance and Results Act (GPRA) of 1993. These reports also provide NSF program officers and administrative offices with information on the progress of supported projects and the way these funds are used. Information in these reports may be made available to the general public through the Freedom of Information Act (FOIA). These reports are fully consistent with and implement the Research Performance Progress Report (RPPR), which is the government-wide standard for use with research and research-related activities. Except where another format is approved by OMB for use by an NSF program, this means that the ''where practicable'' requirement specified in 2 CFR § 200.301 is not required as the RPPR does not relate financial information to performance data.

1. Annual Project Reports

Annual Project Reports should address progress in all activities of the project, including any activities intended to address the Broader Impacts criterion that are not intrinsic to the research. These reports are not cumulative, and should be written specifically for the most recently completed budget period. Unless otherwise specified in the grant, annual project reports should be submitted electronically no later than 90 days prior to the end of the current budget period to allow adequate time for the cognizant Program Officer to review and approve the report.

As reflected in the Project Report System, the report is considered due during the 90 day period. The report becomes overdue the day after the 90 day period ends. Failure to submit timely reports will delay processing of additional funding and administrative actions, including, but not limited to, no cost extensions. In the case of continuing grants, failure to submit timely reports may delay processing of funding increments. See also Chapter VI.E.3.

Annual project reports may not be required for fellowship awards. Specific reporting requirements for fellowships are established in the applicable program solicitation and award conditions.

For multi-year standard grants, PIs are required to submit annual reports as outlined above. In the case of cooperative agreements, the annual report is required before NSF approves any future funding increments.

Continuing grants also are subject to the same policies regarding report submission as outlined above. For continuing grants that have a duration of 18 months or more per increment, two annual reports are required. A report must be submitted for the first 12 months of the project, and then another report for the remaining months of the increment. Continuing grants which include an increment of 24 months will require an annual report for each 12 month period.

2. Final Project Report

The Final Project Report should address progress in all activities of the project, including any activities intended to address the Broader Impacts criterion that are not intrinsic to the research. This report is not cumulative; it is the last annual report of the project and should be written specifically for the most recently completed budget period. By submitting the report, the PI is indicating that the scope of work for the project has been completed and that he/she does not anticipate any further action on the grant, including no cost extension requests, supplemental funding, or transfer of grant. Unless otherwise specified in the award, the final project report should be submitted electronically no later than 120 days following the end date of the grant. As reflected in the Project Report System, the report is considered due during the 120 day period. The report becomes overdue the day

after the 120 day period ends. In addition, the grantee also shall provide to the cognizant NSF Program Officer, within 120 days following the end date of the grant:

- any unique reports or other end items specified in the grant, including any reporting requirements set forth in any NSF brochure, guide, solicitation, etc., referenced in the grant as being directly related to either the award or the administration of the grant.

- a final cost share notification documented and certified by the AOR for grants where there is mandatory cost sharing established for the program.

Final project reports may not be required for institutional graduate research fellowships. However, final reporting requirements for individual fellowships are established in the applicable program solicitation.

3. Project Outcomes Report for the General Public

No later than 120 days following expiration of the grant, a project outcomes report for the general public must be submitted electronically. This report serves as a brief summary, prepared specifically for the public, of the nature and outcomes of the project. This report will be posted electronically by NSF **exactly as it is submitted** and will be accompanied by the following disclaimer:

> "This Project Outcomes Report for the General Public is displayed verbatim as submitted by the Principal Investigator (PI) for this award. Any opinions, findings, and conclusions or recommendations expressed in this Report are those of the PI and do not necessarily reflect the views of the National Science Foundation; NSF has not approved or endorsed its content."

Grantees are to ensure that the report does not contain any confidential, proprietary business information; unpublished conclusions or data that might compromise the ability to publish results in the research literature; or invention disclosures that might adversely affect the patent rights or those of the organization, in a subject invention under the award. Project Outcomes Reports are not to contain any personally identifiable information such as home contact information, individual demographic data or individually identifiable information collected from human research participants.

Section Contents:

a. Describe the project outcomes or findings that address the intellectual merit and broader impacts of the work as defined in the NSF merit review criteria. This description should be a brief (generally, two to three paragraphs) summary of the project's results that is written for the lay reader. PIs are strongly encouraged to avoid use of jargon, terms of art, or acronyms.

b. NSF will automatically include all publications associated with the grant that are reported in annual and final project reports. Other products that have resulted from the grant may also be listed. Examples of other products include collections, data sets, software, as well as educational materials.

c. Information regarding anticipated publication of project results, as well as any other information that would be of interest to the public also may be included in this section.

4. Compliance with Technical Reporting Requirements

PIs must submit final technical reports within the time period specified. **Failure to provide these reports on a timely basis will delay NSF review and processing of pending proposals for all identified PIs and co-PIs on a given grant.**

5. Grant Closeout

Grant closeout is the process by which NSF determines that all applicable administrative actions and all required work of the grant have been completed. Grants will be financially closed out on the first day of each month for all

awards with end dates of 120 or more days prior to the financial closeout day. See also Chapter VI.D.3.c for additional information on no cost extensions. The close out amount will be based on the costs recorded at that time. See also Chapter VIII.E.5 for additional information on post closeout adjustments and final disbursements. Grants are administratively closed after receipt of the Final Project Report and after determination that any other administrative requirements in the grant have been met. In the event a final audit has not been performed prior to the closeout of the grant, NSF reserves the right to recover funds after fully considering the recommendations on disallowed costs resulting from the final audit.

E. Record Retention and Audit

1. Financial records, supporting documents, statistical records and all other records pertinent to the NSF grant must be retained by the grantee for a period of three years from award financial closeout described in Chapter VIII.E.3, except as noted in 2 CFR § 200.333.

2. It is the responsibility of grantees that are States, local governments or non-profit organizations to arrange for the conduct of audits as required by 2 CFR § 200, Subpart F. They shall provide copies of the reports of these audits to the Federal Audit Clearinghouse (see 2 CFR § 200.512(b)). Any Federal audit deemed necessary by NSF shall build upon the results of such audit(s).

3. All awards issued by NSF meet the definition of “Research and Development” (R&D) at 2 CFR § 200.87. As such, auditees should identify NSF awards as part of the R&D cluster on the Schedule of Expenditures of Federal Awards (SEFA). The auditor should test NSF awards for compliance as instructed in Part V, Clusters of Programs. NSF recognizes that some awards may have another classification for purposes of indirect costs (F&A). The auditor is not required to report the disconnect (i.e., the award is classified as R&D for audit purposes but non-research for indirect cost rate (F&A) purposes), unless the auditee is charging indirect costs at a rate other than the rate(s) specified in the award document(s).

Chapter VIII - Financial Requirements and Payments

The acceptance of an award from NSF creates a legal obligation on the part of the grantee organization to use the funds or property made available in accordance with the terms and conditions of the award. Payments may be made in advance of work performed or as a reimbursement for work performed and/or costs incurred by the grantee. Payments, however, may not be made prior to an award being signed by an NSF Grants Officer.

NSF has a revisionary interest in any:

(a) unused funds from advance payments;

(b) improperly applied funds (whether or not received as an advance payment); and

(c) property acquired through the award, to which NSF specifically either retains title or reserves the right to require title transfer.

While the provisions of this Chapter cover all NSF assistance awards (i.e., grants and cooperative agreements), the term "grantee" is used throughout. Graduate fellowship awards to domestic colleges and universities are included, but contracts are excluded. All categories of grantees (academic, non-academic, profit and non-profit) are covered by this chapter. The procedures in this chapter apply primarily to the comptroller's office or business office.

A. Standards for Financial Management

NSF grantees must meet the financial management systems requirements of 2 CFR § 200.302.

B. Definitions

The following definitions are either not included elsewhere in Part II of the PAPPG or are repeated in this Chapter because of their special applicability.

1. ADVANCE PAYMENT - means a payment that NSF makes by any appropriate payment mechanism, including a predetermined payment schedule, before the grantee disburses the funds for program purposes.

2. BUSINESS OFFICER – means the financial official of the grantee organization who has primary responsibility for the accountability for, and reporting on, NSF award funds.

3. CASH ON HAND – means a grantee organization's cash position relative to the funds received from NSF minus the costs incurred for the award.

4. DISBURSEMENTS/OUTLAYS/EXPENDITURES – means charges made by the grantee to a project or program for which an NSF award was received.

5. FINANCIAL FUNCTIONS – means the NSF systems and services used by grantees to transmit financial information to NSF. Grantees must access Financial Functions through Research.gov. The primary Financial Functions used by grantees are:

(a) Award Cash Management Service (ACM$) – means NSF's award payment process under which grantees provide award level detail at the time of the payment request. ACM$ replaced both the reporting of expenditures on the Federal Financial Report (FFR) and the Cash Request Function.

(b) Federal Financial Report History – means the electronic version of the standard "Federal Financial Report". This was used by grantees prior to ACM$ implementation to report the financial activity of NSF awards on a quarterly basis.

6. GRANTEE - means the organization or other entity that receives a grant and assumes legal and financial responsibility and accountability both for the awarded funds and for the performance of the grant-supported activity. NSF grants are normally made to organizations rather than to individual PI/PD(s). Categories of eligible proposers may be found in Chapter I.E.

7. NSF OBLIGATIONS – means funds authorized by an NSF Grants Officer for a specific NSF award creating a balance payable to a grantee.

8. GRANTEE OBLIGATIONS – means orders placed for property and services, contracts and subawards made, and similar transactions during a given period that require payment by the grantee during the same or a future period.

9. PAYMENTS – means the funds transferred from NSF to the grantee by electronic funds transfer (Automated Clearing House (ACH)) and on some rare occasions by check or by wire for same day electronic funds transfer or international payments.

10. UNLIQUIDATED OBLIGATIONS –

(a) for grantees operating on a cash basis, means obligations incurred by the grantee that have not been paid (liquidated).

(b) for grantees operating on an accrual expenditure basis, means obligations incurred by the grantee for which an expenditure has not been recorded.

11. UNOBLIGATED BALANCE – means the amount of funds under an NSF award that the grantee has not obligated. The amount is computed by subtracting the cumulative amount of the grantee's unliquidated obligations and expenditures of funds under the NSF award from the cumulative amount of the funds that NSF has authorized the grantee to obligate.

C. Payment Requirements

1. Requesting Payments

NSF grantees, except for some Special Payment grantees (see Chapter VIII.C.4), and some foreign grantees, are required to request payments electronically through ACM$. Under ACM$, grantees must provide award level detail at the time of the payment request.

Certain Special Payment grantees and foreign grantees without access to a US bank are required to request funds by submitting a "Request for Advance or Reimbursement Form", (SF 270), to NSF either through mail, email or by fax.

2. Payment Policies

The purpose of this section is to prescribe the timing of advances and the procedures to be observed to ensure that cash payments occur only when essential to meet the needs of a grantee for its actual disbursements.

a. Timing of Payments. Advance payments to grantees must be limited to the minimum amounts needed. The timing of advanced payments must be in accordance with the actual, immediate cash requirements of the grantee in carrying out the purpose of the approved program or project. The timing and amount of advance payments must be as close as is administratively practicable to the actual disbursements by the grantee for direct program or project costs and the proportionate share of any allowable indirect costs (F&A).

b. Payments to Subrecipients and Contractors. Payments made by NSF grantees to subrecipients and contractors shall conform to the same standards of timing and amount as apply to payments by NSF to its grantees.

c. Withholding Payments. NSF reserves the right, upon written notice, to withhold future payments after a specified date if the grantee either:

(i) fails to comply with the terms and conditions of an NSF award, including the reporting requirements; or

(ii) is indebted to the US Government.

Payments will be released to the grantee upon subsequent compliance.

d. Safeguarding Funds. In no case will NSF funds be commingled with the personal funds of, or be used for personal purposes by, any officer, employee, or agent of the grantee; nor will any of these funds be deposited in personal bank accounts for disbursement by personal check.

3. Request for Payment

a. Grantees may submit requests for payments as often as they like and may submit payment requests for reimbursement or in advance of costs incurred. The following conditions must exist for grantees submitting payment requests in advance of costs incurred:

(i) Funds for the project period have been obligated by a Grants Officer in the form of an electronically signed grant;

(ii) The grantee has established written procedures that will minimize the time elapsing between the transfer of funds from the US Treasury and their disbursement by the grantee; and

(iii) The grantee's financial management system meets the standards for fund control and accountability prescribed in 2 CFR § 200.302.

b. Grantees shall maintain advances of NSF funds in interest bearing accounts as specified in Chapter VIII.D.3.

4. Special Payment Grantees

When grantees do not meet the conditions specified in Chapter VIII.C.3 above, or when otherwise considered appropriate, NSF may restrict their capability to request funds through ACM$ or they may be required to request funds by using a Request for Advance or Reimbursement (SF 270) form. The cognizant NSF Grants Officer is responsible for establishing the documentation requirements for special payment grantees. Documentation may be submitted by email, by fax to 703-292-9142, or through the mail to:

National Science Foundation
Division of Grants & Agreements
2415 Eisenhower Avenue
Alexandria, VA 22314

5. Working Capital Advance

In those cases where the reimbursement method described in Chapter VIII.C.3 is not feasible, arrangements may be made whereby NSF projects are financed on a working capital advance basis. On this basis, funds may be advanced to the grantee to cover estimated disbursement needs for a given initial period. Thereafter, the grantee would be reimbursed for the amount of its actual cash disbursements. The amount of the initial advance shall be geared to the reimbursement cycle so that after the initial period, the advance approximately equals the average amount of the grantees' unreimbursed program disbursements.

6. Grantee Banking Information for Payments

The System for Award Management (SAM) is the NSF system of record for organizational financial information. Once a grant is awarded, failure to maintain current and complete financial information within SAM could prevent the grantee from receiving funds.

D. Cash Refunds and Credits to NSF

1. Final Unobligated Balance

NSF has a reversionary interest in the unobligated balance of an award upon the end date or completion of the award. Based on final payment amounts submitted through ACM$, the final unobligated balance will be computed by NSF and de-obligated from the award amount.

2. Erroneous Payments

Advances or reimbursements made in error must be refunded to the National Science Foundation. Excess funds should be promptly refunded electronically or by check. Electronic remittances should be submitted through Pay.gov at: https://pay.gov/paygov/forms/formInstance.html?agencyFormId=10506005. Checks shall be mailed to NSF, Attn. Cashier, 2415 Eisenhower Avenue, Alexandria, VA 22314. Contact the NSF Division of Financial Management at (703) 292-8280 for additional information.

The only exception to the requirement for prompt refunding is when the funds involved will be disbursed immediately. This exception for prompt refunding should not be construed as approval by NSF for a grantee to maintain excessive funds on hand.

3. Interest Earned on Advance Payments

The following provisions implement the applicable portions of 2 CFR § 200.305 on interest income.

Grantees shall maintain advances of NSF funds in interest bearing accounts, unless any of the following apply:

a. The grantee receives less than $120,000 in Federal awards per year;

b. The best reasonably available interest bearing account would not be expected to earn interest in excess of $500 per year on Federal cash balances;

c. The depository would require an average or minimum balance so high that it would not be feasible within the expected Federal and non-Federal cash resources; or

d. A foreign government or banking system prohibits or precludes interest bearing accounts.

Grantees may retain interest earned amounts up to $500 per year for administrative expenses. Any additional interest earned on Federal advance payments deposited in interest-bearing accounts must be remitted annually to the Department of Health and Human Services Payment Management System (PMS) through an electronic medium using either Automated Clearing House (ACH) network or a Fedwire Funds Service payment. Remittances must include pertinent information of the payee and nature of payment in the memo area (often referred to as "addenda records" by financial institutions) as that will assist in the timely posting of interest earned on Federal funds. The remittance must be submitted as follows:

(i) For ACH Returns:

Routing Number: 051036706

Account number: 303000

Bank Name and Location: Credit Gateway—ACH Receiver St. Paul, MN

(ii) For Fedwire Returns*:

Routing Number: 021030004

Account Number: 75010501

Bank Name and Location: Federal Reserve Bank Treas NYC/Funds Transfer Division New York, NY

(* Please note organization initiating payment is likely to incur a charge from your Financial Institution for this type of payment)

(iii) For International ACH Returns:

Beneficiary Account: Federal Reserve Bank of New York/ITS (FRBNY/ITS)

Bank: Citibank N.A. (New York)

Swift Code: CITIUS33

Account Number: 36838868

Bank Address: 388 Greenwich Street, New York, NY 10013 USA

Payment Details (Line 70): Agency

Name (abbreviated when possible) and ALC Agency POC: Michelle Haney, (301) 492-5065

(iv) For grantees that do not have electronic remittance capability, please make check** payable to: "The Department of Health and Human Services."

Mail Check to Treasury approved lockbox:

HHS Program Support Center, P.O. Box 530231, Atlanta, GA 30353-0231

(** Please allow 4-6 weeks for processing of a payment by check to be applied to the appropriate PMS account)

(v) Any additional information/instructions may be found on the PMS website at: http://www.dpm.psc.gov/.

4. Program Income

a. Background

The following provisions implement the applicable portions of 2 CFR § 200.307 on program income.

b. Definition

PROGRAM INCOME means gross income earned by the grantee that is directly generated by a supported activity or earned as a result of the grant during the period of performance. Program income includes, but is not limited to, income from fees for services performed, the use of rental or real or personal property acquired under the grant, the sale of commodities or items fabricated under the grant, license fees and royalties on patents and copyrights, and principal and interest on loans made with grant funds. Interest earned on advances of Federal funds is not program income. Except as otherwise provided in Federal statutes, regulations, or the terms and conditions of the grant, program income does not include rebates, credits, discounts, and interest earned on any of them.

Note: Registration fees collected under NSF-supported conferences are considered program income.

c. NSF Policy

(i) Standard Treatment

Unless otherwise specified in the grant, program income received or accruing to the grantee during the period of the grant is to be retained by the grantee, added to the funds committed to the project by NSF, and thus used to further project objectives. The grantee has no obligation to NSF with respect to program income received beyond the period of the grant. The grantee also shall have no obligation to NSF with respect to program income earned from license fees and royalties for copyrighted material, patents, patent applications, trademarks, and inventions produced under an award. However, Patent and Trademark Amendments (35 USC 18) shall apply to inventions made under an award.

Efforts should be made to avoid having unexpended program income remaining at the end date of the grant. Program income earned during the project period should be expended prior to requesting reimbursement against the grant. In the event a grantee has unexpended program income remaining at the end of the grant, it must be remitted to NSF by crediting costs otherwise chargeable against the grant. If it is not possible to record the credit via ACM$, the excess program income must be remitted to NSF electronically or by check payable to the National Science Foundation. (See section D.2 above for further information.)

(ii) Special Treatment

In exceptional circumstances, the NSF Grants Officer, in collaboration with Program Officers and other appropriate NSF offices, may approve use of a special grant provision to restrict or eliminate a grantee's control of income earned through NSF-supported activities if it determines that this would best serve the purposes of a particular program or grant. The special provisions may require treatment of the program income via use of the deductive method, the Federal share of program income be kept in a separate account, or reported on and/or remitted for such periods as may be reasonable under the circumstances.

If, in accordance with the grant terms and conditions program income is designated for deductive treatment, it must be remitted to NSF by crediting costs otherwise chargeable against the grant. Program Income in excess of the award will be remitted to NSF electronically or by check payable to the National Science Foundation.

(iii) Program Income Reporting Requirements

On an annual basis, grantees are required to submit a Program Income Reporting Worksheet to NSF in order to report program income earned and expended for any of their grants or to validate that they did not earn and expend program income for any of their grants during the applicable period.

(a) The Program Income Reporting Worksheet utilizes the standard, OMB-approved government-wide data elements from the Program Income section of the Federal Financial Report (SF 425).

(b) The Program Income Reporting Worksheet in Microsoft Excel is available to grantees through the Program Income page of Research.gov. Grantees are required to report the award number, amount of program income earned, amount of program income expended, and the amount of unexpended program income remaining as of the applicable period. Grantees that have no program income to report will be able to validate that status by an email response. The Program Income Reporting Worksheet is due 45 days after the end of the Federal fiscal year.

Failure to report program income or to validate that no program income was earned/expended could result in suspension of future grant payments.

5. Other Cost Credits

Purchase discounts, rebates, allowances, credits resulting from overhead rate adjustments and other credits relating to any allowable cost received by or accruing to the grantee shall be credited against NSF award costs if the grant has not been financially closed out. See also Chapter X.A.2.c.

E. Award Financial Reporting Requirements and Final Disbursements

NSF does not require grantees to submit FFRs for each award for purposes of final award accountability. NSF procedures have been designed to extract the final financial data from the entries in ACM$. This is accomplished as follows:

For any award listed on the ACM$ Payments screen, the grantee will enter the final payment amount in the Payment Amount Requested column to complete final financial reporting to NSF. Considerations for financial closeout are as follows:

1. After closeout, if final disbursements change by $1.00 or more from the final award amount, then the grantee should submit an "Adjustment to a Financially Closed Award" through the ACM$ payment process.

2. Grantees must liquidate all obligations incurred under their awards not later than 120 calendar days after the award end date.

3. NSF will financially close awards 120 days after the award end date and the award will be removed from the ACM$ payment screen for active awards. Any remaining funds that exceed the final payment amount will be deobligated from the award so the net award balance will equal total payments.

4. Grantees also have the option of using ACM$ to designate awards for financial closeout prior to NSF's regularly scheduled close out date. Grantees can complete that action by selecting the Final Flag on the ACM$ payment screen. (Note that the flag cannot be unchecked at a later date and should typically not be used for original awards that transferred to another awardee organization). Selecting the Final Flag will financially close the award upon posting of the ACM$ transaction to the NSF financial accounting system, typically overnight.

5. Grantees are authorized to make upward or downward adjustments to the Federal share of costs for a financially closed award within the following time limits:

- Upward adjustments may be submitted through ACM$ for up to 14 months after the financial closeout date of the award or until the appropriated funds cancel[53], whichever is earlier.

- Downward adjustments may be submitted through ACM$ until the appropriated funding for the award cancels. The time limitation for ACM$ downward adjustments has no effect on the requirement that the grantee return any funds due to NSF as a result of later refunds, corrections, or other transactions including final indirect cost rate adjustments. In cases where the award appropriation has been canceled, the grantee should return the funds associated with the downward adjustment in accordance with section D. Cash Refunds and Credits to NSF.

6. NSF will notify grantees of any canceling appropriations on open awards in order for grantees to properly expend and draw down funds before the end of the Federal fiscal year. Notifications regarding canceling appropriations must not be interpreted as authorization to draw down remaining grant funds simply to avoid losing them. Grantees are reminded that "the timing and amount of advance payments must be as close and as administratively practicable to the actual disbursements…" in accordance with Chapter VIII.C.2, and that all excess funds drawn must be returned to NSF promptly. See section C. above for additional information on grant payments. If only a portion of the awarded funds are canceling, then NSF will reduce the available balance of the award. If all funds under the award are canceling appropriations, then NSF must financially close the award no later than September 30th regardless of the award end date. No extensions, requests for payment, or upward adjustments will be allowed beyond the end of the Federal fiscal year in which the funds cancel. Although in this situation awards may be financially closed early, grantees will still have the full 120-day closeout period to submit final project reports in accordance with the grant terms and conditions.

[53] In accordance with 31 USC 1552(a), funds will no longer be available for expenditure for any purpose beyond September 30th of the fifth fiscal year after the expiration of a fixed appropriation's period of availability for incurring new obligations.

Chapter IX: Grantee Standards

NSF encourages the increased involvement of academic researchers and educators with industry and private entrepreneurial ventures, but recognizes that such interactions carry with them an increased risk of conflicts of interest. Chapter IX.A contains NSF's policy on conflicts of interest.

2 CFR § 200 prescribes three separate sets of standards related to the financial and program management of Federal grants, each governing a different area: financial management, property management, and procurement management. Chapter IX.C, IX.D and IX.E implement these standards, and extend their applicability to all types of grantees of NSF grants, including for-profit organizations.

A. Conflict of Interest Policies

1. NSF requires each grantee organization employing more than fifty persons to maintain an appropriate written and enforced policy on conflict of interest and that all conflicts of interest for each award be managed, reduced or eliminated prior to the expenditure of the award funds. If the organization carries out agency-funded research through subrecipients or collaborators, the organization must take reasonable steps to ensure that:

a. the entity has its own policies in place that meet the requirements of this policy; or

b. investigators working for such entities follow the policies of the primary organization.

Guidance for development of such policies has been issued by university associations and scientific societies.

2. An organizational conflict of interest policy should require that each investigator disclose to a responsible representative of the organization all significant financial interests of the investigator (including those of the investigator's spouse and dependent children): (i) that would reasonably appear to be affected by the research or educational activities funded or proposed for funding by NSF; or (ii) in entities whose financial interests would reasonably appear to be affected by such activities.

The term "investigator" means the PI/PD, co-PI/co-PDs, and any other person identified on the proposed project who is responsible for the design, conduct, or reporting of research or educational activities funded or proposed for funding by NSF.

The term "significant financial interest" means anything of monetary value, including, but not limited to, salary or other payments for services (e.g., consulting fees or honoraria); equity interest (e.g., stocks, stock options or other ownership interests); and intellectual property rights (e.g., patents, copyrights and royalties from such rights).

The term does not include:

a. salary, royalties or other remuneration from the proposing organization;

b. any ownership interests in the organization, if the organization is an applicant under the Small Business Innovation Research Program or Small Business Technology Transfer Program;

c. income from seminars, lectures, or teaching engagements sponsored by public or non-profit entities;

d. income from service on advisory committees or review panels for public or nonprofit entities;

e. an equity interest that, when aggregated for the investigator and the investigator's spouse and dependent children, meets both of the following tests: (i) does not exceed $10,000 in value as determined

through reference to public prices or other reasonable measures of fair market value; and (ii) does not represent more than a 5% ownership interest in any single entity; or

f. salary, royalties or other payments that, when aggregated for the investigator and the investigator's spouse and dependent children, are not expected to exceed $10,000 during the prior twelve-month period.

3. An organizational policy must ensure that investigators have provided all required financial disclosures at the time the proposal is submitted to NSF. It must also require that those financial disclosures are updated during the period of the award, either on an annual basis, or as new reportable significant financial interests are obtained.

4. An organizational policy must designate one or more persons to review financial disclosures, determine whether a conflict of interest exists, and determine what conditions or restrictions, if any, should be imposed by the organization to manage, reduce or eliminate such conflict of interest. A conflict of interest exists when the reviewer(s) reasonably determines that a significant financial interest could directly and significantly affect the design, conduct, or reporting of NSF-funded research or educational activities.

Examples of conditions or restrictions that might be imposed to manage, reduce or eliminate conflicts of interest include, but are not limited to:

a. public disclosure of significant financial interests;

b. monitoring of research by independent reviewers;

c. modification of the research plan;

d. disqualification from participation in the portion of the NSF-funded research that would be affected by significant financial interests;

e. divestiture of significant financial interests; or

f. severance of relationships that create conflicts.

If the reviewer(s) determines that imposing conditions or restrictions would be either ineffective or inequitable, and that the potential negative impacts that may arise from a significant financial interest are outweighed by interests of scientific progress, technology transfer, or the public health and welfare, then the reviewer(s) may allow the research to go forward without imposing such conditions or restrictions.

5. The organizational policy must include adequate enforcement mechanisms, and provide for sanctions where appropriate.

6. The organizational policy must include arrangements for keeping NSF's Office of the General Counsel (OGC) appropriately informed if the organization finds that it is unable to satisfactorily manage a conflict of interest and if the organization finds that research will proceed without the imposition of conditions or restrictions when a conflict of interest exists.[54]

When OGC is notified of an unmanageable conflict of interest by a grantee, OGC will conduct the following review:

[54] Grantee notifications of conflict of interest that cannot be managed, reduced, or eliminated and awardee notifications of situations where research will proceed without the imposition of conditions or restrictions when a conflict of interest exists, must be signed and submitted by the AOR via use of NSF's electronic systems.

a. Examine a copy of the organization's conflict of interest policy to ascertain if the policy includes procedures for addressing unmanageable conflicts.

b. Contact the grantee organization's representative to determine what actions the organization plans/has taken with respect to the reported unmanageable conflict of interest, ensuring consistency with their conflict of interest policy.

c. Request confirmation from the grantee when proposed actions have been accomplished.

7. Organizations must maintain records of all financial disclosures and of all actions taken to resolve conflicts of interest for at least three years beyond the termination or completion of the grant to which they relate, or until the resolution of any NSF action involving those records, whichever is longer.

B. Responsible Conduct of Research (RCR)

1. Background

The responsible and ethical conduct of research (RCR) is critical for excellence, as well as public trust, in science and engineering. Consequently, education in RCR is considered essential in the preparation of future scientists and engineers. Section 7009 of the America Creating Opportunities to Meaningfully Promote Excellence in Technology, Education, and Science (COMPETES) Act (42 USC 1862o–1) requires that ''each institution that applies for financial assistance from the Foundation for science and engineering research or education describe in its grant proposal a plan to provide appropriate training and oversight in the responsible and ethical conduct of research to undergraduate students, graduate students, and postdoctoral researchers participating in the proposed research project."

The language specified below provides NSF's implementation of Section 7009.

2. Institutional Responsibilities

a. An institution must have a plan in place to provide appropriate training and oversight in the responsible and ethical conduct of research to undergraduates, graduate students, and postdoctoral researchers who will be supported by NSF to conduct research. As noted in Chapter II.C.1.d, institutional certification to this effect is required for each proposal.

b. While training plans are not required to be included in proposals submitted to NSF, institutions are advised that they are subject to review, upon request.

c. An institution must designate one or more persons to oversee compliance with the RCR training requirement.

d. Institutions are responsible for verifying that undergraduate students, graduate students, and postdoctoral researchers supported by NSF to conduct research have received training in the responsible and ethical conduct of research.

C. Financial Management Systems Standards

NSF grantees are required to have financial management systems which meet the requirements of 2 CFR § 200.302.

D. Property Management Standards

2 CFR §§ 200.310-316 prescribe standards for managing and disposing of property furnished by the Federal government or whose cost was charged to a project supported by a Federal grant. In the rare

instances where NSF grants involve the acquisition of real property, the real property standards of 2 CFR § 200.311 are applicable to such NSF grants. NSF implementation of the OMB standards on intangible property is contained in Chapter XI.D.

Title to materials developed and supplies purchased under an NSF grant will vest in the grantee, subject to the conditions identified in paragraph 2. below.

2 CFR § 200.312 contains a special category of "exempt property." Under that provision, any Federal agency which has statutory authority (such as NSF) may vest title in an institution of higher education, hospital or other non-profit organization without further obligation to the Federal government and under conditions the agency considers appropriate. NSF's authority is provided by the Federal Technology Transfer Act (15 USC 3710.)

1. Title to Equipment

a. Title to Equipment - Non-Profit Organizations

(i) Normal Situations. Unless otherwise specified in the grant, title to equipment purchased or fabricated with NSF grant funds by a college or university or other non-profit organization will vest in the grantee organization upon acquisition. Such equipment is considered "exempt property" (see Chapter IX.D) and subject to the conditions of Chapter IX.D.2.

(ii) Special Situations. In special situations the grant may require that title to equipment purchased, acquired or fabricated by the grantee with NSF funds pass directly to the government upon acquisition.

b. Title to Equipment – For-Profit Organizations

Unless otherwise specified in the grant, title to equipment purchased or fabricated with NSF grant funds by a small business or other for-profit organization will vest in the government. Such equipment will be acquired and used in accordance with Chapter IX.D.2, and managed in accordance with Chapter IX.D.4.

2. Conditions for Acquisition and Use of Equipment

a. Grantee Assurance. The grantee will assure each purchase of equipment is:

(i) necessary for the research or activity supported by the grant;

(ii) not otherwise reasonably available and accessible;

(iii) of the type normally charged as a direct cost to sponsored agreements; and

(iv) acquired in accordance with organizational practice.

b. General Purpose Equipment. Expenditures for general purpose equipment are typically not available for support.

c. Equipment Usage. The equipment must remain in use for the specific project for which it was obtained in accordance with 2 CFR § 200.313 unless the provision in 2 CFR § 200.313(c)(4) applies.

d. Equipment Sharing. The equipment must be shared on other projects or programs in accordance with 2 CFR § 200.313(c)(1).

e. Property Management Standards. The grantee shall maintain a property management system which, at a minimum, meets the requirements of 2 CFR § 200.313(d).

f. Competition. In accordance with 2 CFR § 200.313(c)(3), grantees shall not use equipment acquired with Federal funds to provide services for a fee that is less than private companies charge for equivalent services, unless specifically authorized by statute, for as long as the Federal government retains an interest in the equipment.

g. Right to Transfer Title.

(i) In accordance with 2 CFR § 200.313(e), NSF may identify items of equipment having a unit acquisition cost of $5,000 or more where NSF reserves the right to transfer the title to the Federal government or to a third party named by the Federal government.

(ii) In such cases where NSF elects to transfer the title, disposition instructions will be issued no later than 120 days after the end date of the NSF-supported project for which it was acquired.

3. Principles Relating to the Use of NSF-Supported Research Instrumentation and Facilities

The following principles on use of NSF-supported instrumentation and facilities were adopted by the NSB:

> The National Science Foundation seeks the maximum productive use of the Nation's scientific instrumentation and research expertise. Ensuring that the highest quality instrumentation, facilities, and services are available to scientific users, both academic and industrial, is a key requirement, as are harmonious relations and cooperation between industry and universities. Private research and testing laboratories, as well as university, government, and industrial laboratories, have a contribution to make.
>
> The National Science Board recognizes that there may be circumstances where NSF grantees use NSF-supported research instrumentation to provide services in commerce for a fee, to an extent that such practice, (1) detracts from the performance of their obligation under the grant, and/or (2) may have a material and deleterious effect on the success of private companies engaged in the provision of equivalent services. It is contrary to the NSF's intent for grantees to use NSF-supported research instrumentation or facilities to provide services for a fee in competition with private companies in a manner that is prohibited by 2 CFR § 200.313(c)(3).

Grantees should implement the above principles and related grant conditions in a reasonable manner. Grantees are expected to provide fair and adequate consideration of any complaints about use of instrumentation and facilities.

4. Property Management Standards When Title Retained by NSF

In the event that title to equipment or property is vested in the Federal government, such property shall be marked, tagged or segregated in such a manner as to indicate clearly its ownership by the government. Unless otherwise provided in the grant, such government property shall be used only for the performance of the project. The grantee shall submit an annual inventory report by NSF grant number of such property having an original acquisition cost of $5,000 or more, to the NSF Property Administrator, Division of Administrative Services (DAS). A physical inventory of Government-Owned Equipment (GOE) shall be conducted every two years pursuant to 2 CFR § 200.313(d)(2). Upon expiration of the grant, the grantee shall report the property to the Property Section for further agency utilization. (See Chapter IX.D.5.)

5. Excess Government Personal Property

a. Policy

(i) As a means of expanding the ability of grantees to accomplish NSF objectives while conserving supply and equipment funds, NSF will continue to sponsor the transfer of excess government personal property to NSF grantees.

(ii) Excess government personal property includes all types of personal equipment and materials (except consumable items such as drugs, paint, etc.), new or used, owned by the Federal government and no longer needed by the holding agency, but having additional useful life. Under regulations established by the General Services Administration (GSA), the agency charged with operating this program, excess government personal property may be reported to, or requested from, GSA by other Federal agencies, including NSF.

(iii) NSF will sponsor the transfer of excess government personal property to eligible organizations under one of the following conditions:

(a) the use of the property significantly furthers an NSF grant-supported activity;

(b) the property is such that it would have been procured under the grant for which property is being requested if additional grant funds had been available;

(c) the property is used as part of the grant activity and subsequently for research or science education purposes; or

(d) the property is classified by GSA as scientific or engineering research equipment and has a unit acquisition cost of $1,000 or more. (See Chapter IX.D.5.f.)

b. Eligibility

Eligible organizations are NSF grantees that are public or private colleges or universities or non-profit organizations whose primary purpose is the conduct of research or science education activities. State and municipal governments, public health units, hospitals, for-profit firms and individual PI/PDs are not eligible for excess government personal property under NSF sponsorship.

c. Procedures

(i) To access a worldwide inventory of available excess personal property, an eligible grantee should contact the Property Administrator (fsrpts@nsf.gov), DAS to become a registered user of GSAXcess® (GSA's online personal property system located at: http://gsaxcess.gov/).

(ii) Grantees can visit GSAXcess® to screen for items that are necessary to accomplish the NSF supported project by searching GSA's inventory and adding items to the Selection Cart. Excess personal property is reported by Category (Federal Supply Classification (FSC)) and includes the item control number, name, location, quantity available, and unit of issue, original acquisition cost, surplus release date and condition of items posted. In some instances a photograph of the property item is available.

(iii) Materials and equipment so selected should be inspected whenever possible (see Chapter IX.D.5.d), or the holding Federal agency should be contacted by the grantee to verify the condition of the items, because interpretation of condition codes can vary among agencies.

(iv) If the condition of the item is acceptable, the grantee should freeze items by Checkout of the Selection Cart to generate a Transfer Control Number/SF 122, *Transfer Order Excess Personal Property*.

(v) The grantee should next submit the SF 122, *Transfer Order Excess Personal Property* and a separate written justification statement, if necessary, to the Property Administrator, DAS. The justification will explain why the property is needed to reduce the cost or enhance the performance under the specific grant for which the property is requested.

(vi) The SF 122 should be signed by either the PI/PD or the AOR. The following information should also be provided on each SF 122:

(a) name of grantee;

(b) grant number;

(c) grant end date;

(d) the statement "The above equipment is requested for use by the grantee in support of research or education as outlined in the grant"; and

(e) the statement "Transfer is in accordance with the provisions of 41 CFR § 101.43." The grantee should also verify the automatic release date with GSA to preclude loss of property before the transaction is processed.

(vii) The written justification should detail the scientific need for the equipment as it relates to the particular grant under which the equipment is to be used, and should cite the conditions of this section as being binding upon the grantee, should the property be acquired.

(viii) Upon receipt by NSF, the SF 122 will be reviewed and forwarded to the appropriate GSA Office. Items are usually allocated on a first come, first served basis. Since GSA may have several freezes on a piece of equipment, first come, first served is interpreted as the first approved SF 122 received by the GSA office and designated Area Property Officer (APO). However, preference will be given by GSA to agencies which do not grant title to equipment. As confirmation of approval, the grantee will receive copies of the SF 122 from the GSA APO. If the request is disapproved, it will be returned to the grantee with an appropriate explanation.

(ix) Upon receipt of the requested property, the grantee should immediately return a copy of the SF 122 to NSF as evidence of delivery. Cancelations by GSA, or nonreceipt within a reasonable period of time should also be reported to NSF after follow-up inquiries have been made to GSA.

d. Visiting Holding Agency Facilities

(i) Under current GSA regulations all non-Federal grantee representatives wishing to visit holding agency facilities to screen or freeze government excess personal property must receive prior certification from GSA. Because of current security protocols, the holding agency may require written authorization for access.

(ii) The number of screeners on a grant should be limited to no more than two persons. The primary screener should be the PI/PD. However, if the PI/PD finds it impossible to screen, he/she may designate, in writing, a substitute.

(iii) Normally, certification will be on a regional basis; however, NSF will, under certain circumstances, sponsor grantee representatives who need to make interregional visits in order to secure equipment not readily available within their region.

e. Dollar Limitation

To ensure equitable distribution of excess government personal property, grantees may be authorized to acquire property under each NSF grant up to a total acquisition cost equal to the dollar value of that particular grant. Any request for excess property which causes the total to exceed the value of the grant will require additional justification beyond that requested in Chapter IX.D.5.c. A higher percentage of excess property requested under a particular grant by a grantee must be approved by an administrative level in NSF which is higher than the cognizant Program Officer. NSF will give full consideration to all factors in determining whether to approve transfers of excess property above the dollar value of a given grant. Grantees are therefore urged to be selective in their requests for excess government personal property to limit quantities of each item where possible and to avoid stockpiling items for future use.

f. Restrictions

(i) NSF will sponsor the transfer of excess government personal equipment to eligible organizations only under project grants. As defined in the GSA regulations, "project grants" refers to grants made for specific purposes with established termination dates, e.g., grants made to specific organizations to perform specific tasks within set time frames and costs. No excess property may be acquired on behalf of conference, publication-support grants or travel grants. In addition, on "summer-type training grants," no property may be acquired after the training period has terminated. Further, grantees should exercise careful judgment on the appropriateness of requesting excess personal property when only a short period of time exists between the date of the property request and the completion or successful accomplishment of the NSF-supported activity. GSA will consider items of personal property as research equipment for transfer without reimbursement to NSF for use by a grantee when the property requested has a unit acquisition cost of $1,000 or more and is within Federal Supply Classification Groups:

(a) 12 Fire Control Equipment;

(b) 14 Guided Missiles;

(c) 43 Pumps and Compressors;

(d) 48 Valves;

(e) 58 Communication, Detection and Coherent Radiation Equipment;

(f) 59 Electrical and Electronic Equipment Components;

(g) 65 Medical, Dental and Veterinary Equipment and Supplies;

(h) 66 Instruments and Laboratory Equipment;

(i) 67 Photographic Equipment;

(j) 68 Chemical and Chemical Products; or

(k) 70 General Purpose Automatic Data Processing Equipment, Software, Supplies and Support Equipment.

Automatic data processing equipment must be acquired under the provisions in 41 CFR § 201.23.

(ii) GSA will give consideration to the transfer without reimbursement of items of excess property in other Federal supply classification groups and items with a unit acquisition cost of less than $1,000, when NSF certifies that the item requested is a component part of or related to a piece of research equipment or is an otherwise difficult to acquire item needed for scientific or engineering research. Items of property determined by GSA to be common-use or general purpose property, regardless of classification or unit acquisition cost, shall not be transferred to a grantee for the purpose of cannibalization, unless the granting agency sends with the transfer request a supporting statement which clearly indicates that disassembly of the requested item for secondary use of its component parts, or for repair and maintenance of a similar item, has greater potential benefit than utilization of the item in its existing form and that a clear cost savings to the government will result, subject to final determination by GSA.

g. Costs

Excess government personal property is usually secured without cost. However, the grantee should specify the method of shipment and must pay all costs of packing, transportation and subsequent installation, rehabilitation and maintenance if required. Grant funds may be used to pay such costs.

h. Title

Title to excess government personal property obtained by colleges, universities, and other non-profit grantees through NSF sponsorship remains with the government until the property is delivered to the grantee organization. Upon delivery, the grantee should forward to NSF a receipted SF 122 which clearly lists the items of property actually obtained by the grantee. Unless NSF informs the grantee to the contrary, when this SF 122 is received at NSF, title to all property acquired will automatically pass to and be vested in the grantee organization, subject to the understanding that the property will be used for research or for science education purposes as long as it has a useful life. At such time as the property is no longer useful for such purposes, it may be disposed of in accordance with organizational practices, but any proceeds therefrom shall be used by the grantee solely for research or science education purposes. Under certain conditions, such as when highly specialized equipment is involved, NSF may retain title to excess property. When such a condition exists, NSF will inform the grantee. Excess government personal property may not be transferred to a foreign country without the express written approval of the Grants Officer.

i. Accountability and Recordkeeping

(i) While no particular type of classification of accounts or inventory system is required, NSF expects that the responsible officials of the grantee organization will exercise careful stewardship of excess government personal property acquired in support of projects undertaken with NSF's financial assistance. In accordance with Chapter IX.D.5.e, relating to the dollar limitation on the amount of excess government personal property provided by NSF, grantees should maintain appropriate inventory procedures that will enable them to identify those requests which require more extensive administrative and scientific justification. In those cases where title to excess government personal property remains with the government, the grantee must maintain suitable records to identify its location, description, utilization and value. The use of excess government personal property under an NSF grant is subject to inspection and audit by representatives of NSF at all reasonable times during the life of the grant under which the property was acquired.

(ii) Further details may be obtained from the Property Administrator, Division of Administrative Services, National Science Foundation, 2415 Eisenhower Avenue, Alexandria, VA 22314.

E. Procurement Standards

NSF grantees shall adhere to the requirements of 2 CFR §§ 200.317-326 which prescribes standards for use by grantees in establishing procedures for the procurement of supplies and other expendable property, equipment, real property and other services with Federal funds.

Chapter X: Allowability of Costs

A. Basic Considerations

Expenditures under NSF cost reimbursement grants are governed by the Federal cost principles and must conform with NSF policies where articulated in the grant terms and conditions, grant special provisions and grantee internal policies. While grantees are encouraged to seek advice regarding the treatment of costs from the NSF Grants Officer identified in the award notice, it is the grantee that is ultimately responsible for ensuring that all costs charged to NSF awards meet the requirements of the cost principles contained in 2 CFR § 200, Subpart E.[55], grant terms and conditions, and any other specific requirements of both the award notice and the applicable program solicitation. In addition, grantees should ensure that their own internal policies and procedures and other requirements are met for all charges to NSF grants. Otherwise such costs may be disallowed during audit resolution or by specific determination of an NSF Grants Officer.

In the event a grantee anticipates charging an item of direct cost that might subsequently be disputed, an authorized official of the grantee organization should discuss the matter with the cognizant NSF Grants Officer and document the conditions or factors surrounding the item in order to avoid possible subsequent disallowance. If the NSF Grants Officer determines that such costs are appropriate considering the special requirements of a particular NSF sponsored activity, this should be documented through an advance agreement or understanding. Advance agreements regarding the treatment of such costs may be incorporated by specific language in the award notice, or by other written correspondence.

1. Conflicting Guidelines

It is NSF's intent that the following guidance on cost allowability be consistent with the Federal cost principles. However, in the event of any discrepancy between the summary information contained in this Chapter and any specific provision of the cost principles contained in 2 CFR § 200, Subpart E, the cost principles in effect as of the start date of the NSF grant will govern. In the case of a discrepancy between the special provisions of an NSF grant and the standards of the cost principles, the special provisions of the grant will govern.

2. Other Considerations

a. Maximum Obligation

The maximum obligation of NSF for support of the project will not exceed the amount specified in the grant, as amended. NSF does not amend grants to provide additional funds for such purposes as reimbursement for unrecovered indirect costs resulting from the establishment of final negotiated rates, or for increases in salaries, fringe benefits and other costs.

b. Pre-Award Costs

(1) Grantees may incur allowable pre-award costs within the 90-day period immediately preceding the start date of the grant providing:

(a) the approval of pre-award spending is made and documented in accordance with the grantee's procedures; and

(b) the advanced funding is necessary for the effective and economical conduct of the project.[56]

[55] Applicable cost principles for for-profit organizations are contained in Federal Acquisition Regulation Part 31.
[56] In the case of a renewal award, grantees are reminded that costs incurred under the old grant cannot be transferred to the new grant.

(2) Pre-award expenditures are made at the grantee's risk. Grantee authority to approve pre-award costs does not impose an obligation on NSF: (a) in the absence of appropriations; (b) if an award is not subsequently made; or (c) if an award is made for a lesser amount than the grantee anticipated.

(3) Requests for pre-award costs for periods exceeding 90 days must be submitted to NSF via use of NSF's electronic systems. Pre-award expenditures prior to funding of an increment within a continuing grant are not subject to this limitation or approval requirement, but are subject to paragraph (2) above.

Additional information on pre-award costs is available at 2 CFR §§ 200.308(d)(1) & (d)(4).

c. Post-End Date Costs

NSF funds may not be expended subsequent to the end date of the grant, except to liquidate valid commitments that were made on or before the end date, e.g., commitment of project funds for subrecipient or contractor for services rendered during that award period but not billed to the grantee until after the grant ended. (See Chapter VIII.E.2.) Generally, the costs of equipment or materials and supplies ordered after the end date may not be charged to the project.

In addition, the grantee typically should not purchase items of equipment, computing devices, or restock materials and supplies in anticipation of the end date of the grant where there is little or no time left for such items to be utilized in the actual conduct of the research.
However, in accordance with 2 CFR § 200.461, Publication and Printing costs, grantees may charge the NSF award before closeout for the costs of publication or sharing of research results, if the costs are not incurred during the period of performance of the award.

3. Prior Written Approvals

The funding of items identified in the NSF grant budget constitutes NSF's authorization for the grantee to incur these costs, provided there is not a specific limitation in the grant language and the costs are otherwise allowable, allocable, and reasonable in accordance with the cost principles contained in 2 CFR § 200, Subpart E.

If required in furtherance of the project, the grantee is authorized to transfer funds from one budget category to another for allowable expenditures. Grantees should refer to the applicable grant terms and conditions referenced in the grant. The Research Terms and Conditions (RTC), Appendix A, (NSF column) provides a consolidated listing of prior approvals that are required to be obtained from NSF. Unless otherwise specified in the grant notice, no additional prior approvals beyond those specified in RTC Appendix A are required. Chapter VII.A.2 also provides a listing of required notifications to NSF.

When a change requires NSF approval, the request must be submitted via NSF's electronic systems. The request should clearly state which budget items, if any, are to be changed and by what amounts, and should explain the reasons for any changes.

B. Direct Costs

1. Compensation - Personal Services

a. Salaries and Wages

Compensation paid or accrued by the organization for employees working on the NSF-supported project during the grant period is allowable, in accordance with 2 CFR § 200.430.

b. Fringe Benefits

If the proposer's usual accounting practices provide that its contributions to employee benefits (leave, employee insurance, social security, retirement, other payroll-related taxes, etc.) be treated as direct costs, NSF grant funds may be requested to fund fringe benefits as a direct cost. These are typically determined by application of a calculated fringe benefit rate for a particular class of employee (full time or part-time) applied to the salaries and wages requested. They also may be paid based on actual costs for individual employees, if that institutional policy has been approved by the cognizant Federal agency for Indirect Costs.

Fringe benefits that are not accrued but are charged as direct costs and incurred under "pay as you go plans" may be subject to reasonableness determination where the benefits are earned under other work and charged to the last activity on which the employee was working. This is of particular concern for large lump sum payments for leave, disability, pregnancy or other employee fringe benefits. See 2 CFR § 200.431 for the definition and allowability of fringe benefits.

2. Intra-University (IHE) Consulting

Since intra-university consulting is assumed to be undertaken as a university obligation requiring no compensation in addition to full-time salary, the principles summarized in Chapter X.B.1, also apply to those who function as consultants or otherwise contribute to a project conducted by another faculty member of the same institution. However, in unusual cases where consultation is across departmental lines or involves a separate or remote operation, and the work performed by the consultant is in addition to his/her regular appointment, any charges for such work representing extra compensation above the institutional base salary are allowable if consistent with established university policy and the applicable cost principles.

3. Federal Employees

Employees of the Federal government (other than NSF) may be utilized as lecturers or staff members on a project and may receive compensation and/or expenses if they obtain prior approval from their agencies to participate, and if services to the project are performed outside their regular working hours or while they are on leave status from official duties. Under no circumstances may NSF employees receive compensation from an NSF-supported project.

C. Other Direct Costs

1. Rearrangement and Reconversion Costs

a. Except under certain programs, NSF does not normally make grants for construction or facility improvements. However, rearrangement and reconversion costs that do not constitute construction (i.e., rearrangement and reconversion costs aggregating $25,000 or less) may be allowable under NSF grants to adapt space or utilities within a completed structure to accomplish the objective of the NSF-supported activity, provided that the:

(i) grantee is not an individual or a foreign organization;

(ii) building has a usable life consistent with project purposes and is architecturally suitable for conversion;

(iii) rearrangement and reconversion costs are essential to the project supported by the grant; and

(iv) space involved will actually be occupied by the project. In situations where the space is rented, in order for the costs of the rearrangement and reconversion to be allowable, the grantee must secure a lease for the length of the project.

b. Rearrangement and reconversion expenditures which do not exceed $25,000 may be approved by grantees. For rearrangement and reconversion expenditures exceeding $25,000, the grantee must request prior approval from NSF via use of NSF's electronic systems. Otherwise, any plans for such rearrangement or reconversion should be clearly set forth in the proposal. If approved by NSF, such approval must be indicated in the award notice. Note that 2 CFR § 200, Appendix II contains provisions that must be included in contracts made by the grantee.

See 2 CFR § 200.462 for additional information on rearrangement and reconversion costs.

2. News Release Costs

Costs of communicating with the public and press to announce the results and accomplishments of an NSF-supported project are allowable. Grantees should be aware of the restrictions on advertising, organizational promotion, and lobbying costs as outlined in the applicable cost principles. See 2 CFR § 200.421 for additional information on advertising and public relations.

In the event the performing organization wishes to collaborate with NSF in a simultaneous news release, arrangements may be made through the NSF's Office of Legislative and Public Affairs, Public Affairs Group, telephone (703) 292-8070.

3. Travel and Temporary Dependent Care Costs

Travel, meal and hotel expenses of grantee employees who are not on travel status are unallowable. Costs of employees on travel status are limited to those specifically authorized by 2 CFR § 200.474.

Temporary dependent care costs (a dependent is defined in 26 USC 152) above and beyond regular dependent care that directly results from travel to conferences are allowable costs provided that the costs are:

a. a direct result of the individual's travel for the NSF conference award;

b. consistent with the grantee's documented travel policy for all employee travel; and

c. only temporary during the travel period.

See 2 CFR § 200.474 for additional information on travel costs.

D. Indirect Costs

1. NSF Policy

a. Except as noted in an NSF program solicitation, it is NSF policy that grantees are entitled to reimbursement from grant funds for indirect costs (F&A) allocable to the NSF share of allowable direct costs of a project. NSF program staff are not authorized to negotiate indirect costs as a discrete item of a proposal

budget. NSF program staff also are not authorized to suggest or request that PI/PDs seek reductions or waivers of indirect costs.

b. The awarded indirect cost rate is generally based upon a grantee's current Federally negotiated indirect cost rate agreement. When establishing an indirect rate for an award where the domestic grantee does not have a current negotiated rate agreement, NSF will consider the rate proposed in the budget, the grantee's indirect cost proposal submission, the amount of total funding requested and other pertinent financial factors. Supporting documentation is not required for organizations that request a *de minimis* rate of 10% (or less) of modified total direct costs. Since some types of rates limit indirect cost recoveries and require adjustments, grantees receiving awards should ensure that they understand the type of indirect cost rate, the applicable base and the type of rate used in the grant.

Foreign grantees that do not have a US Federally negotiated indirect cost rate are limited to a *de minimis* indirect cost rate recovery of 10% of modified total direct costs. Foreign grantees that have a negotiated rate agreement with a US Federal agency may recover indirect costs at the current negotiated rate.

Types of indirect cost rates that are most frequently used on NSF awards are as follows:

(i) Predetermined Rate – As authorized by 41 USC § 4708, and recommended by the Federal cost principles in 2 CFR § 200, Appendices III, IV, and VI, NSF has elected to use predetermined rates, where appropriate. A predetermined rate is an indirect cost rate, applicable to a specified current or future period, usually the organization's fiscal year. The rate is based on an estimate of the costs to be incurred during the period. A predetermined rate is not subject to adjustment.

Special Limitation concerning Predetermined Rates at Colleges and Universities subject to 2 CFR § 200 Appendix III, paragraph C.7 contains an additional restriction on recovery of indirect costs for colleges and universities and other organizations of higher education. These awardees are subject to a further limitation in that the negotiated rate at the time the award is made shall be used throughout the life of the award. The applicable text from 2 CFR § 200 Appendix III, paragraph C.7 is repeated below:

> "7. Fixed rates for the life of the sponsored agreement.
>
> "Federal agencies must use the negotiated rates except as provided in paragraph (e) of §200.414 Indirect (F&A) costs, in effect at the time of the initial award throughout the life of the Federal award. Award levels for Federal awards may not be adjusted in future years as a result of changes in negotiated rates. "Negotiated rates" per the rate agreement include final, fixed, and predetermined rates and exclude provisional rates. "Life" for the purpose of this subsection means each competitive segment of a project. A competitive segment is a period of years approved by the Federal awarding agency at the time of the award. If negotiated rate agreements do not extend through the life of the Federal award at the time of the initial award, then the negotiated rate for the last year of the award must be extended through the end of the life of the Federal award."

Where grantees receive limited NSF funding, the Foundation may elect to set award specific rates as opposed to a formal annual negotiated indirect cost rate agreement. In these cases, the award notice will specify the rate type and application base. If the award notice is silent on the rate type, the rate approved in the award budget will be considered a predetermined rate.

(ii) Provisional (or billing) rate – A provisional rate is a temporary indirect cost rate applicable to a specified period which is used for funding, interim reimbursement, and reporting indirect costs pending the establishment of a final rate for the period.

Grantees with provisional rates are required to submit indirect cost proposals to their cognizant Federal Agency for rate negotiation within six months after the close of each fiscal year. Adjustments to awards for amounts previously billed at provisional rates are required after final indirect cost rates are established.

(iii) Final rate – A final rate is an indirect cost rate applicable to a specified past period which is based on the actual costs of the period. A final rate is not subject to adjustment.

c. NSF will not amend a grant solely to provide additional funds for changes in indirect cost rates.

d. NSF will generally fund continuing grant increments and supplemental support using the negotiated indirect cost rate(s) approved at the time of the initial award. (See Chapter VI.E.)

e. Any negotiations with respect to business and financial matters on specific grants, including the amount of indirect cost reimbursement, are conducted by the cognizant Grants Officer in DGA with an authorized official of the grantee's organization. When other Federal agencies are responsible for negotiating indirect cost rates and an awardee does not have a current negotiated indirect cost rate in effect at the time of award but had a previous indirect cost rate agreement, DGA may elect to use the most recently negotiated rate for award funding purposes. The NSF Cost Analysis and Pre-Award Review Branch in the Division of Institution and Award Support provides advisory assistance to the Grants Officer.

2. NSF Cognizant Organizations

Organizations for which NSF is the cognizant agency for negotiation of indirect cost rates and who do not have approved award specific rates are required to submit indirect cost proposals, reconciled to financial statements, within six months after the close of each accounting year during which NSF has active awards. Indirect cost proposals should be sent to the Cost Analysis and Pre-Award Review Branch. Grantees are responsible for timely submission of indirect cost rate proposals. If the organization is unable to submit their indirect cost rate proposal within the time frame allotted, then an extension should be requested. Failure to submit the indirect cost proposal and to have a negotiated indirect cost rate in place could lead to NSF withholding reimbursement of indirect costs.

See http://www.nsf.gov/bfa/dias/caar/docs/idcsubmissions.pdf for indirect cost rate proposal submission requirements.

Such proposals and requests for extensions in time to submit proposals should be sent electronically to BFACAARMPR@nsf.gov or by paper copy to Lead Analyst Indirect Costs, National Science Foundation, NSF Cost Analysis and Pre-Award Review Branch, 2415 Eisenhower Avenue, Alexandria, Virginia 22314.

E. Fee Payments under NSF Grants

Payment of fees (profit) is allowable only if expressly authorized by the terms and conditions of the NSF award.

Chapter XI: Other Post Award Requirements and Considerations

A. Non-Discrimination Statutes and Regulations

1. General

a. A number of statutes prohibit NSF grantees from discriminating against individuals who participate in any of their programs, services, and activities. These statues include: Title VI of the Civil Rights Act of 1964 (prohibits discrimination on the basis of race, color, or national origin); Section 504 of the Rehabilitation Act of 1973 (prohibits discrimination on the basis of disability); Title IX of the Educational Amendments of 1972 (prohibits discrimination on the basis of sex in Federally assisted education programs or activities); and the Age Discrimination Act of 1975 (prohibits discrimination on the basis of age). In addition to statutory prohibitions, Executive Order (E.O.) 11246 bars various types of discriminatory employment practices under grants for construction, and E.O. 13166 "Improving Access to Services for Persons with Limited English Proficiency (LEP)" requires government agencies to take steps to provide meaningful access to its programs and activities to members of the public who are limited in their English proficiency, including recipients' programs and activities. The following sections discuss the application of each of these Statutes and E.O. 11246 and E.O. 13166 to NSF grantees.

b. When an NSF grantee receives a complaint alleging discrimination under any of these statutes and the complainant requests that NSF conduct the investigation, the original complaint is to be sent to the Director, Office of Diversity and Inclusion (ODI), National Science Foundation, 2415 Eisenhower Avenue, Alexandria, VA 22314

Information on the complaint process can be found at https://www.nsf.gov/od/odi/titlevi_ix.jsp. The complainant may also use the grantee's internal discrimination complaint process. Such processes are required for NSF grantees to implement under Title IX for sex discrimination complaints, including sexual harassment and under Section 504 for disability discrimination complaints. Grantees are prohibited by these regulations from engaging in acts of intimidation, coercion or retaliation against: a) any person who attempts to assert a right protected by these statutes and their implementing regulations; or b) cooperates in any part of NSF's review, investigation and compliance resolution or enforcement process.

c. NSF proposers and grantees are required under these regulations to keep records deemed pertinent to ascertain a grantee's compliance with these regulations. It also requires the grantee to submit to NSF timely, complete and accurate reports, and in such form and containing such information, as NSF may determine to be necessary to ascertain whether the grantee has complied or is complying with these regulations.

d. NSF proposers and grantees are advised that NSF may conduct pre-award and post-award compliance reviews to ensure that the grantee is complying with NSF's civil rights regulations. Grantees are required to provide NSF with access to information, records, grantee officials, grantee program participants, and facilities deemed pertinent by NSF to ascertain a grantee's compliance with these regulations.

e. NSF proposers and grantees are required under these regulations to make available to its participants, beneficiaries, and other interested persons, information regarding these regulations and their applicability to the program(s) under which the grantee receives Federal financial assistance from NSF. Proposers and grantees are also required to make such information available to these parties in such a manner as NSF finds necessary to apprise such persons of the protections against discrimination assured them by these regulations.

f. NSF proposers and grantees may contact ODI at the address in (b) above or at 1-703-292-8020 with any questions regarding these non-discrimination statutes and their implementing NSF regulations and their applicability to their institutions' programs, services and activities.

2. Certification of Compliance/Civil Rights Certifications

Each of these regulations require that as a condition of approval of an assistance proposal, the proposer must execute a Certification of Compliance, whether or not a similar assurance form has been filed with another Federal agency. (See Exhibit II-6 for additional information.). Before any organization serves as a subrecipient on an NSF grant (for other than the purchase of commercially available materials and supplies, equipment or general support services), it must first file an Assurance of Compliance with the grantee. Each NSF grant contains as part of the grant terms and conditions, an article implementing the applicable nondiscrimination statutes and regulations.

3. Title VI of the Civil Rights Act of 1964

a. Background

Section 602 of the Civil Rights Act of 1964 (42 USC § 2000d, et seq.) provides that no person in the US shall, on the grounds of race, color or national origin, be excluded from participation in, be denied the benefits of, or be otherwise subjected to discrimination under any program or activity receiving Federal financial assistance. Section 602 requires that each Government agency which is empowered to extend such financial assistance issue rules or regulations implementing Title VI with respect to such programs or activities administered by the agency.

b. NSF Regulations

NSF regulations implementing Title VI are found at 45 CFR § 611. These regulations apply to grantees, subrecipients and successors in interest. These regulations do not apply to contracts for commercially available materials and supplies, equipment or general support services.

c. Key Procedural and Programmatic Requirements

The procedures for ensuring NSF grantees' compliance with Title VI are found at 45 CFR §§ 611.6-11. These regulations provide for the compliance and investigative actions that NSF may initiate in order to ascertain grantees' compliance with Title VI. These regulations also provide for the enforcement procedures to compel grantee compliance with Title VI if a grantee refuses to take corrective action for violations found during an NSF complaint investigation or compliance review. NSF's Section 504, Title IX and Age Discrimination Act regulations incorporate by reference the Title VI compliance, investigative and enforcement procedures.

4. Section 504 of the Rehabilitation Act of 1973

a. Background

Section 504 of the Rehabilitation Act of 1973, as amended (29 USC § 794) provides that "no otherwise qualified individual with a disability in the United States...shall, solely by reason of her or his disability, be excluded from the participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance...."

b. NSF Regulations

NSF regulations implementing Section 504 are found at 45 CFR § 605. With a few changes, these regulations mirror the regulations issued by the Department of Health and Human Services (DHHS) at 45 CFR § 84. These regulations also apply to subrecipients and successors in interest. These regulations do not apply to contracts for commercially available materials and supplies, equipment or general support services.

c. Key Procedural and Programmatic Requirements

NSF's Section 504 regulations, in addition to prohibiting discrimination on the basis of disability, requires NSF grantees to designate a Section 504 coordinator, publish and adopt procedures to investigate and adjudicate complaints of internally-filed disability discrimination complaints, and notify the public of its obligation to comply with Section 504. NSF's Section 504 regulation also requires NSF grantees to conduct a self-evaluation to determine the accessibility of its programs, services, activities and facilities, and implement modifications, implement corrective actions identified from the self-evaluation and conduct a transition plan to identify those physical elements of the NSF grantee's facilities that are inaccessible to individuals with disabilities and require retrofit. NSF's Section 504 regulations also require that all new construction and alterations to existing facilities are accessible to individuals with disabilities and meet current accessibility standards. See 45 CFR § 605 for all of the regulatory requirements for NSF grantees.

5. Title IX of the Education Amendments of 1972

a. Background

Subject to exceptions regarding admission policies at certain religious and military organizations, Title IX of the Education Amendments of 1972 (20 USC §§ 1681-1686) prohibits discrimination on the basis of sex in any education program or activity receiving Federal financial assistance.

b. NSF Regulations

NSF regulations implementing Title IX are found at 45 CFR § 618. All NSF grantees who provide or operate educational programs as defined in 45 CFR 618.105 must comply with Title IX. These regulations also apply to subrecipients and successors in interest who operate such educational programs. These regulations do not apply to contracts for commercially available materials and supplies, equipment or general support services.

c. Key Procedural and Programmatic Requirements

NSF's Title IX regulations, in addition to prohibiting discrimination on the basis of sex in education programs, requires NSF grantees to designate a Title IX coordinator, publish and adopt procedures to investigate and adjudicate complaints of internally-filed sex discrimination complaints, notify the public of its obligation to comply with Title IX, conduct a self-evaluation to determine whether its programs, services, activities and facilities comply with Title IX and implement corrective actions identified from the self-evaluation. See 45 CFR § 618 for all of the regulatory requirements for NSF grantees under Title IX.

6. Age Discrimination Act of 1975

a. Background

The Age Discrimination Act of 1975, as amended (42 USC § 6101 et seq.), provides that pursuant to regulations issued by DHHS "no person in the United States shall, on the basis of age, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under, any program or activity receiving Federal financial assistance."

b. NSF Regulations

NSF regulations implementing the Age Discrimination Act are found at 45 CFR § 617. These regulations also apply to subrecipients and successors in interest. These regulations do not apply to contracts for commercially available materials and supplies, equipment or general support services.

c. Key Procedural and Programmatic Requirements

NSF's Age Discrimination Act regulations, in addition to prohibiting discrimination on the basis of age in education programs, requires NSF grantees conduct a self-evaluation to determine each recipient shall identify all age distinctions it uses and justify each age distinction it imposes on the program or activity receiving Federal financial assistance from NSF. See 45 CFR § 617 for all of the regulatory requirements under the Age Discrimination Act for NSF grantees.

7. Equal Employment Opportunity under E.O. 11246

a. Background

E.O. 11246, as amended, requires contractors and subcontractors performing Federally assisted construction projects to provide equal opportunity, without regard to race, color, religion, sex or national origin, to persons employed or seeking employment with them. This E.O. may apply to some NSF grants for construction. E.O. 11246 is enforced by the US Department of Labor's Office of Federal Contract Compliance Programs.

b. Grant Condition

In instances when E.O. 11246 is applicable, the grant will include an equal opportunity clause in conformance with regulations issued by the Secretary of Labor at 41 CFR § 60.

8. Limited English Proficiency under E.O. 13166

a. Background

E.O. 13166 requires Federal agencies and NSF grantees to take steps to provide meaningful access to its programs and activities to program participants who are limited English proficient (LEP). The failure to ensure that LEP persons can effectively participate in or benefit from Federally-assisted programs and activities may violate the prohibition under Title VI of the Civil Rights Act of 1964 and NSF's Title VI implementing regulations against national origin discrimination. The US Department of Justice has published guidance to assist NSF grantees in their efforts to comply with Title VI when providing LEP individuals with access to recipient programs, services and activities.

b. Grant Condition

In instances when E.O. 13166 is applicable, NSF grantees should contact NSF's LEP Coordinator within the Office of Diversity and Inclusion for guidance at2415 Eisenhower Avenue, Alexandria, VA 22314.

B. Protection of Living Organisms

1. Human Subjects

a. Background

The grantee is responsible for the protection of the rights and welfare of human subjects involved in activities supported by NSF. All research involving human subjects supported or otherwise subject to regulation by any Federal agency is covered by a policy set forth in the Common Rule, "Protection of Human Subjects" For projects lacking definite plans for the use of human subjects pursuant to 45 CFR § 690.118, NSF can accept a preliminary approval from an IRB that establishes a limited approval period, requires the PI to submit an amendment or new IRB application prior to the expiration date, and stipulates that no work with human subjects, including recruitment, may be conducted until full IRB approval is obtained. Complete

instructions on preparation and submission of proposals that involve use of human subjects are available in Chapter II.D.5.

b. NSF Regulation

(i) NSF's Common Rule on Protection of Human Subjects is available on the NSF website at: https://www.nsf.gov/bfa/dias/policy/docs/45cfr690.pdf. Guidance about the regulation is available at: https://www.nsf.gov/bfa/dias/policy/human.jsp.

(ii) During the life of the award, additional IRB approval must be obtained if the protocols for the use of human subject has been changed substantively from those originally proposed and approved. When an additional IRB approval is required, the organization must provide to the cognizant NSF Program Officer a signed copy of the new IRB approval letter indicating approval of the covered activities and explicitly referencing the title of the award. In the event the grantee's FWA is canceled or lapses, the grantee must immediately notify the NSF Grants Officer identified in the award.

(iii) Supplements to existing awards do not require a separate IRB approval letter. If the scope of the project has been substantively changed from the award, however, a new signed IRB approval letter is required, indicating approval of the covered activities and explicitly referencing the title of the award.

c. Grant Conditions

Each NSF grant contains, as part of the grant terms and conditions, an article implementing NSF regulations on projects involving research with human subjects. In addition, each award notice contains the following language relating to a grantee's responsibilities regarding the use of human subjects during the life of the grant:

> "It is the grantee's responsibility to ensure that any human subjects work conducted under this award has an Institutional Review Board (IRB) approval, where required, and that such approval remains valid at all times that human subjects work is conducted under the award. Failure to comply with this condition will result in suspension and/or termination of the award."

2. Research Involving Recombinant or Synthetic Nucleic Acid Molecules

a. Applicability

This section applies to all research, for which NSF grant funds are used, that falls within the scope of the Guidelines for Research Involving Recombinant DNA or Synthetic Nucleic Acid Molecules (NIH Guidelines) (http://oba.od.nih.gov/rdna/nih_guidelines_oba.html), as amended in March 2013, hereafter referred to as the "Guidelines".

b. Policy

NSF grantees performing research within the US that falls within the scope of the Guidelines shall comply with the Guidelines, including the procedural requirements and any subsequent revisions as they are published in the Federal Register. Grantee responsibilities include:

(i) Each organization involved in the conduct of NSF-supported recombinant or synthetic nucleic acid research subject to the Guidelines must have a standing Institutional Biosafety Committee (IBC) as specified in Section IV of the Guidelines.

(ii) Recombinant or synthetic nucleic acid research subject to the Guidelines must be registered with the IBC indicating compliance with the containment requirements specified in Part III of the Guidelines.

IBCs are required to keep records of recombinant or synthetic nucleic acid research conducted at their organization in a form that is available to NSF upon request.

c. Research Requiring Prior Approval

In certain instances research should not be initiated or registered with IBCs prior to approval and determination of containment level by the Director, NIH. Normally such experiments are reviewed by the Recombinant DNA Advisory Committee before a decision is made by the Director, NIH. Such instances are:

(i) research for which containment levels are not explicitly specified by the Guidelines;

(ii) research involving experiments prohibited by the Guidelines, i.e., requests for exceptions to the Guidelines; and

(iii) requests to perform experiments without regard to the containment specified in the Guidelines, i.e., exemptions from the Guidelines.

3. Vertebrate Animals

a. Background

The grantee is responsible for the humane care and treatment of any vertebrate animal used or intended for use in such activities as field or laboratory research, development, training, experiments, biological testing or for related purposes supported by NSF grants.

b. Federal Regulations

(i) Any grantee performing research on vertebrate animals[57] shall comply with the Animal Welfare Act [7 USC 2131 et seq.] and the regulations promulgated thereunder by the Secretary of Agriculture [9 CFR 1.1-4.11] pertaining to the humane care, handling, and treatment of vertebrate animals held or used for research, teaching, or other activities supported by Federal awards. The grantee is expected to ensure that the guidelines described in the National Academies of Science, Engineering and Medicine (NASEM) Publication, "*Guide for the Care and Use of Laboratory Animals*" are followed and to comply with the *Public Health Service Policy and Government Principles Regarding the Care and Use of Animals* (included as Appendix D to the NAS Guide). Taxon-specific guidelines may be used as supplemental references.[58] Departures from the Guide must be approved by the Institutional Animal Care and Use Committee (IACUC) and based on scientific, veterinary, medical, or animal welfare issues (for more information, see OLAW-Departures from the Guide).

(ii) During the life of the award, additional IACUC approval must be obtained if the protocols for the care of use of vertebrate animals have been changed substantively from those originally proposed and approved. When an additional IACUC approval is required, the organization must provide to the cognizant NSF Program Officer a signed copy of a new IACUC approval letter indicating approval of the covered activities and explicitly referencing the title of the award. In the event the grantee's PHS Assurance is canceled or lapses, the grantee must immediately notify the NSF Grants Officer identified in the award.

[57] In addition to vertebrate animals covered by the Animal Welfare Act, the requirements specified in this coverage also are extended to rats, birds, and mice.

[58] Guidelines to the Use of Wild Birds in Research; Guidelines of the American Society of Mammalogists for the Use of Wild Mammals in Research; Guidelines for the Use of Fishes in Research; Guidelines for the Use of Live Amphibians and Reptiles in Field and Laboratory Research.

(iii) Supplements to existing awards do not require a separate IACUC approval letter. If the scope of the project has been substantively changed from the parent award, however, a new signed IACUC approval letter is required.

(iv) Research facilities subject to the Animal Welfare Act using or intending to use live animals in research and who receive Federal funding are required to register the facility with the Animal and Plant Health Inspection Service (APHIS), US Department of Agriculture. A current listing of licensed animal dealers may also be obtained from APHIS. The location of the nearest APHIS Regional Office, as well as information concerning this and other APHIS activities, may be obtained at: http://www.aphis.usda.gov/.

(v) Awards to US grantees for projects involving the care or use of vertebrate animals at a foreign institution or foreign field site also require approval of research protocols by the US grantee's IACUC. If the project is to be funded through a grant to a foreign institution or through an individual fellowship award that will support activities at a foreign institution, NSF will require a statement from the international organization explicitly listing the proposer's name and referencing the title of the award to confirm that activities will be conducted in accordance with all applicable laws in the foreign country and that the *International Guiding Principles for Biomedical Research Involving Animals* (see http://www.cioms.ch/) will be followed.

c. Grant Conditions

Each NSF grant contains, as part of the grant terms and conditions, an article implementing NSF regulations on projects involving research with vertebrate animals. In addition, each award notice contains the following language relating to a grantee's responsibilities regarding the care or use of vertebrate animals during the life of the grant:

> "It is the grantee's responsibility to ensure that any vertebrate animal work conducted under this award has an Institutional Animal Care and Use Committee (IACUC) approval, where required, and that such approval remains valid at all times that vertebrate animal work is conducted under the award. Failure to comply with this condition will result in suspension and/or termination of the award."

4. Government Permits and Activities Abroad

a. For awards that include activities requiring permits from appropriate Federal, State, or local government authorities, the grantee should obtain any required permits prior to undertaking the proposed activities.

b. The grantee should ensure that activities carried on outside the US are coordinated as necessary with appropriate US and foreign government authorities and that necessary licenses, permits or approvals are obtained prior to undertaking proposed activities. NSF does not assume responsibility for grantee compliance with the laws and regulations of the country in which the work is to be conducted.

5. Life Sciences Dual Use Research of Concern (DURC)

a. Applicability

This section applies to all research, for which NSF grant funds may be used, that potentially falls within the scope of the *US Government Policy for Institutional Oversight of Life Sciences Dual Use Research of Concern* (http://www.phe.gov/s3/dualuse/Pages/default.aspx) as published in September 2014, hereafter referred to as the "Policy".

b. NSF Implementation of the Policy

NSF is committed to preserving the benefits of life sciences research while minimizing the risk of misuse of the knowledge, information, products, or technologies provided by such research. The purpose of NSF's implementation of this Policy is to clarify grantee expectations about NSF-funded research with certain high-consequence pathogens and toxins with potential to be considered dual use research of concern.

Grantees are responsible for monitoring the research progress and for implementation of all appropriate biosafety and biosecurity risk mitigation measures including compliance with all applicable laws and regulations related to that implementation, including the Policy specified above. While the White House Office of Science and Technology Policy has lifted the research funding pause on gain of function research as of January 2017 (https://www.phe.gov/s3/dualuse/Pages/GainOfFunction.aspx), NSF will not consider funding research that would lead to a gain of function for agents of concern.

C. Construction, Rearrangements and Reconversions

1. Davis-Bacon Act

The Davis-Bacon Act (40 USC §§ 276a et seq.) establishes minimum wages to be paid to laborers and mechanics on construction contracts to which the US is a party involving public buildings or public works within the US. A number of other statutes have extended this provision to specific Federal grant programs involving construction. However, unless specifically stated in the grant, the Davis-Bacon Act does not normally apply to NSF grants since grantees normally retain title to property acquired under the grant and the construction, if any, is normally on non-Government land.

2. Bonding and Insurance

The NSF Act (42 USC § 1870c) provides NSF with authority to enter into grants, contracts or other agreements without performance or other bonds. Therefore, unless the grant specifically provides otherwise, NSF does not require performance or other bonds or insurance.

3. Seismic Safety of Buildings

E.O. 12699 *Seismic Safety of Federal and Federally-assisted or Regulated New Building Construction* dated January 5, 1990, requires that consideration be given to seismic hazards in the design of buildings. Very seldom are NSF grantees involved with Federally-assisted construction and rarely are new buildings involved. NSF ensures compliance with the Order through its grantees by inclusion of a specific grant condition in any appropriate grant.

D. Intellectual Property

1. Patents and Inventions

a. Background

(i) The disposition of rights to inventions made by small business firms and non-profit organizations, including universities and other institutions of higher education, during NSF-assisted research is governed by Chapter 18 of Title 35 of the USC, commonly called the Bayh-Dole Act. In accordance with a Presidential Memorandum entitled *Government Patent Policy* issued on February 18, 1983 and under the authority of Section 12 of the National Science Foundation Act of 1950, as amended (42 USC § 1871), NSF applies the policies of the Bayh-Dole Act to all its grantees. The Department of Commerce (DOC) is the lead agency for implementing the Bayh-Dole Act and has published guidance to Federal agencies in 37 CFR §401. NSF's implementing rules are published in 45 CFR § 650.

(ii) NSF's standard Patent Rights clause, published at 45 CFR § 650.4(a) and below at Chapter XI.D.1.c, "Standard Patent Rights Clause" is identical to that prescribed in the DOC guidance (37 CFR § 401.14(a)) except that:

(a) NSF has tailored the clause to apply to grants and to identify NSF;

(b) pursuant to Section 401.5(d) of the DOC guidance (37 CFR § 401.5(d)), NSF has added to paragraph b. of the clause a stipulation that NSF reserves the right to direct a grantee to transfer to a foreign government or research performer such rights to any subject invention as are required to comply with any international treaty or agreement identified when the grant is made as being applicable to the assisted research;

(c) as permitted by Section 401.5(f) of the DOC guidance (37 CFR § 401.5(f)), NSF has added a subparagraph to the end of paragraph f. of the clause to require grantees or their representatives to send NSF confirmations of the Government licenses for subject inventions and of the page of any United States patent application that contains the Federal support clause;

(d) since NSF normally uses the same clause for all subrecipients, the first two subparagraphs of paragraph g. of the clause specified in the DOC guidance have been reduced to one;

(e) paragraph c.1 of the clause has been changed to require that invention disclosures be submitted electronically via the iEdison system; and

(f) paragraph L. of the clause has been changed to require that all communications required by the Patents Rights clause be submitted electronically via the iEdison system unless prior permission is obtained from the NSF Patent Assistant.

b. National Science Foundation Patent Policy

As authorized by the NSB, the Director of the NSF has adopted the following NSF patent policy.

(i) In accordance with the Bayh-Dole Act and the Presidential Memorandum entitled *Government Patent Policy* issued February 18, 1983, NSF will use the Patent Rights clause prescribed by DOC in all its funding agreements for the performance of experimental, developmental or research work, including grants made to foreign entities, unless NSF determines that some other provision would better serve the purposes of that Act or the interests of the US and the general public.

(ii) In funding agreements covered by a treaty or agreement that provide that an international organization or foreign government, research institute or inventor will own or share patent rights, NSF will acquire such patent rights as are necessary to comply with the applicable treaty or agreement.

(iii) If a grantee elects not to retain rights to an invention, NSF will allow the inventor to retain the principal patent rights unless the grantee, or the inventor's employer, if other than the grantee, shows that it would be harmed by that action.

(iv) NSF will normally allow any patent rights not wanted by the grantee or inventor to be dedicated to the public through publication in scientific or engineering journals or as a statutory invention registration. If another Federal agency is known to be interested in the relevant technology, however, NSF may give it an opportunity to review and patent the invention so long as that does not inhibit the dissemination of the research results to the research community.

c. Standard Patent Rights Clause

Each NSF grant contains as part of the grant terms and conditions, an article implementing the standard patent rights clause.

d. Electronic Invention Handling

Grantees are required to use the iEdison System to disclose NSF subject inventions. Detailed instructions for use of that system are provided at: http://s-edison.info.nih.gov/iEdison/ and should be followed for NSF subject inventions except that:

a. All communications required must be provided electronically as a PDF or TIFF file through iEdison unless prior permission for another form of submission is obtained from the NSF Patent Assistant.

b. NSF may request a Utilization or other report or statement regarding a subject invention.

Questions on use of iEdison and requests for permission to submit material in other forms may be sent to the NSF Patent Assistant at patents@nsf.gov, or at the Office of the General Counsel, National Science Foundation, 2415 Eisenhower Avenue, Alexandria, VA 22314.

2. Copyright

a. Rights to Copyrighted Material

The following principles governing the treatment of copyrighted material produced under NSF grants were adopted by the NSB.

(i) NSF normally will acquire only such rights to copyrighted material as are needed to achieve its purposes or to comply with the requirements of any applicable government-wide policy or international agreement.

(ii) To preserve incentives for private dissemination and development, NSF normally will not restrict, or take any part of income earned from, copyrighted material except as necessary to comply with the requirements of any applicable government-wide policy or international agreement.

(iii) In exceptional circumstances, NSF may restrict or eliminate a grantee's control of NSF-supported copyrighted material and of income earned from it, if NSF determines that this would best serve the purposes of a particular program or grant.

b. Standard Copyrighted Material Clause

Unless a special clause has been negotiated, each NSF grant that relates to scientific or engineering research contains as part of the grant terms and conditions, an article implementing the standard copyrighted material requirements.

c. Public Access to Copyrighted Material

NSF's policy on public access to copyrighted material (Public Access Policy) reflects the Foundation's commitment to making certain that, to the extent possible, the American public, industry and the scientific community have access to the results of Federally funded scientific research. Pursuant to this policy, grantees must ensure that articles in peer-reviewed scholarly journals and papers in juried conference proceedings:

- are deposited in a public access compliant repository (as identified in the Public Access Policy);
- are available for download, reading, and analysis within 12 months of publication;
- possess a minimum set of machine-readable metadata elements as described in the Public Access Policy; and

- are reported in annual and final reports with a persistent identifier.

Either the final printed version or the final peer-reviewed manuscript is acceptable for deposit. NSF's Public Access Policy applies to awards, funded in whole or in part, as a result of proposals submitted, or due, on or after January 25, 2016. NSF's Public Access Policy may be viewed at: http://www.nsf.gov/news/special_reports/public_access/index.jsp.
Each NSF grant contains as part of the grant terms and conditions, an article implementing the public access requirements.

3. Special Patent and Copyright Situations

a. Special Grant Provisions

At the request of the prospective grantee or on recommendation from NSF staff, the NSF Grants Officer, with the concurrence of the cognizant NSF Program Officer, may negotiate special patent or copyright provisions when he/she determines that exceptional circumstances require restriction or elimination of the right of a prospective grantee to control principal rights to subject inventions or writings in order to better achieve the objectives of the program, the National Science Foundation Act, or (in the case of inventions) Chapter 18 of Title 35 of the USC. Every special copyright or patent provision will allow the grantee, after an invention has been made or copyrighted material created, to request that it be allowed to retain principal rights to that invention or material, unless doing so would be inconsistent with an obligation imposed on NSF by statute, international agreement or pact with other participants in, or supporters of, the research.

b. Grants Not Primarily for Research

(i) Grants not primarily intended to support scientific or engineering research generally do not contain patent or copyrighted material provisions. Examples of such grants are travel, conference and equipment grants.

(ii) NSF Fellowships and Traineeships. In accordance with Section 212 of Title 35 of the USC, NSF claims no rights to inventions made by fellows or trainees. The following provision will be included in each fellowship or traineeship program solicitation and made part of the grant:

> **INTELLECTUAL PROPERTY RIGHTS**
>
> The National Science Foundation claims no rights to any inventions or writings that might result from its fellowship or traineeship grants. However, fellows and trainees should be aware that the NSF, another Federal agency, or some private party may acquire such rights through other support for particular research. Also, fellows and trainees should note their obligation to include an Acknowledgment and Disclaimer in any publication.

[END OF PROVISION]

c. Grants Affected by International Agreements

(i) Many of the bilateral and multilateral treaties and agreements underlying NSF's international cooperative research programs contain provisions on allocation of rights to inventions or writings. These sometimes require an allocation of rights different from that provided by the standard Copyrighted Material or Patent Rights clauses. In those cases, the standard clauses will be modified through the addition of the following to the grant:

> "This project is supported under the cooperative program listed below. Your rights in inventions, writings, and data may be affected."

The applicable agreement or treaty will be identified immediately beneath that sentence.

(ii) After an invention is disclosed to the Patent Assistant, the recipient of a grant subject to an international agreement will be informed as to what rights, if any, it must transfer to foreign participants. Grantees also may ask the NSF Program Officer for copies of the identified international agreement before or after accepting a grant.

4. Dissemination and Sharing of Research Results

a. Investigators are expected to promptly prepare and submit for publication, with authorship that accurately reflects the contributions of those involved, all significant findings from work conducted under NSF grants. Grantees are expected to permit and encourage such publication by those actually performing that work, unless a grantee intends to publish or disseminate such findings itself.

b. Investigators are expected to share with other researchers, at no more than incremental cost and within a reasonable time, the primary data, samples, physical collections and other supporting materials created or gathered in the course of work under NSF grants. Grantees are expected to encourage and facilitate such sharing. Privileged or confidential information should be released only in a form that protects the privacy of individuals and subjects involved. General adjustments and, where essential, exceptions to this sharing expectation may be specified by the funding NSF Program or Division/Office for a particular field or discipline to safeguard the rights of individuals and subjects, the validity of results, or the integrity of collections or to accommodate the legitimate interest of investigators. A grantee or investigator also may request a particular adjustment or exception from the cognizant NSF Program Officer.

c. Investigators and grantees are encouraged to share software and inventions created under the grant or otherwise make them or their products widely available and usable.

d. NSF normally allows grantees to retain principal legal rights to intellectual property developed under NSF grants to provide incentives for development and dissemination of inventions, software and publications that can enhance their usefulness, accessibility and upkeep. Such incentives do not, however, reduce the responsibility that investigators and organizations have as members of the scientific and engineering community, to make results, data and collections available to other researchers.

e. NSF program management will implement these policies for dissemination and sharing of research results, in a way appropriate to field and circumstances, through the proposal review process; through award negotiations and grant conditions; and through appropriate support and incentives for data cleanup, documentation, dissemination, storage and the like.

(f) Each NSF grant contains, as part of the grant terms and conditions, an article implementing dissemination and sharing of research results.

5. Tangible Property

a. Background

Some NSF grants support collection or creation of tangible property, such as insects, marine life, drilling core samples and genetically-altered microorganisms. As used in this section “tangible property” means any personal property other than equipment (see Chapter II.C.2.g.(iii)), and intellectual property.

b. Legal Rights to Tangible Property

Unless otherwise provided in the grant, all legal rights to tangible property collected or created during NSF-assisted research remain with the grantee or investigators as determined by the policies of the organization. As members of the scientific and engineering community, both grantees and investigators are responsible for making such tangible property appropriately available to other researchers.

E. Publication/Distribution of Grant Materials

1. NSF Policy

NSF advocates and encourages open scientific and engineering communication. NSF expects significant findings from research it supports to be promptly submitted for publication, with authorship that accurately reflects the contributions of those involved. Copyrighted material published in peer-reviewed scholarly journals and papers included in juried conference proceedings must comply with NSF's Public Access Policy as implemented in the grant terms and conditions.

2. Costs

Cost of documenting, preparing, publishing, disseminating and sharing research findings and supporting material are allowable charges against the grant. (See Chapter X.A.2.c.)

3. Responsibilities

Unless otherwise provided in the grant, preparation, content, editing, identification of authorship and submission for publication of significant research findings are the responsibility of the investigators, consistent with such policies and procedures as the grantee may prescribe.

4. Grantee Obligations

a. Acknowledgement of Support. Unless otherwise provided in the grant, the grantee is responsible for assuring that an acknowledgment of NSF support is made:

(i) in any publication (including web pages) of any material based on or developed under this project, in the following terms:

> "This material is based upon work supported by the National Science Foundation under Grant No. (NSF grant number)."

(ii) NSF support also must be orally acknowledged during all news media interviews, including popular media such as radio, television and news magazines.

b. Disclaimer. The awardee is responsible for assuring that every publication of material (including web pages) based on or developed under this award, except scientific articles or papers appearing in scientific, technical or professional journals, contains the following disclaimer:

> "Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation."

c. Copies for NSF. The grantee is responsible for assuring that the cognizant NSF Program Officer is provided access to, either electronically or in paper form, a copy of every publication of material based on or developed under this award, clearly labeled with the award number and other appropriate identifying information, promptly after publication.

d. Compliance with NSF Public Access Policy. The grantee is responsible for ensuring that copyrighted material published in peer-reviewed scholarly journals and papers in juried conference proceedings are accessible to the public in accordance with the grant terms and conditions.

e. Grantees also should note their obligations in regard to copyrights (see Chapter XI.D.2) and their responsibilities as members of the scientific and engineering community to disseminate and share research results (see Chapter XI.D.4).

f. Each NSF grant contains, as part of the grant terms and conditions, an article implementing the grantee obligations regarding the acknowledgement of support and disclaimer.

F. International Considerations

1. Travel to Foreign Countries

a. Policy

(i) Expenses for transportation, lodging, subsistence and related items incurred by project personnel and by outside consultants employed on the project, (see Chapter II.C.2.g.(iv)) who are on travel status on business related to an NSF-supported project are allowable as prescribed in the governing OMB cost principles.

(ii) Except as provided in the governing OMB cost principles, the difference between economy airfare and a higher-class airfare is unallowable. A train, bus or other surface carrier may be used in lieu of, or as a supplement to, air travel at the lowest first-class rate by the transportation facility used. If such travel, however, could have been performed by air, the allowance will not normally exceed that for jet economy airfare.

(iii) Support for the foreign travel of an investigator's dependents is allowable only under the conditions identified in Chapter X.C.5.

b. Use of US-Flag Air Carriers

(i) In accordance with the Fly America Act (49 USC 40118), any air transportation to, from, between, or within a country other than the US of persons or property, the expense of which will be assisted by NSF funding, must be performed by or under a code-sharing arrangement with a US-flag air carrier if service provided by such a carrier is available (see Comptroller General Decision B-240956, dated September 25, 1991). Tickets (or documentation for electronic tickets) must identify the US flag air carrier's designator code and flight number.

(ii) For the purposes of this requirement, US-flag air carrier service is considered available even though:

(a) comparable or a different kind of service can be provided at less cost by a foreign-flag air carrier;

(b) foreign-flag air carrier service is preferred by, or is more convenient for, NSF or traveler; or

(c) service by a foreign-flag air carrier can be paid for in excess foreign currency.

(iii) The following rules apply unless their application would result in the first or last leg of travel from or to the US being performed by a foreign-flag air carrier:

(a) a US-flag air carrier shall be used to destination or, in the absence of direct or through service, to the farthest interchange point on a usually traveled route.

(b) if a US-flag air carrier does not serve an origin or interchange point, a foreign-flag air carrier shall be used only to the nearest interchange point on a usually traveled route to connect with a US flag air carrier.

c. Use of Foreign-Flag Air Carriers

There are certain circumstances under which use of a foreign-flag air carrier is permissible. These circumstances are outlined below:

(i) Airline "Open Skies" Agreement*:*

A foreign-flag air carrier may be used if the transportation is provided under an air transportation agreement between the United States and a foreign government, which the Department of Transportation has determined meets the requirements of the Fly America Act. For information on "Open Skies" agreements in which the United States has entered, please refer to the GSA website at: http://www.gsa.gov/portal/content/103191.

Note on US/European Union Open Skies Agreement

In 2007, the US entered into an “Open Skies” Agreement with the European Union (EU). This agreement was modified in June 2010. The current Agreement gives European Community airlines (airlines of Member States) the right to transport passengers and cargo on flights funded by the US government, when the transportation is between: (1) any two points outside the United States; or (2) a point in the United States and any point outside the United States that the EU airline is authorized to serve under the “Open Skies” Agreement.

In 2011, two significant changes were made to the US/EU Open Skies Agreement. First, EU airlines are now granted the right to transport civilian agency-funded passengers who are NOT eligible to travel on GSA Airline City Pair Contract fares (e.g., grantees) between a point in the United States and a point outside the United States even if there is a GSA Airline City Pair Contract fare in effect between the origin and destination points. An individual, however, who is traveling on a route for which there is a City Pair Contract fare in effect, *and who is eligible for such a fare* (e.g., Federal employee), are required to fly on a US carrier, absent another applicable exception.

Second, under the amended Agreement, EU airlines are now authorized to transport passengers between points in the United States and points outside the EU if the EU airline is authorized to serve the route under the Agreement. This includes flights that originate, arrive, or stop in the EU. Prior to this change, EU airlines were limited to flying passengers between points in the US and points in the EU.

(ii) Involuntary Rerouting

Travel on a foreign-flag carrier is permitted if a US-flag air carrier involuntarily reroutes the traveler via a foreign-flag air carrier, notwithstanding the availability of alternative US-flag air carrier service.

(iii) Travel To and From the US on non-European Community Airlines

Use of a non-European Community foreign-flag air carrier is permissible if the airport abroad is:

(a) the traveler's origin or destination airport, and use of US-flag air carrier service would extend the time in a travel status by at least 24 hours more than travel by a foreign-flag air carrier; or

(b) an interchange point, and use of US-flag air carrier service would increase the number of aircraft changes the traveler must make outside of the US by two or more, would require the traveler to wait four hours or more to make connections at that point, or would extend the time in a travel status by at least six hours more than travel by a foreign-flag air carrier.

(iv) Travel Between Points Outside the US on non-European Community Airlines

Use of a non-European Community foreign-flag air carrier is permissible if:

(a) travel by a foreign-flag air carrier would eliminate two or more aircraft changes en route;

(b) travel by a US-flag air carrier would require a connecting time of four hours or more at an overseas interchange point; or
(c) the travel is not part of the trip to or from the US, and use of a US-flag air carrier would extend the time in a travel status by at least six hours more than travel by a foreign-flag air carrier.

(v) Short Distance Travel

For all short distance travel, regardless of origin and destination, use of a foreign-flag air carrier is permissible if the elapsed travel time on a scheduled flight from origin to destination airport by a foreign-flag air carrier is three hours or less and service by a US-flag air carrier would double the travel time.

2. Charter Flights

Because of the risk of catastrophic loss, NSF does not encourage the use of charter flights as a means of mass transportation for groups of scientists and engineers nor does it make arrangements for purchase of charter flight airline tickets.

3. Projects in a Foreign Country

a. For awards that include activities requiring permits from appropriate Federal, State, or local government authorities, the grantee should obtain any required permits prior to undertaking the proposed activities.

b. The grantee must comply with the laws and regulations of any foreign country in which research is to be conducted. Areas of potential concern include: (1) requirements for advance approval to conduct research or surveys; (2) special arrangements for the participation of foreign scientists and engineers; and (3) special visas for persons engaged in research or studies. NSF does not assume responsibility for grantee compliance with the laws and regulations of the country in which the work is to be conducted.

c. The grantee also should assure that activities carried on outside the US are coordinated as necessary with appropriate US and foreign government authorities and that necessary licenses, permits or approvals are obtained prior to undertaking the proposed activities.

4. Passports and Visas

NSF assumes no responsibility for securing passports or visas required by any person because of participation in an NSF-supported project. For restrictions concerning directly charging visa costs to an NSF award, see 2 CFR § 200.463.

It should be noted that some countries that normally do not require visas for tourists do require special visas for scientists and engineers engaged in research or studies.

G. Intergovernmental Review of Federal Programs

The Foundation's regulation on Intergovernmental Review of National Science Foundation Programs and Activities is published in 45 CFR Part 660.

H. Handling of Information

1. Questionnaires: Data Collection Under NSF Grants

a. Paperwork Control

Under the OMB regulation, *Controlling Paperwork Burdens on the Public* (5 CFR § 1320), if a grantee obtains information from ten or more persons by means of identical questions, it is considered to be "sponsored" by NSF only if:

(i) the grantee is collecting the information at the specific request of NSF; or

(ii) the terms of the grant require specific approval by NSF of the collection or its procedures.

If either of these conditions is met, OMB approval of the data collection is generally required and grantees should obtain the necessary control number from the cognizant NSF Program Officer.

b. NSF Policy

Data collection activities of NSF grantees are the responsibility of grantees, and NSF support of a project does not constitute NSF approval of the survey design, questionnaire content or data collection procedures. No representation may be made to respondents that such data are being collected for, or in association with, NSF or the government. However, this requirement is not intended to preclude mention of NSF support of the project in response to an inquiry or acknowledgment of such support in any publication of this data (see Chapter XI.E.4).

2. Release of Information by NSF

a. Press Releases

Grants for projects which appear to be of special interest to the general public may be made the subject of an NSF or joint NSF/grantee press release to the news media. (See Chapter X.C.2.)

b. Open Government Legislation

(i) Pursuant to the Freedom of Information Act (FOIA) (5 USC § 552), NSF will provide agency records, with certain exceptions, if the request is in writing, includes the requester's name and mailing address, is clearly identified as a FOIA request, and describes the records sought with sufficient specificity to permit identification. The requester also must agree to pay fees that are chargeable under the NSF regulations. Detailed procedures are contained in 45 CFR § 612. Further information is available at: http://www.nsf.gov/policies/foia.jsp.

(ii) The Government in the Sunshine Act (5 USC § 552b) requires that all meetings of the NSB be open to public observation unless the subject falls within one of ten exemptions. NSF's Sunshine Act regulations are contained in 45 CFR § 614. The Sunshine Act and the FOIA cited above, may require NSF to release to the public information, correspondence and documents received by NSF from grantees, unless they fall within the Acts' limited exceptions.

c. Release of Project Reports

NSF expects significant findings from research it supports to be promptly submitted for publication. To the extent permitted by law, NSF will honor requests from grantees that release of Annual and Final Project Reports be delayed to permit orderly dissemination of significant findings through refereed channels. Unless such a request is received or material is marked as proprietary, such reports may be made available

to others without notice to the grantee. Information, the disclosure of which might invade personal privacy, will be redacted before release.

I. Tax Status

Determination of the tax status of an organization or person receiving compensation in any form as a result of an NSF grant is the responsibility of the IRS, State and local tax authorities and the courts.

J. Protection of Properties in the National Register of Historic Places

NSF is required by 16 USC § 470f to take into account the effect of grant activities on properties included in the National Register of Historic Places. Occasionally, an NSF grant may involve activities that require mitigation or other actions under the National Historic Preservation Act and implementing regulations of the Advisory Council on Historic Preservation (36 CFR § 800). In such cases, as deemed appropriate by NSF, conditions executing the goals of the National Historic Preservation Act may be included in the grant and grantees or prospective grantees may be required to coordinate with State or local historical preservation officers.

K. Environmental Compliance

Prior to making an award, NSF considers the anticipated environmental impacts associated with the activities described in the proposal. The assessment of environmental impacts is based, in part, on information provided by the organization. If, while performing the work required by the grant, the grantee learns of any potential or actual unanticipated environmental impacts, the grantee shall immediately notify NSF of such impacts. The grantee also shall cease all work anticipated to cause or causing such unanticipated environmental impacts until NSF has had a reasonable opportunity to assess the situation, comply with all relevant environmental laws, and provide further direction to the grantee.

L. National Security

NSF grants are intended for unclassified, publicly releasable research. The grantee will not be granted access to classified information. NSF does not expect that the results of the research project will involve classified information.

If, however, in conducting the activities supported under a grant, the PI/PD is concerned that any of the research results involve potentially classifiable information that may warrant Government restrictions on the dissemination of the results, the PI/PD should promptly notify the cognizant NSF Program Officer.

M. Miscellaneous

1. Liabilities and Losses

NSF cannot assume any liability for accidents, bodily injury, illness, breach of contract, any other damages or loss, or any claims arising out of any activities undertaken pursuant to the grant, whether with respect to persons or property of the grantee or third parties. The grantee is advised to insure or otherwise protect itself or others, as it may deem desirable.

2. Pre-College Students and Experimental Curriculum Development Projects

As required by 42 USC § 1869 a and b, grantees of projects which involve pre-college students in research or development, or pilot-testing, evaluation or revision of, experimental or innovative curriculum development projects will:

a. provide to the school board, or comparable authority responsible for the schools considering participation in the project, information concerning the need for and purposes of, the particular education project, the proposed content of the material to be used, the expected benefits to be derived and other information to assist the jurisdiction in arriving at a decision on participation;

b. obtain written approval for participation in the project activities after the responsible authority has carried out its procedures;

c. provide information and materials to the responsible school authority to assist it in carrying out its own established procedures regarding the participation of students in project activities;

d. provide information to NSF describing compliance with the above provisions; and

e. provide in every publication, testing or distribution agreement involving instructional material developed under a grant (including but not limited to teacher's manuals, textbooks, films, tapes or other supplementary material) that such material will be made available within the school district using such material, for inspection by parents or guardians of children engaged in educational programs or projects of that school district.

3. Use of Metric Measurements

The Metric Conversion Act of 1975 (15 USC §§ 205a-k) and E.O. 12770 (3 CFR § 1991 comp.) encourage Federal agencies to use the Metric System in procurement, grants and other business-related activities. The NSF grant will contain a provision encouraging PI/PDs to submit project reports, final reports, other reports and publications produced under grants that employ the metric system of measurements.

4. Executive Order 13788, Buy American and Hire American

Pursuant to Executive Order 13788, dated April 18, 2017, it is the policy of the Executive Branch of the Federal Government to maximize, consistent with law and regulation, the use of goods, products, and materials produced in the US. Further, it is the policy of the Executive Branch that relevant agencies will rigorously enforce and administer the laws governing entry into the US of workers from abroad.

Chapter XII: Grant Administration Disputes and Misconduct

A. Suspension and Termination Procedures

1. Definitions

a. SUSPENSION means an action by NSF that temporarily withholds Federal support of a project pending corrective action by the grantee or a decision by NSF to terminate the grant.

b. TERMINATION means the ending of the NSF award, in whole or in part at any time prior to the planned end of the period of performance.

2. Suspension and Termination

a. NSF Policy

(i) A grant may be suspended or terminated in whole or in part in any of the following situations by:

(a) NSF when the grantee fails to comply with the terms and conditions of the grant;

(b) NSF when the Foundation has cause;

(c) NSF when ordered by the Deputy Director under NSF's Regulation on Research Misconduct (45 CFR § 689);

(d) mutual agreement of NSF and the grantee; or

(e) the grantee on written notice to NSF setting forth the reasons for such action, the effective date, and, in the case of partial termination, the portion to be terminated or suspended (with the understanding that if NSF determines that the unterminated portion will not accomplish the purposes of the grant it may suspend or terminate the entire grant).

(ii) Normally, action by NSF to suspend or terminate a grant will be taken only after the grantee has been informed by NSF of the proposed action, or informed of any deficiency on its part and given an opportunity to correct it. NSF, however, may immediately suspend or terminate a grant without notice when it believes such action is reasonable to protect the interests of the government.

(iii) No costs incurred during a suspension period or after the effective date of a termination will be allowable, except those costs which, in the opinion of NSF, the grantee could not reasonably avoid or eliminate, or which were otherwise authorized by the suspension or termination notice, provided such costs would otherwise be allowable under the terms of the grant and the governing cost principles.

(iv) Within 30 days of the termination date the grantee will furnish a summary of progress under the grant and an itemized accounting of costs incurred prior to the termination date or pursuant to (iii) above. Final allowable costs under a termination settlement shall be in accordance with the terms of the grant, including this section, and the governing cost principles, giving due consideration to the progress under the grant. In no event will the total of NSF payments under a terminated grant exceed the grant amount or the NSF pro rata share when cost sharing was anticipated, whichever is less.

(v) A notice of termination other than by mutual agreement and/or the final settlement amount may be subject to review pursuant to Chapter XII.B.

(vi) NSF will report award terminations to the OMB-designated integrity and performance system in accordance with Federal regulation, but only after the grantee has had an opportunity to exhaust the review procedures contained in Chapter XII.B.

b. Procedures for Suspension or Termination by NSF

(i) When it is believed that a grantee has failed to comply with one or more of the terms and conditions of a grant, the NSF Grants Officer will normally advise the grantee in writing of the nature of the problem and that failure to correct the deficiency may result in suspension or termination of the grant. The grantee will be requested to respond in writing within 30 calendar days of the date of such letter, describing the action taken or the plan designed to correct the deficiency. Copies of such correspondence will be furnished to the PI/PD and to the cognizant NSF Program Officer. NSF, however, may immediately suspend or terminate a grant without notice when it believes such action is reasonable to protect the interests of the government.

(ii) If a satisfactory response is not received within the above period, the NSF Grants Officer may issue a notice immediately suspending authority to further obligate grant funds, in whole or in part. Notice of suspension is sent to the AOR, with a copy to the PI/PD. Within NSF, copies are furnished to the NSF Division of Financial Management and to the cognizant NSF Program Officer. The notice will set forth the terms of the suspension and its effective date.

(iii) Normally, the suspension will remain in effect for a maximum of 60 days to allow the grantee to take corrective action. In the event that the deficiency is not corrected to the satisfaction of NSF, the NSF Grants Officer may issue a notice of termination. The notice will set forth the reasons for the action and its effective date.

(iv) The remedies described in Chapter XII.B do not preclude a grantee from being subject to debarment and suspension under the OMB Guidelines to Agencies on Government-wide Debarment and Suspension (Nonprocurement) published at 2 CFR § 180 and NSF's Implementation of the OMB Guidelines, located at 2 CFR Chapter XXV.

(v) Suspension or termination due to research misconduct will be imposed as provided in that regulation.

3. Termination by Mutual Agreement

a. NSF Policy

Circumstances may arise in which either NSF or the grantee wishes to terminate a project. If both parties agree that continuation of the project would not produce results commensurate with the further expenditure of funds, or if there arises any other reason, the grant may be terminated by mutual agreement.

b. Procedures

(i) If the grantee wishes to terminate the project, the AOR should advise the NSF Grants Officer in writing and send a copy to the cognizant NSF Program Officer.

(ii) If NSF wishes to terminate the project, the NSF Grants Officer will advise the grantee's AOR in writing and send copies to the PI/PD and the cognizant NSF Program Officer.

(iii) Within 30 days after receipt of request from either party for termination by mutual agreement, the other party will provide an appropriate written response. In the event of disagreement between the parties, the NSF Grants Officer will make a final decision, subject to the review procedures prescribed by Chapter XII.B.

(iv) Following termination, grant closeout procedures will be initiated.

4. NSF Suspension or Termination Review Procedure

Grantees should refer to Chapter XII.B.3 for procedures to request review of a suspension or termination notice. Pending resolution of the request for review, a notice of termination shall remain in effect.

B. Informal Resolution of Grant Administration Disputes

1. Background

Consistent with the *Recommendation on Grant Disputes* by the Administrative Conference of the US, and with the intent of the provisions of Alternative Dispute Resolution, the Foundation provides the informal resolution processes described below concerning disputes or disagreements that may arise over Grants Officer post-award decisions under an NSF grant.

2. Scope of Post-Award Disputes Covered

The disputes below are covered under the process described in Chapter XII.B.3:

a. cost disallowances pursuant to a Grants Officer's decision (e.g., specific disallowances under an individual grant or as a result of an audit report);

b. termination orders; and

c. the final settlement amount under a termination.

3. Procedures

a. The grantee should submit a letter addressed to both the Division Director, Division of Grants and Agreements (DGA) and the Division Director, Division of Acquisition and Cooperative Support (DACS), National Science Foundation, 2415 Eisenhower Avenue, Alexandria, VA 22314. This letter must specify the grantee's disagreement or dispute and identify the NSF Grants Officer's decision in question, giving reasons for the request for review and providing any other material pertinent to the request. NSF will determine the appropriate Division to respond to the dispute.

b. The letter to the Division Directors, DGA and DACS, must be either postmarked or stamped received by NSF no later than 30 days after the date of the NSF letter notifying the grantee of the decision in question. The time for filing a request for review is strictly enforced and no extensions will be granted.

c. The request for review need not follow a prescribed format; however, it must contain a full statement of the grantee's position with respect to the disputed matter and the facts and rationale that support the grantee's position. Dispute requests will be reviewed if the grantee:

- submits new information (which was unavailable at the time of the original decision);
- identifies an error in fact or application of NSF policy in the original decision; or
- improper procedures were followed in the original decision.

d. The Division Director, DGA or DACS, will review or designate one or more individuals to review the matter. One reviewing official will be at least at a management level equivalent to the official who made the decision that is being reviewed. In no case, will the review be conducted by any individual involved with

the original decision or involved in recommending and/or monitoring the programmatic aspects of the project, or responsible for negotiating and/or administering its business or financial aspects.

e. The designated individual(s) will review and consider all relevant information available. A report which identifies the conclusion and recommendation will be completed, and in disputes covered under:

(i) Chapter XII.B.2.a and Chapter XII.B.2.b, the report will be completed within 30 days and forwarded to the Director, DGA or DACS or their designee for a final and unappealable written decision for the agency. The Director, DGA or DACS or their designee will communicate the decision in writing to the grantee, normally within 15 days of receipt of the report, unless otherwise specified by NSF.

(ii) Chapter XII.B.2.c, the report will be completed within 90 days and forwarded to the NSF Deputy Director or his/her designee. The NSF Deputy Director or his/her designee will make the final and unappealable decision for the agency and will communicate the decision in writing to the grantee within 15 days of receipt of the report unless otherwise specified by NSF.

C. Research Misconduct

RESEARCH MISCONDUCT means fabrication, falsification, or plagiarism in proposing or performing research funded by NSF, reviewing research proposals submitted to NSF, or in reporting research results funded by NSF.

1. NSF Policies and Responsibilities

a. NSF will take appropriate action against individuals or organizations upon a determination that misconduct has occurred. It may also take interim action during an investigation. Possible actions include sending a letter of reprimand to the individual or organization, requiring prior NSF approval of particular activities by an individual or organization, requiring special assurances of compliance with particular policies, restricting designated activities or expenditures under particular grants, suspending or terminating grants, debarring or suspending an individual or organization and prohibiting participation by an individual as an NSF reviewer, advisor or consultant.

b. NSF will find misconduct only after careful inquiry and investigation by a grantee, by another Federal agency or by NSF. An “inquiry” consists of preliminary information-gathering and preliminary fact-finding to determine whether an allegation or apparent instance of misconduct has substance. An investigation must be undertaken if the inquiry determines the allegation or apparent instance of misconduct has substance. An “investigation” is a formal development, examination, and evaluation of a factual record to determine whether misconduct has taken place or, if misconduct has already been confirmed, to assess its extent and consequences or determine appropriate action.

c. Before NSF makes any final finding of misconduct or takes any final action on such a finding, NSF will normally afford the accused individual or organization notice, a chance to provide comments and rebuttal and a chance to appeal. In structuring procedures in individual cases, NSF may take into account procedures already followed by other entities investigating or adjudicating the same allegation of misconduct.

d. Debarment or suspension for misconduct will be imposed only after further procedures described in applicable debarment and suspension regulations (2 CFR § 180 and 2 CFR Chapter XXV).

e. The OIG oversees investigations of research misconduct and conducts any NSF inquiries and investigations into suspected or alleged research misconduct.

f. The Deputy Director adjudicates research misconduct proceedings and the Director decides appeals.

g. After receiving an investigation report, the subject's rebuttal and recommendations of the OIG, the NSF Deputy Director may initiate further investigation or hearings or order interim or final actions. A written disposition specifying actions to be taken will be sent to affected individuals or organizations and will include instructions on how to pursue an appeal to the Director of the Foundation.

2. Role of Grantees

a. Grantees bear primary responsibility for prevention and detection of misconduct. In most instances, NSF will rely on grantees to promptly:

(i) initiate an inquiry into any suspected or alleged misconduct;

(ii) conduct a subsequent investigation, if the inquiry finds substance;

(iii) take action necessary to ensure the integrity of research, the rights and interests of research subjects and the public and the observance of legal requirements or responsibilities; and

(iv) provide appropriate safeguards for subjects of allegations as well as informants.

b. If a grantee wishes NSF to defer independent inquiry or investigation, it should:

(i) inform NSF immediately if an initial inquiry finds substance;

(ii) keep NSF informed during such an investigation;

(iii) notify NSF even before deciding to initiate an investigation or as required during an investigation:

(a) if there is reasonable indication of possible violations of civil or criminal law;

(b) if public health or safety is at risk;

(c) if NSF's resources, reputation, or other interests need protecting;

(d) if Federal action may be needed to protect the interests of a subject of the investigation or of others potentially affected;

(e) if the research community or the public should be informed; or

(f) if research activities should be suspended.

(iv) provide NSF with the final report from any investigation.

c. If a grantee wishes NSF to defer independent inquiry or investigation, it should complete any inquiry and decide whether an investigation is warranted within 90 days. It should similarly complete any investigation and reach a disposition within 180 days. If completion of an inquiry or investigation is delayed, but the grantee wishes NSF deferral to continue, NSF may require submission of periodic status reports.

d. Grantees should maintain and effectively communicate to their staff appropriate policies and procedures relating to misconduct, which should indicate when NSF must or should be notified.

e. Online research ethics training is available through the Department of Health and Human Services, Office of Research Integrity.

3. Reporting Possible Misconduct

Possible misconduct in activities funded by NSF should be reported to the Office of the Inspector General, National Science Foundation, 2415 Eisenhower Avenue, Alexandria, VA 22314, (703) 292-7100 or (800) 428-2189 or via e-mail at: oig@nsf.gov.

Privacy Act and Public Burden Statements

The information requested on proposal forms and project reports is solicited under the authority of the National Science Foundation Act of 1950, as amended. The information on proposal forms will be used in connection with the selection of qualified proposals; and project reports submitted by awardees will be used for program evaluation and reporting within the Executive Branch and to Congress. The information requested may be disclosed to qualified reviewers and staff assistants as part of the proposal review process; to proposer institutions/grantees to provide or obtain data regarding the proposal review process, award decisions, or the administration of awards; to government contractors, experts, volunteers and researchers and educators as necessary to complete assigned work; to other government agencies or other entities needing information regarding Proposers or nominees as part of a joint application review process, or in order to coordinate programs or policy; and to another Federal agency, court, or party in a court or Federal administrative proceeding if the government is a party. Information about Principal Investigators may be added to the Reviewer file and used to select potential candidates to serve as peer reviewers or advisory committee members. See Systems of Records, NSF-50, "Principal Investigator/Proposal File and Associated Records," 79 Federal Register 76398 (December 22, 2014), and NSF-51, "Reviewer/Proposal File and Associated Records," 79 Federal Register 76398 (December 22, 2014). Submission of the information is voluntary. Failure to provide full and complete information, however, may reduce the possibility of receiving an award.

An agency may not conduct or sponsor, and a person is not required to respond to, an information collection unless it displays a valid OMB control number. The OMB control number for this collection is 3145-0058. Public reporting burden for this collection of information is estimated to average 120 hours per response, including the time for reviewing instructions. Send comments regarding the burden estimate and any other aspect of this collection of information, including suggestions for reducing this burden, to:

ScInterinstitutional Assurance

The Interinstitutional Assurance is used by U.S. institutions that receive Public Health Service (PHS) funds through a grant or contract award when the institution has neither its own animal care and use program, facilities to house animals, nor an Institutional Animal Care and Use Committee (IACUC) and will conduct the animal activity at an Assured institution (named as a performance site).

I. Awardee Institution

Name of Awardee Institution:
Address: *(street address, city, state, zip code)*
Project Title: *(from grant application/contract proposal)*
Grant/Contract Number:
Principal Investigator:

A. Applicability

This Interinstitutional Assurance between the awardee institution and the Assured institution is applicable to research, research training, and biological testing involving live vertebrate animals supported by the PHS and conducted at the Assured institution.

B. Awardee and Assured Institutional Responsibilities

i. The institutions agree to comply with all applicable provisions of the Animal Welfare Act and other Federal statutes and regulations relating to animals.

ii. The institutions agree to be guided by the U.S. Government Principles for the Utilization and Care of Vertebrate Animals Used in Testing, Research, and Training and comply with the PHS Policy on Humane Care and Use of Laboratory Animals (Policy).

iii. The institutions acknowledge and accept responsibility for the care and use of animals involved in activities covered by this Assurance. As partial fulfillment of this responsibility, the institutions will make a reasonable effort to ensure that all individuals involved in the care and use of laboratory animals understand their individual and collective responsibilities for compliance with this Assurance, as well as all other applicable laws and regulations pertaining to animal care and use.

iv. The awardee institution acknowledges and accepts the authority of the IACUC of the Assured institution where the animal activity will be performed and agrees to abide by all conditions and determinations as set forth by that IACUC.

Name of Assured Institution:
Address: *(street address, city, state, zip code)*

II. Institutional Endorsement

By signing this document, the authorized official at the awardee institution and the Institutional Official and IACUC Chairperson at the Assured institution (performance site) provide their assurances that the project identified in Part I will be conducted in compliance with the PHS Policy and the Assurance of the Assured institution.

Required Application Instructions

It is critical that applicants follow the Research (R) Instructions in the SF424 (R&R) Application Guide (//grants.nih.gov/grants/guide/url_redirect.htm?id=12000), except where instructed to do otherwise (in this FOA or in a Notice from the *NIH Guide for Grants and Contracts (//grants.nih.gov/grants/guide/)*). Conformance to all requirements (both in the Application Guide and the FOA) is required and strictly enforced. Applicants must read and follow all application instructions in the Application Guide as well as any program-specific instructions noted in Section IV. When the program-specific instructions deviate from those in the Application Guide, follow the program-specific instructions. **Applications that do not comply with these instructions may be delayed or not accepted for review.**

There are several options available to submit your application through Grants.gov to NIH and Department of Health and Human Services partners. You **must** use one of these submission options to access the application forms for this opportunity.

1. Use the NIH ASSIST system to prepare, submit and track your application online.

   Apply Online Using ASSIST

2. Use an institutional system-to-system (S2S) solution to prepare and submit your application to Grants.gov and eRA Commons (http://public.era.nih.gov/commons/) to track your application. Check with your institutional officials regarding availability.

3. Use Grants.gov (http://www.grants.gov/web/grants/applicants/download-application-package.html#search=true&oppNum=RFA-AI-19-028) Workspace to prepare and submit your application and eRA Commons (http://public.era.nih.gov/commons/) to track your application.

Section I. Funding Opportunity Description

Purpose

The purpose of this Funding Opportunity Announcement (FOA) is to establish a coordinated network of Emerging Infectious Disease Research Centers (EIDRCs) in regions around the globe where emerging and re-emerging infectious disease outbreaks are likely to occur. Multidisciplinary teams of investigators will conduct pathogen/host surveillance, study pathogen transmission, including evaluating zoonotic hosts and reservoirs, study pathogenesis and immunologic responses in the host, and will develop reagents and diagnostic assays for improved detection for important emerging pathogens and their vectors. These EIDRC will conduct research project(s) and will collaborate under the direction of a separate EIDRC Coordinating Center (EIDRC CC, RFA-AI-19-029 (https://grants.nih.gov/grants/guide/rfa-files/rfa-ai-19-029.html)), to develop and formulate strategies for detecting, controlling and preventing emergence or re-emergence of infectious diseases. Rapid translation of these findings to development of reagents, diagnostic tools, etc. that will be provided to downstream partners to advance therapeutic and preventive interventions is key.

Background

A core component of the NIAID mission in the 2017 Strategic Plan is to "develop flexible domestic and international capacity to efficiently undertake research required in response to newly emerging threats wherever they occur." Clearly, recent infectious pathogens with significant potential to threaten the United States are emerging /re-emerging with increasing frequency. Most of these naturally occurring outbreaks have been caused by RNA viral pathogens characterized by zoonotic reservoirs and/or arthropod vectors propagating transmission to humans. These outbreaks have revealed gaps in the research infrastructure that impact the ability to respond rapidly and effectively to these emerging pathogens; obtaining contemporary knowledge of the pathophysiology and natural history, accurate detection/diagnosis of the infections, and development of critical research and product development reagents, were challenges during previous outbreaks.

This FOA and its companion (https://grants.nih.gov/grants/guide/rfa-files/rfa-ai-19-029.html), will serve as important components of the broader NIAID strategy for pandemic preparedness by establishing infrastructure and scientific expertise in geographical regions of the world that are prone to emerging and re-emerging infectious diseases. These Centers will draw on skills from teams of multidisciplinary scientists, including infectious disease clinicians, epidemiologists, virologists, clinical microbiologists, veterinarians, and entomologists, to conduct field studies of endemic diseases that have the greatest potential of becoming pandemic threats, such as zoonotic and vector-borne viruses, develop reagents for the broader research community and have the flexibility and ability to re-direct work among the EIDRC in the event of an outbreak to mount a rapid and effective research response.

Research Objectives and Scope

The Emerging Infectious Diseases Program comprised of the EIDRC CC and the EIDRCs, is designed to improve our knowledge of emerging and re-emerging infectious diseases, complement

and leverage existing NIAID international research efforts when possible, and allow NIAID to develop the flexibility and capacity to respond rapidly and effectively to outbreaks where they occur. The program as a whole is designed to improve our knowledge of the natural history, incidence, and prevalence of emerging/re-emerging infectious diseases. In many instances, re-emerging pathogens circulate at low levels for several years before breaking out and causing major public health problems, in other cases new pathogens emerge rapidly.

Research activities at the centers may include pathogen discovery; surveillance in humans, animal reservoirs, and vectors as it relates to assessment of prevalence and molecular epidemiology of specific pathogens in their geographic regions; evaluation of factors related to transmission, emergence and adaptation to new hosts; natural history of infection and contemporary clinical disease in humans as well as immunologic responses to the infection; development of reagents, new diagnostic methods for improved detection of infectious agents, and development of appropriate animal models, if/when necessary. Clinical cohorts with symptoms of acute infections may be used to define the pathophysiology and clinical outcomes of the infection and disease, describe the spectrum of disease presentation and severity, elucidate factors associated with disease transmission and progression, evaluate important immune responses to the emerging pathogen, determine clinical and molecular diagnostic criteria, and provide the basis for sample collection.

Importantly, the centers will provide reagents, tools and assays to NIAID and partners to support the development of translational products and will readily share information, data, samples, diagnostics, reagents and tools across the network in the event of an outbreak. In that regard, the centers will provide a clear plan for accomplishing effective coordination and collaboration with the entire network and the EIDRC CC.

The EIDRCs will complement and leverage existing NIAID international research efforts- such as the Centers of Excellence for Influenza Research and Surveillance (CEIRS), International Centers of Excellence for Malaria Research (ICEMR), Tropical Medicine Research Centers (TMRC), and Centers for AIDS Research (CFAR)- and/or other US Government or internationally funded research infrastructure as needed to conduct proposed research and exhibit the flexibility to expand capacity in response to outbreaks in their geographic area, as directed by NIAID and the EIDRC CC. Each EIDRC will have the flexibility to study any emerging pathogen (viral, bacterial or eukaryotic), however, the initial focus will be on infectious pathogens that are most likely to emerge/remerge including, but not limited to: Flaviviruses, Filoviruses, Alphaviruses, Coronaviruses, Bunyaviruses, and Enteroviruses that are not already studied by other NIAID funded networks (e.g. HIV, influenza, malaria) and for which countermeasures are not developed or are sub-optimal.

Each EIDRC will have relevant scientific expertise and experience working in one or more geographic areas located within the tropical or subtropical regions of the world (Tropics: latitude between 23.5o -Tropic of Cancer and Capricorn-Subtropics: between tropic and temperate zones (35-66.5o N and S of the equator) with the goal to establish multiple sites in targeted areas of the globe such as South and Central America, West/Central Africa and Southeast Asia. In an effort to train the next generation of investigators, develop expertise in emerging infectious disease research and expand regional capacity in these countries, the centers will be required to conduct a pilot project research program, that will be coordinated, including the awarding of projects, by the EIDRC CC.

EIDRC Structure

Administration and Leadership Team

The Administration and Leadership Team, led by the Program Director(s)/Principal Investigator(s), will be responsible for organizing, coordinating, and providing oversight for the implementation of activities that facilitate progress and completion of the research project(s) and conduct of pilot research projects, if awarded. This team will provide administrative oversight, coordination and facilitated communications with other EIDRCs and interact directly with the EIDRC CC and NIAID.

Data Management and Analysis Team

The Data Management and Analysis Team will be responsible for implementing standard procedures provided by the EIDRC CC for the collection, oversight and inventory of data and biological samples, including; harmonization, quality control, and uniformity of data collection processes, troubleshooting data system problems and developing solutions. Team members will also work with the Administration and Leadership Team, to develop efficient study designs and statistical calculations and provide support for the preliminary and final data analyses for the study. This team will serve as the hub for expertise with sharing data portal(s) as approved by NIAID. This team is responsible for directly depositing all relevant data, samples, reagents, tools, etc. as outlined to the EIDRC CC

Clinical Research Support Team

The Clinical Research Support Team will be responsible for coordinating the functions at all enrollment sites to recruit, enroll, and collect data and biological samples from participants. This Team will ensure adherence to NIH and EIDRC CC guidelines on research and data quality and all local and other regulatory oversight pertaining to all human subjects' research. This team will serve as the process and procedure hub for the interaction among the clinical sites and other functional work areas.

External Advisory Committee (EAC)

One External Advisory Committee, comprised of experts in the field outside of the EIDRCs and EIDRC CC, will be established after award to review progress for the Emerging Infectious Diseases Program (EIDRCs and EIDRC CC) and to share recommendations for the program with NIAID as part of the annual programmatic meeting. **Note that applicants should not name or contact potential EAC members in their application.**

Annual Programmatic Meetings

Each EIDRC will attend a combined kick-off meeting and annual program meetings under the leadership of the EIDRC CC to articulate and establish the major roles and functions of the program and to facilitate collaborations, provide progress reporting, seek new research directions and ideas, and update NIAID on issues of need. These meetings will be attended by the PD(s)/PI(s), Key personnel, NIAID staff, and the EAC membership and will be held in the Washington DC area.

Applications proposing any of the following topic areas will be considered nonresponsive and will not be reviewed:

- Applications that focus on pathogens that are not on the NIAID list of Emerging diseases (https://www.niaid.nih.gov/research/emerging-infectious-diseases-pathogens (https://www.niaid.nih.gov/research/emerging-infectious-diseases-pathogens)). Research focus should be emerging/remerging viruses, but if studying coinfected population with a

pathogen not on the Emerging Diseases list, application should include a strong justification and rationale for inclusion.
- Pathogens already studied by other NIAID funded networks, such as influenza, tuberculosis, malaria and antibiotic resistant bacteria. Please contact the Scientific/Research Contact if further clarification is needed.
- HIV, SIV or AIDS studies.
- Genome-wide association studies (GWAS).
- Behavioral research.

See Section VIII. Other Information for award authorities and regulations.

Section II. Award Information

Funding Instrument

Cooperative Agreement: A support mechanism used when there will be substantial Federal scientific or programmatic involvement. Substantial involvement means that, after award, NIH scientific or program staff will assist, guide, coordinate, or participate in project activities. See Section VI.2 for additional information about the substantial involvement for this FOA.

Application Types Allowed

New

The OER Glossary (//grants.nih.gov/grants/guide/url_redirect.htm?id=11116) and the SF424 (R&R) Application Guide provide details on these application types.

Clinical Trial?

Not Allowed: Only accepting applications that do not propose clinical trials

Need help determining whether you are doing a clinical trial? (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82370)

Funds Available and Anticipated Number of Awards

NIAID intends to commit $6M in FY 2020 to fund 2-4 awards.

Award Budget

Applications budget are limited to up to $850,000 per year in direct costs and need to reflect the actual needs of the proposed project.

Award Project Period

The scope of the proposed project should determine the project period. The maximum period is 5 years.

NIH grants policies as described in the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120)* will apply to the applications submitted and awards made from this FOA.

Section III. Eligibility Information

1. Eligible Applicants

Eligible Organizations

Higher Education Institutions

- Public/State Controlled Institutions of Higher Education
- Private Institutions of Higher Education

The following types of Higher Education Institutions are always encouraged to apply for NIH support as Public or Private Institutions of Higher Education:

- Hispanic-serving Institutions
- Historically Black Colleges and Universities (HBCUs)
- Tribally Controlled Colleges and Universities (TCCUs)
- Alaska Native and Native Hawaiian Serving Institutions
- Asian American Native American Pacific Islander Serving Institutions (AANAPISIs)

Nonprofits Other Than Institutions of Higher Education

- Nonprofits with 501(c)(3) IRS Status (Other than Institutions of Higher Education)
- Nonprofits without 501(c)(3) IRS Status (Other than Institutions of Higher Education)

For-Profit Organizations

- Small Businesses
- For-Profit Organizations (Other than Small Businesses)

Governments

- State Governments
- County Governments
- City or Township Governments
- Special District Governments
- Indian/Native American Tribal Governments (Federally Recognized)
- Indian/Native American Tribal Governments (Other than Federally Recognized)
- Eligible Agencies of the Federal Government
- U.S. Territory or Possession

Other

- Independent School Districts
- Public Housing Authorities/Indian Housing Authorities
- Native American Tribal Organizations (other than Federally recognized tribal governments)
- Faith-based or Community-based Organizations
- Regional Organizations
- Non-domestic (non-U.S.) Entities (Foreign Institutions)

Foreign Institutions

Non-domestic (non-U.S.) Entities (Foreign Institutions) **are** eligible to apply.

Non-domestic (non-U.S.) components of U.S. Organizations **are** eligible to apply.

Foreign components, as defined in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11118), **are** allowed.

Required Registrations

Applicant Organizations

Applicant organizations must complete and maintain the following registrations as described in the SF 424 (R&R) Application Guide to be eligible to apply for or receive an award. All registrations must be completed prior to the application being submitted. Registration can take 6 weeks or more, so applicants should begin the registration process as soon as possible. The NIH Policy on Late Submission of Grant Applications (//grants.nih.gov/grants/guide/notice-files/NOT-OD-15-039.html) states that failure to complete registrations in advance of a due date is not a valid reason for a late submission.

- Dun and Bradstreet Universal Numbering System (DUNS) (http://fedgov.dnb.com/webform) - All registrations require that applicants be issued a DUNS number. After obtaining a DUNS number, applicants can begin both SAM and eRA Commons registrations. The same DUNS number must be used for all registrations, as well as on the grant application.
- System for Award Management (SAM) (https://www.sam.gov/portal/public/SAM/)– Applicants must complete and maintain an active registration, **which requires renewal at least annually**. The renewal process may require as much time as the initial registration. SAM registration includes the assignment of a Commercial and Government Entity (CAGE) Code for domestic organizations which have not already been assigned a CAGE Code.
    - NATO Commercial and Government Entity (NCAGE) Code (//grants.nih.gov/grants/guide/url_redirect.htm?id=11176) – Foreign organizations must obtain an NCAGE code (in lieu of a CAGE code) in order to register in SAM.
- eRA Commons (//grants.nih.gov/grants/guide/url_redirect.htm?id=11123) - Applicants must have an active DUNS number to register in eRA Commons. Organizations can register with the eRA Commons as they are working through their SAM or Grants.gov registration, but all registrations must be in place by time of submission. eRA Commons requires organizations to identify at least one Signing Official (SO) and at least one Program Director/Principal Investigator (PD/PI) account in order to submit an application.
- Grants.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=82300) – Applicants must have an active DUNS number and SAM registration in order to complete the Grants.gov registration.

Program Directors/Principal Investigators (PD(s)/PI(s))

All PD(s)/PI(s) must have an eRA Commons account. PD(s)/PI(s) should work with their organizational officials to either create a new account or to affiliate their existing account with the applicant organization in eRA Commons. If the PD/PI is also the organizational Signing Official, they must have two distinct eRA Commons accounts, one for each role. Obtaining an eRA Commons account can take up to 2 weeks.

Eligible Individuals (Program Director/Principal Investigator)

Any individual(s) with the skills, knowledge, and resources necessary to carry out the proposed research as the Program Director(s)/Principal Investigator(s) (PD(s)/PI(s)) is invited to work with his/her organization to develop an application for support. Individuals from underrepresented racial

and ethnic groups as well as individuals with disabilities are always encouraged to apply for NIH support.

For institutions/organizations proposing multiple PDs/PIs, visit the Multiple Program Director/Principal Investigator Policy and submission details in the Senior/Key Person Profile (Expanded) Component of the SF424 (R&R) Application Guide.

Applicants for the EIDRC CC (RFA-AI-19-029 (https://grants.nih.gov/grants/guide/rfa-files/rfa-ai-19-029.html)) may also apply to this FOA.

2. Cost Sharing

This FOA does not require cost sharing as defined in the *NIH Grants Policy Statement. (//grants.nih.gov/grants/guide/url_redirect.htm?id=11126)*

3. Additional Information on Eligibility

Number of Applications

Applicant organizations may submit more than one application, provided that each application is scientifically distinct.

The NIH will not accept duplicate or highly overlapping applications under review at the same time. This means that the NIH will not accept:

- A new (A0) application that is submitted before issuance of the summary statement from the review of an overlapping new (A0) or resubmission (A1) application.
- A resubmission (A1) application that is submitted before issuance of the summary statement from the review of the previous new (A0) application.
- An application that has substantial overlap with another application pending appeal of initial peer review (see NOT-OD-11-101 (//grants.nih.gov/grants/guide/notice-files/NOT-OD-11-101.html)).

Section IV. Application and Submission Information

1. Requesting an Application Package

The application forms package specific to this opportunity must be accessed through ASSIST, Grants.gov Workspace or an institutional system-to-system solution. Links to apply using ASSIST or Grants.gov Workspace are available in Part 1 of this FOA. See your administrative office for instructions if you plan to use an institutional system-to-system solution.

2. Content and Form of Application Submission

It is critical that applicants follow the Research (R) Instructions in the SF424 (R&R) Application Guide (//grants.nih.gov/grants/guide/url_redirect.htm?id=12000), except where instructed in this funding opportunity announcement to do otherwise. Conformance to the requirements in the Application Guide is required and strictly enforced. Applications that are out of compliance with these instructions may be delayed or not accepted for review.

Letter of Intent

Although a letter of intent is not required, is not binding, and does not enter into the review of a subsequent application, the information that it contains allows IC staff to estimate the potential review workload and plan the review.

By the date listed in Part 1. Overview Information, prospective applicants are asked to submit a letter of intent that includes the following information:

- Descriptive title of proposed activity
- Name(s), address(es), and telephone number(s) of the PD(s)/PI(s)
- Names of other key personnel
- Participating institution(s)
- Number and title of this funding opportunity

The letter of intent should be sent to:

Eleazar Cohen, Ph.D.
Telephone: 240-669-5081
Email:ecohen@niaid.nih.gov (mailto:ecohen@niaid.nih.gov)

Page Limitations

All page limitations described in the SF424 Application Guide and the Table of Page Limits (//grants.nih.gov/grants/guide/url_redirect.htm?id=11133) must be followed, with the following additional instructions.

For this specific FOA, the Research Strategy is limited to 30 pages.

Instructions for Application Submission

The following section supplements the instructions found in the SF424 (R&R) Application Guide and should be used for preparing an application to this FOA.

SF424(R&R) Cover

All instructions in the SF424 (R&R) Application Guide must be followed.

SF424(R&R) Project/Performance Site Locations

All instructions in the SF424 (R&R) Application Guide must be followed.

SF424(R&R) Other Project Information

All instructions in the SF424 (R&R) Application Guide must be followed. With the following additional instructions:

Facilities and Other Resources:

In a separate section entitled "Information Technology Access" include a brief description of the features of the institutional environment that are relevant to the effective implementation of the proposed unified collaborations across Teams and functions. Describe in general available IT resources associated with the enrollment and field sites with respect to access to computers, source and status of reliable, secure internet connections, and other communications.

In a separate section entitled "Biological Sample Storage and Access", describe the facilities available to store, manage and retrieve biological specimens for use by the PD(s)/PI(s) and key personnel.

SF424(R&R) Senior/Key Person Profile

All instructions in the SF424 (R&R) Application Guide must be followed. With the following additional instructions:

- Within the Biosketch under Personal Statement, describe the leadership approach and experience of the PD(s)/PI(s) with respect to developing and executing multi-disciplinary research program(s) of a similar size and nature.
- Within the Biosketch under Personal Statement, all Key Personnel should demonstrate strong administrative, technical, and management expertise in areas critical to the success of the application, including experience working productively in team collaborative environments. Demonstrate how specific expertise supports the multi-disciplinary approach to guarantee a successful, integrated effort towards the goals of the research project.

R&R or Modular Budget

All instructions in the SF424 (R&R) Application Guide must be followed. With the following additional instructions:

In Year 01, include funds in the budget for the PD(s)/PI(s), collaborators, key personnel to travel and attend a kickoff meeting to be held shortly after the award over 1 full day in the Bethesda, MD area. Beginning in Year 02 include funds in the budget for an annual program meeting to be held over two full days in the Bethesda, MD area. Do not include costs associated with organizing and holding the kickoff or annual program meetings.

Include costs associated with submission of data into publicly accessible portal(s) approved by NIAID. Also include costs associated with biological sample collection, processing, shipping, and storage as well as costs for depositing data, reagents and tools to the EIDRC CC.

R&R Subaward Budget

All instructions in the SF424 (R&R) Application Guide must be followed.

PHS 398 Cover Page Supplement

All instructions in the SF424 (R&R) Application Guide must be followed.

PHS 398 Research Plan

All instructions in the SF424 (R&R) Application Guide must be followed, with the following additional instructions:

Specific Aims: List in priority order, the broad, long-range objectives and goals of the proposed research including surveillance, transmission, pathogenesis and immunologic responses in the host, and reagent and diagnostic assay development for improved detection for important emerging pathogens and their vectors and indicate how these goals will be accomplished. Concisely describe the hypothesis or hypotheses to be tested with an initial emphasis on RNA viruses and plans for incorporation of other pathogens and emerging infectious diseases. Indicate how the work proposed dovetails to address the overall goals and objectives of the research.

Research Strategy:

In a clearly labeled section entitled "Administrative Plan":

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long-range goals and objectives.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.
- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

In a clearly labeled section entitled "Data Management Plan":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

In a clearly labeled section entitled "Clinical Management Plan":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.
- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.
- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

In a clearly labeled section within the Research Strategy entitled "Statistical Analysis Plan":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.
- Describe any unique or innovative approaches to statistical analysis that may be utilized.

In a clearly labeled section entitled "Project Milestones and Timelines":

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Note: if the proposed research includes a clinical study, specific information for that study will be entered using the PHS Human Subjects and Clinical Trials Information and should not be duplicated in the Research Strategy.

Letters of Support: Include any letter necessary to demonstrate the support of consortium/site participants.

Resource Sharing Plan: Individuals are required to comply with the instructions for the Resource Sharing Plans as provided in the SF424 (R&R) Application Guide, with the following modification:

- All applications, regardless of the amount of direct costs requested for any one year, should address a Data Sharing Plan that details the rapid sharing, release and access of datasets, analysis tools, computational models, reagents, and other resources, which are generated by the Center to the broader scientific community in adherence to the requirements and timelines described in the NIAID Data and Reagents Sharing and Release Guidelines (https://www.niaid.nih.gov/research/data-sharing-and-release-guidelines) and the NIH Genomic Data Sharing (GDS) Policy (https://grants.nih.gov/grants/guide/notice-files/NOT-OD-14-124.html).
- NIAID encourages the use of NIH supported open access Data Sharing Repositories as a first choice and a list of them can be found at

https://www.nlm.nih.gov/NIHbmic/nih_data_sharing_repositories.html. (https://www.nlm.nih.gov/NIHbmic/nih_data_sharing_repositories.html) Provide a timeline for the planned acceptance, quality check, transfer and upload of data of all types.

- All investigators funded under this FOA will be expected to share their data through a portal (s) approved by NIAID as well as any collected biological samples, including clinical and animal research specimens. Therefore, the Resource Sharing plan should include a summary of how the applicant will manage data submission and interactions with the chosen portal(s), as well as sharing of biological samples with the scientific community.
- All Investigators are expected to be aware of and abide by all applicable NIH guidance for sharing of research resources and data, consistent with existing laws, regulations, and policies.
- All investigators should provide a plan for how to accomplish sharing of critical diagnostic reagents and tools when necessary, to NIAID, NIAID supported repositories, the other EIDRCs, the CC, and the broader research community.

Appendix:

Only limited Appendix materials are allowed. Follow all instructions for the Appendix as described in the SF424 (R&R) Application Guide.

PHS Human Subjects and Clinical Trials Information

When involving NIH-defined human subjects research, clinical research, and/or clinical trials (and when applicable, clinical trials research experience) follow all instructions for the PHS Human Subjects and Clinical Trials Information form in the SF424 (R&R) Application Guide, with the following additional instructions:

If you answered "Yes" to the question "Are Human Subjects Involved?" on the R&R Other Project Information form, you must include at least one human subjects study record using the **Study Record: PHS Human Subjects and Clinical Trials Information** form or **Delayed Onset Study** record.

Study Record: PHS Human Subjects and Clinical Trials Information

All instructions in the SF424 (R&R) Application Guide must be followed with the following additional instructions:

Section 3 - Protection and Monitoring Plans

3.1 Protection of Human Subjects

3.1.1 Risks to Human Subjects

3.1.1.b Study Procedures, Materials and Potential Risks

Additional Instructions

For applications proposing to use samples from ongoing or completed clinical research, provide a timeline for the request, transportation and receipt of the biological samples, and the timeline associated with the preparation and use of the biological samples.

For all research projects provide information on:

- Describe the type(s) of biosamples to be used

- Describe the handling and processing of biosamples at the collection site (collection, processing, storage, transportation and quality control measures to ensure sample integrity)
- List the research laboratory(ies) to be used and describe the selection rationale and qualifications
- Describe the laboratory methodology(ies) to be used for each proposed assay/test and provide evidence of assay feasibility

Delayed Onset Study

Note: Delayed onset (https://grants.nih.gov/grants/glossary.htm#DelayedOnsetHumanSubjectStudy) does NOT apply to a study that can be described but will not start immediately (i.e., delayed start).

All instructions in the SF424 (R&R) Application Guide must be followed.

PHS Assignment Request Form

All instructions in the SF424 (R&R) Application Guide must be followed.

Foreign Institutions

Foreign (non-U.S.) institutions must follow policies described in the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11137)*, and procedures for foreign institutions.

3. Unique Entity Identifier and System for Award Management (SAM)

See Part 1. Section III.1 for information regarding the requirement for obtaining a unique entity identifier and for completing and maintaining active registrations in System for Award Management (SAM), NATO Commercial and Government Entity (NCAGE) Code (if applicable), eRA Commons, and Grants.gov

4. Submission Dates and Times

Part I. Overview Information contains information about Key Dates and times. Applicants are encouraged to submit applications before the due date to ensure they have time to make any application corrections that might be necessary for successful submission. When a submission date falls on a weekend or Federal holiday (https://grants.nih.gov/grants/guide/url_redirect.htm?id=82380), the application deadline is automatically extended to the next business day.

Organizations must submit applications to Grants.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=11128) (the online portal to find and apply for grants across all Federal agencies). Applicants must then complete the submission process by tracking the status of the application in the eRA Commons (//grants.nih.gov/grants/guide/url_redirect.htm?id=11123), NIH's electronic system for grants administration. NIH and Grants.gov systems check the application against many of the application instructions upon submission. Errors must be corrected and a changed/corrected application must be submitted to Grants.gov on or before the application due date and time. If a Changed/Corrected application is submitted after the deadline, the application will be considered late. Applications that miss the due date and time are subjected to the NIH Policy on Late Application Submission.

Applicants are responsible for viewing their application before the due date in the eRA Commons to ensure accurate and successful submission.

Information on the submission process and a definition of on-time submission are provided in the SF424 (R&R) Application Guide.

5. Intergovernmental Review (E.O. 12372)

This initiative is not subject to intergovernmental review. (//grants.nih.gov/grants/guide/url_redirect.htm?id=11142)

6. Funding Restrictions

All NIH awards are subject to the terms and conditions, cost principles, and other considerations described in the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120)*.

Pre-award costs are allowable only as described in the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11143)*.

7. Other Submission Requirements and Information

Applications must be submitted electronically following the instructions described in the SF424 (R&R) Application Guide. Paper applications will not be accepted.

Applicants must complete all required registrations before the application due date. Section III. Eligibility Information contains information about registration.

For assistance with your electronic application or for more information on the electronic submission process, visit How to Apply – Application Guide (https://grants.nih.gov/grants/how-to-apply-application-guide.html). If you encounter a system issue beyond your control that threatens your ability to complete the submission process on-time, you must follow the Dealing with System Issues (https://grants.nih.gov/grants/how-to-apply-application-guide/due-dates-and-submission-policies/dealing-with-system-issues.htm) guidance. For assistance with application submission, contact the Application Submission Contacts in Section VII.

Important reminders:

All PD(s)/PI(s) must include their eRA Commons ID in the Credential field of the Senior/Key Person Profile Component of the SF424(R&R) Application Package. Failure to register in the Commons and to include a valid PD/PI Commons ID in the credential field will prevent the successful submission of an electronic application to NIH. See Section III of this FOA for information on registration requirements.

The applicant organization must ensure that the DUNS number it provides on the application is the same number used in the organization's profile in the eRA Commons and for the System for Award Management. Additional information may be found in the SF424 (R&R) Application Guide.

See more tips (//grants.nih.gov/grants/guide/url_redirect.htm?id=11146) for avoiding common errors.

Upon receipt, applications will be evaluated for completeness and compliance with application instructions by the Center for Scientific Review and responsiveness by components of participating

organizations, NIH. Applications that are incomplete, non-compliant and/or nonresponsive will not be reviewed.

Post Submission Materials

Applicants are required to follow the instructions for post-submission materials, as described in the policy (//grants.nih.gov/grants/guide/url_redirect.htm?id=82299). Any instructions provided here are in addition to the instructions in the policy.

Section V. Application Review Information

1. Criteria

Only the review criteria described below will be considered in the review process.

Applications submitted to the NIH in support of the NIH mission (//grants.nih.gov/grants/guide/url_redirect.htm?id=11149) are evaluated for scientific and technical merit through the NIH peer review system.

Overall Impact

Reviewers will provide an overall impact score to reflect their assessment of the likelihood for the project to exert a sustained, powerful influence on the research field(s) involved, in consideration of the following review criteria and additional review criteria (as applicable for the project proposed).

Scored Review Criteria

Reviewers will consider each of the review criteria below in the determination of scientific merit, and give a separate score for each. An application does not need to be strong in all categories to be judged likely to have major scientific impact. For example, a project that by its nature is not innovative may be essential to advance a field.

Significance

Does the project address an important problem or a critical barrier to progress in the field? Is the prior research that serves as the key support for the proposed project rigorous? If the aims of the project are achieved, how will scientific knowledge, technical capability, and/or clinical practice be improved? How will successful completion of the aims change the concepts, methods, technologies, treatments, services, or preventative interventions that drive this field?

Investigator(s)

Are the PD(s)/PI(s), collaborators, and other researchers well suited to the project? If Early Stage Investigators or those in the early stages of independent careers, do they have appropriate experience and training? If established, have they demonstrated an ongoing record of accomplishments that have advanced their field(s)? If the project is collaborative or multi-PD/PI, do the investigators have complementary and integrated expertise; are their leadership approach, governance and organizational structure appropriate for the project?

Specific for this FOA: Is the level of commitment of the PD(s)/PI(s) and key personnel adequate to manage the overall project? Do the investigators/collaborators have a previous history of translational research efforts?

Do the investigators have relevant scientific expertise and experience working in one or more geographic areas located within the tropical or subtropical regions of the world (Tropics: latitude

between 23.5o -Tropic of Cancer and Capricorn- Subtropics: between tropic and temperate zones (35-66.5o N and S of the equator)? Does the team have a multidisciplinary expertise that could successfully be applied to characterizing the clinical features and transmission cycle of a newly emerging infectious disease?

Innovation

Does the application challenge and seek to shift current research or clinical practice paradigms by utilizing novel theoretical concepts, approaches or methodologies, instrumentation, or interventions? Are the concepts, approaches or methodologies, instrumentation, or interventions novel to one field of research or novel in a broad sense? Is a refinement, improvement, or new application of theoretical concepts, approaches or methodologies, instrumentation, or interventions proposed?

Approach

Are the overall strategy, methodology, and analyses well-reasoned and appropriate to accomplish the specific aims of the project? Have the investigators included plans to address weaknesses in the rigor of prior research that serves as the key support for the proposed project? Have the investigators presented strategies to ensure a robust and unbiased approach, as appropriate for the work proposed? Are potential problems, alternative strategies, and benchmarks for success presented? If the project is in the early stages of development, will the strategy establish feasibility and will particularly risky aspects be managed? Have the investigators presented adequate plans to address relevant biological variables, such as sex, for studies in vertebrate animals or human subjects?

If the project involves human subjects and/or NIH-defined clinical research, are the plans to address

1) the protection of human subjects from research risks, and

2) inclusion (or exclusion) of individuals on the basis of sex/gender, race, and ethnicity, as well as the inclusion or exclusion of individuals of all ages (including children and older adults), justified in terms of the scientific goals and research strategy proposed?

Specific to this FOA: Do the investigators provide a clear plan for how to add new sites and/or expand scientific areas of research when needed for an accelerated response to an outbreak? Has the investigator described the establishment of a clinical cohort (or cohorts) that is likely to improve our understanding of the natural history of an emerging pathogen? Is the rationale for eligibility for inclusion in the cohort sound? Are the recruitment and retention plans and study timelines reasonable?

Do the targeted pathogen(s)/disease(s) address the FOA's intent to focus on the most relevant emerging pathogens? Are the contributions of each individual activity proposed within the research design well integrated with the aims of the project? Are the coordination and synergy within the project adequate to ensure the achievement of its central objectives?

Are the proposed host systems adequate, well-documented and characterized? If using animal models, are the models relevant and appropriate to investigate emerging ID infections?

Are the proposed technologies well justified, critical and relevant to the project aims?

Do the investigators provide a clear plan for achieving defined project milestones and timelines?

Are the described data management activities sufficient?

Environment

Will the scientific environment in which the work will be done contribute to the probability of success? Are the institutional support, equipment and other physical resources available to the investigators adequate for the project proposed? Will the project benefit from unique features of the scientific environment, subject populations, or collaborative arrangements?

Specific to this FOA: Do the investigators plan to complement and leverage existing NIAID international research efforts- such as the Centers of Excellence for Influenza Research and Surveillance (CEIRS), International Centers of Excellence for Malaria Research (ICEMR), Tropical Medicine Research Centers (TMRC), and Centers for AIDS Research (CFAR) and/or other US and internationally funded existing infrastructure as needed to conduct proposed research?

Additional Review Criteria

As applicable for the project proposed, reviewers will evaluate the following additional items while determining scientific and technical merit, and in providing an overall impact score, but will not give separate scores for these items.

Protections for Human Subjects

For research that involves human subjects but does not involve one of the categories of research that are exempt under 45 CFR Part 46, the committee will evaluate the justification for involvement of human subjects and the proposed protections from research risk relating to their participation according to the following five review criteria: 1) risk to subjects, 2) adequacy of protection against risks, 3) potential benefits to the subjects and others, 4) importance of the knowledge to be gained, and 5) data and safety monitoring for clinical trials.

For research that involves human subjects and meets the criteria for one or more of the categories of research that are exempt under 45 CFR Part 46, the committee will evaluate: 1) the justification for the exemption, 2) human subjects involvement and characteristics, and 3) sources of materials. For additional information on review of the Human Subjects section, please refer to the Guidelines for the Review of Human Subjects (//grants.nih.gov/grants/guide/url_redirect.htm?id=11175).

Inclusion of Women, Minorities, and Individuals Across the Lifespan

When the proposed project involves human subjects and/or NIH-defined clinical research, the committee will evaluate the proposed plans for the inclusion (or exclusion) of individuals on the basis of sex/gender, race, and ethnicity, as well as the inclusion (or exclusion) of individuals of all ages (including children and older adults) to determine if it is justified in terms of the scientific goals and research strategy proposed. For additional information on review of the Inclusion section, please refer to the Guidelines for the Review of Inclusion in Clinical Research (//grants.nih.gov/grants/guide/url_redirect.htm?id=11174).

Vertebrate Animals

The committee will evaluate the involvement of live vertebrate animals as part of the scientific assessment according to the following criteria: (1) description of proposed procedures involving animals, including species, strains, ages, sex, and total number to be used; (2) justifications for the use of animals versus alternative models and for the appropriateness of the species

proposed; (3) interventions to minimize discomfort, distress, pain and injury; and (4) justification for euthanasia method if NOT consistent with the AVMA Guidelines for the Euthanasia of Animals. Reviewers will assess the use of chimpanzees as they would any other application proposing the use of vertebrate animals. For additional information on review of the Vertebrate Animals section, please refer to the Worksheet for Review of the Vertebrate Animal Section (//grants.nih.gov/grants/guide/url_redirect.htm?id=11150).

Biohazards

Reviewers will assess whether materials or procedures proposed are potentially hazardous to research personnel and/or the environment, and if needed, determine whether adequate protection is proposed.

Resubmissions

Not Applicable

Renewals

Not Applicable

Revisions

Not Applicable

Additional Review Considerations

As applicable for the project proposed, reviewers will consider each of the following items, but will not give scores for these items, and should not consider them in providing an overall impact score.

Applications from Foreign Organizations

Reviewers will assess whether the project presents special opportunities for furthering research programs through the use of unusual talent, resources, populations, or environmental conditions that exist in other countries and either are not readily available in the United States or augment existing U.S. resources.

Select Agent Research

Reviewers will assess the information provided in this section of the application, including 1) the Select Agent(s) to be used in the proposed research, 2) the registration status of all entities where Select Agent(s) will be used, 3) the procedures that will be used to monitor possession use and transfer of Select Agent(s), and 4) plans for appropriate biosafety, biocontainment, and security of the Select Agent(s).

Resource Sharing Plans

Reviewers will comment on whether the following Resource Sharing Plans, or the rationale for not sharing the following types of resources, are reasonable: (1) Data Sharing Plan (//grants.nih.gov/grants/guide/url_redirect.htm?id=11151); (2) Sharing Model Organisms (//grants.nih.gov/grants/guide/url_redirect.htm?id=11152); and (3) Genomic Data Sharing Plan (GDS) (//grants.nih.gov/grants/guide/url_redirect.htm?id=11153). Do the investigators provide a clear and concise plan for sharing of information, data, and biological samples, and the development and sharing of critical research reagents and tools when necessary, according to specified timelines to NIAID supported repositories, the other EIDRCs, the CC, and the broader research community?

Authentication of Key Biological and/or Chemical Resources:

For projects involving key biological and/or chemical resources, reviewers will comment on the brief plans proposed for identifying and ensuring the validity of those resources.

Budget and Period of Support

Reviewers will consider whether the budget and the requested period of support are fully justified and reasonable in relation to the proposed research.

2. Review and Selection Process

Applications will be evaluated for scientific and technical merit by (an) appropriate Scientific Review Group(s) convened by the National Institute of Allergy and Infectious Diseases, in accordance with NIH peer review policy and procedures (//grants.nih.gov/grants/guide/url_redirect.htm?id=11154), using the stated review criteria. Assignment to a Scientific Review Group will be shown in the eRA Commons.

As part of the scientific peer review, all applications:

- May undergo a selection process in which only those applications deemed to have the highest scientific and technical merit (generally the top half of applications under review) will be discussed and assigned an overall impact score.
- Will receive a written critique.

Appeals (//grants.nih.gov/grants/guide/notice-files/NOT-OD-11-064.html) of initial peer review will not be accepted for applications submitted in response to this FOA.

Applications will be assigned to the appropriate NIH Institute or Center. Applications will compete for available funds with all other recommended applications submitted in response to this FOA. Following initial peer review, recommended applications will receive a second level of review by the National Advisory Allergy and Infectious Diseases Council. The following will be considered in making funding decisions:

- Scientific and technical merit of the proposed project as determined by scientific peer review.
- Availability of funds.
- Relevance of the proposed project to program priorities.

3. Anticipated Announcement and Award Dates

After the peer review of the application is completed, the PD/PI will be able to access his or her Summary Statement (written critique) via the eRA Commons (//grants.nih.gov/grants/guide/url_redirect.htm?id=11123). Refer to Part 1 for dates for peer review, advisory council review, and earliest start date.

Information regarding the disposition of applications is available in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11156).

Section VI. Award Administration Information

1. Award Notices

If the application is under consideration for funding, NIH will request "just-in-time" information from the applicant as described in the *NIH Grants Policy Statement* (//grants.nih.gov/grants/guide/url_redirect.htm?id=11157).

A formal notification in the form of a Notice of Award (NoA) will be provided to the applicant organization for successful applications. The NoA signed by the grants management officer is the authorizing document and will be sent via email to the grantee's business official.

Awardees must comply with any funding restrictions described in Section IV.5. Funding Restrictions. Selection of an application for award is not an authorization to begin performance. Any costs incurred before receipt of the NoA are at the recipient's risk. These costs may be reimbursed only to the extent considered allowable pre-award costs.

Any application awarded in response to this FOA will be subject to terms and conditions found on the Award Conditions and Information for NIH Grants (//grants.nih.gov/grants/guide/url_redirect.htm?id=11158) website. This includes any recent legislation and policy applicable to awards that is highlighted on this website.

2. Administrative and National Policy Requirements

All NIH grant and cooperative agreement awards include the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120)* as part of the NoA. For these terms of award, see the *NIH Grants Policy Statement Part II: Terms and Conditions of NIH Grant Awards, Subpart A: General (//grants.nih.gov/grants/guide/url_redirect.htm?id=11157)* and Part II: Terms and Conditions of NIH Grant Awards, Subpart B: Terms and Conditions for Specific Types of Grants, Grantees, and Activities (//grants.nih.gov/grants/guide/url_redirect.htm?id=11159). More information is provided at Award Conditions and Information for NIH Grants (//grants.nih.gov/grants/guide/url_redirect.htm?id=11158).

Recipients of federal financial assistance (FFA) from HHS must administer their programs in compliance with federal civil rights law. This means that recipients of HHS funds must ensure equal access to their programs without regard to a person's race, color, national origin, disability, age and, in some circumstances, sex and religion. This includes ensuring your programs are accessible to persons with limited English proficiency. HHS recognizes that research projects are often limited in scope for many reasons that are nondiscriminatory, such as the principal investigator's scientific interest, funding limitations, recruitment requirements, and other considerations. Thus, criteria in research protocols that target or exclude certain populations are warranted where nondiscriminatory justifications establish that such criteria are appropriate with respect to the health or safety of the subjects, the scientific study design, or the purpose of the research.

For additional guidance regarding how the provisions apply to NIH grant programs, please contact the Scientific/Research Contact that is identified in Section VII under Agency Contacts of this FOA. HHS provides general guidance to recipients of FFA on meeting their legal obligation to take reasonable steps to provide meaningful access to their programs by persons with limited English proficiency. Please see https://www.hhs.gov/civil-rights/for-individuals/special-topics/limited-english-proficiency/index.html (https://www.hhs.gov/civil-rights/for-individuals/special-topics/limited-english-proficiency/index.html). The HHS Office for Civil Rights also provides guidance on complying with civil rights laws enforced by HHS. Please see https://www.hhs.gov/civil-rights/for-individuals/section-1557/index.html (https://www.hhs.gov/civil-rights/for-individuals/section-1557/index.html); and https://www.hhs.gov/civil-rights/for-providers/laws-regulations-guidance/index.html (https://www.hhs.gov/civil-rights/for-providers/laws-regulations-guidance/index.html). Recipients of FFA also have specific legal obligations for serving qualified individuals with disabilities. Please see https://www.hhs.gov/civil-rights/for-individuals/disability/index.html (https://www.hhs.gov/civil-

rights/for-individuals/disability/index.html). Please contact the HHS Office for Civil Rights for more information about obligations and prohibitions under federal civil rights laws at https://www.hhs.gov/ocr/about-us/contact-us/index.html (https://www.hhs.gov/ocr/about-us/contact-us/index.html) or call 1-800-368-1019 or TDD 1-800-537-7697. Also note it is an HHS Departmental goal to ensure access to quality, culturally competent care, including long-term services and supports, for vulnerable populations. For further guidance on providing culturally and linguistically appropriate services, recipients should review the National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care at http://minorityhealth.hhs.gov/omh/browse.aspx?lvl=2&lvlid=53 (http://minorityhealth.hhs.gov/omh/browse.aspx?lvl=2&lvlid=53).

In accordance with the statutory provisions contained in Section 872 of the Duncan Hunter National Defense Authorization Act of Fiscal Year 2009 (Public Law 110-417), NIH awards will be subject to the Federal Awardee Performance and Integrity Information System (FAPIIS) requirements. FAPIIS requires Federal award making officials to review and consider information about an applicant in the designated integrity and performance system (currently FAPIIS) prior to making an award. An applicant, at its option, may review information in the designated integrity and performance systems accessible through FAPIIS and comment on any information about itself that a Federal agency previously entered and is currently in FAPIIS. The Federal awarding agency will consider any comments by the applicant, in addition to other information in FAPIIS, in making a judgement about the applicant's integrity, business ethics, and record of performance under Federal awards when completing the review of risk posed by applicants as described in 45 CFR Part 75.205 "Federal awarding agency review of risk posed by applicants." This provision will apply to all NIH grants and cooperative agreements except fellowships.

Cooperative Agreement Terms and Conditions of Award

The following special terms of award are in addition to, and not in lieu of, otherwise applicable U.S. Office of Management and Budget (OMB) administrative guidelines, U.S. Department of Health and Human Services (DHHS) grant administration regulations at 45 CFR Part 75, and other HHS, PHS, and NIH grant administration policies.

The administrative and funding instrument used for this program will be the cooperative agreement, an "assistance" mechanism (rather than an "acquisition" mechanism), in which substantial NIH programmatic involvement with the awardees is anticipated during the performance of the activities. Under the cooperative agreement, the NIH purpose is to support and stimulate the recipients' activities by involvement in and otherwise working jointly with the award recipients in a partnership role; it is not to assume direction, prime responsibility, or a dominant role in the activities. Consistent with this concept, the dominant role and prime responsibility resides with the awardees for the project as a whole, although specific tasks and activities may be shared among the awardees and the NIH as defined below.

The PD(s)/PI(s) will have the primary responsibility for:

- Serving as the administration oversight for the proposed research, including overseeing, managing, and coordinating the overall Centers/proposed research.
- Sharing data collected under this award through a NIAID approved portal(s), as well as sharing any collected biological samples with the scientific community, as appropriate and consistent with achieving the goals of the program.

- Awardees will retain custody of and have primary rights to the data and software developed under these awards, subject to Government rights of access consistent with current DHHS, PHS, and NIH policies.
- Rapidly responding to outbreaks as directed by NIAID and the EIDRC CC. Examples include but are not limited to; providing information, samples, data, reagents, etc. to another Center, the Coordination Center and/or other collaborators, in addition to planning and/or performing critical experiments to advance the development of new diagnostic tools and reagents.
- Publishing research results, presenting at professional meetings, developing quality diagnostic capability and managing pilot projects.
- Demonstrating collaborative effort within the larger EIDRC network, including the other EIDRCs, the CC and NIAID

NIH staff have substantial programmatic involvement that is above and beyond the normal stewardship role in awards, as described below:

- Coordinate NIAID staff assistance, including participation in periodic on-site monitoring with respect to compliance with Federal regulations, quality control, accuracy of data recording, sample accrual, enrollment, etc.
- Facilitate collaborations with and access to other NIAID-supported research resources and services.
- Serve as liaison/facilitator between the awardee and the EIDRC CC, related to database and biological sample storage (approved by NIAID).
- Assist in establishing an External Advisory Committee (EAC).
- The NIH Project Scientist will review and assist in developing the operating guidelines and consistent policies for dealing with situations that require coordinated action.
- The NIH Project Scientist will periodically review the data generated under this award.
- Additionally, an agency program official or IC program director will be responsible for the normal scientific and programmatic stewardship of the award and will be named in the award notice.

Areas of Joint Responsibility include:

- The PD(s)/PI(s) and NIH Project Scientist will review the entirety of program milestones annually and update them based on recommendations from the EAC.
- The NIH Project Scientist and the PD(s)/PI(s) will coordinate the overall Center objectives and progress at the annual workshop to facilitate the achievement of program goals.

Dispute Resolution:

Any disagreements that may arise in scientific or programmatic matters (within the scope of the award) between award recipients and the NIH may be brought to Dispute Resolution. A Dispute Resolution Panel composed of three members will be convened. It will have three members: a designee of the Steering Committee chosen without NIH staff voting, one NIH designee, and a third designee with expertise in the relevant area who is chosen by the other two; in the case of individual disagreement, the first member may be chosen by the individual awardee. This special dispute resolution procedure does not alter the awardee's right to appeal an adverse action that is otherwise appealable in accordance with PHS regulation 42 CFR Part 50, Subpart D and DHHS regulation 45 CFR Part 16.

3. Reporting

When multiple years are involved, awardees will be required to submit the Research Performance Progress Report (RPPR) (//grants.nih.gov/grants/rppr/index.htm) annually and financial statements as required in the NIH Grants Policy Statement. (//grants.nih.gov/grants/guide/url_redirect.htm?id=11161)

A final RPPR, invention statement, and the expenditure data portion of the Federal Financial Report are required for closeout of an award, as described in the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11161)*.

The Federal Funding Accountability and Transparency Act of 2006 (Transparency Act), includes a requirement for awardees of Federal grants to report information about first-tier subawards and executive compensation under Federal assistance awards issued in FY2011 or later. All awardees of applicable NIH grants and cooperative agreements are required to report to the Federal Subaward Reporting System (FSRS) available at www.fsrs.gov (//grants.nih.gov/grants/guide/url_redirect.htm?id=11170) on all subawards over $25,000. See the *NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11171)* for additional information on this reporting requirement.

In accordance with the regulatory requirements provided at 45 CFR 75.113 and Appendix XII to 45 CFR Part 75, recipients that have currently active Federal grants, cooperative agreements, and procurement contracts from all Federal awarding agencies with a cumulative total value greater than $10,000,000 for any period of time during the period of performance of a Federal award, must report and maintain the currency of information reported in the System for Award Management (SAM) about civil, criminal, and administrative proceedings in connection with the award or performance of a Federal award that reached final disposition within the most recent five-year period. The recipient must also make semiannual disclosures regarding such proceedings. Proceedings information will be made publicly available in the designated integrity and performance system (currently FAPIIS). This is a statutory requirement under section 872 of Public Law 110-417, as amended (41 U.S.C. 2313). As required by section 3010 of Public Law 111-212, all information posted in the designated integrity and performance system on or after April 15, 2011, except past performance reviews required for Federal procurement contracts, will be publicly available. Full reporting requirements and procedures are found in Appendix XII to 45 CFR Part 75 – Award Term and Conditions for Recipient Integrity and Performance Matters.

Section VII. Agency Contacts

We encourage inquiries concerning this funding opportunity and welcome the opportunity to answer questions from potential applicants.

Application Submission Contacts

eRA Service Desk (Questions regarding ASSIST, eRA Commons, application errors and warnings, documenting system problems that threaten submission by the due date, and post-submission issues)

Finding Help Online: http://grants.nih.gov/support/ (preferred method of contact)
Telephone: 301-402-7469 or 866-504-9552 (Toll Free)

General Grants Information (Questions regarding application instructions, application processes, and NIH grant resources)

Email: GrantsInfo@nih.gov (mailto:GrantsInfo@nih.gov) (preferred method of contact)
Telephone: 301-945-7573

Grants.gov Customer Support (Questions regarding Grants.gov registration and Workspace)
Contact Center Telephone: 800-518-4726
Email: support@grants.gov (mailto:support@grants.gov)

Bora Mpinja
National Institute of Allergy and Infectious Diseases (NIAID)
Telephone: 301-761-5434
Email address: bora.mpinja@nih.gov (mailto:bora.mpinja@nih.gov)

Section VIII. Other Information

Recently issued trans-NIH policy notices (//grants.nih.gov/grants/guide/url_redirect.htm?id=11163) may affect your application submission. A full list of policy notices published by NIH is provided in the *NIH Guide for Grants and Contracts (//grants.nih.gov/grants/guide/url_redirect.htm?id=11164)*. All awards are subject to the terms and conditions, cost principles, and other considerations described in the NIH Grants Policy Statement (//grants.nih.gov/grants/guide/url_redirect.htm?id=11120).

Authority and Regulations

Awards are made under the authorization of Sections 301 and 405 of the Public Health Service Act as amended (42 USC 241 and 284) and under Federal Regulations 42 CFR Part 52 and 45 CFR Part 75.

[Insert Letterhead here]

06 June 2019

Dr. Peter Daszak
President
EcoHealth Alliance
460 W 34th St. 17th Floor
New York, NY 10001 USA

Dear Dr. Daszak,

This letter expresses the high interest that staff at [insert name of institution] has in collaborative research with EcoHealth Alliance and other partners on the proposed NIAID Emerging Infectious Diseases Research Center (EIDRC) submission (FOA: RFA-AI-19-028), titled “Understanding risk of zoonotic virus emergence in EID hotspots of Southeast Asia”.

The [insert name of institution] recognizes the mutual benefits to be gained through research cooperation and a successful partnership in this center, including sharing of technology, samples, reagents, data and research results. The research proposed will advance our understanding of the ability of wildlife-origin coronaviruses, henipaviruses and filoviruses to spillover into high-risk human populations and cause illnesses that may have been previously unreported, or undiagnosed. We believe the results will be scientifically important, and have great public health value in the region, and globally, by identifying key pandemic threats in an EID hotspot region.

We at [insert name of institution] have collaborated successfully with all partners on this proposal, and look forward to continuing our work together. Our work will include managing [Insert sentence on key roles in project, e.g. “human surveillance, sample collection, testing, and development of laboratory diagnostics”]. We will also actively take part in technology transfer and research cross-training with other partners, and are ready, willing and able to work in surge capacity to conduct research during outbreak situations, in collaboration with all other EIDRCs and the EIDCC.

Sincerely,

[Insert signature]

[Insert full name, title, institution, address, and email]

Equipment

EcoHealth Alliance, New York, USA (Drs. Daszak and Olival) EA1

EcoHealth Alliance is equipped with fiber optic Internet access and video conferencing facilities to facilitate easy communication between collaborators. EcoHealth Alliance employees have around-the-clock access to servers, VPNs, encryption software, IT support, and all necessary software including Git and Github (Hosted software revision/audit service), Sublime and Vim text editors, Vagrant and Oracle Virtualbox virtual machines, Google Apps (Hosted email and collaboration web based software), Ansible (Server provisioning software framework), Python, NodeJS, and R programming languages, Meteor (Javascript framework), Bash shell scripts, Jenkins (Continuous Integration server), Microsoft Office and Adobe CS6 running on both Apple Mac OS X, Ubuntu linux, and Windows Operating Systems. EcoHealth Alliance has a dedicated quad-core Linux server and another dedicated dual quad-core Mac Pro Server - each with 4TB hard drives. Either server individually or in combination may be used for intensive computational modeling and/or database processing by all the grantees. Access to the cloud and supercomputing services (Amazon) is provided by core funding to EcoHealth Alliance. EA2

Page 1 Comments

EA1 Here, list (1) name of institution, (2) location of institution, and (3) name(s) of Key Personnel from your institution contributing to this proposal

EcoHealth Alliance, 6/4/2019 09:40 AM

EA2 List major items of equipment already available for this project and, if appropriate, identify the equipment's location and pertinent capabilities

EcoHealth Alliance, 6/4/2019 09:40 AM

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Daszak, Peter

eRA COMMONS USER NAME (credential, e.g., agency login): daszak

POSITION TITLE: President & Chief Scientist

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE *(if applicable)*	Completion Date MM/YYYY	FIELD OF STUDY
Bangor University, UK	B.S. (hons)	07/1986	Zoology
University of East London, UK	Ph.D.	03/1993	Infectious Diseases

A. Personal Statement

I have 20+ years NIH-funded research experience on emerging viral zoonoses, and the scientific management experience to support this proposed work that involves international interdisciplinary teams working on field surveillance in wild mammals, human behavioral risk surveys and clinical sampling, development of novel diagnostic approaches, and viral characterization *in vitro* and *in vivo*. I am President and Chief Scientist of EcoHealth Alliance, a US-based 501(c)(3) institution that conducts research on emerging zoonoses. My research background is focused on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of SARS-CoV and SADS-CoV, analyzing the causes of West Nile, Nipah and Hendra virus emergence and spread, publishing the first unbiased analysis of global emerging disease hotspots, and analyzing patterns of viral spillover into human populations in EID hotspots. I have been the PI on 5 multidisciplinary R01s that use modeling, epidemiology, laboratory and field science to test hypotheses on the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah and Hendra virus, Avian influenza and novel viruses from bats. I have also led large contracts from USAID (institutional lead on $75 million PREDICT-1 and $138 million PREDICT-2) involving successful management of teams of virologists, field biologists, mathematical modelers, veterinarians, epidemiologists, laboratorians and anthropologists. Much of the groundwork for the current proposed work has developed from my previous collaborative research with each member of our proposed EIDRC consortium.

B. Positions and Honors

Positions and Employment

1993 -98 Senior Faculty Research Scientist, Kingston University UK
1998 Guest Researcher, Centers for Disease Control and Prevention (CDC)
1999 -01 Faculty Research Scientist, University of Georgia
2001 - Sr. Adjunct Faculty, Columbia University
2001 -09 Executive Director, Consortium for Conservation Medicine, EcoHealth Alliance, New York
2009 - President & Chief Scientist, EcoHealth Alliance New York

Other Experience and Professional Membership

2003 -07 NIH: ad hoc member, ZRG1 IDM-G 90 (2003-5) ZRG1 IRAP-Q (2005-7)
2004 - Editorial Board, *Conserv. Biol.*
2005 NIAID: Steering Committee, workshop on virus-host shifts & emergence of new pathogens
2010 - Editor-in-Chief, *EcoHealth*; Member of IOM Forum on Microbial Threats; External Advisory Board, DHS and Kansas State Univ. Ctr. of Excellence for Emerg. & Zoonotic Animal Diseases (CEEZAD)
2011 Steering Committeee, NIAID Workshop on Arboviruses
2014 - Member NRC Advisory Committee to advise the US Global Change Research Program (USGCRP)
2015 - Member of Supervisory Board, One Health Platform; Editorial Board *One Health*
2016 - Member, WHO Expert group on Public Health Emergency Disease Prioritization
2016 - Member, Core Steering Committee & Co-Chair, Science & Technol WG, Global Virome Project
2017 External Review Committee, CSIRO Health & Biosecurity Business Unit
2017 - Chair, Forum on Microbial Threats, National Academies of Science, Engineering & Medicine

Honors

1999 Meritorious service award, CDC
2000 CSIRO silver medal for collaborative research
2002 Honored by the naming of a new species of centipede, *Cryptops daszaki* (*J Nat Hist* 36: 76-106)
2003 6th Annual Lecturer, Medicine & Humanities, Texas A&M
2007 Finalist, Director's Pioneer Award
2008 Presidential Lecturer, University of Montana
2012 Elected member of the Cosmos Club, Washington DC
2013 Honored by the naming of a new parasite species, *Isospora daszaki* (*Parasit. Res.* 111:1463-1466)
2013 Hsu-Li Distinguished Lectureship in International Epidemiology, Univ. Iowa
2015 Robert Leader Endowed Lecture in Food Safety, Michigan State Univ.
2018 - Member, National Academy of Medicine (NAM), USA.

C. Contribution to Science

1. Research on the bat origins of emerging viruses. Numerous high impact emerging viruses appear to have bat reservoirs (e.g. SARS-CoV, EBOV, NiV, HeV, MERS-CoV, SADS-CoV). As PI on four prior R01s, my work has helped demonstrate their bat origin (SARS-CoV, SADS-CoV), analyze the drivers of their emergence and risk factors for spillover. Collaborating with virologists in China, we have isolated and characterized SARS-like CoVs from bats that use the same human host cell receptor (ACE-2) as SARS-CoV. This work provides critical reagents and resources that have helped advance understanding of virus-host binding and may contribute to vaccine development. My other work identified factors leading to the emergence of NiV from *Pteropus* bats in Malaysia and Bangladesh; a likely bat origin for MERS-CoV; and proof that bats harbor a significantly higher proportion of zoonoses than all other mammalian groups.

2. **Analyzing the process of disease emergence.** Emerging infectious diseases are a significant threat to global health. However, their emergence is sporadic, complex, and seemingly unpredictable. In the early 2000s I started to use analytical approaches to identify predictable patterns in the process of disease emergence. By collating a database of all known prior EID events, identifying their point origins, and correcting for reporting biases, I published the first ever predictive 'hotspots' maps of where future disease emergence is most likely. I have continued this line of research, publishing spatial analyses of the drivers of disease spread, and outlining strategies to predict pandemic emergence.

   a. Kilpatrick AM, Chmura AA, Gibbons DW, Fleischer RC, Marra PP & **Daszak P** (2006). Predicting the global spread of H5N1 avian influenza. **PNAS** 103: 19368-19373.

3. **Studies of wildlife disease ecology to understand emerging zoonoses.** The majority of EIDs are zoonotic, with the majority of these originating in wildlife. I reviewed this field in a paper in *Science* in 2000 and in a more recent paper in *Nature* on the links among biodiversity and health. During the last two decades, I have led collaborative research programs on how the ecology of specific wildlife-origin zoonoses can help explain patterns of risk to people. This includes my role as PI on 4 R01s, as institutional lead for USAID-EPT-PREDICT, and Chief of Party for USAID-IDEEAL. This work includes estimations of the diversity of yet-to-be discovered viruses which forms the rationale for the Global Virome Project.

Abstract

A new highly virulent swine acute diarrhoea syndrome coronavirus (SADS-CoV) emerged in Guangdong province in 2017 followed by fatal diarrhoea that involved the death of 24,693 piglets. And yet from May 2017 to January 2019, there were no new SADS cases arising in pig herds in Guangdong. In this study, we reported the recent diarrhoea outbreak of SADS-CoV in Southern China on February 2019. Intestinal samples collected from diarrhoeal piglets were detected for common swine virus and confirmed that SADS-CoV was responsible for the diarrhoea case. Meanwhile, serological investigation of sows' sera implied that SADS-CoV has existed in the farm and PEDV antibody may not directly contribute to the amplification of SADS-CoV. Homology and phylogenetic analysis of the whole genome showed that the re-emerging SADS-CoV strain shared high sequence identities with existing SADS-CoV strains and all strains clustered together in Alpha coronavirus. All in all, the report herein emphasized the re-emerging of SADS-CoV and highlights continuous monitoring for this virus.

phylogenetic analysis, re-emerging, SADS-CoV, Southern China

1 | INTRODUCTION

Swine acute diarrhoea syndrome (SADS) was first identified in South China in January 2017 as a disease causing high mortality in neonatal piglets (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). It is quickly demonstrated that the causative agent of SADS is a novel HKU2-related coronavirus, swine acute diarrhoea syndrome coronavirus (SADS-CoV) which originated from the same genus of horseshoe bats (*Rhinolophus*) as severe acute respiratory syndrome coronavirus (SARS-CoV), but the mechanism of transmission of bat-originated coronavirus in pigs needs further illumination (Cui, Li, & Shi, 2019; Zhou et al., 2018). Based on the analysis of genomes, SADS-CoV is classified into the genus *Alphacoronavirus* within the subfamily *Orthocoronavirinae* of the family *Coronaviridae* (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). So far, besides porcine epidemic diarrhoea virus (PEDV), transmissible gastroenteritis virus (TGEV) and porcine deltacoronavirus (PDCoV), SADS-CoV is the fourth porcine enteric coronavirus that circulated in pigs in China (Dong et al., 2015; Xuan et al., 1984). A retrospective investigation showed that SADS-CoV emerged in China at least since August 2016 (Zhou et al., 2019). Li et al. (2018) reported one SADS-CoV strain that was isolated from fecal and small intestinal samples collected from Fujian province and suggested that SADS-CoV might have spread from Guangdong to Fujian province.

In the first outbreak of SADS-CoV occurring between January and May 2017, in order to reduce mortality in suckling pigs, the minced intestines from acutely infected piglets were filtered, centrifuged and inactivated before feeding back to pregnant sows to allow maternal antibodies to be obtained in neonatal piglets. Hence, after May 2017, the epidemic was controlled. And with a period of quiescence, SADS-CoV seemed to have disappeared from pig herds in South China. While on February 2019, there was a large-scale

outbreak of approximately 2000 piglets dying of diarrhoea in one farm, which was near the origin of the SADS pandemic in 2017. The extensive aetiological investigation for common swine viruses suggested that the causative agent of this recent diarrhoea outbreak was SADS-CoV. In this study, we compared the infections of piglets with the original and re-emerging SADS-CoV strains by clinical signs, epidemiological investigation, serological investigation and phylogenetic analysis. The results highlight the significance of SADS-CoV and the disease it causes.

At the beginning of the latest outbreak on February 2019, infected suckling piglets developed acute diarrhoea, vomiting and died after 2–6 days of the diarrhoea, which were consistent with the clinical signs reported in SAD-CoV outbreaking farms (Zhou et al., 2018). Two weeks after the onset, mortality did not increase due to the effective inactivated SADS-CoV vaccine which was propagated in vitro (data unpublished). Clinical small intestine samples were collected rapidly from piglets, and intestinal samples were homogenized, centrifuged and filtered for virus isolate. Viral nucleic acid was extracted using TRIzol reagent (Invitrogen, USA) according to the manufacturer's instruction. The potential swine viral pathogens were examined, including SADS-CoV, PEDV, PDCoV, porcine rotavirus (RV), TGEV, reovirus (REO), senecavirus A (SVA), foot and mouth disease virus (FMDV), porcine pseudorabies virus (PRV), porcine circovirus 2 (PCV2), porcine circovirus 3 (PCV3), porcine reproductive

and respiratory syndrome virus (PRRSV), porcine parainfluenza virus 1 (PPIV1), swine influenza virus (SIV), atypical porcine pestivirus (APPV), haemophilus parasuis (HPS), hog cholera (HC), porcine parvovirus (PPV), porcine bocavirus (PBoV), porcine sapelovirus (PSV) and porcine kobuvirus (PKV) by PCR or RT-PCR following the established protocol of Key Laboratory of Animal Health Aquaculture and Environmental Control. The extensive aetiological investigations for common swine viruses showed that only SADS-CoV was detected positively, which suggested that the causative agent of the most recent diarrhoea outbreak on February was SADS-CoV.

Furthermore, a total of 18 blood samples were simultaneously collected from healthy sows for serological investigation. Sera samples were obtained after coagulation and centrifugation (2,000 *g*, 10 min) and stored at −20°C until ELISA implemented. The PEDV antibody production was detected by means of commercial ELISA test kit (ZhenRui, China), of which, sample S/P ratios with ≥0.4 were considered positive and <0.4 were considered negative. And for SADS-CoV, ELISA was conducted following the modified procedures established in Key Laboratory of Animal Health Aquaculture and Environmental Control (P/N ≥ 2.1 considered positive). The absorbance at 450 nm wavelength was measured (Multiskan™ FC, Thermo Fisher). The results of ELISA assay revealed that all sera (100%) were negative for the PEDV and 13 of 18 (72.2%) were positive for SADS-CoV (Figure 1). In our previously clinical investigations, PEDV had caused prior outbreaks at most farms with SADS-CoV outbreaks (Zhou et al., 2018). It is possible that the presence of PEDV antibody may have somehow facilitated the amplification of the SADS-CoV. However, our results showed that PEDV antibodies were undetectable in all SADS-CoV antibody-positive sera samples, suggesting that it is SADS-CoV that caused the lethal infection in pigs on February 2019. Collectively, the re-emergence of SADS-CoV in pig herds in South China was confirmed by ELISA test and the association between PEDV and SADS-CoV infection requires further validation.

Subsequently, one SADS-CoV genome was amplified as previously described (Zhou et al., 2019). The novel SADS-CoV strain was named as SADS-CoV/CN/GDLX/2019 (accession number: MK651076). Sequence alignment and phylogenetic analysis were performed with Lasergene coresuite 10 (DNASTAR Inc.). Phylogenetic tree was constructed using the neighbour-joining method with MEGA 7.0 software (Kumar, Stecher, & Tamura, 2016). Bootstrap analysis was carried out on 1,000 replicate data sets

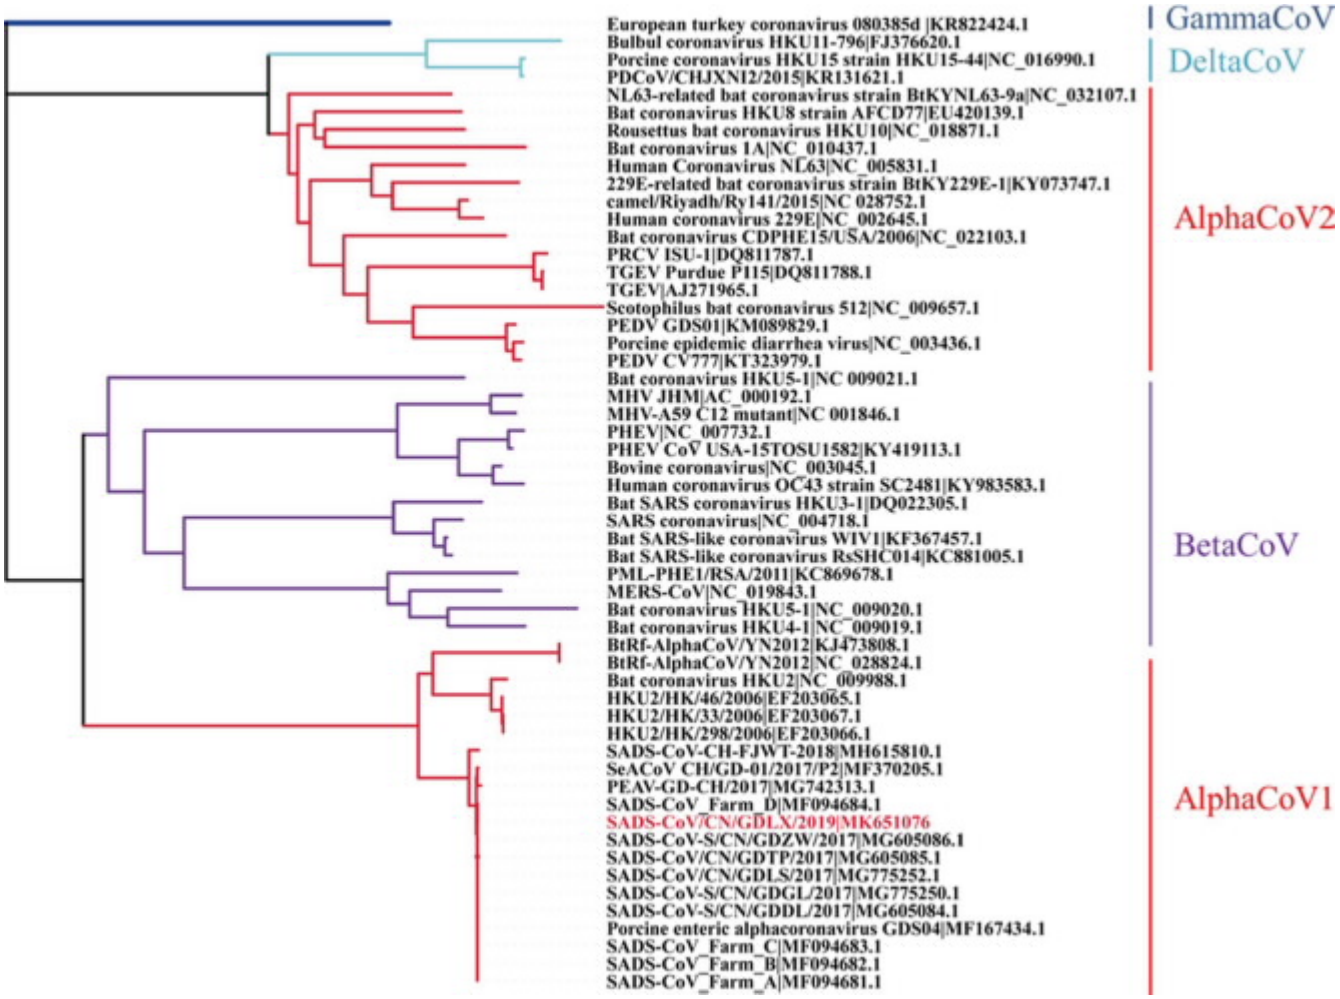

FIGURE 3 Phylogenetic analysis of the S gene of SADS-CoV and reference coronavirus species. The tree was constructed using MEGA 7.0 software with neighbour-joining methods and 1,000 replicate sets on bootstrap analysis [Colour figure can be viewed at wileyonlinelibrary.com]

(Felsenstein, 1985). For the whole genomes, sequence alignment results revealed that the nucleotide identities between SADS-CoV/CN/GDLX/2019 and previously reported SADS-CoV strains ranged from 99.3% to 100%. Moreover, the phylogenetic tree indicated that the novel SADS-CoV complete genome clustered together with other reported SADS-CoV strains and located in the Alpha coronavirus branch (Figure 2). Phylogenetic analysis based on S genes was also conducted, and the result showed that all SADS-CoV, bat HKU2 and BtRf-AlphaCoV strains were separated from other AlphaCoVs and clustered within BetaCoVs (Figure 3), which is consistent with previous studies (Pan et al., 2017; Xu et al., 2019; Zhou et al., 2019). Notably, the S gene of SADS-CoV/CN/GDLX/2019 had high identities of 99.2%–99.9% with other SADS-CoV strains detected in Guangdong and lowest identities of 97.5% with SADS-CoV-CH-FJWT-2018 reported from Fujian. Additionally, the comparative analysis of amino acids encoded by S gene revealed that the S protein of the novel strain had a two-amino-acid mutation (F306 and I882) compared with that of other SADS-CoV strains. It is well known that the S protein of coronavirus play an important role in cellular entry and determining the immunogenicity (Li, Frank, He, Peter, & Berend-Jan, 2016). In view of the lowest identities of Spike gene between the strains from Guangdong and Fujian, continuous monitoring of SADS-CoV genetic evolution is important for better understanding its epidemiology and establishing efficient strategies against its further circulating in pigs in China.

Here, we reported a new case of acute diarrhoea outbreak from a swine farm in Guangdong province on February 2019. Pathogenic and serologic analysis determined that SADS-CoV re-emerged in Guangdong and was responsible for the recent acute diarrhoea outbreak. Phylogenetic analysis based on whole genomes showed that SADS-CoV/CN/GDLX/2019 shared high nucleotide identities with previously reported SADS-CoV strains. Taken together, our study highlighted the significant threat of SADS-CoV and the potential outbreak of SADS epidemic in following months in Guangdong. Therefore, the persistent surveillance and vaccination countermeasures will be necessary to control the spread of SADS-CoV.

ABSTRACT

Outbreaks of severe diarrhea in neonatal piglets in Guangdong, China in 2017 resulted in isolation and discovery of a novel swine enteric alphacoronavirus (SeACoV) derived from the species *Rhinolophus bat coronavirus HKU2* (Vet Microbiol, 2017, 211:15-21). SeACoV was later referred to as swine acute diarrhea syndrome (SADS) CoV by another group (Nature, 2018, 556:255-258). The present study was set up to investigate potential species barriers of SADS-CoV *in vitro* and *in vivo*. We first demonstrated that SADS-CoV possesses a broad species tropism and is able to infect cell lines from diverse species including bats, mice, rats, gerbils, hamsters, pigs, chickens, nonhuman primates and humans. Trypsin contributes to, but is not essential for SADS-CoV propagation *in vitro*. Furthermore, C57BL/6J mice were inoculated with the virus via oral or intraperitoneal routes. Although the mice exhibited only subclinical infection, they supported viral replication and prolonged infection in the spleen. SADS-CoV nonstructural proteins and double-stranded RNA were detected in splenocytes of the marginal zone on the edge of lymphatic follicles, indicating active replication of SADS-CoV in the mouse model. We identified that splenic dendritic cells (DCs) are the major targets of virus infection by immunofluorescence and flow cytometry approaches. Finally, we demonstrated that SADS-CoV does not utilize known CoV receptors for cellular entry. The ability of SADS-CoV to replicate in various cells lines from a broad range of species and the unexpected tropism for murine DCs provide important insights into the biology of this bat-origin CoV, highlighting its possible ability to cross interspecies barriers.

43 **IMPORTANCE**

44 Infections with bat-origin CoVs (SARS-CoV and MERS-CoV) have caused severe illness
45 in humans after "host jump" events. Recently, a novel bat-HKU2-like CoV named swine acute
46 diarrhea syndrome CoV (SADS-CoV) has emerged in southern China, causing a lethal diarrhea
47 in newborn piglets. It is important to assess the species barriers of SADS-CoV infection since the
48 animal hosts (other than pigs and bats) and zoonotic potential are still unknown. An *in vitro*
49 susceptibility study revealed a broad species tropism of SADS-CoV, including various rodent
50 and human cell lines. We established a mouse model of SADS-CoV infection, identifying its
51 active replication in splenic dendritic cells, which suggests that SADS-CoV has the potential to
52 infect rodents. These findings highlight the potential cross-species transmissibility of SADS-CoV,
53 though further surveillance in other animal populations is needed to fully understand the ecology
54 of this bat-HKU2-origin CoV.

INTRODUCTION

The spread of zoonotic pathogens remains among the leading threats to global public health . Coronaviruses (CoVs) can infect a wide variety of animals and humans, resulting in several diseases with respiratory, enteric, and neurological pathologies of varying severity (1-4). Because of the various routes of infection and extensive phagocytosis in tissues, close contact between humans and animals provides potential scenarios for adaptive mutation and interspecies transmission (5).

The source of the severe acute respiratory syndrome (SARS)-CoV was traced to civets in animal markets and ultimately to bats, leading to more than 8,000 human infections and 774 deaths after its emergence in 2002 (5-7). The emergence of Middle East respiratory syndrome (MERS)-CoV in 2012 (2) resulted in more than 1,000 clinical cases with a mortality rate of 35%, making it the second marked threatening CoV of the 21st century (8, 9). Although camels can be infected with MERS-CoV, bats are also thought to be the original host of MERS-CoV (5). Both SARS-CoV and MERS-CoV originated in bats, illustrating the damage caused by CoVs during interspecies transmission events, and highlighting the need for increased global vigilance of CoV-associated disease (1, 5, 10).

In February 2017, outbreaks of severe diarrhea of suckling piglets occurred in swine herds in Guangdong Province, China (11). Clinical signs consisted of acute vomiting and watery diarrhea, but porcine viruses commonly associated with diarrhea including porcine epidemic diarrhea virus (PEDV), transmissible gastroenteritis virus (TGEV) and porcine deltacoronavirus (PDCoV) were not detected in any of the clinical samples (11). The new enteric pathogen of

commercial pigs that was isolated was finally identified as a new porcine CoV belonging to the species *Rhinolophus bat coronavirus HKU2* (11-13). Our research group tentatively designated this newly emerged virus as swine enteric alphacoronavirus (SeACoV) (11), and it was later named swine acute diarrhea syndrome (SADS)-CoV by Zhou *et al.* (14). It is also known by other names, such as porcine enteric alphacoronavirus (PEAV) (13). For purposes of unity, SADS-CoV is the name used to refer to this new virus in the current study. The expanded host range of bat-origin HKU2 to pigs indicates that bats play an important role in the ecology and evolution of SADS-CoV, though the mechanism of bat-to-swine transmission remains unclear. In view of the damage caused by SARS and MERS for both animal and public health, careful attention must be paid to the prevalence of CoV-associated disease among humans and domestic animals (15).

Therefore, there is an urgent need for more information on the details of SADS-CoV infection. It is critically important to assess potential species barriers of SADS-CoV transmission since the animal hosts (other than pigs and bats) and zoonotic potential are still unknown. In the present study, we demonstrated that SADS-CoV possesses a very broad species tropism *in vitro* and is able to infect cell lines from diverse species including rodents and humans. Furthermore, *in vivo* evidence from experimental infection of mice with SADS-CoV identified splenic dendritic cells (DCs) as the major site of SADS-CoV replication in mice. Finally, we demonstrated that SADS-CoV does not utilize known CoV protein receptors for cellular entry. These results present the possibility that rodents are among the susceptible hosts of SADS-CoV, highlighting the potential cross-species transmissibility of SADS-CoV.

101

102 **MATERIALS AND METHODS**

103 **Virus stocks and viral antibodies.** The SADS-CoV isolate CH/GD-01/2017 at passage 10
104 was used in all experiments and cultured in Vero cells (16). The virus was passaged serially using
105 the culture supernatant to infect fresh Vero cells at a multiplicity of infection (MOI) of 0.1, and
106 viral titers were determined in Vero cells by endpoint dilution as the 50% tissue culture infective
107 dose 50% ($TCID_{50}$). Rabbit polyclonal antibodies (pAb) against the membrane (M),
108 nucleocapsid (N) and the nonstructural protein 3 (Nsp3) acidic domain (AC) of SADS-CoV were
109 generated in-house, and validated in SADS-CoV-infected Vero cells (16). A mouse
110 anti-SADS-CoV-N pAb was also produced to allow double staining when mixed with the rabbit
111 pAb. A monoclonal antibody (MAb) against dsRNA (anti-dsRNA mAb J2, Cat# J2-1702,
112 SCICONS, Hungary) was used to specifically detect viral replication of SADS -CoV.

113 **Cell lines and cell culture.** Twenty-four cell lines derived from tissues of different species
114 were used (Table 1), including human (Huh-7, HepG2/C3A, 293T, A549 and HeLa), monkey
115 (Marc-145, Cos-7, BSC-40, Vero), swine [ST, PK15, LLC-PK1, IPEC-J2 (17)], bat [BFK (18),
116 Tb-1], canine (MDCK), mouse (NIH/3T3, RAW 264.7), hamster (BHK -21, CHO), rat (BRL-3A,
117 NRK-52E), chicken (DF-1) cell lines and a primary kidney cell line from Mongolian gerbils
118 (prepared in-house). The BFK cell line was a generous gift from Dr. Changchun Tu at the
119 Institute of Military Veterinary Medicine, Changchun, China. Each cell line was cultured in
120 Dulbecco's modified Eagle's medium (DMEM, Hyclone) supplemented wit h 10% (v/v) fetal
121 bovine serum (FBS, Biological Industries), 100 U/m1 penicillin and 100 U/ml streptomycin at

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

122 37 °C, 5% CO_2, and water-saturated humidity conditions.

123 To determine viral susceptibility, each cell line was cultured at 70% confluence in 12-well
124 plates with maintenance medium (MM) containing DMEM, 0.3% tryptose phosphate broth
125 (TPB), and 1% penicillin/streptomycin, or MM with addition of 5 μg/ml trypsin (MMT) (Sigma,
126 Cat#T7186-50TAB, St Louis, MO, USA). After washing with phosphate buffered saline (PBS),
127 cells were inoculated with SADS-CoV diluted in MM or MMT at an MOI of 0.01 for 2 h.
128 Non-attached viruses were removed by washing the cells three times with DMEM, and cell
129 monolayers were subsequently incubated in MM or MMT at 37 °C for 5 days. To determine the
130 effect of trypsin on viral entry, cell monolayers were infected by SADS-CoV in three conditions:
131 1) no trypsin treatment, infected with SADS-CoV diluted in MM, subsequently incubated in MM;
132 2) pre-trypsin treatment, inoculated with SADS-CoV diluted in MMT, subsequently incubated in
133 MM; and 3) double-trypsin treatment, inoculated with SADS-CoV in MMT, subsequently
134 incubated in MMT. Supernatants from cells were collected at 12, 24, 36, 48, 72, and 120 hours
135 post-infection (hpi) for one-step quantitative RT-PCR analysis. Cell cultures were examined for
136 cytopathic effects (CPE) and immunofluorescence assay at 48-72 hpi.

137 **Immunofluorescence assay (IFA) for cell line susceptibility.** Different cells infected with
138 SADS-CoV in 12-well plates were washed twice with PBS and fixed in 4% paraformaldehyde in
139 PBS and then permeabilized with 0.1% Triton X-100 in PBS. Cells were then incubated with the
140 rabbit anti-SADS-CoV-M pAb at 1:5000 dilution for 1 h at 37 °C, washed with PBS and stained
141 with the Alexa Fluor 488-conjugated goat anti-rabbit secondary antibody (Thermo Fisher
142 Scientific, USA) at 1:1000 dilution. After incubation for 1 h at 37 °C, the cells were washed with

143 PBS, stained with 4′,6-diamidino-2-phenylindole (DAPI) at 1:1000 dilution and visualized on a
144 fluorescence microscope.

145 **One-step quantitative RT-PCR analysis targeting the N gene.** The full-length SADS-CoV
146 N gene was inserted into an appropriately digested pET-28a vector using two unique restriction
147 sites, *Nde*I and *Xho*I, and then linearized with *Xho*I. The N gene was *in vitro* transcribed using
148 the T7 High Efficiency Transcription Kit (TransGen Biotech Co., LTD, Beijing China). Standard
149 curves were generated using dilutions of known quantity of N gene RNA to allow absolute
150 quantitation of SADS-CoV RNA copy numbers in samples.

151 Total RNA was extracted from culture supernatants or tissue homogenates using Trizol
152 (ThermoFisher Scientific, USA) following the manufacturer's instructions. SADS-CoV RNA
153 titer was determined by one-step qRT-PCR (TOYOBO Co., LTD) targeting the N gene with the
154 primers: 5'-CTAAAACTAGCCCCACAGGTC-3' and 5'-TGATTGCGAGAACGAGACTG-3',
155 and the probe FAM-GAAACCCAAACTGAGGTGTAGCAGG-TAMRA. Samples with a cycle
156 threshold value <35 were considered positive based upon validation data using the RNA
157 standards.

158 **Mouse infections, tissue harvest and viral load determination.** Wild-type C57BL/6J mice
159 (Jackson no. 000664) were purchased from the Model Animal Research Center of Nanjing
160 University and housed in animal facilities at the Zhejiang University under
161 specific-pathogen-free condition. For SADS-CoV infections, 6- to 8-week-old female and male
162 mice were inoculated with 5×10^5 $TCID_{50}$ (equal to 6×10^8 genome copies) of SADS-CoV, either
163 per oral infection (p.o.) with 25 μl inoculum (2×10^7 $TCID_{50}$/ml) or intraperitoneal infection (i.p.)

with 200 µl inoculum (2.5×10^6 $TCID_{50}$/ml). For viral load determination in specific tissues, mice were euthanized at 1, 3, 5, 7, 14, 21, and 28 days post-infection (dpi), and tissues were harvested including stomach, duodenum, jejunum, ileum, cecum, colon, mesenteric lymph nodes, spleen, kidney, liver, heart, lung, blood and feces. Tissues were weighed and homogenized in medium (DMEM contained 2% FBS) by bead beating using sterile zirconium oxide beads (Cat# ZrOB20 MidSci). Total RNA was extracted from tissue homogenates and tested by quantitative RT-PCR analysis targeting the SADS-CoV N gene, as described above. Blood samples were collected from the heart and serum was separated for virus-specific antibody detection.

Enzyme-linked immunosorbent assay (ELISA). SADS-CoV virus particles were purified from infected cell culture supernatants by sucrose density gradient centrifugation, and protein concentration was determined by the BCA Protein Assay kit (Beyotime Biotechnology, Shanghai, China). The optimal dilution of antigen was determined by square titration. The IgG antibodies contained in serum at a 1:100 dilution were detected in wells coated with purified SADS-CoV virus particles (6.25 ng/well) as antigen.

Histopathology, immunohistochemistry and immunofluorescence assay for murine spleen. Mice were infected i.p. with SADS-CoV and at 3 dpi, spleens were harvested and fixed in 4% paraformaldehyde for 24 h and embedded in paraffin. Tissue sections were then deparaffinized and rehydrated in three changes of xylene, 15 min each, dehydrated in two changes of pure ethanol for 5 min, followed by rehydration in an ethanol gradient of 85% and 75% ethanol. After washing in distilled water, tissues were subjected to hematoxylin and eosin staining for histopathological examinations.

185 For antigen retrieval, deparaffinized and rehydrated sections were immersed in sodium
186 citrate antigen retrieval solution (pH 6.0) and maintained at a sub-boiling temperature for 8 min,
187 let stand at 98 °C for 8 min and then incubated again at sub-boiling temperature for 7 min. After
188 allowing to cool to room temperature (RT) and washing three times with PBS (pH 7.4),
189 endogenous peroxidase was blocked by immersion in 3% hydrogen peroxide at RT for 30 min
190 and again washed with PBS. Tissue sections were blocked in 3% BSA at RT for 30 min, then
191 incubated with 1:500 dilution of each primary antibody (anti-dsRNA MAb, anti-SADS-CoV-M
192 pAb or anti-SADS-CoV-AC pAb) overnight at 4 °C. After washing slides three times with PBS
193 (pH 7.4), they were stained with appropriate secondary antibodies labeled with horseradish
194 peroxidase at RT for 50 min. Freshly prepared diaminobenzidine chromogenic reagent was added
195 and counterstained with hematoxylin, then dehydrated and visualized on a light microscope.
196 Spontaneous fluorescence quenching reagent (Wuhan servicebio technology Co., Ltd,
197 Wuhan, China) was added to the tissue sections and incubated for 5 min after antigen retrieval.
198 The sections were then washed in running water, followed with blocking and antibody staining
199 as described above. In addition, the primary antibody was supplement with a CD11c antibody
200 (Wuhan servicebio technology Co., Ltd, Wuhan, China) at a 1:200 dilution, then stained with
201 appropriate secondary antibodies. Finally, DAPI was added and sections were visualized on a
202 fluorescence microscope; nuclei labeled with DAPI appear blue, positive cells are green by
203 labeling with CD11/c or red by labeling with virus-specific antibody.
204 **Preparation of murine splenocytes and flow cytometry.** Mice infected with SADS-CoV
205 were euthanized at 3 dpi, and spleens were removed and placed in 5 ml complete DMEM. After

grinding the excised spleen through a 100-μm cell strainer using the plunger end of a 5-ml syringe, cells were washed with an excess of DMEM and centrifuged at 200 ×g for 5 min. After resuspending cells in 3 ml of red blood cell lysis buffer (Solarbio Life Sciences, Beijing, China) and incubation at RT for 10 min, 5 ml of DMEM was added and cells were passed through another strainer to remove clumps. After centrifugation at 200 ×g for 5 min, the supernatant was discarded and cells were resuspended in 10 ml fresh DMEM for cell counting and viability checks using trypan blue and a hemocytometer.

For flow cytometry, cultured cells were resuspended in Fc Block buffer (containing anti-mouse CD16 Fc Block Antibody at 1:500 dilution) and incubated on ice. Cells in Fc Block buffer were added to 96-well plates at 1×10^6 cells/well. After 30 min incubation, cells were centrifuged at 200 ×g for 10 min, the supernatant was discarded and pellets resuspended in 100 μl Cytofix/Cytoperm solution (Cytofix/Cytoperm Soln Kit; BD Biosciences, San Jose, CA, USA) to fix cells. After incubation on ice for 20 min protected from light , cells were centrifuged at 800 ×g for 5 min at 4 °C, supernatant was removed without disturbing cell pellets and cells were washed twice in 150 μl of 1x Perm/Wash buffer. After addition of 50 μl virus-specific primary antibody (anti-dsRNA MAb, anti-SADS-CoV-N pAb or anti-SADS-CoV-AC pAb) diluted in 1× Perm/Wash buffer with 3% BSA and incubation at 4 °C for 30 min, cells were centrifuged at 200 ×g for 10 min. Cells were washed twice in 150 μl of 1× Perm/Wash buffer followed by staining with appropriate secondary antibodies conjugated to Alexa Fluor 488 (Thermo Fisher Scientific, USA) at 4 °C for 30 min. After centrifuging at 800 ×g for 5 min at 4 °C and washing with 1× Perm/Wash buffer, pellets were resuspended in 0.2 ml FACS buffer and analyzed by flow

227 cytometry.

228 **Infection of splenocytes *in vitro*.** To detect replication of SADS-CoV in mouse splenic cells
229 *in vitro*, splenocytes were extracted from naïve mice, plated in 100- or 35-mm dishes and
230 infected with SADS-CoV at an MOI of 0.1. At 48 hpi, splenocytes were harvested and placed in
231 a 15-ml tube, centrifuged at 200 ×g for 10 min at 4 °C, and analyzed by flow cytometry as
232 described above. Infected mouse splenic cells in 35-mm dishes were detected by
233 immunofluorescence assay with anti-SADS-CoV-N antibodies, and infection supernatants were
234 collected at 0, 12, 24, 36, 48 and 72 hpi for one-step quantitative RT-PCR analysis.

235 **FACS analysis of splenocytes with cell marker staining.** Mice infected with SADS-CoV
236 were euthanized at 3 dpi, and splenocytes were prepared for flow cytometry by staining with
237 appropriate antibodies: anti-SADS-CoV-AC following secondary antibodies conjugated to Alexa
238 Fluor 647 (Thermo Fisher Scientific, USA); anti-CD19-FITC (eBioscience, Catalog no.4318813)
239 for B cells; anti-CD4-PE (eBioscience, Catalog no.4329629) for T cells; anti-CD11/c-PE-Cy7
240 (BD Bioscience, Catalog no.561022) for DCs; and anti-F4/80-PE/Cy5 (Biolegend, Catalog
241 no.123111) for macrophages. Stained cells were resuspended in 0.2 ml FACS buffer and
242 analyzed by flow cytometry.

243 **Production and transduction of S protein-pseudotyped lentiviruses.** Pseudovirions with
244 various CoV spike proteins were produced as described previously (19). Briefly, each of the
245 plasmids encoding TGEV, SARS-CoV, MERS-CoV, and mouse hepatitis virus (MHV) S proteins
246 were cotransfected into 293T cells with pLenti-Luc-green fluorescent protein (GFP) and psPAX2
247 plasmids (kindly provided by Dr. Zhaohui Qian, Chinese Academy of Medical Sciences &

248 Peking Union Medical College) at a molar ratio of 1:1:1 by using polyethylenimine (PEI). The
249 cells were fed with fresh medium in the next 24 h and the supernatant media containing
250 pseudovirions were then collected and centrifuged at 800 ×g for 5 min to remove debris. To
251 quantify S protein-mediated entry of pseudovirions, MDCK cells were seeded at about 25-30%
252 confluency in 24-well plates and transfected with either pAPN-Flag, hDPP4-Flag,
253 mCEACAM1a-Flag, hACE2-GFP (kindly provided by Dr. Zhaohui Qian) (19) or the control
254 backbone vector by using Lipofectamine 3000 (Thermo Fisher). The MDCK cells
255 overexpressing each receptor were inoculated with 500 µl of 1:1 diluted corresponding
256 pseudovirions at 24 h post-transfection. At 40 hpi, cells were lysed at room temperature with 110
257 µl of medium with an equal volume of Steady-Glo (Promega, Madison, WI). The cell lysates
258 were also used to confirm the expression of each receptor by using western blotting.
259 Transduction efficiency was monitored by quantitation of luciferase activity using a Modulus II
260 microplate reader (Turner Biosystems, Sunnyvale, CA). On the other hand, the MDCK cells
261 overexpressing each receptor were inoculated with SADS-CoV (MOI=1) at 24 h
262 post-transfection. IFA was performed to test for SADS-CoV susceptibility using anti-N pAb. The
263 replication competency of SADS-CoV in MDCK cells was further determined by a reverse
264 genetics system. Development of a DNA-launched SADS-CoV (SeACoV) infectious cDNA
265 clone (named pSEA) and rescue of SADS-CoV by transfection of cultured cells with pSEA
266 followed by passaging on Vero cells have been described recently by our lab (16).

267 **Ethics statement.** All animal experiments were performed in strict accordance with the
268 Experimental Animal Ethics Committee of Zhejiang University (approval no. ZJU20170026).

RESULTS

SADS-CoV can infect cell lines originating from various species. Previously, we reported that SADS-CoV was isolated in Vero cells supplemented with trypsin (11). Since exogenous trypsin is essential for propagation of PEDV isolates *in vitro* (20), likely by mediating activation of membrane fusion by S glycoprotein proteolysis (21), we were interesting to know whether it is also required for SADS-CoV growth in cell culture. A total of 24 cell lines originating in various tissues of humans and different animal species were tested for susceptibility to SADS-CoV treated with or without trypsin (Table 1). In brief summary of the results, 21 of the 24 cell lines showed significant susceptibility to SADS-CoV infection, defined by efficient viral replication, antigen expression and the appearance of CPE. The three cell lines that were not infected by SADS-CoV were MDCK, BFK and RAW 264.7.

First, CPE was examined by inverted light microscopy at 48 hpi, and scores are shown in Table 1. As the 293T, NIH/3T3, CHO, BRL-3A and NRK-52E cell lines were sensitive to trypsin, they couldn't be tested for SADS-CoV infection in MMT. Apart from that, CPE was visible in Vero, ST and BRL-3A cell lines without trypsin, and prominent CPE appeared or was enhanced with trypsin in Marc-145, Cos-7, BSC-40, Vero, ST, PK15, LLC-PK1 and BHK-21 cell lines (Table 1).

As some cells did not display CPE after SADS-CoV infection, all cell lines were subsequently tested for viral M protein expression by IFA (Fig. 1), revealing the same range as seen by CPE in the different cell lines (data not shown). Syncytia formation was prominent in

Accepted Manuscript Posted Online

Journal of Virology

JVI

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

290 Huh-7, Vero and BHK-21 cells, whereas in MDCK, BFK and RAW 264.7 cells the antigen
291 expression was much less prominent than in the other cell lines (Figs. 1A, 1C and 1I). Most cell
292 lines tested showed evidence of productive infection as indicated by expression of the M protein,
293 while the inefficient antigen expression in Marc-145, LLC-PK1 and IPEC-J2 cells suggested
294 only a limited infection.

295 Next, viral load in the culture supernatants was detected over 5 dpi by quantitative RT-PCR
296 (Fig. 2A-2C). A higher mean viral load was detected by qRT-PCR after trypsin treatment in
297 HepG2, HeLa, Marc-145, Cos-7, BSC-40, Vero, LLC-PK1, IPEC-J2, BHK-21 and DF-1 cells.
298 Therefore, trypsin contributes to, but is not essential for SADS-CoV propagation in these cell
299 lines. There was no difference after trypsin treatment in the other cell lines, though Huh-7 and
300 Tb-1 cells had high levels of SADS-CoV RNA regardless of trypsin treatment.

301 The progressive release of infectious SADS-CoV into the culture medium of six
302 representative cell lines infected with SADS-CoV was determined by titration of supernatants in
303 Vero cells (Fig. 2D). Unlike in MDCK cells, SADS-CoV infection of HeLa, Vero, Tb-1,
304 BHK-21 and PK-15 cells was productive, with HeLa cells showing the greatest susceptibility
305 (Fig. 2D).

306 **Wild-type C57BL/6J mice can be infected by SADS-CoV via oral and intraperitoneal**
307 **routes.** With the observation that SADS-CoV could infect diverse rodent cell lines (from mice,
308 rats and hamsters as well as gerbil primary kidney cells), we hypothesized that mice may be
309 susceptible to SADS-CoV. To test this, we inoculated 6- to 8-week-old wild-type B6 mice with
310 5×10^5 $TCID_{50}$ of SADS-CoV by the p.o. or i.p. route and monitored them for 28 days for clinical

Accepted Manuscript Posted Online

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

311 symptoms. The mice did not succumb to the infection nor did they develop diarrhea or
312 experience weight loss during the incubation period (data not shown).

313 To determine whether SADS-CoV infected the animals asymptomatically, tissue and fecal
314 samples from inoculated mice were collected at 1, 3, 5, 7, 14, 21 and 28 dpi to determine viral
315 growth kinetics and shedding. Analysis of tissue samples by qRT-PCR suggested that
316 SADS-CoV replicated modestly in the stomach early after i.p. or p.o. infection, declining and
317 reaching undetectable levels at 7 or 14 dpi and thereafter (Fig. 3A). A very limited viral
318 replication was observed in each region of the small intestine, with the ileum via i.p. infection
319 showing continuous and decent detectable viral RNA (Fig. 3B). In the large intestine, i.p.
320 infection also resulted in viral RNA loads slightly above the limit of detection at each time point
321 in the ceca, whereas it led to higher viral RNA levels at 1-3 dpi, and much lower viral RNA at
322 21-28 dpi in the colon compared to the p.o. route (Fig. 3C). However, this replication in the large
323 intestine did not translate into higher shedding, as hardly any viral genomes were detected even
324 at 1 dpi in the fecal samples collected from i.p.-infected mice (Fig. 3F). On the contrary,
325 significantly more virus was detected in the feces of p.o.-infected mice at 1 and 3 dpi, indicating
326 that i.p. inoculation does not lead to higher virus shedding.

327 Finally, SADS-CoV replicated more efficiently in the spleen following the i.p. route, with
328 significantly higher viral RNA loads at 21 dpi (Fig. 3D). More importantly, the virus was not
329 cleared from this tissue by 28 dpi in the i.p.-infected group and by 14 dpi in the p.o.-infected
330 group, suggestive of a SADS-CoV prolonged infection in the spleen independent of inoculation
331 route. In contrast to the spleen, only very low levels of viral RNA were detected in the local

JVI

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

lymphoid tissue of mesenteric lymph nodes (MLNs) at 1-3 dpi, and no virus was detectable at later time points (Fig. 3D). We also looked for virus in other extraintestinal sites including the heart, lungs, liver, kidneys and blood, but they were all negative or had extremely low levels (Fig. 3E). IgG antibody levels after 7 days detected by SADS-CoV virion-based ELISA showed that the i.p. route could effectively elicit host immune responses (Fig. 3G).

Splenocytes support SADS-CoV replication. With the mouse infection model described above, our next step was to determine the cell tropism of SADS-CoV *in vivo*. Thus, we performed immunohistochemistry (IHC) on sections of small and large intestine and spleen from mice infected i.p. with 5×10^5 $TCID_{50}$ of SADS-CoV at 3 dpi. A monoclonal antibody against dsRNA was used to identify cells that supported active virus replication, as dsRNA is an intermediate that only exists during intracellular viral replication. SADS-CoV dsRNA signals were observed in the splenic white pulp in the marginal zone on the edge of lymphatic follicles, and in the margins of the periarteriolar lymphocyte sheath (Fig. 4A). Staining of tissue sections from mock-infected mice were used as a control (Fig. 4B). In addition to dsRNA, we also used rabbit pAbs to detect expression of viral structural protein (M) or nonstructural protein (Nsp3-AC). At 3 dpi, anti-M or anti-AC staining was observed in the white pulp around the lymphatic nodules (Fig. 4C), similar to the localization of dsRNA staining (Fig. 4A). Tissue sections from SADS-CoV or mock-infected mice probed with preimmune sera were negative, indicating the specificity of the SADS-CoV antibody. Unfortunately, neither viral proteins (structural or nonstructural) nor dsRNA were detected in the intestine of infected mice, consistent with the detection of only very low levels of viral RNA in these tissues by qRT-PCR

353 (Fig. 3).

354 Next, SADS-CoV infection was quantified in the spleen using flow cytometry. We
355 inoculated B6 wild-type mice with 5×10^5 $TCID_{50}$ of virus either i.p. or p.o., and extracted the
356 bulk immune cells from the spleen of infected animals at 3 dpi. The flow cytometry method was
357 first validated in Vero cells infected with SADS-CoV at an MOI of 0.01 followed by staining
358 with pAb against the N or AC protein at 24 hpi (Fig. 4D). As the anti-AC pAb exhibited optimal
359 intracellular staining for viral signals (Fig. 4D), it was used to determine the percentage of
360 infected splenocytes. Approximately 1.5- and 2.5-fold increase of total splenocytes were positive
361 for virus replication after p.o. and i.p. inoculation, respectively (Fig. 4E, the left panel; Fig. 4F),
362 with a significant increase in the total number of AC-positive splenocytes in i.p.-infected mice
363 compared to p.o. (Fig. 4E, the right panel). This data is consistent with the significantly lower
364 viral loads in the spleen at 1 and 3 dpi in p.o.-inoculated mice (Fig. 3D), suggesting better virus
365 dissemination and replication and escape from mucosal immune clearance.

366 We then evaluated the growth characteristics of SADS-CoV in splenocytes by assessing
367 antigen production and replication kinetics *ex vitro*. Splenocytes were first extracted from naïve
368 mice, plated in 100 mm dishes and infected with 1×10^5 $TCID_{50}$ of SADS-CoV. We observed
369 clusters of infected cells that appeared to have been engulfed by phagocytes (Fig. 4G, the middle
370 panel), and the structural N protein was shown in the cytoplasm of infected cells by confocal
371 microscopy (Fig. 4G, the middle and right panels). The percentage of infected cells was
372 quantified by flow cytometry using anti-AC pAb, revealing that nearly 2-fold increase of the
373 splenocytes were positive for viral signals (Fig. 4H), very similar to the percentage of infection

374 observed *in vivo*. To further characterize the growth kinetic of SADS-CoV in primary
375 splenocytes, cells were infected with 1×10^5 $TCID_{50}$ of SADS-CoV, and culture supernatants
376 were harvested at 0, 12, 24, 48 and 72 hpi. Active viral replication was confirmed, with a 1.5-log
377 time-dependent increase in genomic RNA equivalents, plateauing from 24 to 72 hpi (Fig. 4I).
378 This data suggests that although only ~2% of splenocytes were infected, these cells supported a
379 decent level of viral replication. Together, these results indicate that SADS-CoV productively
380 infects mouse splenocytes.

381 **Splenic DCs support SADS-CoV replication.** Splenocytes were harvested from
382 i.p.-infected mice at 3 dpi, and the extracted cells were co-stained with antibodies against
383 SADS-CoV-AC and each of four cell surface markers (anti-CD19 for B cells; anti-CD4 for T
384 cells; anti-$CD11/c^+$ for DCs and anti-$F4/80^+$ for macrophages) using flow cytometry (Fig. 5A).
385 The percentage of infected $CD11/c^+$ cells was significantly higher than the other cell subgroups,
386 indicating that DCs are the major targets of SADS-CoV infection in the spleen.

387 The phenotype was further confirmed by double-staining IFA with anti-dsRNA, anti-M or
388 anti-AC antibody plus anti-$CD11/c^+$ in splenic sections. As expected, dsRNA staining
389 overlapped with the CD11/c surface marker on the edges of lymphatic follicles (Fig. 5B),
390 whereas no viral signals were seen in the mock-infected control (Fig. 5C). Similar patterns of
391 co-staining were detected by M and AC antibodies (Fig. 5D). To gain insight into the relative
392 quantity of DCs compared to other undefined target cells, cells positive for dsRNA and CD11/c
393 were counted in 10-15 different microscope fields of spleens from 3 infected mice (Fig. 5E),
394 showing that 61.76% of SADS-CoV-infected cells were DCs (Fig. 5F).

395 **SADS-CoV does not utilize known CoV protein receptors for cellular entry.** To our
396 knowledge, these results reveal the most extensive cell tropism among known CoVs, suggesting
397 the functional receptor(s) for SADS-CoV is likely to be a very common molecule. In order to test
398 this hypothesis, it was first necessary to find a cell line that was refractory to infection only at the
399 internalization step. MDCK cells, which showed undetectable virus production in early infection
400 tests (Fig. 1 and Fig. 2), were chosen as a potential candidate. There are four known types of
401 functional CoV protein receptors, including angiotensin converting enzyme 2 (ACE2) for
402 SARS-CoV (22), dipeptidyl peptidase 4 (DPP4) for MERS-CoV (23), aminopeptidase N (APN)
403 for TGEV (24) and PDCoV (25, 26), and mouse carcinoembryonic antigen-related cell adhesion
404 molecule 1a (mCEACAM1a) for MHV (27). To test whether one of these molecules serves as the
405 SADS-CoV receptor, we attempted to inoculate non-susceptible MDCK cells overexpressing
406 porcine APN, human DPP4, mouse CEACAM1a, or human ACE2 with SADS-CoV, but none of
407 them allowed infection as staining with anti-SADS-CoV-N pAb was negative (Fig. 6A).
408 Meanwhile, the expression of each receptor in MDCK cells was confirmed by IFA (Fig. 6A) and
409 western blot analysis (Fig. 6B) using antibodies against the tags fused to the receptors. As
410 positive controls, we confirmed that lentiviruses pseudotyped with TGEV, SARS-CoV,
411 MERS-CoV or MHV spike (i.e., pseudoviruses) efficiently entered MDCK cells exogenously
412 expressing the respective receptors (Fig. 6C).

413 Next, we demonstrated that MDCK cells can confer SADS-CoV replication competency by
414 transfection of a SADS-CoV/SeACoV infectious cDNA clone established recently (16), as
415 simultaneous expression of Nsp3-AC and N proteins were clearly detected by IFA (Fig. 6D).

Moreover, passaging of supernatants from pSEA-transfected MDCK cells onto fresh Vero cells resulted in progeny SADS-CoV infection, as evidenced by expression of the N protein (Fig. 6E), indicating that MDCK cells can also support infectious SADS-CoV production without cell-to-cell spread. Therefore, SADS-CoV apparently does not utilize any of the known CoV receptors for cellular entry. The same conclusion was reached using HeLa cells overexpressing each of the four classical CoV receptors followed by SADS-CoV inoculation by Zhou et al (14); however, the HeLa cell line itself was most susceptible to SADS-CoV infection in the present study (Fig. 2D).

DISCUSSION

In order to assess the potential species barriers of SADS-CoV infection, a cell line susceptibility study was first conducted using 24 different cell lines. As SADS-CoV probably originated from a bat SADSr-CoV (14) derived from HKU2-CoV identified in *Rhinolophus sinicus* (Chinese horseshoe bats) (12), we commenced testing viral susceptibility in two available bat cell lines, BFK from *Myotis daubentonii* (18) and Tb-1 from *Tadarida brasiliensis*. Although BFK cells did not support SADS-CoV replication, it replicated efficiently in Tb-1 cells (Fig. 1A and Fig. 2), suggesting that other bat species in addition to horseshoe bats are likely susceptible to SADS-CoV infection.

Interestingly, SADS-CoV protein expression was detected in almost all of the rodent cells (hamster, gerbil, mouse and rat) including BHK-21, which is not susceptible to other known human CoVs such as SARS-CoV and MERS-CoV (28, 29) as well as three swine enteric CoVs,

437 PEDV, PDCoV and TGEV (25). Given the fact that SADS-CoV infects both primary and
438 passaged or primary cell lines originating from rodents, we hypothesized that rodents may be
439 susceptible to SADS-CoV infection. To explore this possibility, we challenged wild-type B6
440 mice with SADS-CoV by two different inoculation routes.

441 The challenged animals neither succumbed to infection nor manifested any signs of
442 gastroenteritis. In fact, experimental infection of neonatal piglets with a higher dose of purified
443 SADS-CoV in our laboratory only resulted in mild diarrheal signs or subclinical infection (11).
444 Also, there was a lack of robust viral replication in the intestines during infection, and no tissue
445 damage was detected throughout the intestines (Fig. 3B and 3C), reflecting the suboptimal
446 infection by SADS-CoV in immunocompetent wild-type mice. On the contrary, the virus had
447 more efficient replication within the spleen, reflected by a continuous detection of viral genomic
448 RNA in the immune cells at all time points over a 28-day period (Fig. 3D). The phenotype was
449 also consistent with the replication kinetics in extracted splenocytes *in vitro*, in which viral
450 genomic RNA peaked and plateaued at 72 hpi (Fig. 4G and 4I). This data collectively led to
451 speculation that SADS-CoV favors splenic cells over other tissues. The most logical explanation
452 for these tissue-specific discrepancies in virus replication is: i) target cells are more concentrated
453 in the spleen and more sporadic in the intestine; or ii) splenic immune cells have enhanced
454 expression of the unknown receptor(s) over intestinal cells. The animals were more susceptible
455 to i.p. infection, resulting in higher virus replication in the distal section of the small intestine,
456 large intestine and spleen, and perhaps a delayed clearance of viral infection in the cecum (Fig.
457 3B to 3E), suggesting the important role of mucosal immunity for controlling early infection in

458 SADS-CoV in mice. It should be note that mice (C57BL/6J mice in this study) may not be the
459 optimal rodent species for SADS-CoV infection, as wild rats are more commonly seen in
460 Chinese pig farms. In addition, other transmission routes may be considered. Recently, PDCoV
461 has been shown to possibly spread via the respiratory route in addition to fecal-oral transmission
462 (30). Therefore, it will be interesting to try intranasal route for inoculation in rats or the other
463 rodent species to mimic SADS-CoV natural transmission in future studies.

464 More interestingly, we identified DCs to be the precise cell population that supported
465 SADS-CoV replication (Fig. 5). There have been a few reports of immune cell tropism for CoVs.
466 Macrophages are susceptible to MHV infection, representing the largest group of innate immune
467 cells that infiltrate the central nervous system after infection with neurotropic MHV strains (31).
468 In addition, based on the fact that SARS-CoV spike-pseudotyped HIV-based vectors can
469 efficiently transduce human DCs, Kobinger *et al*. hypothesized that SARS-CoV infection in
470 immature DCs contributes to viral pathogenesis (32). Yang *et al*. demonstrated that SARS-CoV
471 can infect myeloid DCs via S glycoprotein-associated cell entry, and DC infection mediated viral
472 transmission to other cells *in vivo* (33). These previous evidences support our present results,
473 showing that SADS-CoV can efficiently replicate in DCs.

474 Furthermore, this study gives us a novel inspiration that rodents may potentially serve as
475 susceptible hosts for SADS-CoV in addition to bats and pigs. Of note, the species *Rhinolophus*
476 *bat α-CoV HKU2*, including SADS-CoV, possesses unique S genes closely related to the
477 betacoronavirus (β-CoV), in a manner similar to some globally distributed rodent α-CoVs (11, 34,
478 35), implying an unknown evolutionary connection between the bat α-CoV HKU2 and rodents

479 α-CoVs. In the field conditions of China, direct contact between pigs and flying bats is a low
480 probability; however, rodents (especially rats) are frequently visible in the swine industry,
481 causing great nuisance due to feed loss. It is possible that as bats prey on insects near pig
482 facilities, they leave feces containing HKU2-like CoVs that contaminate pig feed, which is then
483 eaten by pig and rodents that subsequently become carriers of SADS-CoV. Rats and mice are
484 increasingly implicated as external vectors for a wide range of different pig pathogens, such as *L.*
485 *intracellularis* (36). Rodents not only spread pathogens, but also harm the practitioners of the
486 swine industry, as they are thought to be the major source of leptospirosis in pigs and piggery
487 workers (37). Future study on identifying SADS-CoV-positive samples in rodents near pig farms
488 are warranted to test this hypothesis.

489 In addition to rodents, we also measured the SADS-CoV susceptibility of cell lines from
490 humans, monkeys, chickens and dogs, revealing a remarkably broad spectrum of tropism (Table
491 1 and Fig. 1). As for the ability of SADS-CoV to grow efficiently in human cell lines, we should
492 not underestimate the risk that this bat-origin CoV may 'jump' from pigs to humans. It is
493 noteworthy that camel workers with high rates of exposure to camel nasal and oral secretions had
494 evidence of MERS-CoV infection (38). Considering that SARS-CoV and MERS-CoV originated
495 from bats and spread from one species to another through intermediate hosts (civets and camels,
496 respectively), SADS-CoV may pose a similar risk to human health through transmission from
497 pigs or other susceptible hosts.

498 The cell susceptibility study and testing of overexpression of four known CoV receptors in
499 non-susceptible MDCK cells (Fig. 6) demonstrated that SADS-CoV might use a new receptor

molecule that is conserved in bats, pigs, rodents, chickens, monkeys and humans, indicating a low barrier to cross-species transmission. This is in line with the unusual feature of SADS-CoV's apparently broad species tropism.

In summary, these results provide important insights into the ecology of this bat-origin CoV, highlighting the possibility of its jumping interspecies barriers and the potential role of rodents as susceptible hosts in the field. Identification of the unknown SADS-CoV cellular receptor and further surveillance of other animal populations are needed to fully understand the biology of SADS-CoV.

Abstract

A new highly virulent swine acute diarrhoea syndrome coronavirus (SADS-CoV) emerged in Guangdong province in 2017 followed by fatal diarrhoea that involved the death of 24,693 piglets. And yet from May 2017 to January 2019, there were no new SADS cases arising in pig herds in Guangdong. In this study, we reported the recent diarrhoea outbreak of SADS-CoV in Southern China on February 2019. Intestinal samples collected from diarrhoeal piglets were detected for common swine virus and confirmed that SADS-CoV was responsible for the diarrhoea case. Meanwhile, serological investigation of sows' sera implied that SADS-CoV has existed in the farm and PEDV antibody may not directly contribute to the amplification of SADS-CoV. Homology and phylogenetic analysis of the whole genome showed that the re-emerging SADS-CoV strain shared high sequence identities with existing SADS-CoV strains and all strains clustered together in Alpha coronavirus. All in all, the report herein emphasized the re-emerging of SADS-CoV and highlights continuous monitoring for this virus.

KEYWORDS
phylogenetic analysis, re-emerging, SADS-CoV, Southern China

1 | INTRODUCTION

Swine acute diarrhoea syndrome (SADS) was first identified in South China in January 2017 as a disease causing high mortality in neonatal piglets (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). It is quickly demonstrated that the causative agent of SADS is a novel HKU2-related coronavirus, swine acute diarrhoea syndrome coronavirus (SADS-CoV) which originated from the same genus of horseshoe bats (*Rhinolophus*) as severe acute respiratory syndrome coronavirus (SARS-CoV), but the mechanism of transmission of bat-originated coronavirus in pigs needs further illumination (Cui, Li, & Shi, 2019; Zhou et al., 2018). Based on the analysis of genomes, SADS-CoV is classified into the genus *Alphacoronavirus* within the subfamily *Orthocoronavirinae* of the family *Coronaviridae* (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). So far, besides porcine epidemic diarrhoea virus (PEDV), transmissible gastroenteritis virus (TGEV) and porcine deltacoronavirus (PDCoV), SADS-CoV is the fourth porcine enteric coronavirus that circulated in pigs in China (Dong et al., 2015; Xuan et al., 1984). A retrospective investigation showed that SADS-CoV emerged in China at least since August 2016 (Zhou et al., 2019). Li et al. (2018) reported one SADS-CoV strain that was isolated from fecal and small intestinal samples collected from Fujian province and suggested that SADS-CoV might have spread from Guangdong to Fujian province.

In the first outbreak of SADS-CoV occurring between January and May 2017, in order to reduce mortality in suckling pigs, the minced intestines from acutely infected piglets were filtered, centrifuged and inactivated before feeding back to pregnant sows to allow maternal antibodies to be obtained in neonatal piglets. Hence, after May 2017, the epidemic was controlled. And with a period of quiescence, SADS-CoV seemed to have disappeared from pig herds in South China. While on February 2019, there was a large-scale

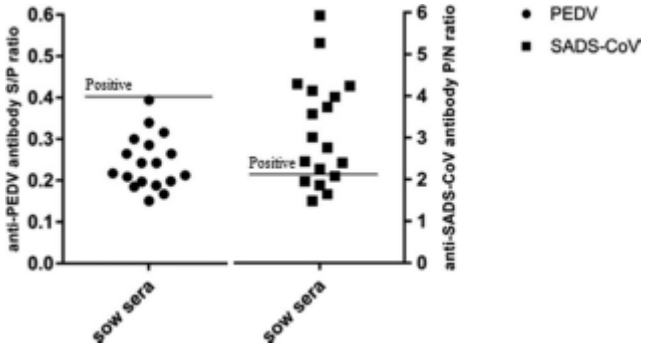

FIGURE 1 The results of ELISA test, *n* = 18 sows sera from outbreak farm. Detection of PEDV antibodies, sample S/P ratios ≥ 0.4 were considered positive. Detection of SADS-CoV antibodies, P/N ratios ≥ 2.1 were considered positive

outbreak of approximately 2000 piglets dying of diarrhoea in one farm, which was near the origin of the SADS pandemic in 2017. The extensive aetiological investigation for common swine viruses suggested that the causative agent of this recent diarrhoea outbreak was SADS-CoV. In this study, we compared the infections of piglets with the original and re-emerging SADS-CoV strains by clinical signs, epidemiological investigation, serological investigation and phylogenetic analysis. The results highlight the significance of SADS-CoV and the disease it causes.

At the beginning of the latest outbreak on February 2019, infected suckling piglets developed acute diarrhoea, vomiting and died after 2–6 days of the diarrhoea, which were consistent with the clinical signs reported in SAD-CoV outbreaking farms (Zhou et al., 2018). Two weeks after the onset, mortality did not increase due to the effective inactivated SADS-CoV vaccine which was propagated in vitro (data unpublished). Clinical small intestine samples were collected rapidly from piglets, and intestinal samples were homogenized, centrifuged and filtered for virus isolate. Viral nucleic acid was extracted using TRIzol reagent (Invitrogen, USA) according to the manufacturer's instruction. The potential swine viral pathogens were examined, including SADS-CoV, PEDV, PDCoV, porcine rotavirus (RV), TGEV, reovirus (REO), senecavirus A (SVA), foot and mouth disease virus (FMDV), porcine pseudorabies virus (PRV), porcine circovirus 2 (PCV2), porcine circovirus 3 (PCV3), porcine reproductive

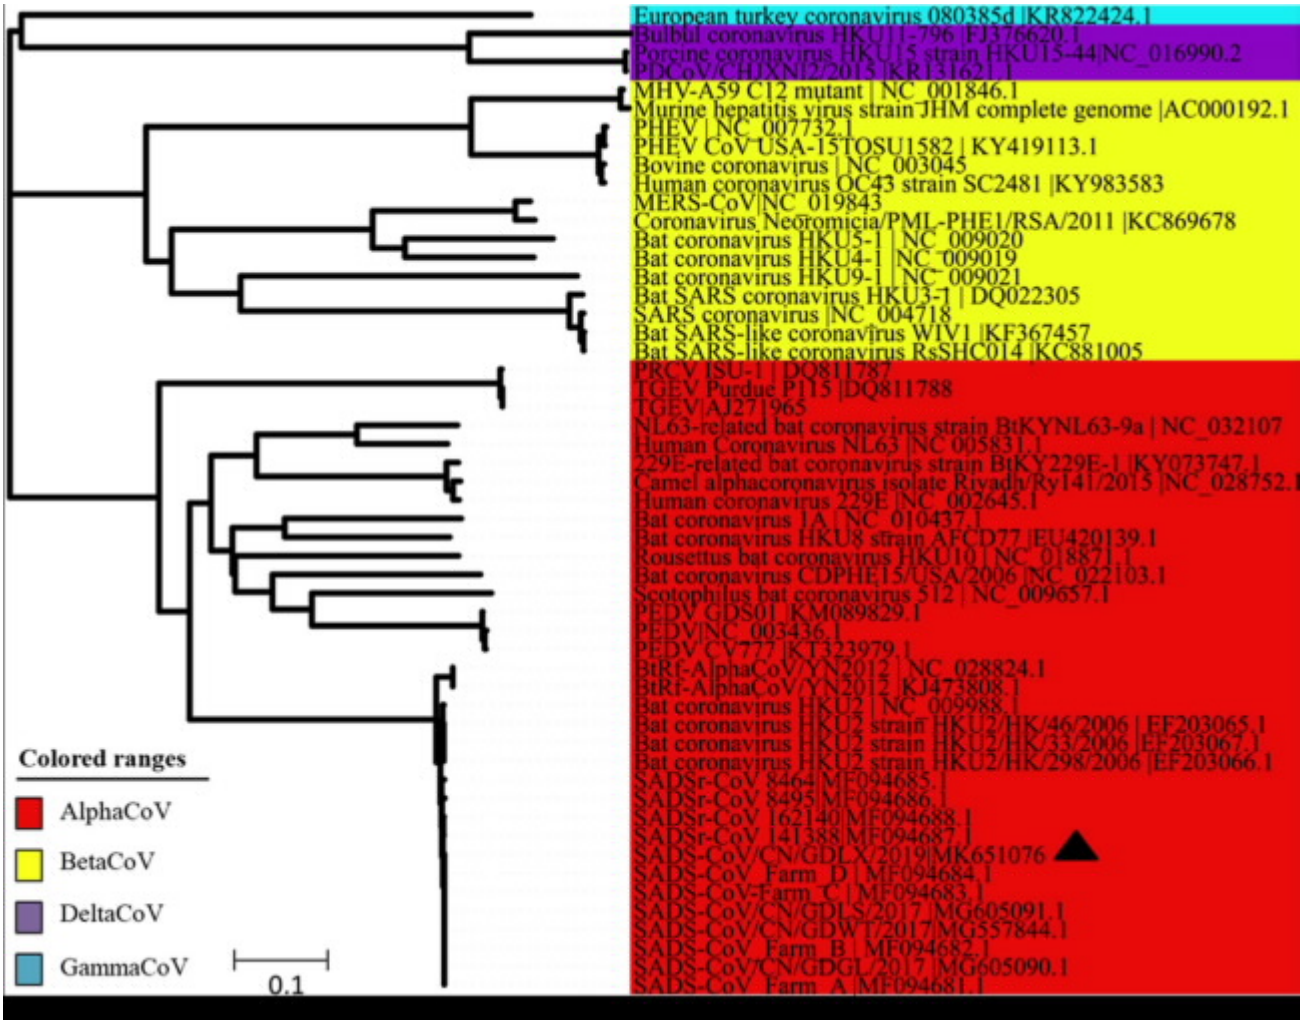

FIGURE 2 Phylogenetic analysis of the complete genome of SADS-CoV and reference coronavirus species. The tree was constructed using MEGA 7.0 software with neighbour-joining methods and 1,000 replicate sets on bootstrap analysis [Colour figure can be viewed at wileyonlinelibrary.com]

and respiratory syndrome virus (PRRSV), porcine parainfluenza virus 1 (PPIV1), swine influenza virus (SIV), atypical porcine pestivirus (APPV), haemophilus parasuis (HPS), hog cholera (HC), porcine parvovirus (PPV), porcine bocavirus (PBoV), porcine sapelovirus (PSV) and porcine kobuvirus (PKV) by PCR or RT-PCR following the established protocol of Key Laboratory of Animal Health Aquaculture and Environmental Control. The extensive aetiological investigations for common swine viruses showed that only SADS-CoV was detected positively, which suggested that the causative agent of the most recent diarrhoea outbreak on February was SADS-CoV.

Furthermore, a total of 18 blood samples were simultaneously collected from healthy sows for serological investigation. Sera samples were obtained after coagulation and centrifugation (2,000 *g*, 10 min) and stored at −20°C until ELISA implemented. The PEDV antibody production was detected by means of commercial ELISA test kit (ZhenRui, China), of which, sample S/P ratios with ≥0.4 were considered positive and <0.4 were considered negative. And for SADS-CoV, ELISA was conducted following the modified procedures established in Key Laboratory of Animal Health Aquaculture and Environmental Control (P/N ≥ 2.1 considered positive). The absorbance at 450 nm wavelength was measured (Multiskan™ FC, Thermo Fisher). The results of ELISA assay revealed that all sera (100%) were negative for the PEDV and 13 of 18 (72.2%) were positive for SADS-CoV (Figure 1). In our previously clinical investigations, PEDV had caused prior outbreaks at most farms with SADS-CoV outbreaks (Zhou et al., 2018). It is possible that the presence of PEDV antibody may have somehow facilitated the amplification of the SADS-CoV. However, our results showed that PEDV antibodies were undetectable in all SADS-CoV antibody-positive sera samples, suggesting that it is SADS-CoV that caused the lethal infection in pigs on February 2019. Collectively, the re-emergence of SADS-CoV in pig herds in South China was confirmed by ELISA test and the association between PEDV and SADS-CoV infection requires further validation.

Subsequently, one SADS-CoV genome was amplified as previously described (Zhou et al., 2019). The novel SADS-CoV strain was named as SADS-CoV/CN/GDLX/2019 (accession number: MK651076). Sequence alignment and phylogenetic analysis were performed with Lasergene coresuite 10 (DNASTAR Inc.). Phylogenetic tree was constructed using the neighbour-joining method with MEGA 7.0 software (Kumar, Stecher, & Tamura, 2016). Bootstrap analysis was carried out on 1,000 replicate data sets

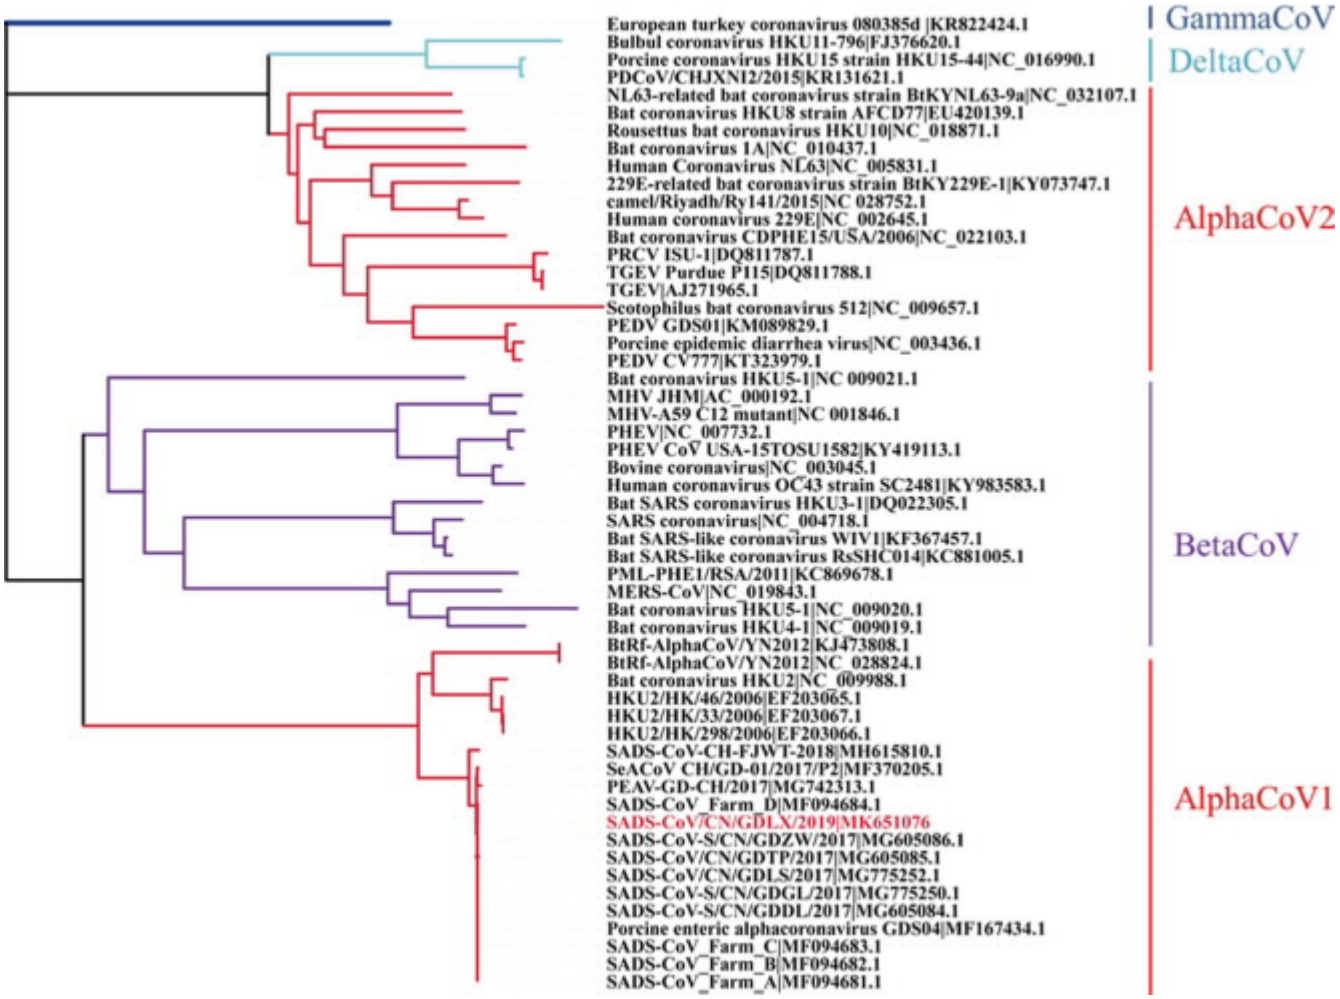

FIGURE 3 Phylogenetic analysis of the S gene of SADS-CoV and reference coronavirus species. The tree was constructed using MEGA 7.0 software with neighbour-joining methods and 1,000 replicate sets on bootstrap analysis [Colour figure can be viewed at wileyonlinelibrary.com]

(Felsenstein, 1985). For the whole genomes, sequence alignment results revealed that the nucleotide identities between SADS-CoV/CN/GDLX/2019 and previously reported SADS-CoV strains ranged from 99.3% to 100%. Moreover, the phylogenetic tree indicated that the novel SADS-CoV complete genome clustered together with other reported SADS-CoV strains and located in the Alpha coronavirus branch (Figure 2). Phylogenetic analysis based on S genes was also conducted, and the result showed that all SADS-CoV, bat HKU2 and BtRf-AlphaCoV strains were separated from other AlphaCoVs and clustered within BetaCoVs (Figure 3), which is consistent with previous studies (Pan et al., 2017; Xu et al., 2019; Zhou et al., 2019). Notably, the S gene of SADS-CoV/CN/GDLX/2019 had high identities of 99.2%–99.9% with other SADS-CoV strains detected in Guangdong and lowest identities of 97.5% with SADS-CoV-CH-FJWT-2018 reported from Fujian. Additionally, the comparative analysis of amino acids encoded by S gene revealed that the S protein of the novel strain had a two-amino-acid mutation (F306 and I882) compared with that of other SADS-CoV strains. It is well known that the S protein of coronavirus play an important role in cellular entry and determining the immunogenicity (Li, Frank, He, Peter, & Berend-Jan, 2016). In view of the lowest identities of Spike gene between the strains from Guangdong and Fujian, continuous monitoring of SADS-CoV genetic evolution is important for better understanding its epidemiology and establishing efficient strategies against its further circulating in pigs in China.

Here, we reported a new case of acute diarrhoea outbreak from a swine farm in Guangdong province on February 2019. Pathogenic and serologic analysis determined that SADS-CoV re-emerged in Guangdong and was responsible for the recent acute diarrhoea outbreak. Phylogenetic analysis based on whole genomes showed that SADS-CoV/CN/GDLX/2019 shared high nucleotide identities with previously reported SADS-CoV strains. Taken together, our study highlighted the significant threat of SADS-CoV and the potential outbreak of SADS epidemic in following months in Guangdong. Therefore, the persistent surveillance and vaccination countermeasures will be necessary to control the spread of SADS-CoV.

Summary

Swine acute diarrhoea syndrome coronavirus (SADS-CoV), a novel coronavirus, was first discovered in southern China in January 2017 and caused a large scale outbreak of fatal diarrheal disease in piglets. Here, we conducted a retrospective investigation of 236 samples from 45 swine farms with a clinical history of diarrheal disease to evaluate the emergence and the distribution of SADS-CoV in pigs in China. Our results suggest that SADS-CoV has emerged in China at least since August 2016. Meanwhile, we detected a prevalence of SADS-CoV (43.53%), porcine deltacoronavirus (8.83%), porcine epidemic diarrhoea virus (PEDV) (78.25%), rotavirus (21.77%), and transmissible gastroenteritis virus (0%), and we also found the co-infection of SADS-CoV and PEDV occurred most frequently with the rate of 17.65%. We screened and obtained two new complete genomes, five N and five S genes of SADS-CoV. Phylogenetic analysis based on these sequences revealed that all SADS-CoV sequences in this study clustered with previously reported SADS-CoV strains to form a well defined branch that grouped with the bat coronavirus HKU2 strains. This study is the first retrospective investigation for SADS-CoV and provides the epidemiological information of this new virus in China, which highlights the urgency to develop effective measures to control SADS-CoV.

phylogenetic analysis, prevalence, retrospective detection, Swine Acute Diarrhoea Syndrome Coronavirus

1 | INTRODUCTION

Swine acute diarrhoea syndrome coronavirus (SADS-CoV) is a newly discovered coronavirus which is an enveloped, positive and single-stranded sense RNA virus with a genome size of approximately 27 kb (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). SADS-CoV belongs to the family Coronaviridae which contains four genera, Alphacoronavirus, Betacoronavirus, Gammacoronavirus, and Deltacoronavirus (Woo, Huang, Lau, & Yuen, 2010; Woo et al., 2012). So far, six coronaviruses have been identified from pigs, which include porcine epidemic diarrhoea virus (PEDV), porcine respiratory coronavirus (PRCV), SADS-CoV and transmissible gastroenteritis virus (TGEV) that all belong to the Alphacoronavirus genus, as well as one betacoronavirus, porcine hemagglutinating encephalomyelitis virus (PHEV) and one deltacoronavirus, porcine deltacoronavirus (PDCoV) (Lin, Saif, Marthaler, & Wang, 2016; Wesley, Woods, & Cheung, 1991; Woo et al., 2010). Among these viruses, SADS-CoV is the most newly discovered coronavirus, which has been first reported in 2017 in China and is considered to be an HKU2-related coronavirus with a bat-origin (Gong et al., 2017; Zhou et al., 2018). In January 2017, SADS-CoV was detected in a swine farm and subsequently spread rapidly to three other farms in

Guangdong Province and caused the fatal swine acute diarrhoea syndrome (SADS) characterized by the clinical signs with severe, acute diarrhoea and rapid weight loss of piglets. The symptoms of SADS-CoV are similar to those that caused by other swine enteric coronaviruses such as PDCoV and PEDV, but SADS-CoV is more harmful than these viruses because it has led to the death of almost 25,000 piglets in a short time and resulted in more significant economic losses (Dong et al., 2015; Sun, Wang, Wei, Chen, & Feng, 2016; Zhou et al., 2018). So, it is urgent to investigate the molecular epidemiology and transmission patterns of SADS-CoV for establishing effective controls for this new coronavirus.

In the present study, we performed the retrospective PCR testing on diarrheal samples from 45 swine farms in Guangdong Province to evaluate the emergence and the distribution of SADS-CoV in pigs in China. The prevalence and co-infection information of SADS-CoV from eleven SADS-CoV-positive farms was provided. The sequences of SADS-CoV, including two complete genomes, five nucleocapsid protein (N) genes and five spike protein (S) genes, were also identified and characterized to investigate the phylogenetic relationships of SADS-CoV.

2 | MATERIALS AND METHODS

2.1 | Sample collection

A total of 236 clinical diarrhoea samples including faeces and intestinal contents were collected from piglets and sows from 45 swine farms in the cities Qingyuan and Shaoguan of North Guangdong Province between August 2016 and May 2017 in accordance with the recommendations of National Standards for Laboratory Animals of the People's Republic of China (GB149258-2010). Samples were preserved at - 80 °C from the time of original receipt until use.

2.2 | Nucleic acid extraction and molecular diagnosis

Samples were homogenized in phosphate-buffered saline (PBS) (20% w/v), frozen and thawed three times, then centrifuged for 10 min at 10,000 *g*. Viral nucleic acid was extracted following the manufacturer's recommendations of AxyPrep™ Body Fluid Viral DNA/RNA Miniprep Kit (Axygen Scientific, Inc). The virus nucleic acid was stored at - 80°C until PCR was performed. A pair of primers (forward primer 5′-GGTCCCTGTGACCGAAGTTTTA-3′, reverse primer 5′- GCGTTCTGCGATAAAGCTTAAAACTATTA-3′) was designed to detected SADS-CoV based on the conserved N gene of this virus. One step RT-PCR using PrimeScript™ One Step RT-PCR Kit Ver.2 with Dye Plus (Takara, Biotechnology, Dalian, China) was carried out to amplify the target fragments by the following thermal profile of 50°C for 30 min, 94°C for 3 min, 35 cycles of denaturation at 94°C for 30 s, annealing at 55°C for 30 s, an extension at 72°C for 30 s, and a final step of 72°C for 5 min. Four other diarrheal pathogens including PEDV, PDCoV, rotavirus (RV), and TGEV from SADS-CoV-positive farms were also tested by RT-PCR according to the previously described methods (Liu, Zhu, Liao, Xu, & Zhou, 2015; Mai et al., 2017; Stevenson et al., 2013).

2.3 | Amplification of the N gene, the S gene, and the complete genome of SADS-CoV

Specific primer pairs based on reported SADS-CoV strains (GenBank accession numbers: MF094681-MF094684) were designed for S genes, N genes and complete genome amplifications, respectively (Table S1). PCR assays were performed with the following thermal profile: 95°C for 5 min, 35 cycles of 95°C for 30 s, 50°C for 30 s, and 72°C for 1 min 15 s, followed by a final 10 min extension at 72°C. The products were purified following the manufacturer's instructions of Gel Band Purification Kit (Omega Bio-tek, USA) and then cloned into the PMD19-T vector (Takara, Biotechnology, Dalian, China) and transformed *E. coli* DH5α competent cells. The positive clones were screened out and sent to Beijing Genomics Institute (Shenzhen, Guangdong, China) for further sequencing.

2.4 | Sequence alignment and phylogenetic analysis

The nucleotide sequences were assembled and aligned using the DNASTAR program (DNAStar V7.1, Madison, WI, USA). Phylogenetic trees were constructed using the neighbour-joining method in MEGA 7.0 software with bootstrap analysis of 1,000 replicates. Percentages of replicate trees in which the associated taxa clustered are shown as nearby branches (Chenna et al., 2003; Kumar, Stecher, & Tamura, 2016; Tamura, Nei, & Kumar, 2004).

3 | RESULTS

3.1 | SADS-CoV detection

Of 236 clinical diarrhoea samples from 45 swine farms, 53 samples collected from eleven swine farms between August 2016 and May 2017 were tested positive for SADS-CoV and the locations of these eleven farms were indicated in Figure 1. The farms SM, GL, DL, DE, TP, WT, DCD, and SC were in Qingyuan, and the farms LS, ZW, and YX were in Shaoguan. From these eleven SADS-CoV-positive farms, a total of 170 archived diarrheal samples including 55 faeces and 115 intestinal contents were collected to further investigate diarrhoeal pathogens including SADS-CoV, PEDV, RV, PDCoV, and TGEV. The infection rates of these five pathogens in order were 43.5% (74/170), 78.2% (133/170), 21.8% (37/170), 8.8% (15/170), and 0% (0/170). SADS-CoV was tested positively both in the intestinal and faecal samples and the detection rates were 49.6% (57/115) and 30.9% (17/55), respectively, which were both the second highest among the five tested pathogens. PEDV had the highest positive rate at 84.3% (97/115) for intestinal and 65.5% (36/55) for faecal samples. TGEV was tested negatively in all 170 diarrheal samples (Table S2).

The cases of individual infection or co-infection for SADS-CoV, PDCoV, PEDV, and RV were also detected. More than half the

FIGURE 1 Locations of positive farms for study of SADS-CoV in Guangdong Province, China [Colour figure can be viewed at wileyonlinelibrary.com]

samples were only infected by one of the four viruses at a rate of 58.82% (100/170), and the individual infection of PEDV had the highest rate of 37.06% (63/170). In the 74 SADS-CoV-positive samples, 28 samples were infected alone by SADS-CoV, and the rest 46 samples were infected by SADS-CoV combined with one to three other pathogens. The co-infection of SADS-CoV and PEDV occurred most frequently with the rate of 17.65% (30/170) (Table 1).

The earliest cases with SADS-CoV-positive infection were found in the farms LS, TP and ZW on August 2016 according to Table S2. The intestinal contents from these eleven farms were tested positive for SADS-CoV and the positive rates ranged from 25% to 77.78%. While the faecal samples from two farms ZW and YX were tested negative for SADS-CoV, but positive for PDCoV, PEDV, and RV infections. The positive rates of SADS-CoV in the faecal samples of other nine farms varied from 13.33% to 100%. The farm LS had the highest positive rate of 77.8% (7/9) for intestinal samples and the farms DCD and SC had 100% positive rates for faecal samples.

3.2 | Sequence identities and phylogenetic analyses

The two complete genomes (accession number MG605090 and MG605091), five N genes (accession number MG605087, MG605088, MG605089, MG775251, and MG775253) and five S genes (accession number MG605084, MG605085, MG605086, MG775250 and MG775252) were sequenced and available in GenBank. The lengths of the complete genome, N gene and S gene were 27,163 bp, 1,128 bp, and 3,390 bp, respectively. The two new complete sequences, five N genes and five S genes sequences each shared high sequence identities of 99.8%–100%, 99.8%–100%, and 99.6%–100% with previous reported complete genomes, N genes and S genes of SADS-CoV. The two full-length sequences of SADS-CoV showed 95%–95.1% nucleotide identities with four bat coronavirus HKU2 strains, and the nucleotide identities between the N genes of SADS- CoV studied here and those of bat coronavirus HKU2 strains ranged from 94.2% to 94.3%. The S genes of SADS-CoV in this paper shared low nucleotide identities of 79.9%–80% with the S genes of bat coronavirus HKU2 strains. Phylogenetic analyses based on the complete genomes, N genes and S genes indicated that all SADS-CoV sequences clustered together to form a well-defined branch and group with four bat coronavirus HKU2 strains In the phylogenetic trees of the full-length genomes and N genes, all SADS-CoV strains were phylogenetically located within the AlphaCoVs, while the phylogenetic tree of S genes exhibited that all SADS-CoV sequences, four bat HKU2 and two BtRf-AlphaCoV strains separated from other AlpaCoVs sequences and clustered with the BeltaCoV sequences (Figures 2, 3 and 4).

4 | DISCUSSION

In this study, we performed the retrospective investigation of SADS-CoV in 45 pig farms from Guangdong Province based on 236

diarrhoea samples.Our results showed that the first SADS-CoV positive sample was collected in August 2016 from the farm LS with a history of diarrhoea, as well as from other two farms TP and ZW, which indicates that SADS-CoV has emerged in pigs in China at least since August 2016. And this time point is 5 months earlier than the first discovered time reported by our previous study (Zhou et al., 2018). As the same time, clinical signs of SADS-CoV during the retrospective investigation included sever and acute vomiting and diarrhoea, leading to death in piglets that were less than 5 days of age with a mortality rate of around 50%. These clinical presentations were similar to those signs in the large scale outbreak of SADS-CoV reported by Zhou et al. (2018), except the mortality rate in piglets later increased to 90%.

Based on the rates of infection documented in our work, it revealed that PEDV (78.25%) was still the primary cause of the porcine diarrhoea, which is consistent with previous studies that PEDV has been considered to be the major pathogen responsible for the porcine diarrhoea epidemic in China since 2010 (Ge et al., 2013; Sun et al., 2012; Zhao et al., 2016). Except PEDV, SADS-CoV had the second high infection rate (43.53%),which exhibits an evidently prevailing tendency in pigs. Meanwhile, of the SADS-CoV positive samples, 62.2% were co-infections with one to four other viruses, revealing a high prevalence of co-infection in the sampled farms. Notably, our results also showed that SADS-CoV and PEDV were simultaneously present in all co-infection samples of SADA-CoV. Considering the fact that PEDV has caused prior outbreaks of the porcine diarrhoea at the pig farm where Zhou et al. (2018) later reported the occurrence of SADS-CoV, PEDV seems to be able to contribute to the infection of SADS-CoV in pigs. Thus, SADS-CoV may be pathogenic as secondary infection following the infection of PEDV, which needs further studies to better understand the pathogenesis of this novel coronavirus.

The phylogenetic relationships of SADS-CoV sequences were also identified in this study. The results showed that all SADS-CoV sequences clustered together to form an independent branch and separated from other viral sequences in the genus Alphacoronavirus. Our results also indicated that both the complete genomes, N genes and S genes of all SADS-CoV strains shared the highest nucleotides identifies with those corresponding sequences of four bat coronavirus HKU2 strains. In this work, The phylogenetic trees of full length genomes and S genes of SADS-CoV sequences showed that the SADS-CoV branch clustered with these four HKU2 strains, which is same to previous results (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). Besides the genomes and S genes, the tree of N genes in our study revealed the identical result too. So far, a total of eight full-length genomes of SADS-CoV have been reported in Guangdong Province of China (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018; this study). The two new genomes of SADS-CoV sequences in this work shared 100% nucleotides identities with the sequence MF167434 published by Gong et al. (2017) and our four previously reported sequences (Zhou et al., 2018), and shared 99.8% nucleotides identities with the sequence MF370205 studied by Pan et al. (2017). The results suggest that these eight SADS-CoV sequences may come from the same origin. Only the phylogenetic tree of S genes in our work showed that sequences of the AlphaCoV were divided into two sublineages,AlphaCoV1 which contained all SADS-CoV sequences and AlphaCoV2, clustering together with sequences of the BeltaCoV and the DelatCov, respectively. And this result was consistent with the study of Pan et al. (2017). As a newly discovered coronavirus, the availability of SADS-CoV sequences data is limited which prevents better understandings of the molecular epidemiology of this virus. Meanwhile, being a RNA virus, SADS-CoV may mutate rapidly and exhibit high genetic differences (Drummond, Pybus, Rambaut, Forsberg, & Rodrigo, 2003; Kühnert, Wu, & Drummond, 2011). So, new more available sequences data are warranted to give a deep insight of viral genetic origin, evolution, and transmission patterns of SADS-CoV.

In summary, our retrospective study suggests that SADS-CoV has emerged in pigs in China at least since August 2016. The severe clinical symptoms and the strong transmission in short term highlights the urgency to develop effective measures to control this new discovered virus. Further studies, such as the epidemiology, virology and pathobiology should be performed for better understanding of SADS-CoV in China.

Origin and evolution of pathogenic coronaviruses

Jie Cui[1], Fang Li[2] and Zheng-Li Shi[1]

Abstract | Severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV) are two highly transmissible and pathogenic viruses that emerged in humans at the beginning of the 21st century. Both viruses likely originated in bats, and genetically diverse coronaviruses that are related to SARS-CoV and MERS-CoV were discovered in bats worldwide. In this Review, we summarize the current knowledge on the origin and evolution of these two pathogenic coronaviruses and discuss their receptor usage; we also highlight the diversity and potential of spillover of bat-borne coronaviruses, as evidenced by the recent spillover of swine acute diarrhoea syndrome coronavirus (SADS-CoV) to pigs.

Severe acute respiratory syndrome
A serious form of pneumonia that is characterized by diffuse alveolar damage and that has the potential to progress to acute respiratory distress.

Type II pneumocytes
Epithelial cells that line the lung alveoli; type II cells are round and produce surfactants to lower the surface tension of water and allow the membrane to separate, thereby increasing the capability to exchange gases.

Coronaviruses cause respiratory and intestinal infections in animals and humans[1]. They were not considered to be highly pathogenic to humans until the outbreak of severe acute respiratory syndrome (SARS) in 2002 and 2003 in Guangdong province, China[2–5], as the coronaviruses that circulated before that time in humans mostly caused mild infections in immunocompetent people. Ten years after SARS, another highly pathogenic coronavirus, Middle East respiratory syndrome coronavirus (MERS-CoV) emerged in Middle Eastern countries[6]. SARS coronavirus (SARS-CoV) uses angiotensin-converting enzyme 2 (ACE2) as a receptor and primarily infects ciliated bronchial epithelial cells and type II pneumocytes[7,8], whereas MERS-CoV uses dipeptidyl peptidase 4 (DPP4; also known as CD26) as a receptor and infects unciliated bronchial epithelial cells and type II pneumocytes[9–11]. SARS-CoV and MERS-CoV were transmitted directly to humans from market civets and dromedary camels, respectively[12–14], and both viruses are thought to have originated in bats[15–21]. Extensive studies of these two important coronaviruses have not only led to a better understanding of coronavirus biology but have also been driving coronavirus discovery in bats globally[21–31]. In this Review, we focus on the origin and evolution of SARS-CoV and MERS-CoV. Specifically we emphasize the ecological distribution, genetic diversity, interspecies transmission and potential for pathogenesis of SARS-related coronaviruses (SARSr-CoVs) and MERS-related coronaviruses (MERSr-CoVs) found in bats, as this information can help prepare countermeasures against future spillover and pathogenic infections in humans with novel coronaviruses.

Coronavirus diversity

Coronaviruses are members of the subfamily *Coronavirinae* in the family *Coronaviridae* and the order *Nidovirales* (International Committee on Taxonomy of Viruses). This subfamily consists of four genera—*Alphacoronavirus*, *Betacoronavirus*, *Gammacoronavirus* and *Deltacoronavirus*—on the basis of their phylogenetic relationships and genomic structures (Fig. 1). The alphacoronaviruses and betacoronaviruses infect only mammals. The gammacoronaviruses and deltacoronaviruses infect birds, but some of them can also infect mammals[24]. Alphacoronaviruses and betacoronaviruses usually cause respiratory illness in humans and gastroenteritis in animals. The two highly pathogenic viruses, SARS-CoV and MERS-CoV, cause severe respiratory syndrome in humans, and the other four human coronaviruses (HCoV-NL63, HCoV-229E, HCoV-OC43 and HKU1) induce only mild upper respiratory disease in immunocompetent hosts, although some of them can cause severe infections in infants, young children and elderly individuals[1,28,29]. Alphacoronaviruses and betacoronaviruses can pose a heavy disease burden on livestock; these viruses include porcine transmissible gastroenteritis virus[32], porcine enteric diarrhoea virus (PEDV)[33] and the recently emerged swine acute diarrhoea syndrome coronavirus (SADS-CoV)[34]. On the basis of current sequence databases, all human coronaviruses have animal origins: SARS-CoV, MERS-CoV, HCoV-NL63 and HCoV-229E are considered to have originated in bats; HCoV-OC43 and HKU1 likely originated from rodents[28,29]. Domestic animals may have important roles as intermediate hosts that enable virus transmission from natural hosts to humans. In addition, domestic animals themselves can suffer disease caused by bat-borne or closely related coronaviruses; genomic sequences highly similar to PEDV were detected in bats[35–38], and SADS-CoV is a recent spillover from bats to pigs[34] (Fig. 2). Currently, 7 of 11 ICTV-assigned *Alphacoronavirus* species and 4 of 9 *Betacoronavirus* species were identified only in bats (Fig. 3). Thus, bats are

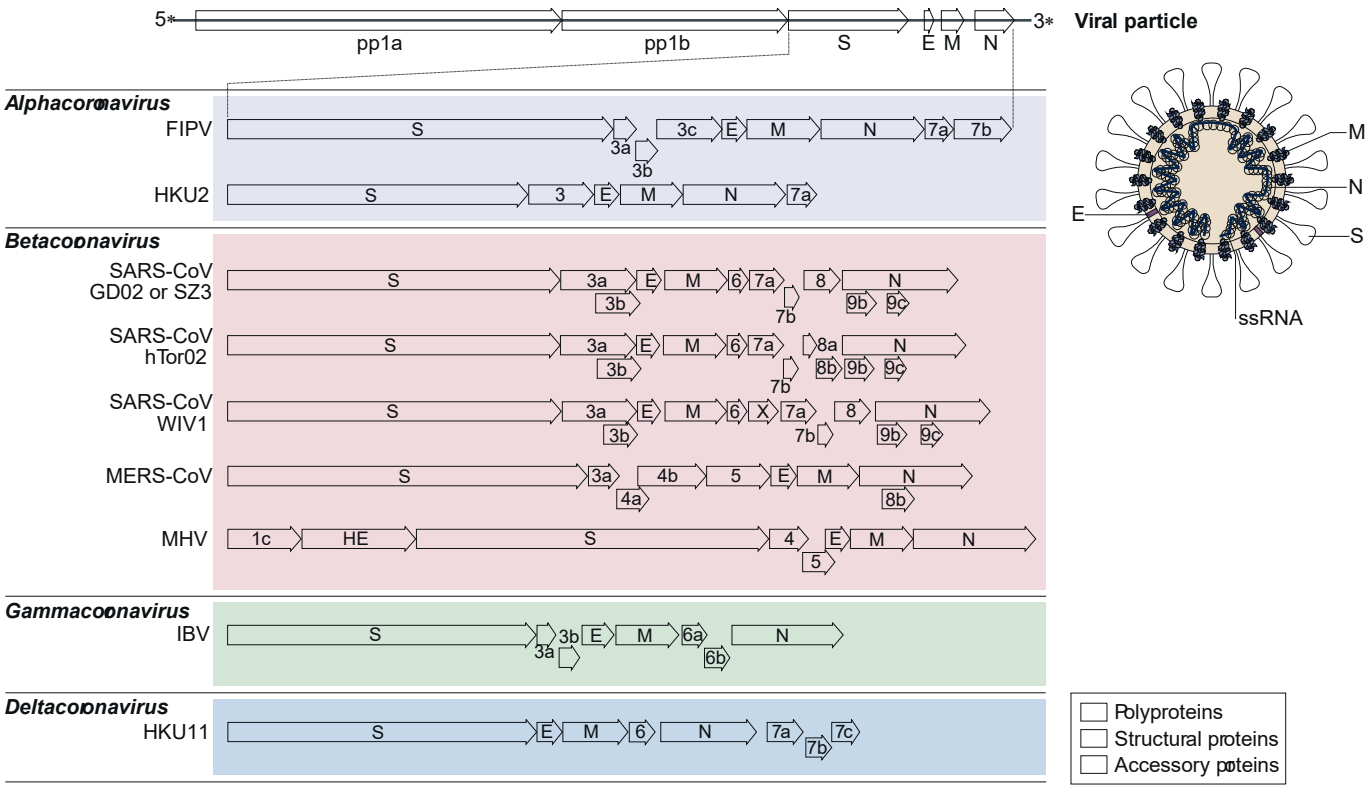

Fig. 1 | **The genomes, genes and proteins of different coronaviruses.** Coronaviruses form enveloped and spherical particles of 100–160 nm in diameter. They contain a positive-sense, single-stranded RNA (ssRNA) genome of 27–32 kb in size. The 5′-terminal two-thirds of the genome encodes a polyprotein, pp1ab, which is further cleaved into 16 non-structural proteins that are involved in genome transcription and replication. The 3′ terminus encodes structural proteins, including envelope glycoproteins spike (S), envelope (E), membrane (M) and nucleocapsid (N). In addition to the genes encoding structural proteins, there are accessory genes that are species specific and dispensable for virus replication. Here, we compare prototypical and representative strains of four coronavirus genera: feline infectious peritonitis virus (FIPV), *Rhinolophus* bat coronavirus HKU2, severe acute respiratory syndrome coronavirus (SARS-CoV) strains GD02 and SZ3 from humans infected during the early phase of the SARS epidemic and from civets, respectively, SARS-CoV strain hTor02 from humans infected during the middle and late phases of the SARS epidemic, bat SARS-related coronavirus (SARSr-CoV) strain WIV1, Middle East respiratory syndrome coronavirus (MERS-CoV), mouse hepatitis virus (MHV), infectious bronchitis virus (IBV) and bulbul coronavirus HKU11.

likely the major natural reservoirs of alphacoronaviruses and betacoronaviruses[24].

Animal origin and evolution of SARS-CoV

At the beginning of the SARS epidemic, almost all early index patients had animal exposure before developing disease. After the causative agent of SARS was identified, SARS-CoV and/or anti-SARS-CoV antibodies were found in masked palm civets (*Paguma larvata*) and animal handlers in a marketplace[12,16,39–42]. However, later, wide-reaching investigations of farmed and wild-caught civets revealed that the SARS-CoV strains found in market civets were transmitted to them by other animals[16,39]. In 2005, two teams independently reported the discovery of novel coronaviruses related to human SARS-CoV, which were named SARS-CoV-related viruses or SARS-like coronaviruses in horseshoe bats (genus *Rhinolophus*)[15,43]. These discoveries suggested that bats may be the natural hosts for SARS-CoV and that civets were only intermediate hosts. Subsequently, many coronaviruses phylogenetically related to SARS-CoV (SARSr-CoVs) were discovered in bats from different provinces in China and also from European, African and Southeast Asian countries[15,20,38,43–54] (Fig. 4; Supplementary Fig. S1a). According to the ICTV criteria, only the strains found in *Rhinolophus* bats in European countries, Southeast Asian countries and China are SARSr-CoV variants. Those from *Hipposideros* bats in Africa are less closely related to SARS-CoV and should be classified as a new coronavirus species[54]. These data indicate that SARSr-CoVs have wide geographical spread and might have been prevalent in bats for a very long time. A 5-year longitudinal study revealed the coexistence of highly diverse SARSr-CoVs in bat populations in one cave of Yunnan province, China[18,20,55]. This location is a diversity hot spot, and the SARSr-CoVs in this location contain all the genetic diversity found in other locations of China. Furthermore, the viral strains that exist in this one location contain all genetic elements that are needed to form SARS-CoV (Fig. 5). As no direct progenitor of SARS-CoV was found in bat populations despite 15 years of searching and as RNA recombination is frequent within coronaviruses[56], it is highly likely that SARS-CoV newly emerged through recombination of

bat SARSr-CoVs in this or other yet-to-be-identified bat caves. This hypothesis is consistent with previous data showing that a direct progenitor of SARS-CoV emerged before 2002 (refs[42,57,58]). Recombination analysis also strongly supported the hypothesis that the civet SARS-CoV strain SZ3 arose through recombination of two existing bat strains, WIV16 and Rf4092 (ref.[20]).

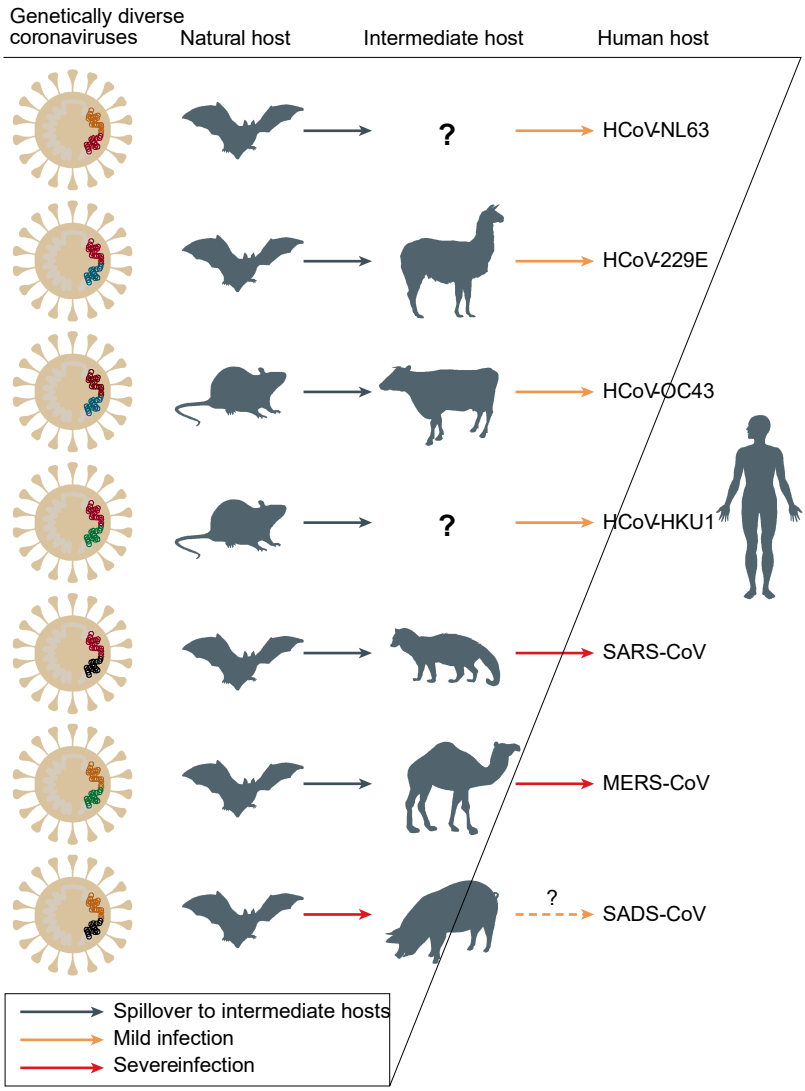

Fig. 2 | **Animal origins of human coronaviruses.** Severe acute respiratory syndrome coronavirus (SARS-CoV) is a new coronavirus that emerged through recombination of bat SARS-related coronaviruses (SARSr-CoVs)[20]. The recombined virus infected civets and humans and adapted to these hosts before causing the SARS epidemic[42,62]. Middle East respiratory syndrome coronavirus (MERS-CoV) likely spilled over from bats to dromedary camels at least 30 years ago[100] and since then has been prevalent in dromedary camels. HCoV-229E and HCoV-NL63 usually cause mild infections in immunocompetent humans. Progenitors of these viruses have recently been found in African bats[133,134], and the camelids are likely intermediate hosts of HCoV-229E[134,135]. HCoV-OC43 and HKU1, both of which are also mostly harmless in humans, likely originated in rodents. Recently, swine acute diarrhoea syndrome (SADS) emerged in piglets. This disease is caused by a novel strain of *Rhinolophus* bat coronavirus HKU2, named SADS coronavirus (SADS-CoV)[84]; there is no evidence of infection in humans. Solid arrows indicate confirmed data. Broken arrows indicate potential interspecies transmission. Black arrows indicate infection in the intermediate animals, yellow arrows indicate a mild infection in humans, and red arrows indicate a severe infection in humans or animals.

Furthermore, WIV16, the closest relative to SARS-CoV found in bats, likely arose through recombination of two other prevalent bat SARSr-CoV strains[20]. The most frequent recombination breakpoints are within the *S* gene, which encodes the spike (S) protein that contains the receptor-binding domain (RBD), and upstream of *orf8*, which encodes an accessory protein[20,58,59]. Given the prevalence and great genetic diversity of bat SARSr-CoVs, their close coexistence and the frequent recombination of the coronaviruses it is expected that novel variants will emerge in the future[60,61]. Because there were no SARS cases in Yunnan province during the SARS outbreak, we hypothesize that the direct progenitor of SARS-CoV was produced by recombination within bats and then transmitted to farmed civets or another mammal, which then transmitted the virus to civets by faecal–oral transmission. When the virus-infected civets were transported to Guangdong market, the virus spread in market civets and acquired further mutations before spillover to humans.

Variability of SARS-CoV in humans and civets

The genome sequences of SARS-CoVs from market civets are almost identical to the genomes of human SARS-CoVs[42,62]. However, two genes show major variation. The first variable region is located in the *S* gene. The SARS-CoV S protein is functionally divided into two subunits, denoted S1 and S2, which are responsible for receptor binding and fusion with the cellular membrane, respectively[1]. S1 is further divided into the amino-terminal domain (S1-NTD) and the carboxy-terminal domain (S1-CTD). The S1-CTD functions as the RBD and is responsible for binding ACE2 and entering cells[7,63,64]. Two amino acid residues in the RBD, 479 and 487, were identified to be essential for ACE2-mediated SARS-CoV infection and critical for virus transmission from civets to humans[36,78].

The second major location of variation is the accessory gene *orf8* (Fig. 5). On the basis of SARS spread, the SARS 2002–2003 outbreak could be divided into three phases, with the early phase characterized by a limited number of localized cases, followed by a middle phase during which a superspreader event occurred in a hospital and finally the late phase of international spread[92]. The viral genomes from early-phase patients contain two genotypes of *orf8*, one with a complete *orf8* (369 nucleotides) and the other containing an 82-nucleotide deletion. By contrast, viral genomes from late-phase patients and most of the genomes from middle-phase patients contain a split *orf8* (*orf8a* and *orf8b*) owing to a 29-nucleotide deletion; two exceptions were found in middle-phase genomes, one containing an 82-nucleotide deletion in *orf8* and the other with the whole *orf8* deleted. The human isolates from 2004 and all civet SARS-CoV genomes have a complete *orf8* except one civet strain with an 82-nucleotide deletion[62]. These data indicate that *orf8* genes underwent adaptations during transmission from animals to humans during the SARS epidemic. A limited functional analysis suggested that the ORF8a protein is dispensable for SARS-CoV replication in Vero E6 cells but may have a role in modulating endoplasmic reticulum

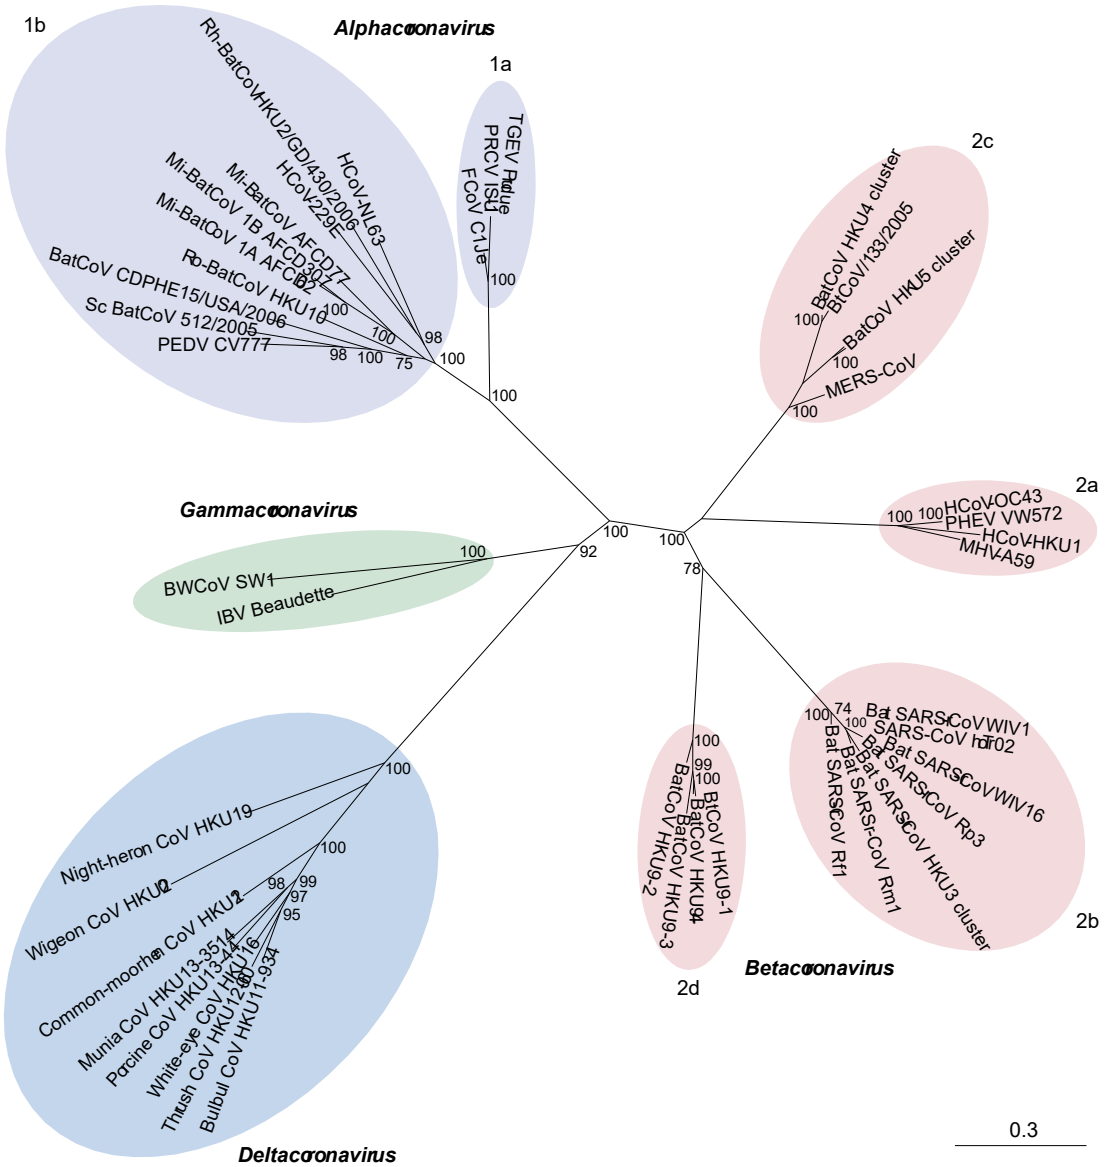

Fig. 3 | **Phylogenetic relationships in the *Coronavirinae* subfamily.** The highly human-pathogenic coronaviruses belong to the subfamily *Coronavirinae* from the family *Coronaviridae*. The viruses in this subfamily group into four genera (prototype or representative strains shown): *Alphacoronavirus* (purple), *Betacoronavirus* (pink), *Gammacoronavirus* (green) and *Deltacoronavirus* (blue). Classic subgroup clusters are labelled 1a and 1b for the alphacoronaviruses and 2a–2d for the betacoronaviruses. The tree is based on published trees of *Coronavirinae*[25,136] and reconstructed with sequences of the complete RNA-dependent RNA polymerase coding region of the representative coronaviruses (maximum-likelihood method under the GTR + I + Γ model of nucleotide substitution as implemented in PhyML, version 3.1 (rEF.[137])). Only nodes with bootstrap support above 70% are shown. IBV, infectious bronchitis virus; MERS-CoV, Middle East respiratory syndrome coronavirus; MHV, mouse hepatitis virus; PEDV, porcine enteric diarrhoea virus; SARS-CoV, severe acute respiratory syndrome coronavirus; SARSr-CoV, SARS-related coronavirus.

stress, inducing apoptosis and inhibiting interferon responses in host cells[20,65–69]. Whether and how these adaptations were involved in SARS-CoV virulence are not fully clarified.

Variability of bat SARSr-CoVs

SARS-CoVs and bat SARSr-CoVs mainly vary in three regions: S, ORF8 and ORF3 (Fig. 5). Bat SARSr-CoVs share high sequence identity with SARS-CoV in the S2 region but are highly variable in the S1 region. Compared with human and civet SARS-CoV, bat SARSr-CoV S1 can be divided into two clades: clade 1, which is found only in Yunnan province, has the same size S protein as human and civet isolates[8–20,51], whereas clade 2, which is found in many locations, has a shorter size S protein owing to deletions of 5, 12 or 13 amino acids in length[15,43–45,48,50]. Among the sequenced bat SARSr-CoVs, those with deletions in their RBDs show 78.2–80.2% amino acid sequence identity with SARS-CoV in the S protein, whereas those without deletions are much more closely related to SARS-CoV, with 90.0–97.2% amino acid sequence identity.

The second variable region is located in ORF8. Most of bat SARSr-CoVs retain an intact *orf8* (366 or 369 nucleotides) and share 47.7–100% sequence identity among themselves and 50.6–98.4% with SARS-CoV in civets and early-phase patients. A split *orf8* (364 nucleotides) owing to a 5-nucleotide deletion was found in one bat SARSr-CoV strain, similar to that of SARS-CoVs from middle-phase and late-phase patients[20]. The European bat SARSr-CoV has completely lost *orf8* (rEF.[45]). These data show that the *orf8* gene in bat SARSr-CoVs are constantly evolving in their natural reservoirs. Considering the variability of *orf8* in bats, civets and humans, investigating the function of *orf8* is a priority, particularly the contribution of these different variants to viral pathogenesis.

The third variable region is in ORF3. The SARS-CoV genome encodes a 154-amino acid ORF3b, which is an interferon antagonist. Bat SARSr-CoVs and SARS-CoV are highly similar in ORF3a (96.4–98.9% amino acid identity), but bat SARSr-CoVs have different sizes of ORF3b (54–154 amino acids) (a large part of the region encoding ORF3b overlaps with the ORF3a coding region)[20,70]. ORF3b retains the anti-interferon function in some bat SARSr-CoVs but has lost the function in other bat SARSr-CoVs[70].

A novel accessory gene, named *orfx* and located between *orf6* and *orf7*, was identified in the genomes of several bat SARSr-CoVs from Yunnan province[18–20] (FIg. 5). A preliminary study indicated that ORFX is involved in an anti-interferon response[71].

Receptor usage of SARS-CoV and SARSr-CoV

ACE2 binding is a critical determinant for the host range of SARS-CoV[72,73]. Electron microscopic studies have shown that the SARS-CoV S protein forms a clover-shaped trimer, with three S1 heads and a trimeric S2 stalk[74,75]. The RBD is located on the tip of each S1 head. The RBD binds to the outer surface of ACE2, away from its zinc-chelating enzymatic site[77,141] (FIg. 6a). Different SARS-CoV strains isolated from several hosts vary in their binding affinities for human ACE2 and consequently in their infectivity of human cells[76,78] (FIg. 6b). The epidemic strain hTor02 was isolated from humans during the late phase of the outbreak in 2002–2003. It has a high affinity for human ACE2 and high infectivity in human cells, and consequently, it was transmitted efficiently between humans[82]. Strains cSz02 and cHb05 were isolated from palm civets in 2002–2003 and 2005, respectively. Both have low affinity for human ACE2 and low infectivity in human cells but have high affinity for civet ACE2 and high infectivity in civet cells[12,79]. Strain hcGd03 was isolated from both humans and palm civets in 2003–2004 and has moderate affinity for human ACE2 and moderate infectivity in human cells; it infected humans but did not transmit between humans[80]. Strain hHae08 was isolated from human cell culture and has high affinity for human ACE2 and high infectivity in human cells[81]. Understanding the molecular basis for human receptor usage by different SARS-CoV strains is crucial for understanding the cross-species transmission of SARS-CoV and for epidemiological monitoring of potential future outbreaks.

SARS-CoV mutations that affect human and civet receptor binding. Crystal structures of the SARS-CoV RBD complexed with human ACE2 revealed that the SARS-CoV RBD contains a core structure and a receptor-binding

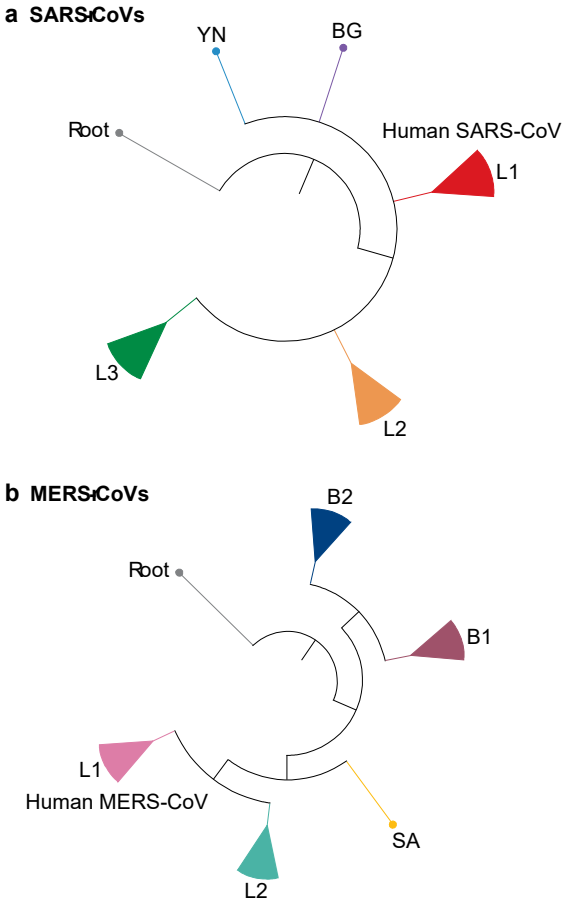

Fig. 4 | **Phylogenetic analysis of SARSr-CoVs and MERSr-CoVs. a** | The figure shows a simplified phylogenetic tree of severe acute respiratory syndrome-related coronaviruses (SARSr-CoVs) from bats. SARSr-CoVs cluster into three lineages, L1–L3, and human severe acute respiratory syndrome coronaviruses (SARS-CoVs) embed in L1. Two individual SARSr-CoVs do not cluster into these lineages: YN, a virus isolated from Yunnan province, China, and BG, a virus from Bulgaria, Europe. The tree is based on published trees[20,138] and reconstructed using sequences of the complete RNA-dependent RNA polymerase-coding region (maximum-likelihood method under the GTR + I + Γ model of nucleotide substitution as implemented in PhyML, version 3.1 (rEF.[137])). The strain Zhejiang2013 (GenBank No. KF636752) was used as a root. **b** | By contrast, Middle East respiratory syndrome-related coronaviruses (MERSr-CoVs) form two major viral lineages, L1 and L2. L1 is found in humans and camels, and L2 is found only in camels. Two small clusters, B1 (bat 1) and B2, and one single virus, SA, from South Africa, were found in bats. The phylogenetic tree of MERSr-CoVs is based on a published trees[94,139] and reconstructed using full-genome alignment of all coding regions using the same method as above. HKU4-1 (EF065505) and HKU5-1 (EF065509), two 2c betacoronaviruses, served as the root of the tree. Detailed phylogenetic trees and grouping information can be found in Supplementary Fig. S1. MERS-CoV, Middle East respiratory syndrome coronavirus.

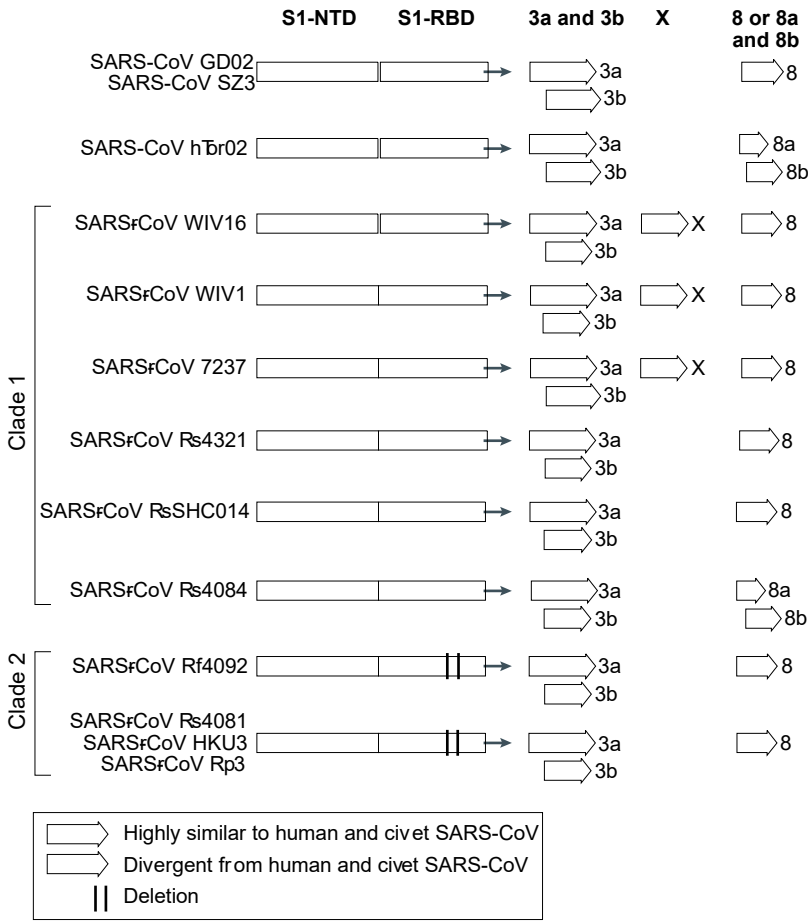

Fig. 5 | **Variable regions in different SARS-CoV and bat SARSr-CoV isolates.** Variability and thus species adaptation majorly affect three severe acute respiratory syndrome coronavirus (SARS-CoV) and SARS-related coronavirus (SARSr-CoV) proteins: the spike protein (S) (both the S1 amino-terminal domain (S1-NTD) and the S1 receptor-binding domain (S1-RBD) show variability), ORF3 (3a and 3b) and ORF8 (8a and b). SARS-CoV GD02 and hTor02 represent strains that were isolated from patients during the early, and middle or late phase of the SARS epidemic in 2002–2003, respectively; SARS-CoV CZ3 is a representative of strains isolated from civets in 2003 and 2004 (rEFs [42,62]). All bat SARSr-CoVs, except HKU3 and Rp3, were discovered in Yunnan province during 2011–2015. On the basis of deletions in the RBD, bat SARSr-CoVs can be divided into two clades. Those without a deletion and thus an identical size in S1 to SARS-CoV can be further divided into four genotypes: genotype 1, represented by WIV16, is highly similar to SARS-CoV in both the NTD and the RBD; genotype 2, represented by WIV1, differs in NTD from SARS-CoV; genotype 3, represented by Rs4231, differs in RBD from SARS-CoV; and genotype 4, represented by SHC014 and Rs4084, differs in both NTD and RBD from SARS-CoV [20]. The differences in S influence species-specific receptor binding, whereas differences in the accessory proteins, including potentially the newly discovered ORFX (X), mainly affect immune responses and viral immune evasion. Adapted from rEF. [20], CC BY 4.0 (https://creativecommons.org/licenses/by/4.0/).

motif (RBM) [82,141] (Fig. 6a). Two virus-binding hot spots have been identified at the interface of the RBD and human ACE2, centring on ACE2 residues Lys31 (hot spot 31) and Lys353 (hot spot 353) [83,84] (Fig. 6b). They both consist of a salt bridge (between Lys31 and Glu35 for hot spot 31 and between Lys353 and Asp38 for hot spot 353); both salt bridges are buried in hydrophobic pockets and contribute a substantial amount of energy to RBD–ACE2 binding as well as filling voids at the RBD–ACE2 interface. Naturally selected RBM mutations all interact with the hot spots (Fig. 6b; TAbIE 1) and affect RBD–ACE2 binding.

Salt bridge
A structure in proteins that forms a bond between oppositely charged residues that are sufficiently close to each other to experience electrostatic attraction.

Mutations in RBM residue 479 had an important role in the civet-to-human transmission of SARS-CoV [42,76,78,85]. Residue 479 is an asparagine in strains hTor02, hGd03 and hHae08 but is a lysine in strain cSz02 and an arginine in strain cHb05 (TAbIE 1). Asn479 is located near hot spot 31, without interfering with the structure of hot spot 31 (rEF. [85]) (Fig. 6b, c). However, a change to Lys479 leads to steric and electrostatic interference with hot spot 31, reducing the binding affinity between the SARS-CoV RBD and human ACE2. By contrast, Arg479 reaches the vicinity of hot spot 353 and forms a salt bridge with ACE2 residue Asp38 (rEF. [83]) (Fig. 6d). Hence, strains hTor02, hGd03 and hHae08 (all of which contain Asn479) and strain cHb05 (which contains Arg479) recognize human ACE2 and infect human cells efficiently, whereas strain cSz02 (which contains Lys479) recognizes human ACE2 inefficiently and infects human cells inefficiently. The above structural analyses are supported by biochemical, functional and epidemiological data [42,76,78,83–85]. Because of residue differences between human ACE2 and civet ACE2, both Asn479 and Lys479 fit well into the interface between the RBD and civet ACE2, although Arg479 fits even better [83,85]; consequently, strains hTor02, cSz02, hGd03 and cHb05 (which contain either Asn479, Lys479 or Arg479) recognize civet ACE2 and infect civet cells efficiently [79]. In sum, Asn479 and Arg479 are viral adaptations to human ACE2, whereas Lys479 is incompatible with human ACE2; Arg479 is a viral adaptation to civet ACE2, whereas Asn479 and Lys479 are also compatible with civet ACE2.

Mutations in RBM residue 487 had an important role in the human-to-human transmission of SARS-CoV. Residue 487 is a threonine in strain hTor02 but is a serine in the other strains isolated from humans and civets. The methyl group of Thr487 interacts with hot spot 353 in human ACE2 by providing stacking support for the formation of the salt bridge between Lys353 and Asp38; consequently, strain hTor02 recognizes human ACE2 efficiently and was transmitted between humans during the 2002–2003 SARS epidemic. By contrast, Ser487 cannot provide support to hot spot 353, and hence the other strains isolated from humans and civets recognize human ACE2 inefficiently. Consequently, neither cSz02 nor hGd03 was transmitted between humans. The above structural analyses are supported by biochemical, functional and epidemiological data [42,76,78,83–85]. Because of residue differences between human ACE2 and civet ACE2, Ser487 fits well into the RBD–civet ACE2 interface although still not as well as Thr487 (rEFs [83,85]); consequently, strains SZ02, hGd03 and cHb05 (which contain Ser487) recognize civet ACE2 and infect civet cells efficiently [79]. In sum, Thr487 is a viral adaptation to both human and civet ACE2, and Ser487 is much more compatible with civet ACE2 than with human ACE2 (Fig. 6b).

RBM residues 442, 472 and 480 also contribute to receptor recognition and host range of SARS-CoV although not as much as residues 479 and 487. Detailed structural, biochemical and functional analyses showed that Phe442, Phe472 and Asp480 are viral adaptations to human ACE2, whereas Tyr442, Leu472 or Pro472, and Gly480 are viral adaptations to civet ACE2 (rEFs [72,83]).

To corroborate the importance of these residues for SARS-CoV binding to either human or civet ACE2, two SARS-CoV S proteins, hOptimize and cOptimize, were rationally designed: the former contains all of the human ACE2-adapted residues (Phe442, Phe472, Asn479, Asp480 and Thr487), whereas the latter contains the civet ACE2-adapted residues (Tyr442, Pro472, Arg479, Gly480 and Thr487). These two S proteins demonstrate exceptionally high affinity for human ACE2 and civet ACE2, confirming that the human ACE2-adapted and civet ACE2-adapted RBM residues help determine SARS-CoV host range[72,83]. In addition to

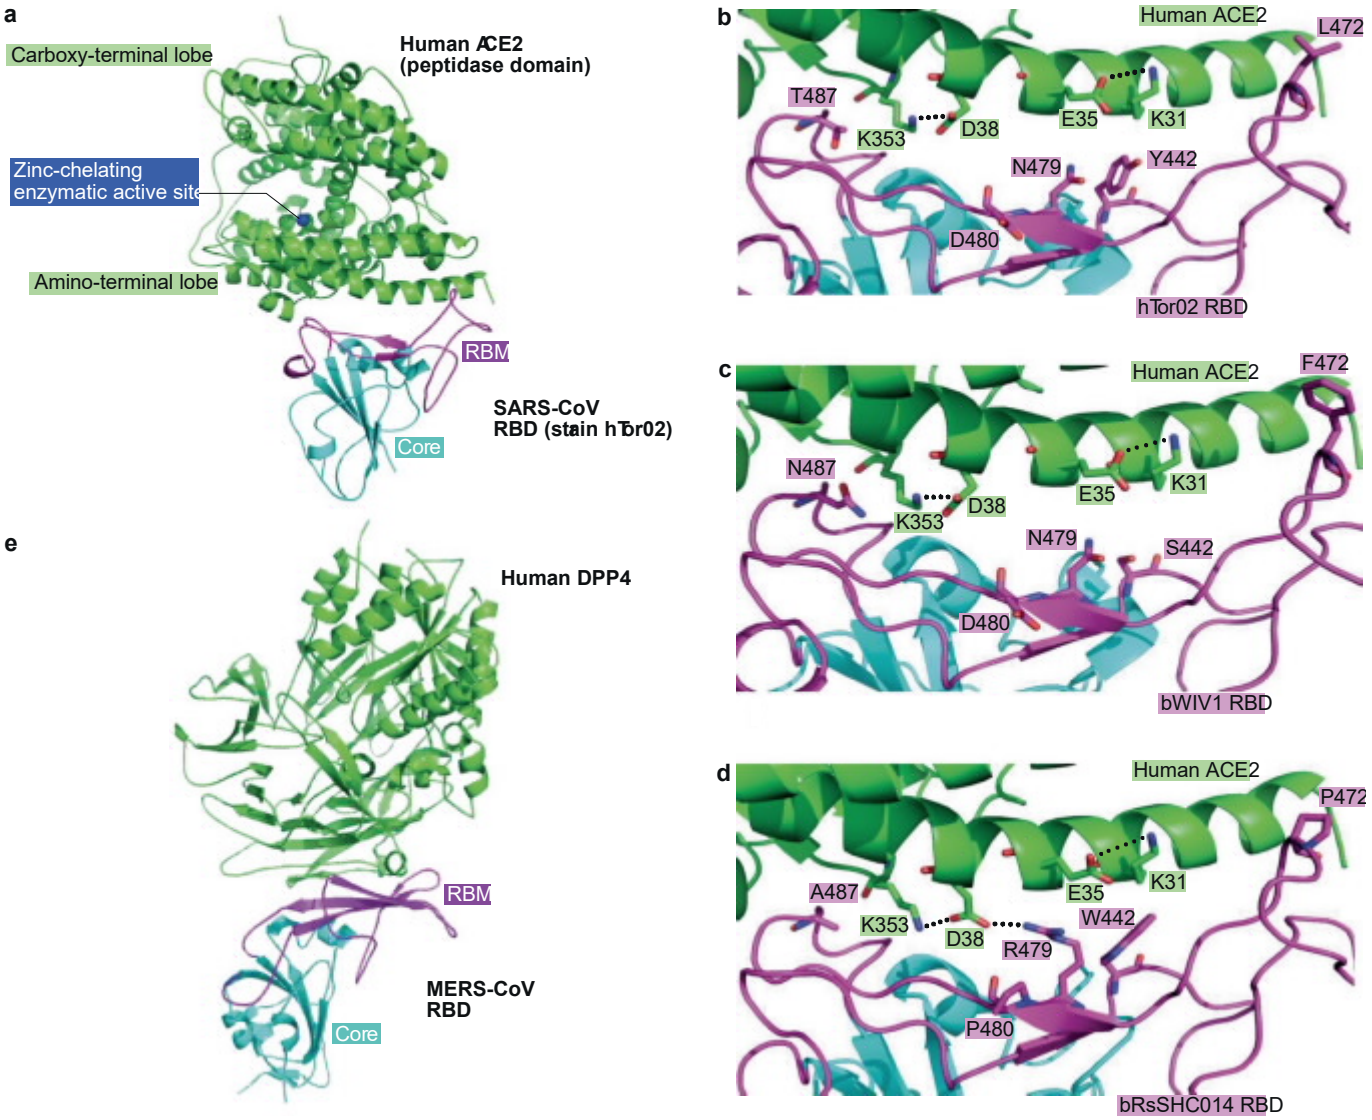

Fig. 6 | **Receptor recognition by SARS-CoV and MERS-CoV. a** | Severe acute respiratory syndrome coronavirus (SARS-CoV) uses its receptor-binding domain (RBD) (as shown in the structure of strain hTor02, containing core structure (cyan) and receptor-binding motif (RBM; magenta)) to bind human angiotensin-converting enzyme 2 (ACE2 green; Protein Data Bank ID: 2AJF). ACE2 is a peptidase with zinc (blue) in its active centre. **b** | Several residues in the host and viral receptor, as well as two salt bridges that stabilize the structure (dotted lines) and form two binding hot spots, are crucial for binding of the severe acute respiratory syndrome (SARS) epidemic strain hTor02. Hydrophobic residues surrounding the two salt bridges are present in the structure but are not shown in the figure. **c** | By contrast, the SARS-related coronavirus (SARS-CoV) strain bWIV1, which was isolated from bats and can infect both civet and human cells, differs in residues 442, 472 and 487. The mutation from threonine to asparagine in residue 487 introduces a polar side chain and is predicted to interfere with binding at hot spot 353. The model shown here was built on the basis of the structure of hTor02 RBD complexed with human ACE2 (Protein Data Bank ID: 2AJF) in which residues 442, 472 and 487 were mutated from those in strain hTor02 to those in strain bWIV1. **d** | The bat SARS-CoV strain bRsSHC014 can also infect human and civet cells; it carries an alanine in position 487, and the short side chain of this residue does not support the structure of hot spot 353. The model was built on the basis of the structure of cOptimize RBD complexed with human ACE2 (Protein Data Bank ID: 3SCJ) in which residues 442, 480 and 487 were mutated from those in strain cOptimize to those in strain bWIV1. **e** | The Middle East respiratory syndrome coronavirus (MERS-CoV) RBD (core structure in cyan and RBM in magenta) binds human dipeptidyl peptidase 4 (DPP4 green; Protein Data Bank ID: 4KR0). Structure figures were made using PyMOL[141]. Modelled mutations in panels **c** and **d** were performed using Coot[140]. Panels **a**–**d** are adapted from rEF.[83]: this research was originally published in *The Journal of Biological Chemistry* Wu, K. L., Peng, G. Q., Wilken, M., Geraghty, R. J. & Li, F. Mechanisms of host receptor adaptation by severe acute respiratory syndrome coronavirus. *J. Biol. Chem.* 2012; **287**: 8904–8911 © American Society for Biochemistry and Molecular Biology.

Table 1 | **Mutations in the receptor-binding motif of SARS-CoV**

Strain	Host	Year	Truncation in receptor-binding motif	Residue 442	Residue 472	Residue 479	Residue 480	Residue 487
hTor02	Human	2002–2003	No	Tyr	Leu	Asn	Asp	Thr
cSz02	Civet	2002–2003	No	Tyr	Leu	Lys	Asp	Ser
hcGd03	Human and civet	2003–2004	No	Tyr	Pro	Asn	Gly	Ser
cHb05	Civet	2005	No	Tyr	Pro	Arg	Gly	Ser
hHae08	Human	2008	No	Phe	Phe	Asn	Asp	Ser
hOptimize	Human	In vitro design	No	Phe	Phe	Asn	Asp	Ser
cOptimize	Civet	In vitro design	No	Tyr	Pro	Arg	Gly	Thr
bHKU3	Bat	2005	Yes	Ser	Gly	Ser	Thr	Val
bWIV1	Bat	2013	No	Ser	Phe	Asn	Asp	Asn
bRsSHC014	Bat	2013	No	Trp	Pro	Arg	Pro	Ala

Data from Hu et al. 2012 (rEF.[83]). SARS-CoV, severe acute respiratory syndrome coronavirus.

receptor binding, proteolytic cleavage of S and potentially other mutations that affect virion and trimer stability may also be important for virus transmissibility in different hosts, and these factors need to be studied further.

SARSr-CoV mutations that affect receptor binding. To date, numerous SARSr-CoV strains have been identified from bats[5,16,18–20]. These bat SARSr-CoVs are the likely progenitors of SARS-CoV that infected humans and civets, and hence understanding their interactions with human or civet ACE2 is critical for tracing the origins of SARS-CoV and for preventing and controlling future SARS-CoV outbreaks in humans. The RBD sequences of these bat SARSr-CoVs fall into three major groups; the representative strains from each group are bHKU3 (isolated in 2005), bWIV1 (isolated in 2013) and bRsSHC014 (isolated in 2013) (TAbIE 1). Strains bWIV1 and bRsSHC014, but not strain bHKU3, use both human and civet ACE2 and hence can infect both human and civet cells[16,18–20,86,87]. Strain bHKU3 has a truncated RBM (TAbIE 1), which distorts the structure of the RBM and abolishes its binding to human and civet ACE2. Neither strain bWIV1 nor strain bRsSHC014 contains truncations in its RBM, and hence, their RBMs likely retain the same structure as SARS-CoV RBMs. Here, we analysed the potential interactions between these two strains (bWIV1 and bRsSHC014) and human ACE2 by building homology structural models of their RBDs complexed with human ACE2, focusing on residues 479 and 487 (FIg. 6c, d). Strain bWIV1 contains Asn479 and Asn487 in its RBM. Whereas Asn479 is a viral adaptation to human ACE2, the polar side chain of Asn487 may have unfavourable interactions with the aliphatic portion of residue Lys353 in human ACE2, which is part of hot spot 353 (FIg. 6c). Strain bRsSHC014 contains Arg479 and Ala487 in its RBM. Whereas Arg479 is a viral adaptation to human ACE2, the small side chain of Ala487 does not provide support to the structure of hot spot 353 (FIg. 6d). Therefore, although both bWIV1 and bRsSHC014 can infect human airway cells, they bind human ACE2 less well than hTor02 and produce less severe symptoms than the epidemic strain of SARS-CoV in vivo[88,89]. Similarly, both bWIV1 and bRsSHC014 can infect civet cells, but they bind civet ACE2 less well than cSz02. Thus, it is predicted that both strains will be attenuated compared with early-phase or late-phase human SARS epidemic viruses. Future evolution of bat SARSr-CoV strains bWIV1 and bRsSHC014 in crucial RBM residues may allow them to cross the species barriers between bats, civets and humans, posing potential health threats.

Origin and evolution of MERS-CoV

Whereas the emergence of SARS involved palm civets, most of the early MERS index cases had contact with dromedary camels. Indeed, MERS-CoV strains isolated from camels were almost identical to those isolated from humans[90–95]. Moreover, MERS-CoV-specific antibodies were highly prevalent in camels from the Middle East, Africa and Asia[13,14,96–103]. MERS-CoV infections were detected in camel serum samples collected in 1983 (rEF.[100]), suggesting that MERS-CoV was present in camels at least 30 years ago. Genomic sequence analysis indicated that MERS-CoV, *Tylonycteris* bat coronavirus HKU4 and *Pipistrellus* bat coronavirus HKU5 are phylogenetically related (denoted as beta coronavirus lineage C)[21]. The viruses in this lineage have identical genomic structures and are highly conserved in their polyproteins and most structural proteins, but their S proteins and accessory proteins are highly variable. MERSr-CoVs were found in at least 14 bat species from two bat families, Vespertilionidae and Nycteridae. However, none of these MERSr-CoVs is a direct progenitor of MERS-CoV, as their S proteins differ substantially from that of MERS-CoV[98,104–106].

To understand the evolutionary relationships between MERS-CoV and MERSr-CoVs, we constructed a phylogenetic tree on the basis of the alignment of all the coding regions (FIg. 4b; Supplementary Fig. S1b). The phylogenetic tree contains two main clusters and several small clades or strains. Overall, the genetic diversity within the L1 and L2 viral lineages is low, indicating that humans and camels have been infected by viruses from the same source within a short time period. The L1 viruses include human and camel MERS-CoVs mainly

from the Middle East (the United Arab Emirates, the Kingdom of Saudi Arabia, Oman and Jordan) and two Asian countries (South Korea and Thailand) that had caused outbreaks in human populations. It is worth noting that the cases reported in South Korea and Thailand were related to those in the Middle East. The L2 viruses include camel MERS-CoVs from Africa (Nigeria, Burkina Faso and Ethiopia) and one Middle East country (Morocco); these viruses have not caused any human infection. Clearly, these two viral lineages share a common ancestor but have diverged in their potential to cause human infections. The MERSr-CoV strain Neoromicia/5038 (GenBank No. MF593268) isolated in South Africa was the closest relative to MERS-CoVs in the phylogenetic tree. Overall, all the MERSr-CoV isolated from bats support the hypothesis that MERS-CoV originated from bats. However, given the phylogenetic gap between the bat MERSr-CoVs and human and camel MERS-CoVs, there should be other yet-to-be-identified viruses that are circulating in nature and directly contributed to the emergence of MERS-CoV in humans and camels. Hopefully, such viruses will be found in bats in the future.

Not surprisingly, recombination events have taken place in the evolution and emergence of MERS-CoV[94,105,107–109]. Phylogenetic trees constructed using genes encoding *orf1ab* and *S* were incongruent with the tree topology of the complete genomes, suggesting potential recombination in these genes[108]. Numerous recombinations imply that MERS-CoV originated from the exchange of genetic elements between different viral ancestors, including those isolated from camels and the assumed natural host bats[94,105,107,110,111].

Variability of human and camel MERS-CoV

The full-length genomic sequences of MERS-CoVs isolated from humans and camels are almost identical (>99% identity). The major variations are located in S, ORF4b and ORF3, particularly in African camel MERS-CoVs[94]. Substitutions of a few amino acid residues were found in the S protein of some camel MERS-CoVs, but none of them was located in the RBD[94,112]. Neutralization assays indicated that camel sera that are positive for MERS-CoV can completely neutralize the human MERS-CoV strains, suggesting that MERS-CoVs isolated from humans and camels are antigenically similar to each other[94]. MERS-CoVs from both humans and camels contain variable ORF3 and ORF4 proteins with different lengths owing to either terminal truncations or internal deletions[94]. ORF4b is known to be an interferon antagonist[113,114]. MERS-CoV isolates from West African camels with a truncated ORF4b gene replicate less efficiently in human cell culture and are less pathogenic in human DPP4 transgenic mice[94]. Curiously, deletion of the *orf4* gene in the human MERS-CoV strain EMC did not substantially reduce virus replication, although it induced a stronger interferon response[94]. Another study demonstrated that the deletion of *orf3–orf5* dramatically attenuated MERS-CoV virulence, primarily through increased host responses, including disrupted cellular processes, increased activation of the interferon pathway and robust inflammation[115].

Variability of bat MERSr-CoVs

To date, bat MERSr-CoVs and human and camel MERS-CoVs share the same genomic structures but differ substantially in their genomic sequences[105,106,110,111,116]. The highest overall genomic sequence identity between bat MERSr-CoV and human and camel MERS-CoV is ~85%. On the basis of their genomic sequences, several bat MERSr-CoV strains discovered in China, such as li-MERSr-CoV, Ve-MERSr-CoV and Hy-MERSr-CoV, have just reached the taxonomic threshold to be considered the same species as MERS-CoV[106,110,111].

Compared with human and camel MERS-CoV, bat MERSr-CoVs vary most in *S* and accessory genes. The sequence identity of the S protein between bat MERSr-CoVs and human and camel MERS-CoVs is approximately 45–65%, with even lower sequence identity in the RBD region[110,111]. The size of these S proteins differs in these strains, mainly because of deletions in their RBD region and/or the S1 and S2 boundary. These deletions are considered to be related to the differences in receptor binding and cell entry[111,116]. The accessory genes, including those encoding ORF3, ORF4a, ORF4b and ORF5, are also highly variable in length and sequence between bat MERSr-CoVs and human and camel MERS-CoVs, suggesting substantial evolution of these genes in their natural hosts[105,106,110,111,116].

Receptor usage of MERS-CoV and MERSr-CoV

In contrast to SARS-CoV, which uses ACE2 as its receptor, MERS-CoV uses DPP4. Similar to SARS-CoV S1-CTD, MERS-CoV S1-CTD functions as the viral RBD[10,117]. Like the SARS-CoV S1-CTD, the MERS-CoV S1-CTD also contains two subdomains, a core structure and an RBM[9,118–120] (Fig. 6e). The core structures of these two S1-CTDs are similar to each other, with both containing a five-stranded β-sheet as the main scaffold. However, their RBMs differ substantially whereas the SARS-CoV RBM mainly contains loops, the MERS-CoV RBM mainly contains a four-stranded β-sheet. The structural differences between MERS-CoV and SARS-CoV RBMs account for the different receptor specificities of the two viruses[121].

Like the interactions between SARS-CoV and ACE2, the interactions between MERS-CoV and DPP4 have been extensively examined. DPP4 from humans, camels, horses and bats can function as a receptor for MERS-CoV, whereas DPP4 from mice, hamsters and ferrets cannot[112,122–125]. Key residue differences between human DPP4 and the DPP4 from other species affect the species specificities of MERS-CoV. For example, two residues (288 and 330) in mouse DPP4 and five residues (291, 295, 336, 341 and 346) in hamster DPP4 are largely responsible for the incompatibility of mouse and hamster DPP4s with MERS-CoV[112,123]. Mutating these residues to the corresponding residues in human DPP4 makes mouse and hamster DPP4 functional receptors for MERS-CoV. On the other hand, MERS-CoV and MERSr-CoVs have been isolated from camels and bats, respectively. MERS-CoV strains isolated from humans and camels are highly similar to each other, and they both use human DPP4 efficiently[112]. MERSr-CoVs from bats in general share only ~60–70% sequence identity with MERS-CoV in the RBD, and only some of these bat viruses, including HKU4,

recognize DPP4 as the receptor[110,111,126]. However, they bind DPP4 less efficiently than MERS-CoV. Mutating three residues in the HKU4 RBD (540, 547 and 558) substantially increased its affinity for human DPP4 (rEF.[127]). Overall, as in the case of SARS-CoV, receptor recognition is a crucial determinant of the host range of MERS-CoV.

SADS-CoV

From 28 October 2016 to 2 May 2017, swine acute diarrhoea syndrome (SADS) was observed in four pig breeding farms in Guangdong province, with a mortality up to 90% for piglets 5 days or younger. A novel HKU2-related bat coronavirus, named SADS-CoV, was identified as the causative agent[34,128,129]. The SADS-CoV isolates from piglets of the four farms were almost identical and shared 95% identity with *Rhinolophus* bat coronavirus HKU2 (rEF.[130]), indicating the bat origin of this pig virus. Immediately after the SADS outbreak, SADS-related CoVs (SADSr-CoVs) with 96–98% sequence identity to SADS-CoV were detected in 9.8% of anal swabs collected from different *Rhinolophus* species in Guangdong province during 2013–2016. Although genetically highly similar, bat SADSr-CoVs show high genetic diversity in the *S* gene, with 72–92% nucleotide and 80–98% amino acid identity to SADS-CoV. Receptor analysis indicated that none of the known coronavirus receptors, ACE2, DPP4 and aminopeptidase N, are essential for SADS-CoV entry[34]. The mechanism of transmission of SADS-CoV from bats to pigs and the pathogenesis of bat-originated SADSr-CoVs in pigs need further exploration. This is the first documented spillover of a bat coronavirus that caused severe disease in domestic animals, although molecular evolution data suggested PEDV probably originated in bats[37,38].

Conclusions and future perspectives

The collected data on genetic evolution, receptor binding and pathogenesis demonstrated that SARS-CoV most likely originated in bats through sequential recombination of bat SARSr-CoVs. Recombination likely occurred in bats before SARS-CoV was introduced into Guangdong province through infected civets or other infected mammals from Yunnan. The introduced SARS-CoV underwent rapid mutations in *S* and *orf8* and successfully spread in market civets. After several independent spillovers to humans, some of the strains underwent further mutations in *S* and became epidemic during the SARS outbreak in 2002–2003. However, a recent serological investigation revealed the presence of antibodies against the SARSr-CoV nucleocapsid in humans living around a bat cave but who had not shown clinical signs of disease, suggesting that the virus can infect humans through frequent contact[31].

A similar scenario might have happened for MERS-CoV. Since its outbreak in 2012, MERSr-CoVs and related viruses (HKU4 and HKU5) have been found in different bat species in five continents[17,21,106,110,111,116,126,127,132]. The ORF1ab of these viruses is highly similar to MERS-CoV ORF1ab, but they are highly diverse in their S proteins. Surprisingly, some bat MERSr-CoVs and HKU can use the same receptor, DPP4, as MERS-CoV[110,111,126,127]. Given the massive number of coronaviruses carried by different bat species, the high plasticity in receptor usage and other features such as adaptive mutation and recombination, frequent inter-species transmission from bats to animals and humans is expected.

Currently, no clinical treatments or prevention strategies are available for any human coronavirus. Given the conserved RBDs of SARS-CoV and bat SARSr-CoVs, some anti-SARS-CoV strategies in development, such as anti-RBD antibodies or RBD-based vaccines, should be tested against bat SARSr-CoVs. Recent studies demonstrated that anti-SARS-CoV strategies worked against only WIV1 and not SHC014 (r EFs[71,88,89]). In addition, little information is available on HKU3-related strains that have much wider geographical distribution and bear truncations in their RBD. Similarly, anti-S antibodies against MERS-CoV could not protect from infection with a pseudovirus bearing the bat MERSr-CoV S[111]. Furthermore, little is known about the replication and pathogenesis of these bat viruses. Thus, future work should be focused on the biological properties of these viruses using virus isolation, reverse genetics and in vitro and in vivo infection assays. The resulting data would help the prevention and control of emerging SARS-like or MERS-like diseases in the future.

It is widely accepted that many viruses have existed in their natural reservoirs for a very long time. The constant spillover of viruses from natural hosts to humans and other animals is largely due to human activities, including modern agricultural practices and urbanization. Therefore, the most effective way to prevent viral zoonosis is to maintain the barriers between natural reservoirs and human society, in mind of the 'one health' concept.

Swine acute diarrhea syndrome coronavirus (SADS-CoV)
Quantitative PCR
Detection

ABSTRACT

Swine acute diarrhea syndrome coronavirus (SADS-CoV)is a novel coronavirus which was associatedwith severe diarrhea diseasein pigs. SADS-CoVwas first detected and identified as the causative agent of a devastating swine disease outbreak in southern China in 2017. Routine monitoring and early detection of the source of infection is therefore integral to the prevention and control of SADS-CoVinfection. In this study, a SYBRgreen-based real-time reverse transcription quantitative polymerase chain reaction (RT-qPCR)technique was established for rapid detection and monitoring of this emerging virus. Specific primers were designed based on the conservedregion within the M geneof the viral genome.The lowest detection limit of the RT-qPCRassaywas 10 copies/μL. This assaywas specific and had no cross-reactionwith other 11 swine viruses. The positive rate of 84 clinical samples for the SYBRgreen-basedRT-qPCRand the conventional RT-PCRwas 73.81% (62/84) and 53.57% (45/84), respectively. Theseresults demonstrated that the SYBRgreen-basedRT-qPCRtechnique was an effectively diagnostic method with higher sensitivity than probe-basedRT-qPCRand gel-basedRT-PCRfor detection and epidemiological investigations of SADS-CoV.

Swine acute diarrhea syndrome coronavirus (SADS-CoV), a new member of the genus Alphacoronavirus, contributed to a devastating swine disease outbreak in Guangdong province, China, which caused death to more than twenty thousand piglets acrossfour farms and huge economic losses(Zhou et al., 2018b). The piglets infected with SADS-CoV mainly exhibited the clinical manifestations of acute vomiting and diarrhea and death (Gong et al., 2017; Xu et al., 2018; Zhou et al., 2018b). It was notable that the genome sequenceof the causative agent of this large-scale outbreak shares remarkable homology with a bat coronavirus detected in a cave near the pig farm, implying SADS-CoV most likely originated from bats (Gong et al., 2017; Lau et al., 2007; Zhou et al., 2018b). Considering the high lethality of this new emerging virus and the clinical signs of the infected pigs that are similar to that caused by other porcine enteric coronaviruses, there is an urgent need to establish a sensitive and reliable diagnostic method that will be of help to early discovery and identification of SADS-CoVinfection.

Cytopathic effect (CPE) could be observed only after serial passages of SADS-CoVin Vero cells, so isolation and detection of the virus by cell culture are time-consuming (Pan et al., 2017; Zhou et al., 2018b). Immunofluorescence (IF) staining has been used for the detection of SADS-CoV(Pan et al., 2017; Zhou et al., 2018b), however virus-specific antibody and fluorescently-labeled antibody are required to react with the SADS-CoVantigen, this procedure makes the IF method complex and time-consuming. Recently, a reverse transcription loop-mediated isothermal amplification method (RT-LAMP) was established for the detection of SADS-CoV,however it couldn't be used for quantitative analysis of the viral copiesin the samples(Wang et al., 2018). Real-time quantitative PCR(qPCR)is a powerful diagnostic method and has been widely used for detection and quantitation of pathogenic microorganism becauseof high sensitivity and reproducibility (Jensen et al., 2018; Yang et al., 2018; Yuan et al., 2016; Zhou et al., 2018a). Recently, a study reported a probe-based real time RT-qPCRfor the detection of SADS-CoV,with a detection limit of 30 DNA copies/μL (Zhou et al., 2018a). Whereas,the SYBRgreen-basedqPCRassaydoes not require an expensive probe, and is more cost-effective and easier to design than probe-based RT-qPCR.However, up to now, there is no report about SYBRgreen-basedreal-time RT-qPCRfor the detection of SADS-CoV.

In this study, a SYBRgreen-basedreal-time RT-qPCRassaytargeted

the mostly conserved gene of SADS-CoVwas established for rapid, sensitive and quantitative detection of the virus infection.

Complete genome sequencesof 34 SADS-CoVisolates in total retrieved from GenBank were aligned using MegAlign7.1.0 (DNAStar, USA), and Matrix (M) gene sequencewas found to be highly conserved among all the strains of SADS-CoVin the database.The primers named as SADS-F (5′-ATGACTGATTCTAACAACAC-3′) (covering nucleotides 24,784–24,803) and SADS-R (5′-TTAGACTAAATGCAGCAATC-3′) (complementary to nucleotides 25,451–25,470) were designed and used to amplify the M gene. Viral RNA was isolated from the cells infected with SADS-CoVisolate SADS-CoV/CN/GDWT/2017 (Accession number: MG557844) by TGuide virus DNA/RNA kit (TIANGEN, China) following the manufacturer's instruction. The viral RNA was transcribed and amplified by using PrimeScript™ One Step RT-PCR Kit (Takara, China) with the primers SADS-Fand SADS-R.The amplicon was subjected to gel electrophoresis and purified by using DNA Gel Extraction Kit (Beyotime, China). The purified amplicon was inserted into pGEM-T vector and transformed to Escherichiacoli DH5α competent cells. The insert of positive clone was confirmed by sequencingand named as SADS-N. SADS-N plasmid was linearized by endonuclease digestion and transcribed in vitro by RiboMAX™ Large Scale RNA Production System (Promega, USA) according to the instruction of the kit manual. The in vitro transcribed RNA was purified, quantified and converted into copy number as the previously reported method (Yuan et al., 2016). Ten-fold serially diluted RNA ranged from 1×10^0–1×10^7 copies/μL were prepared with DEPC-treated water and used as the molecular standards in the following assays.

For the SYBRgreen-basedRT-qPCR,the forward primer (5′-ATGTGGCTCCTATGGCCCTT-3′) (covering nucleotides 24,943–24,962) and the reverse primer (5′-ACGTTCGCGTTCTGCGATAA-3′) (complementary to nucleotides 25,095–25,114) were used to optimize the performance of the assay.The SYBRgreen-basedRT-qPCRwas carried out using the one step SYBRPrimeScript RT-PCRKit (Takara, China) following the kit manual. The RT-qPCRassayin a 20 μL reaction volume contained 10 μL of 2×one step SYBRRT-PCRBuffer, 0.4 μL of

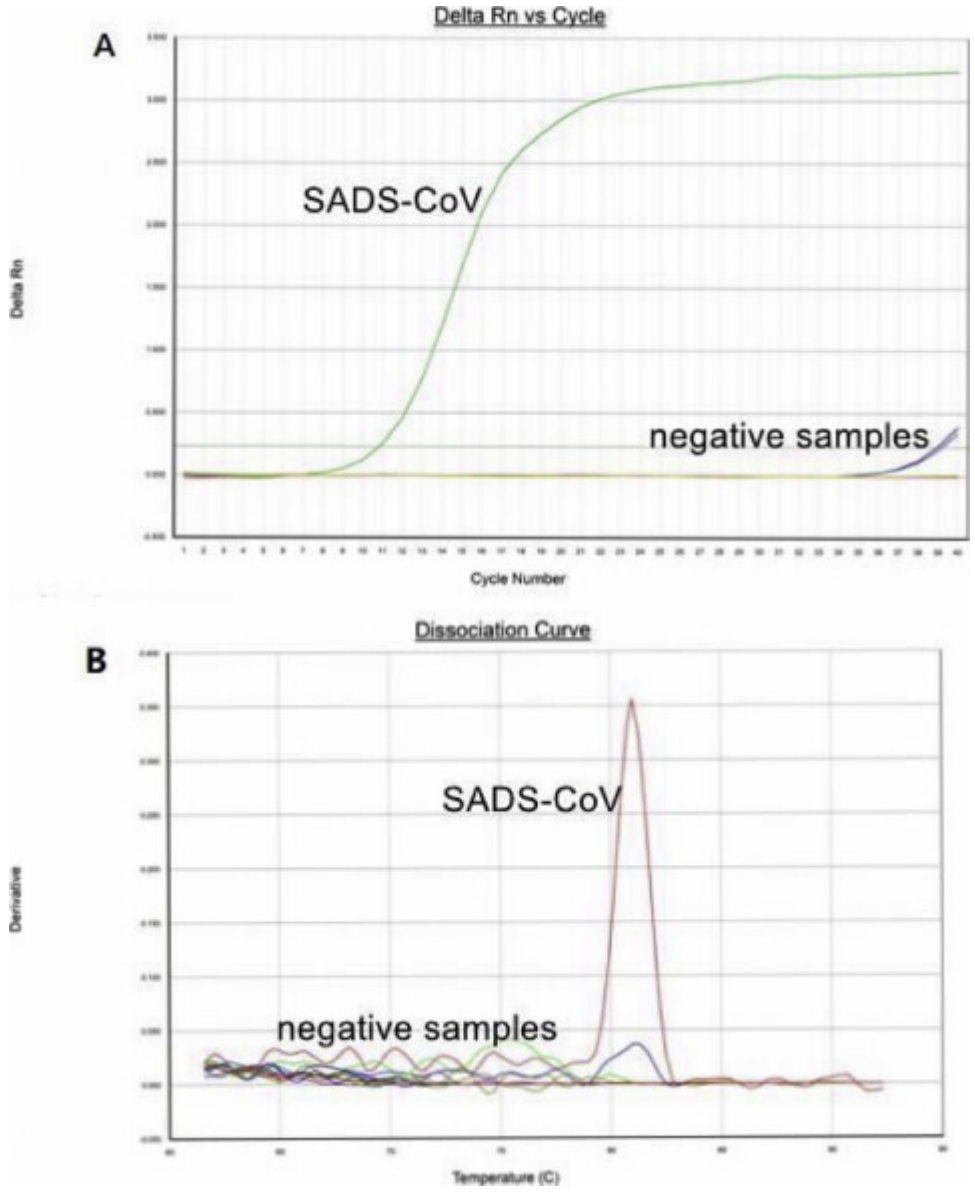

Fig. 2. Specificity of SYBRgreen-basedRT-qPCR.SADS-CoVand negative sampleswere testedby the RT-qPCRassay.Negative samplesincluded PRRSV,PEDV,PRV, CSFV,PCV2,TGEV,RV, PPV,FMDV, PDCoV,SIV and distilled water. A: Only SADS-CoVproduced a strong fluorescencesignal under RT-qPCR.B: Melting peak was observed at 81 °C for only SADS-CoVin RT-qPCR.

TaKaRaEx Taq HS, 0.4 μL of PrimeScript RT Enzyme Mix, 0.4 μL of ROX Reference Dye II, 0.4 μL (10 μM) of each primer, 7.0 μL of RNase free water and 1.0 μL of template. Amplification reaction was performed by Applied Biosystems 7500 Real-Time PCR System (Thermo Fisher Scientific, USA). Amplification condition was set up as follows: reverse transcription (RT) step at 42 °C for 5 min; initial denaturation at 95 °C for 30 s, followed by 40 cycles of 95 °C for 5 s, 60 °C for 34 s. After the cycles completed, a dissociation analysis step was added: 95 °C for 15 s, 60 °C for 60 s, 95 °C for 15 s. Data were collected and analyzed by the Applied Biosystems7500 SDSSoftware (Version 1.4).

The limit of detection of the RT-qPCRwas determined by testing the serially diluted RNA standards in triplicate. Meanwhile, the detection limit of gel-based RT-PCRwas also determined. As shown in Fig. 1A, RT-qPCRcould detect as few as 10 copies RNA molecule, but standard sample containing one RNA molecule or distilled water only didn't generate positive signals. The dissociation curve analysis indicated the RNA dilutions range from 1×10^1–$1 \times 1\ 0^7$ copies/μL showed almost the same melting temperature (Tm) value (mean Tm values ± standard deviation: 81.57 ± 0.15 °C), meanwhile sample containing one RNA molecule and distilled water as a negative control didn't generate the similar dissociation curve (Fig. 1C). The detection limit of the conventional RT-PCRin this study was 100 copies (Fig. 1D), which was 10 times less sensitive than RT-qPCR.Fig. 1B shows the standard curve generated by plotting the RNA copy number against the cycle (Ct) values of the RNA dilutions tested by RT-qPCRin triplicate using Prism 5.0 software (GraphPad, USA). The Ct values displayed a strong linear correlation (R^2 = 0.9937) with the logarithm of the RNA copy numbers (Fig. 1B), indicating robust amplification efficiency of the assay. RNA dilutions ranged from 1×10^7–$1 \times 1\ 0^2$ copies/μL were used to evaluate the reproducibility of the RT-qPCRassay. Intra- and inter-assay coefficients of variation (CV) were calculated as the method previously described (Zhou et al., 2018a). The intra- and inter-assay CVs of the SYBRgreen-basedRT-qPCRranged from 0.04% to 2.63% and 0.69% to 3.57% respectively, suggesting remarkable reproducibility and high reliability of the assay.

To assessthe specificity of this RT-qPCRmethod, a panel of viruses including porcine reproductive respiratory syndrome virus (PRRSV), porcine epidemic diarrhea virus (PEDV), pseudorabies virus (PRV),

Table 2
Comparative results of clinical samples tested by conventional RT-PCR, SYBR green-based RT-qPCR and probe-based RT-qPCR for SADS-CoV detection.

classical swine fever virus (CSFV), porcine circovirus type 2 (PCV2), transmissible gastroenteritis virus of swine (TGEV), porcine rotavirus (RV), porcine parvovirus (PPV), pig foot-and-mouth disease virus (FMDV), porcine deltacoronavirus (PDCoV) and swine influenza virus (SIV) were tested. All viruses were positive in conventional PCR by their own specific primers and negative by SADS-CoV specific primers. The specific primers were included in Table 1. Distilled water was used as the negative control. The viral genome was extracted by using TGuide virus DNA/RNA kit (TIANGEN, China) following the instruction. When these viruses were tested by the SYBR green-based RT-qPCR assay developed in present study, strong fluorescence signal was only observed for SADS-CoV. No amplification signal was observed throughout the experiment for most of the viruses. Although the fluorescence signal slightly increased after 35 cycles for the PCV2 and PRRSV (Fig. 2A), no specific melting peaks at about 81.57 °C were observed (Fig. 2B), further confirming the specificity of the assay.

To assess the clinical performance of the RT-qPCR for the detection of SADS-CoV, 84 tissue samples from 84 piglets with diarrheal symptoms were collected from a commercial farm in Guangdong, China, and analyzed by the assay. The SADS-CoV-positive status of the samples was determined by the combination of the amplification curve and the melting curve analysis. The samples were also evaluated by conventional RT-PCR and probe-based RT-qPCR which were reported before (Pan et al., 2017; Zhou et al., 2018a). Of 84 samples, 62 samples were SADS-CoV-positive confirmed by SYBR RT-qPCR. When these samples were tested by gel-based RT-PCR, only 45 samples were positive. The positive samples determined by conventional RT-PCR were all positive by SYBR RT-qPCR. Seventeen samples determined negative by conventional RT-PCR were identified as positive samples by SYBR RT-qPCR. When these samples were tested by probe-based RT-qPCR, the detection result was consistent with result by SYBR RT-qPCR. The detection results were summarized in Table 2.

SADS-CoV is a recently discovered virus that has resulted in serious outbreaks and huge financial losses to pig farming industry in south China (Fu et al., 2018; Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018b). Most of these studies applied the conventional RT-PCR to detection of SADS-CoV. However, RT-PCR is time-consuming and cannot determine the amounts of viral copies. A RT-qPCR assay is required for rapid and quantitative detection of SADS-CoV which has been epidemic in the south China.

Recently Zhou et al. reported a probed-based RT-qPCR technique with a detection limit of 30 RNA copies/μL (Zhou et al., 2018a). However the hydrolysis probe increased the experimental cost and the difficulty of assay design. Thus we established a cost-effective SYBR green-based RT-qPCR assay with high sensitivity and reliability for detection of SADS-CoV. This assay doesn't require a probe and is cost-effective. The limit of detection of the SYBR green-based RT-qPCR is 10 RNA copies/μL, 10 times and 3 times more sensitive than that of the conventional RT-PCR and probed-based RT-qPCR, respectively (Zhou et al., 2018a). The detection limit with 10 RNA copies in this study was theoretical analytical sensitivity, since that the sensitivity experiment was done by serial dilution of RNA standard in water, as the method described in a previous study (Zhou et al., 2018a). To determine more realistic sensitivity of the assay, the sensitivity experiment would be done by spiked RNA from negative tissue homogenate in the future. The positive rate of the clinical samples determined by the SYBR green-based RT-qPCR assay was 73.81%, whereas that of the conventional RT-PCR was merely 53.57%, further demonstrating the higher sensitivity of the SYBR green-based RT-qPCR assay. In the future, it is necessary to detect rectal swabs by the SYBR green-based RT-qPCR assay to evaluate the effect of bacteria in the samples on the detection capacity of the method. The sequences of the primers used in the SYBR RT-qPCR assay are 100% identity with all known SADS-CoV strains and a coronavirus isolated from the bat, suggesting the RT-qPCR assay not only can be used to detect the clinical samples from the swine, but also that from the bats.

In summary, a rapid, sensitive, reliable and cost-effective SYBR green-based RT-qPCR assay was established for the detection of SADS-CoV that poses a huge threat to pig industry. The RT-qPCR not only can be applied to the monitoring of SADS-CoV infection, but also the epidemiology study of the virus. In addition, this assay is of great use for the pathogenicity study of SADS-CoV in pigs. It will prompt the understanding of the tissue tropism of the virus and viral distribution in specific organs.

Conflicts of interest

The authors declare that they have no conflict of interest.

Emerging and re-emerging coronaviruses in pigs

Qiuhong Wang, Anastasia N Vlasova, Scott P Kenney and Linda J Saif

Porcine epidemic diarrhea virus (PEDV), porcine deltacoronavirus (PDCoV), and swine acute diarrhea syndrome-coronavirus (SADS-CoV) are emerging/reemerging coronaviruses (CoVs). They cause acute gastroenteritis in neonatal piglets. Sequence analyses suggest that PEDV and SADS-CoV may have originated from bat CoVs and PDCoV from a sparrow CoV, reaffirming the interspecies transmission of CoVs. The clinical signs and pathogenesis of the three viruses are similar. Necrosis of infected intestinal epithelial cells occurs, causing villous atrophy that results in malabsorptive diarrhea. The severe diarrhea and vomiting may lead to dehydration and death of piglets. Natural infection induces protective immunity, but there is no cross-protection among the three viruses. Besides strict biosecurity measures, individual vaccines are needed for each virus for disease prevention and control.

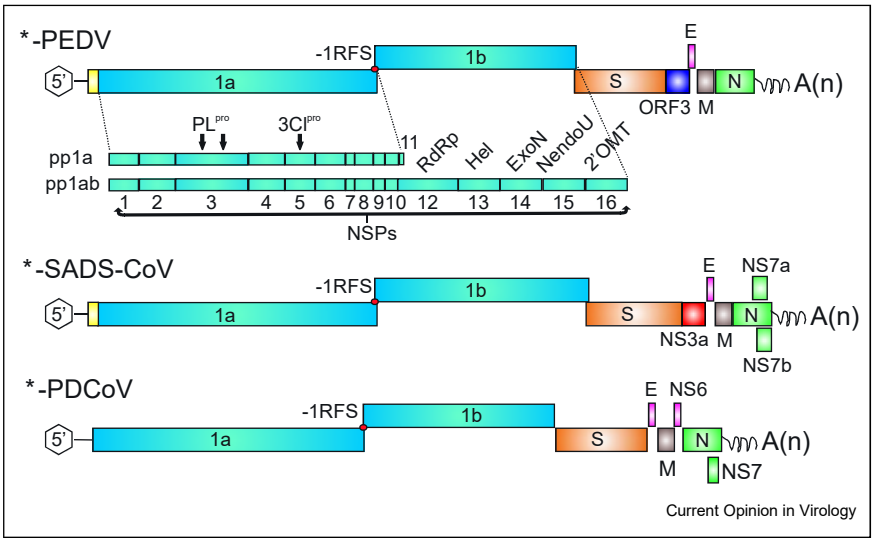
Introduction

Coronaviruses (CoVs) are the largest positive-sense, single-stranded RNA (+RNA) viruses. They belong to the Coronaviridae family of the Nidovirales order. Four genera are established: Alphacoronavirus, Betacoronavirus, Gammacoronavirus, and Deltacoronavirus. Currently, six CoVs infect pigs, including four alphacoronaviruses [transmissible gastroenteritis virus (TGEV), porcine respiratory coronavirus (PRCV), porcine epidemic diarrhea virus (PEDV), and swine acute diarrhea syndrome-coronavirus (SADS-CoV)], one betacoronavirus [porcine hemagglutinating encephalomyelitis virus (PHEV)], and a porcine deltacoronavirus (PDCoV) (Figures 1 and 2). Among them, TGEV, PRCV, and PHEV have been circulating in pigs for decades, whereas PEDV, PDCoV, and SADS-CoV are considered as emerging coronaviruses. Although classical PEDV was first discovered in Europe in the early 1970s [1], and it later spread to Asia in 1970s [2], a re-emerging highly virulent PEDV caused massive outbreaks, with high mortality in suckling piglets, in late 2010 [3]. In 2013–2014, PEDV caused nationwide outbreaks in the US, culminating in major losses to the pork industry. PDCoV was initially detected from pig fecal samples in 2009 in Asia, but its etiological role was not identified until 2014 when it caused diarrhea in pigs in the US [4,5]. Most recently, another highly pathogenic enteric CoV, SADS-CoV, emerged in China in 2016 with high mortality among baby pigs [6,7,8]. All three newly emerged porcine enteric CoVs were first detected in China. To date, the emerging PEDV strains have spread to other Asian and North American countries and to Europe. PEDV has become the second most important pathogen for swine in China (containing > 50% of the world's pig population), after porcine reproductive and respiratory syndrome virus (PRRSV). PDCoV has spread to the US, Canada, and other Asian countries [9]. No SADS-CoV has been reported from other countries besides China. In addition, recombinant viruses between TGEV and PEDV had been reported in Italy, Germany, and Slovakia [10–12]. These recombinant swine enteric coronaviruses (SeCoV), Italy/213306/2009 and GER/L00930/2012, share similar recombination pattern and 99.5% nucleotide identity and have potential parental strains TGEV H16 strain (major, backbone) and classical PEDV CV777 strain (minor, S gene). Because there were no more reports on SeCoV outbreaks, virulence, and tissue tropism, we will not discuss SeCoV further in this review.

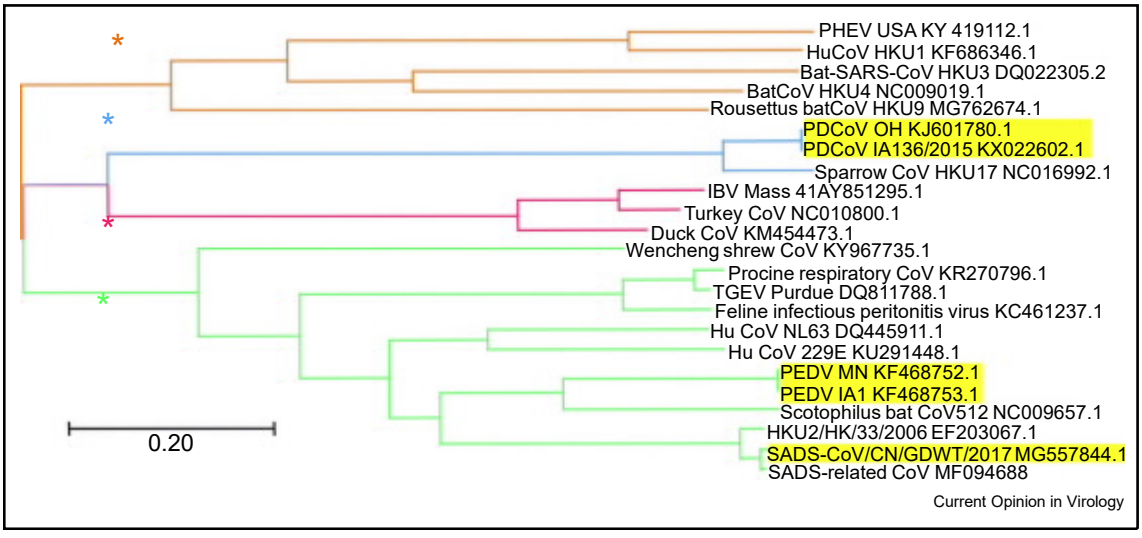
The basic genomic organization is shared among CoVs [13]. The genome size is about 25–30 kb. It contains at least six open reading frames (ORFs) in the order: ORF1a, ORF1b, spike (S), envelope (E), membrane (M), and nucleocapsid (N) (Figure 1). Each virus contains one to several accessory genes, the ORF3 of PEDV, NS3a, NS7a and NS7b of SADS-CoV, and NS6 and NS7 of PDCoV. ORF1a and ORF1b are at the 5^0-end and comprise two-thirds of the genome. They encode two non-structural polyproteins that are processed to generate an estimated 14–16 nonstructural proteins (NSPs) involved in proteolytic processing, genome replication and transcription [13]. Among the structural proteins, the

Figure 1



Genomic organization of alphacoronavirus porcine epidemic diarrhea virus (a-PEDV), swine acute diarrhea syndrome-coronavirus (a-SADS-CoV), and porcine deltacoronavirus (d-PDCoV). Each genome is 5^0capped and 3^0 polyadenylated. Viral genomes are flanked by UTRs and are polycistronic encoding replicase ORFs1a and 1b followed by the genes encoding spike glycoprotein (S), envelope (E), membrane (M), and nucleocapsid (N) proteins. Among the structural protein genes, the genome also contains accessory genes: ORF3 of PEDV; NS3a, NS7a and NS7b of SADS-CoV; and NS6 and NS7 of PDCoV. Expression of ORF 1a and 1b yields 2 polyproteins (pp1a and pp1ab) through a -1 programmed ribosomal frameshift (-1RFS). The polyprotein is co-translationally or post-translationally processed into an estimated 14–16 nonstructural proteins (NSPs): PLpro, papain-like cysteine protease; 3CLpro, main 3C-like cysteine protease; RdRp, RNA-dependent RNA polymerase; Hel, helicase; ExoN, 3^0-5^0 exonuclease; NendoU, nidovirus uridylate-specific endoribonuclease; 2^0OMT, ribose-2^0-O-methyltransferase.

Figure 2



Phylogenetic comparison of the full-length genomes of PEDV, SADS-CoV, and PDCoV with other coronavirus species. Evolutionary history was inferred using the Maximum Likelihood method [112]. The tree with the highest log likelihood (511751.49) is shown. Initial tree(s) for the heuristic search were obtained automatically by applying Neighbor-Joining and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior log likelihood value. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved 23 nucleotide sequences. There were a total of 32,538 positions in the final dataset. Evolutionary analyses were conducted in MEGA X [113].

S glycoprotein is most important to elicit virus neutralizing antibodies and is diverse among strains. The N protein, which is the most abundant structural protein, binds to the viral genomic RNA and is packed into the nucleocapsid, while the M and E are membrane proteins.

In this review, we will focus on the origin and potential for intra/interspecies transmission, host receptors for virus replication, antigenic relationships, comparative pathogenesis, and disease control and prevention of the three emerging porcine CoVs. For PEDV, we will focus on the highly virulent PEDV strains.

Origin and potential for intra/interspecies transmission

Coronaviruses, including emerging porcine CoVs of two different genera, alphacoronaviruses and deltacoronaviruses, exhibit an increased propensity for interspecies transmission [14,15]. Scattered genome-wide point mutations normally appear within host evolution of CoVs and are not associated with major changes in their biological functions [16,17]. In contrast, significant gene modifications (deletions or insertions in accessory or spike protein genes) are often involved in or occur following CoV host-shift or tissue tropism change events [18,19,20,21,22–24]. However, in the case of PEDV, a large deletion (194-216-aa Del) in the N terminus of S protein results in partial attenuation of the virus but did not alter tissue tropism [25,26]. This differs from PRCV whereby the large S deletion (207-227-aa) changes the major tissue tropism from enteric to respiratory compared with the parental TGEV. This may reflect the different receptor usage of these two alphacoronaviruses. TGEV uses aminopeptidase N (APN) as the receptor, and APN is distributed ubiquitously in many tissues. PEDV does not use APN as the receptor, which was confirmed by the fact that PEDV infects APN-knockout pigs [27]. Also, the size and localization of the deletions in the spike gene are virus species-specific with variable biological outcomes [28]. Frequent host-shifting (animal-to-animal and occasionally animal-to-human) events are characteristic for CoV evolution, with severe acute respiratory syndrome (SARS)-and Middle East respiratory syndrome (MERS)-CoVs being the most prominent recent examples [29–32]. While palm civets, raccoon dogs, Chinese ferret badgers, or dromedary camels were implicated as incidental hosts that facilitated SARS- or MERS-CoV spread to humans, respectively, bats are considered the natural reservoirs for these viruses [33,34]. Besides SARS- and MERS-CoVs, molecular analyses confirmed that numerous animal and human CoVs emerged as a result of recombination and interspecies transmission events. Those CoVs include alphacoronaviruses, betacoronaviruses, and deltacoronaviruses and are summarized below [14]. Canine CoV (CCoV) II has reportedly emerged via recombination between the original CCoV-I and an unknown CoV, while feline CoV (FCoV) II acquired the CCoV-II spike gene and the backbone from FCoV-I [20]. Another alphacoronavirus, TGEV, is suggested to have originated from CCoV-II because of the high genetic relatedness between the two viruses and by the presence of ORF3 remnants in both genomes [20,35].

Recent studies have further emphasized that bats are important reservoirs contributing to the immense diversity of human and animal CoVs. For example, it was demonstrated that Ghana bat CoV group I and HCoV-229E share a common ancestor [36,37]. Additionally, a recent transmission of bat-CoV-HKU10 from Leschenault's rousettes to Pomona leaf-nosed bats has been reported [38]. Among betacoronaviruses, there are the two human CoVs, respiratory HCoV OC43 associated with common colds and human enteric CoV (HECoV-4408) isolated from a child with diarrhea that are suggested to have been introduced into human population from bovine species [23,39]. Additionally, bovine-like CoVs were identified in captive wild ruminants and camelids such as waterbuck, sambar deer, white-tailed deer, elk, giraffe, sable antelope [18,40–42], alpaca, llama, and dromedary camel [43]. Deltacoronaviruses are genetically highly heterogenous and represent the only genus in the Coronaviridae family that infects avian and mammalian species with frequent host-shift events [44,45]. Recent molecular analysis of avian deltacoronaviruses in the Middle East provided long-sought evidence of interspecies transmission between falcons and their prey, houbara bustards and pigeons, as well as avian-to-swine transmission associated with recombination events in the spike gene [46].

There are no historic large-scale surveillance data that definitively establish that PEDV was introduced into the pig population from bats in the 1970s [47]. However, recently, it was demonstrated that PEDV is genetically more closely related to BtCoV/512/2005 than to TGEV, leading to the hypothesis that PEDV may have originated from bats (Figure 2) [47]. Additionally, PEDV infects cells from pigs, humans, monkeys, duck, and bats, further supporting the theory that PEDV had crossed the bat-swine interspecies barrier sometime in the past (Table 1) [48,49]. PEDV has been detected from feral pigs in Korea and the US [50,51], with the latter study suggesting that PEDV may have spilled over from domestic to feral pigs. However, because there are no control measures to prevent PEDV circulation in feral pigs, they may represent a PEDV reservoir that can lead to PEDV outbreaks in the future.

The SADS-CoV genome was shown to be highly similar (95% nucleotide identity) to another bat CoV (HKU2-CoV) identified in 2007 (Figure 2) [6,7,8,52]. However, the S gene sequence identity is only 86%, suggesting

Table 1

Summary of the three emerging enteric coronaviruses in pigs

Coronavirus (Genus)	Year of emergence (re-emergence	Prototype (GenBank Accession no.)	Receptor	Mortality in neonatal piglets	Infect other animal species besides pigs	Cell lines for virus propagation	Potential ancestor (GenBank Accession no.)
PEDV (Alphacoronavirus)	1971 (2010)	CV777 (NC_003436)	Unknown	Approaching 100% [71]	No	African green monkey kidney (Vero and MARC-145), swine intestine (IECs), bladder, kidney (PK15 and IB-RS-2), testis (ST), and alveolar macrophage (3D4), bat lung (Tb1-Lu), duck intestine (MK-DIEC), and human liver (HuH-7) and lung (MRC-5) [49]	CHN/BtCoV/512/2005 (DQ648858) [47]
PDCoV (Deltacoronavirus)	2009	HKU15-44 (JQ065042)	APN; others?	Up to 40% [9]	Bovine [111]	Swine ST, LLC-PK1, IPEC-J2, PKFA, SK6, PD5, and PK15, galline hepatoma (LMH) and fibroblast (DF-1), human hepatoma (Huh7), A549, HeLa, and HRT-18 [53 ,114,115]	Recombinant between Sparrow CoV HKU17/2007 (NC_016992) and bulbul CoV HKU11 (FJ376619)[4 ,46]
SADS-CoV (Alphacoronavirus)	2016	GDS04 (MF167434); CH/GD-01/2017 (MF370205); CH/GDWT/2017 (MG557844)	Unknown	90-100% in pigs ! 5 days of age and 5% in pigs > 8 days of age [8 ,72]	unknown	Vero [7,8 ,72]	BtCoV/HKU2/HK/33/2006 (EF203067); Bt/SADSr-CoV 162140/2016 (MF094688) [8 ,52]

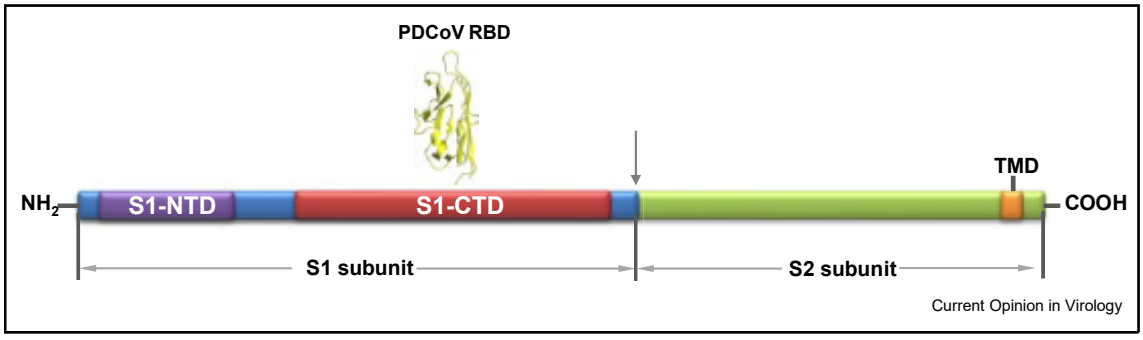
that HKU2-CoV may not be the direct progenitor of SADS-CoV, but that they may share a common ancestor. This prompted the search for new CoVs in bat specimens collected in Guangdong Province between 2013 and 2016. SADS-related CoVs (sharing 96–98% sequence identity with SADS-CoV) were identified in 9.8% of bats, predominantly in horseshoe bats (Rhinolophus spp) that are known reservoirs of SARS-related CoV (Figure 2) [8].

In contrast, molecular clock analyses suggest that PDCoV originated relatively recently from a host-switching event between avian and mammalian species (Figure 2) [4 ,44]. Most recent phylogenetic analyses have confirmed that quail deltacoronavirus UAE-HKU30 belongs to the same deltacoronavirus species as porcine coronavirus HKU15 (Por CoV HKU15) and sparrow coronavirus HKU17 (SpCoV HKU17) [46]. In addition, PDCoV was shown to efficiently infect cells of broad host range, including swine, humans, and chickens (Table 1) [53]. Accordingly, PDCoV S protein was found to target the phylogenetically conserved catalytic domain of APN [53]. Moreover, transient expression of porcine, feline, human, and chicken APN renders cells susceptible to PDCoV infection [53].

Host receptors

The major determinant for attachment and entry is binding of the S glycoprotein to receptors on the cell surface. This step is one of the key divergence points among CoVs, contributing significantly to species tropism, tissue tropism, the resultant pathogenesis in the host, and the ability to cross between species. The S protein is a type I glycoprotein consisting of S1 and S2 subunits present on the virion surface as a trimer (Figure 3) [54,55]. The S1 is involved in receptor binding and contains N-terminal and C-terminal domains (S1-NTD and S1-CTD, respectively), both of which may serve as a receptor-binding domain (RBD) [56]. The S2 subunit forms the stalk of the spike trimer, involved in triggering the fusion of the viral envelope and target cell membrane [53 ,55]. Identification of specific viral receptors can often be difficult due to the S protein potentially binding to multiple cell receptors, the necessity for co-receptors, and the involvement of potential host receptor proteins in viral replication stages other than initial binding. In the case of PEDV, there appears to be promiscuous binding to cell receptors [48]. APN and sialic acid have both been suggested as binding receptors for PEDV [48,57]. Further research suggests that porcine APN (pAPN) is not a functional receptor, but rather it contributes to PEDV infection

Figure 3



Schematic diagram of S protein of emerging porcine coronaviruses. S1-NTD – S1 subunit N terminal domain is shown in purple; S1-CTD – S1 subunit C terminal domain is shown in red; RBD – PDCoV receptor binding domain is shown in yellow; TMD – trans-membrane domain is shown in orange.

through its protease activity [27, 58 ,59,60]. This is confirmed by the recent report that APN-knockout pigs became resistant to TGEV infection, but remained susceptible to PEDV infection [27]. Furthermore, the binding efficiency of PEDV to sialic acid appears to be strain-specific. Sialic acid binding is variably required for other CoV infections in cell culture with sialic acid serving as a primary receptor in some instances (A1 lineage betacoronaviruses) [57], as a potential secondary receptor (TGEV) [61,62,63], or it may be dispensable for entry into cells as noted in cell culture (TGEV) [64]. A similar quandary exists for PDCoV where the S1 domain binds to APN of many different species, allowing functional infection of diverse cell types; however, removal of APN does not render cells completely resistant to infection [53 ,65]. These findings suggest that PDCoV not only utilizes APN, but it can also utilize another unknown receptor(s) in the absence of APN. Less research has been done on the emerging SADS-CoV binding receptor due to its recent identification [6,7,8].

Antigenic relationships

The antigenic relationships among porcine CoVs are complex and include intergenus and intragenus cross-reactivity [66–68]. One-way cross-reactivity was observed between TGEV (Miller strain) and classical and current US PEDV strains. This cross-reactivity was due to at least one epitope on the N-terminal region of the N protein [67] and is similar to the N protein-mediated antigenic cross-reactivity between SARS-CoV and alphacoronaviruses of porcine, canine and feline origin reported previously [66,68]. Because it was confirmed that PEDV does not utilize pAPN as a cellular receptor [27,58 ,59,60], whereas TGEV does, the biological relevance of the observed antigenic cross-reactivity between TGEV and PEDV needs to be evaluated further, but could interfere in diagnostic tests based on whole virus or N protein.

The fact that pAPN acts as a cross-genus CoV functional receptor for both the enteropathogenic PDCoV and alphacoronavirus (TGEV) suggests that some sequence/structural homology may exist to enable this functional interaction between pAPN and the PDCoV/TGEV S protein receptor binding domain region [53]. The existence and extent of antigenic cross-reactivity between TGEV and PDCoV are unknown; however, N-protein mediated two-way cross-reactivity between PEDV and PDCoV was recently confirmed [69]. Thus, the above data suggest that receptor selection in the emergence of porcine CoVs is subject to certain restrictions and may lead to structural re-arrangements in the spike as well as other viral proteins, including the highly conserved (and therefore cross-reactive) N protein. Furthermore, recent experiments demonstrated that angiotensin-converting enzyme 2 (ACE2), pAPN and dipeptidyl peptidase 4 (DPP4) do not function as receptors for SADS-CoV [8]. Thus, additional experimental work is needed to identify cellular receptors for PEDV and SADS-CoV, as well as to gain mechanistic understanding of antigenic interrelationships among emerging porcine CoVs. Specifically, additional information is needed to establish whether there is co-regulation between receptor usage and antigenic cross-reactivity among these CoVs.

Comparative pathogenesis

PEDV, PDCoV, and SADS-CoV are all enteric pathogens, causing indistinguishable acute gastroenteritis in all ages of pigs (Table 1). Clinical signs include mainly anorexia, diarrhea and vomiting that may lead to dehydration, loss of body weight, lethargy, and death. Those clinical signs generally do not last over 10 days. Disease is generally more severe and often lethal in neonatal piglets, especially those born from seronegative sows. In older pigs, such as weaned pigs and sows, morbidity is high but the mortality rate is low. In general, the emerging highly virulent PEDV is more virulent than PDCoV strains tested [9]. During the first year of outbreaks in the US,

the pig morbidity rate due to PEDV and PDCoV was about 100% and 30%, respectively [70]. PEDV and PDCoV caused up to 100% and up to 40% mortality rates in neonatal piglets, respectively [9,71]. The mortality rates of SADS-CoV in piglets less than five days of age and older than eight days of age were 90–100% and 5%, respectively [8 ,72]. Diseases caused by porcine enteric CoVs (TGEV, PEDV, SADS-CoV, and PDCoV) cannot be differentiated without laboratory diagnosis. Transmission is mainly via the fecal-oral route. Vehicles include contaminated feed/ingredients, transportation trucks/trailers, environment, etc. [71]. Airborne transmission was reported for both PEDV and PDCoV, probably via ingestion of aerosolized virus particles [71]. Recently, Li et al. [73] investigated the potential mechanisms of airborne transmission of PEDV. They concluded that the virions can replicate in the nasal epithelial cells, then are carried by dendritic cells (DCs) and passed to CD3+ T cells that transport PEDV to the gut to infect intestinal cells. However, such a conclusion cannot be made based on the data presented in the paper. The major concern is that the authors used extremely high inoculum dose (7 $\log_{10}$ PFU/pig) to intranasally inoculate five-day-old CDCD piglets. Considering the very low infectious dose for neonatal piglets of the emerging highly virulent PEDV, ingestion of even a very small portion (1/10 million, 1 PFU) of this inoculum, which was highly possible, can result in a 100% infection rate in piglets within 24 hpi, as described previously [74,75]. Therefore, although PEDV can replicate in nasal epithelial cells and be taken up by DCs and T cells, whether the virions carried by the DCs and T cells can cause intestinal infection and diarrhea should be investigated further. Also, PEDV is more prevalent than PDCoV in the field [76]. Infectious PEDV can be shed in the feces of infected pigs weeks after clinical signs cease posing difficulties for disease management on farms [71]. Co-infections with more than one pig enteric pathogen are common and often more severe clinically [77,78].

The pathogenesis of PEDV and PDCoV has been studied in different ages of pigs [9,71,79,80]. Disease is more severe in younger pigs than in older pigs, which is called age-dependent resistance probably due to the immature immune responses and lower rate of enterocyte regeneration in younger pigs [81 ,82–84]. In general, pathological changes in young pigs are similar between these two viruses. Clinical signs appear at 1–3 days post-inoculation. Viral replication occurs quickly and mainly in the villous epithelial cells of the small intestine, resulting in villous atrophy. Therefore, diarrhea is probably a consequence of malabsorption due to massive loss of absorptive enterocytes. PEDV and PDCoV antigens also were detected occasionally in crypt cells, but may not contribute significantly to pathogenesis since enterocyte regeneration capacity was preserved [9,79]. No histopathologic changes have been observed in the caecum/colon, although PEDV and PDCoV antigens were detected in the epithelial cells of these intestinal sections. During the acute phase of virus infection, large number of viruses are shed in feces. Viral RNA was also detected transiently in the serum. Low levels of viral RNA were detected in multiple organs by real-time reverse transcription (RT)-PCR possibly due to viremia, since no viral antigen was detected. A recent study showed significantly lower levels of serotonin-secreting enteroendocrine cells in duodenum, mid-jejunum, ileum, or colon in PEDV-infected pigs that had vomiting than in negative control pigs, suggesting that serotonin secretion during PEDV infection might contribute to vomiting [85]. The pathogenesis of the recently emerging SADS-CoV was studied in piglets by three laboratories [7,8 ,72]. Pan et al. [7] noted that SADS-CoV caused only mild-moderate intestinal lesions in three-day-old piglets. In the second study, SADS-CoV proteins were detected in only a few jejunal epithelial cells, which may not correlate with the 50% (3/6) mortality in the inoculated three-day-old piglets [8]. In the most recent study Xu et al. [72] reported that SADS-CoV mainly infects the intestine, causing 100% (12/12) and 50% (2/4) mortality rates in five-day-old and contact control conventional piglets (infected at 7 days of age based on fecal shedding data), respectively. SADS-CoV RNA was also detected from the heart, liver, spleen, kidneys, stomach, and lungs, but not the blood of piglets euthanized at 7 dpi when pigs still had severe diarrhea. Therefore, more detailed pathogenesis studies are warranted to understand SADS-CoV replication in vivo, factors contributing to disease severity, tissue tropism, etc.

Immune responses and disease control and prevention

Immune responses have been studied for PEDV infection, but there are few reports for PDCoV and SADS-CoV [86–89]. Serum PEDV IgG Ab responses were studied in seven-week-old conventional pigs inoculated with non-S INDEL PEDV via the oragastric route at 7 to 42 days post-inoculation (dpi). IgG antibodies were detected as early as 7 dpi for the S1 subunit of the S protein and 10 dpi for the N and M structural proteins and the whole virus particles [90]. The antibody titers peaked at 14–17 dpi and remained detectable through 42 dpi. However, no E protein-specific IgG antibodies were detected throughout the study. Also, the PEDV S1 does not cross-react with IgG antibodies against the other porcine enteric coronaviruses, TGEV (and its variant PRCV) and PDCoV. Therefore, the S protein is the most sensitive and specific marker for PEDV infection. In 11-day-old conventional pigs, a strong positive correlation exists between protection against PEDV challenge and the levels of IgA and IgG antibody secreting cells (ASCs) in the gut associated lymphoid tissues (duodenum and ileum lamina propria and mesenteric lymph nodes) and the blood as well as between protection and serum IgG

and IgA antibody titers [91,92]. In sows exposed to PEDV in the field, IgA and IgG PEDV ASCs were detected in the intestine of sows at one month post-PEDV exposure, then waned, but remained detectable at six months post-PEDV exposure [93]. Additionally, PEDV IgA antibody was detectable in oral fluids [93]. Several experimental challenge studies using naive animals of different ages demonstrated that serum viral neutralizing antibodies became detectable around 10 dpi, peaked around 18 dpi, decreased slightly around 21 dpi, and remained at high level through 42 dpi [88].

T cell immune responses may play an important role in inducing protective immunity because pigs infected with the attenuated and highly virulent PEDV PC22A strain generated similar level of humoral immune responses, but only pigs infected with the virulent PEDV were protected from challenge with homologous virulent virus [94]. However, limited experimental data are available on cellular immune responses focusing mainly on cytokine responses [82]. PEDV-infected suckling pigs had significantly lower natural killer (NK) cell frequencies, undetectable NK cell activity and lower IFN-γ producing CD3$^-$ CD4$^-$ CD8$^+$ NK cells in blood and ileum compared with PEDV-infected weaned pigs [82]. Deficiency in the innate immune function of neonatal NK cells may contribute to the more severe PEDV infection in suckling pigs compared with weaned pigs as also reported for TGEV infections [95]. Inflammatory responses play a significant role in the pathogenesis of enteric coronaviruses. Compared with suckling pigs, weaned pigs had a delayed pro-inflammatory cytokine induction that coincided with the delayed onset of infection, disease and shedding of PEDV RNA in feces [82]. Toll-like receptor 2 (TLR2), TLR3, and TLR9 may contribute to NF-κB activation in response to PEDV infection in small intestinal epithelial cells in vitro [96]. The viral proteins E and N upregulated IL-8 expression by inducing endoplasmic reticulum stress and subsequent activation of the NF-κB pathway [97,98]. PEDV can evade host innate immune responses via at least 11 proteins (nsp1, nsp3, nsp5, nsp7, nsp14, nsp15, nsp16, ORF3, E, M, and N) that function as interferon (IFN) antagonists [99–102]. Identification of the virus-encoded IFN antagonists and understanding their mechanism of action may lead to novel therapeutic targets and more effective vaccines. In summary, infection of PEDV induces protection against homologous virus challenge in neonatal, growing and adult pigs [89,103,104]. Although there is only one serotype of PEDV, only incomplete cross-protection exists among different genetic clusters of PEDV variants [3,103]. Sows previously infected with PEDV can generate lactogenic immunity and passively protect nursing piglets from disease [86,104]. Mucosal IgA antibody levels correlate to protective viral neutralizing antibody levels and the neutralizing epitopes are mainly located in the S glycoprotein [105–107].

Rapid diagnosis is critical for the control of these diseases to prevent them from spreading. Diagnostic methods for PEDV and PDCoV for the detection of viral RNA, viral antigens, and antibodies have been reviewed [76,88]. No specific antiviral drugs are available to treat infected pigs. High level biosecurity and vaccines are still the best choice to prevent these enteric infections [104]. No cross-neutralization exists between antibodies to PEDV and PDCoV [69]. SADS-CoV outbreaks occurred at a swine farm that suffered from recent PEDV infections, suggesting no cross-protection between PEDV and SADS-CoV [8]. Therefore, the prevention of these three emerging porcine CoV diseases will require the development of separate virus-specific vaccines. Although PED occurs in pigs of all ages, piglets up to one week of age experience high mortality and need to be protected by transfer of maternal antibodies, especially neutralizing antibodies, via colostrum and milk from immunized dams. The mechanisms of lactogenic protection described for TGEV and other enteric viral infections apply to PEDV as well [86,108]. Colostrum and milk IgA or neutralizing antibody titers are better markers for lactogenic immunity than antibodies in serum [109]. Live, inactivated, and subunit (S) PEDV vaccines targeting sows have been developed in China, Japan, Korea and the US [104,110]. However, their efficacy has not been sufficient to control PEDV outbreaks that still occur on farms with PEDV-vaccinated pigs. No reports are yet available on vaccine development for PDCoV or SADS-CoV. Some farms use feedback methods with intentional exposure of pregnant sows pre-farrowing to autogenous virus using minced intestines from acutely infected piglets [108]. The goal is to stimulate lactogenic immunity in sows and reduce mortality in nursing pigs. The problem with these methods is that PEDV infection may become persistent on farms and other enteric pathogens could be transmitted to the entire herd.

Conclusions

PDCoV, SADS-CoV, and highly virulent PEDV emerged or reemerged recently (Table 1). PEDV has spread to Asian, North American, and European countries, causing huge economic losses in the swine industry. Among the three enteric CoVs, PEDV has been studied more extensively and some vaccines have been developed, although their efficacy in the field is still questionable. For PDCoV and SADS-CoV, more research is needed to better understand their emergence, evolution, pathogenesis, and immune responses. Currently, disease control and prevention mainly depend on swine farm management, focusing on high biosecurity measures and disease containment within and among farms. Coronaviruses often spill over to other species: PEDV and PDCoV can infect cells from different species, and PDCoV can also infect calves [111]. Currently, these emerging porcine CoVs are only known to infect pigs, but not humans [48,53].

Nevertheless, continued monitoring of these porcine CoVs is necessary for both swine and public health.

This study reported that PDCoV uses APN as an entry receptor via binding to the phylogenetically conserved catalytic domain of APN. It partially explains the fact that PDCoV efficiently infects cells of a broad species range and the mechanism of interspecies transmission of the virus from birds to pigs.

Abstract

Porcine enteric alphacoronavirus (PEAV) was first discovered in China in February 2017, and the origin and virulence of this novel porcine coronavirus were not fully characterized. Here, we isolated a strain of PEAV, named GDS04 that is identified by immunofluorescence and typical crown-shaped particles observed with electron microscopy. Genomic analysis reveals that PEAV GDS04 shares a close relationship with SADS-CoV and SeACoV. Furthermore, newborn piglets orally challenged with PEAV GDS04 developed typical clinical symptoms as watery diarrhoea in neonatal piglets. Viral RNA was detected in faeces and various tissues of the infected piglets. Moreover, macroscopic and microscopic lesions in whole intestinal tract were observed, and viral antigen could be detected in the small intestines by immunohistochemical staining and electron microscopy. Importantly, the mortality rate of inoculated-newborn piglets was 100% and half of the cohabiting piglets died. Collectively, we demonstrate that PEAV is highly pathogenic in newborn piglets.

KEYWORDS
newborn piglets, pathogenicity, Porcine enteric alphacoronavirus (PEAV)

1 | INTRODUCTION

Coronaviruses (CoVs), belonging to the subfamily Coronavirinae in the family Coronaviridae within the order Nidovirales (Zhang, 2016), are found in a wide variety of animals (Felippe, da Silva, Santos, Spilki, & Arns, 2010; Pan et al., 2012; Rihtaric, Hostnik, Steyer, Grom, & Toplak, 2010; Stohlman, Brayton, Fleming, Weiner, & Lai, 1982; Tsunemitsu, el-Kanawait, Smith, Reed, & Saif, 1995). Porcine CoVs are significant enteric and respiratory pathogens of swine. Six porcine CoVs have so far been identified: transmissible gastroenteritis virus (TGEV) (Doyle & Hutchings, 1946), porcine respiratory coronavirus (PRCV) (Wesley, Woods, Hill, & Biwer, 1990), porcine epidemic diarrhoea virus (PEDV) (Pensaert & de Bouck, 1978), and porcine enteric alphacoronavirus (PEAV) (Gong et al., 2017) in the Alphacoronavirus genus; porcine haemagglutinating encephalomyelitis virus (PHEV) (Sasseville, Boutin, Gelinas, & Dea, 2002) in the Betacoronavirus genus; porcine deltacoronavirus (PDCoV) (Woo et al., 2012) in the Deltacoronavirus genus. PEAV as the newest member was first detected by our team by genomic analysis of samples collected from a diarrhoea-outbreak swine herds routinely vaccinated with PEDV vaccine in a farm in Guangdong, China in February 2017, and complete genome of the PEAV strain GDS04 was then sequenced (Gong et al., 2017).

Porcine enteric alphacoronavirus is an enveloped, single-stranded, positive-sense RNA virus with a genome of appropriately 27 kb in length (Gong et al., 2017). The genome organization of PEAV is similar to that of bat-like HKU2 strains of coronavirus, with an order of: 5′ untranslated region (UTR), open reading frame 1a/1b (ORF1a/1b), spike (S), nonstructural protein 3 (NS3), envelope (E), membrane (M), nucleocapsid (N), nonstructural protein 7a (NS7a), and 3′ UTR (Lau et al., 2007). The S protein of CoVs is the pivotal surface glycoprotein involved in virus attachment and entry, and induction of neutralizing

 © 2018 Blackwell Verlag GmbH

antibodies in vivo (Cruz, Kim, & Shin, 2008; Woo, Huang, Lau, & Yuen, 2010). GDS04 strain of PEAV has the smallest S protein among all coronaviruses (Gong et al., 2017).

The clinical symptoms in newborn piglets from pig farm with reported PEAV are similar to that by other porcine enteric pathogens such as PEDV and TGEV, which include vomiting, diarrhoea, dehydration, and mortality rate as high as 90% in piglets (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). Since the new bat-HKU2-like coronavirus (PEAV) was detected in pigs with severe diarrhoea (Gong et al., 2017), another two swine enteric HKU2-related CoV (SADS-CoV and SeACoV) strains were identified in the same region, which reproduced clinical diarrhoeal disease by experimentally infecting piglets with isolated SADS-CoV and SeACoV strains (Pan et al., 2017; Zhou et al., 2018).

Although PEAV GDS04 was detected by genomic analysis in pigs (Gong et al., 2017), detailed information remains unclear. In this study, we isolated a PEAV strain from Guangdong province of China using Vero cells, characterized its genome based on s genes, n genes, and whole-genome, and investigated its pathogenicity in 5-day-old conventional pigs by clinical assessment,virus shedding, virus distribution, histological test, immunohistochemical study, and the mortality rate of inoculated piglets. The results suggest that the isolate of PEAV GDS04 is closely related to SADS-CoV and SeACoV but caused 100% mortality in neonatal piglets, indicating its potential role as pathological agent responsible for severe watery diarrhoea and death in neonatal piglets in the field case.

2 | MATERIALSAND METHODS

2.1 | PEAV-positive specimens

In early February 2017, an outbreak of PEAV was reported in swine herds in Guangdong, China (Gong et al., 2017), with a mortality rate ranging up to 90% (Zhou et al., 2018). To increase the virus titres for isolation, fresh excreta from infected PEDV-vaccinated newborn piglets were inoculated into 5-day-old nonvaccinated piglets as described previously (Gong et al., 2017). Intestinal contents were collected from an inoculated piglet developing symptoms of severe diarrhoea and vomiting, and stored at - 80°C until further use. Prior to virus isolation, intestinal contents were diluted one time using sterile 1× phosphate buffer saline (PBS) (pH 7.4). The supernatants were then collected by centrifugation at 6000× g for 5 min at 4°C, and filtered through 0.22-μm-pore-size filters (Millipore, USA).

2.2 | Virus isolation, plaque purification, and propagation in Vero cells

Vero cells were obtained from ATCC (ATCC number: CCL-81) (USA) and were used to isolate PEAV from the intestinal contents of piglet. Vero cells were cultured in DMEM (Hyclone, USA) supplemented with penicillin (100 U/ml), streptomycin (100 U/ml), and 10% foetal bovine serum (FBS) (BOVOGEN, Australia). The maintenance medium for PEAV propagation was DMEM supplemented with 10 μg/ml trypsin (Gibco, USA).

Virus isolation, plaque purification, and propagation were performed as previously described with some modifications (Lee, Kim, & Lee, 2015; Oka et al., 2014; Pan et al., 2017). Briefly, for the first inoculation, Vero cells were cultured in 6-well plates, and washed three times with sterile 1× PBS (pH 7.4) at a confluency of 90%. Two hundred microlitres of the filtered inoculums, together with 300 μl maintenance medium was added to each well. After adsorption for 1.5 hr at 37°C in 5% CO_2, cells were washed three times with the maintenance medium, and then 2 ml maintenance medium was added. The cells were cultured continuously at 37°C in 5% CO_2 for cytopathic effect (CPE) observation. The plates were frozen at - 80°C and thawed twice around 4 day postinoculation (d.p.i). The cells and supernatant termed as "passage 1 (P1)" were harvested together. Samples collected at 0-hr postinoculation and 4 d.p.i. were tested by PEAV-specific RT-PCR as described previously (Gong et al., 2017). The RT-PCR positive samples were used as seed stocks for the next passageand plaque purification. For virus plaque purification, supernatants from virus-infected cells were serially diluted and used to infect Vero cells in the maintenance medium for 1.5 hr at 37°C in 5% CO_2 and then the maintenance medium was discarded, followed by overlaying 2 ml maintenance medium containing 1.25% Agarose LM GQT (TaKaRa, Dalian) to immobilize the virus. After 24 hr, cells were fixed and visualized with 2 ml maintenance medium containing 1.25% Agarose LM GQT and 0.01% Neutral red solution (Sigma,USA). The plaques were picked by using sterile pipette tips, and the agaroseplaque was placed into a microcentrifuge tube containing 0.5 ml maintenance medium. The selected plaques of PEAV were named GDS04 and used for viral propagation. Vero cells were cultured in T175 flasks, and washed three times with sterile 1× PBS (pH 7.4) at a confluency of 90%. One mL of PEAV together with 50 ml maintenance medium was added into the flask. The cell pellets and supernatant were cultured continuously at 37°C in 5% CO_2 to observe CPE. When CPE was evident in the inoculated cell monolayers (around 1 d.p.i.), the plates were frozen at - 80°C and thawed twice. The cells and supernatant were harvested together to determine viral titres.

2.3 | Infectious-virus titrations by a $TCID_{50}$ assay

Vero cells were seeded on 96-well plates and cultured overnight before washed two times with sterile 1× PBS (pH 7.4). One hundred microlitre of 10-fold dilutions of PEAV was inoculated in eight replicates per dilution, then the cells were cultured continuously at 37°C in 5% CO_2. Viral CPE was observed for 5–7 days, and virus titre was calculated using the Reed-Muench method (Reed, 1938) and expressed as $TCID_{50}$ per millilitre.

2.4 | Immunofluorescence assay (IFA)

Immunofluorescence assay was conducted to observe PEAV-infected Vero cells as described previously with some modifications (Dong et al., 2016). Briefly, Vero cells (1×10^5) were seeded on 24-well plates

and cultured overnight, then infected with PEAV at a multiplicity of infection (MOI) of 1. At 24 hr after inoculation, the cells were fixed with 4% paraformaldehyde for 15 min and then permeabilized with 0.2% Triton X-100 for 15 min at room temperature. The cells were then blocked with 1% bovine serum albumin (BSA), and incubated with PEAV-specific mouse antisera (Guangdong Wen' s Foodstuffs Group Co., Ltd, China) (1:250), followed by fluoresceinisothiocyanate (FITC)-labelled goat anti-mouse secondary antibody (KPL, USA) (1:1,000) for 1 hr. Then, the stained cells were observed with a fluorescence microscope (LEICADMi8, Germany).

2.5 | Electron microscopic observation

Electron microscopy (EM) was conducted to observe virus samples as described previously with some modifications (Alsaad et al., 2018; Hu, Jung et al., 2015; Kong et al., 2010). For visualization of the viral particles in infected-cell culture medium, PEAV-infected Vero cells were frozen at - 80°C and thawed twice, and the cell culture was centrifugated at 7,000× g for 30 min at 4°C. The supernatant was supplemented with 6% PEG6000 for 12 hr at 4°C. The mixture was centrifuged at 12,000× g for 1 hr at 4°C, and the pellet was resuspended in sterile 1× PBS (pH 7.4) buffer, followed by equilibrium in 8 mL nonlinear 20%–60% sucrose-TNE gradients by centrifugation at 110,000× g for 2 hr at 4°C with an ultracentrifuge (Hitachi Koki himac CP 100WX, Japan). After purification by sucrose gradient centrifugation, purified virions were diluted with sterile 1× PBS (pH 7.4) buffer and the sucrose was removed by centrifugation at 7,000× g for 2 hr at 4°C with centrifugal filter units (Millipore, USA). The purified virus pellets were resuspended in sterile 1× PBS (pH 7.4) buffer and negatively stained with 3% phosphotungstic acid. After blotting and drying, the grids were examined with a JEM-100 CX-II electron microscope (JEOLLTD,Japan).

For visualization of the viral particles in jejunum of PEAV-inoculated piglets, portion of jejunum was fixed in 5% glutaraldehyde fixative prepared in sterile 1× PBS (pH 7.4) for 4 weeks and underwent postfixation in 1% osmium tetraoxide for 1 hr. The samples were washed twice by sterile 1× PBS (pH 7.4) and dehydrated using increasing concentrations of acetone. The samples were then embedded in Araldit 520 resin and polymerized in oven at 90°C for 24 hr. Tissue semithin sections (1 μm) were prepared, stained by Toludin blue stain for 5 min and inspected under conventional light microscope. Ultrathin sections (70 nm) were prepared using Leica EM UC7 ultramicrotome, collected on 200 mesh copper grid (PELCO) and stained with uranyl acetate for 15 min and lead citrate for 5 min. The ultrathin sections were screened by 120-kV JOEL1230 transmission electron (TEM) (Akishima, Japan) and images were obtained using side-mounted digital camera (Gatan780AJ03FA, Pleasanton, CA, USA).

2.6 | Genomic cloning and phylogenetic analysis of the s genes, n genes, and whole-genome

Total RNA was prepared from the isolated virus using a RNeasy kit (Magen, China) and was treated with DNase I. The cDNA was synthesized by reverse transcription using RT-PCR kit (TaKaRa,Dalian). A total of 18 primer pairs based upon the PEAV GDS04 (GenBank accession no. MF167434.1; Supporting information Table S1) were designed to amplify the complete genome of PEAV GDS04 "passage 12 (P12)". The PCR products were cloned into the pMD19-T (TaKaRa, Dalian) and sequenced to determine the consensus sequence. The sequences were assembled and analysed using the DNASTAR program. Sequence alignment analysis was performed using the Clustal W program implemented in DNAStar software Lasergene 7.0. A phylogenetic tree was then constructed by the neighbour-joining method using the Molecular Evolutionary Genetics Analysis (MEGA) software version 5 (http://www.megasoftware.net/) based on the s genes, n genes, and whole-genome from PEAV GDS04 strain P12 together with other different CoVs (alpha, beta, gamma, and delta), like PEDV, PDCoV, and TGEV.

2.7 | Experimental infection with the PEAV GDS04 strain in newborn piglets

The animal study was approved by the Institutional Animal Care and Use Committee of Sun Yat-sen University and performed in accordance with regulation and guidelines of this committee. Twenty-four 4-day-old conventional newborn piglets were randomly divided into two groups (8 piglets in group 1 and 16 piglets in group 2). Piglets were fed a mixture of skim milk powder (Inner Mongolia Yi Li Industrial Group Co., Ltd, China) with warm water. Prior to inoculation, piglets were confirmed negative for the major porcine enteric viruses (PDCoV, PEDV, TGEV, PRoV) by testing of rectal swabs using specific RT-PCR according to previously described method (Hu, Li et al., 2015; Jeong et al., 2009; SaengChuto et al., 2017). After 1-day acclimation, piglets in group 1 were orally inoculated with 5 ml of maintenance medium and served as uninfected controls. Twelve piglets in group 2 were orally challenged with 5 ml of maintenance medium containing 5×10^5 $TCID_{50}$ of the PEAV GDS04 P12 and the remaining four piglets served as cohabitation control.

All piglets were observed daily for clinical signs of vomiting, diarrhoea, lethargy, and body condition. Diarrhoea severity was scored with the following criteria (Chen et al., 2015): 0 = normal, 1 = soft (cowpie), 2 = liquid with some solid content, 3 = watery with no solid content.

Rectal swabs were collected daily from each piglet from 1 d.p.i. to 14 d.p.i. and were submerged into 1 ml sterile 1× PBS (pH 7.4) immediately after collection. Two piglets from each group were necropsied at 7 d.p.i. At necropsy, the fresh samples (serum, heart, liver, spleen, lung, kidney, stomach, duodenum, jejunum, ileum, caecum, and colon) were collected and then formalin-fixed. The fresh samples were stored at - 80°C for viral RNA distribution analysis and formalin-fixed samples were used for histopathology and immunohistochemistry analysis. In addition, the mortality of newborn piglets in each group was recorded daily.

2.8 | Real-time RT-PCR analysis

Rectal swabs, serum, and various tissues were tested by a PEAV n gene-based real-time RT-PCR including viral standards with known

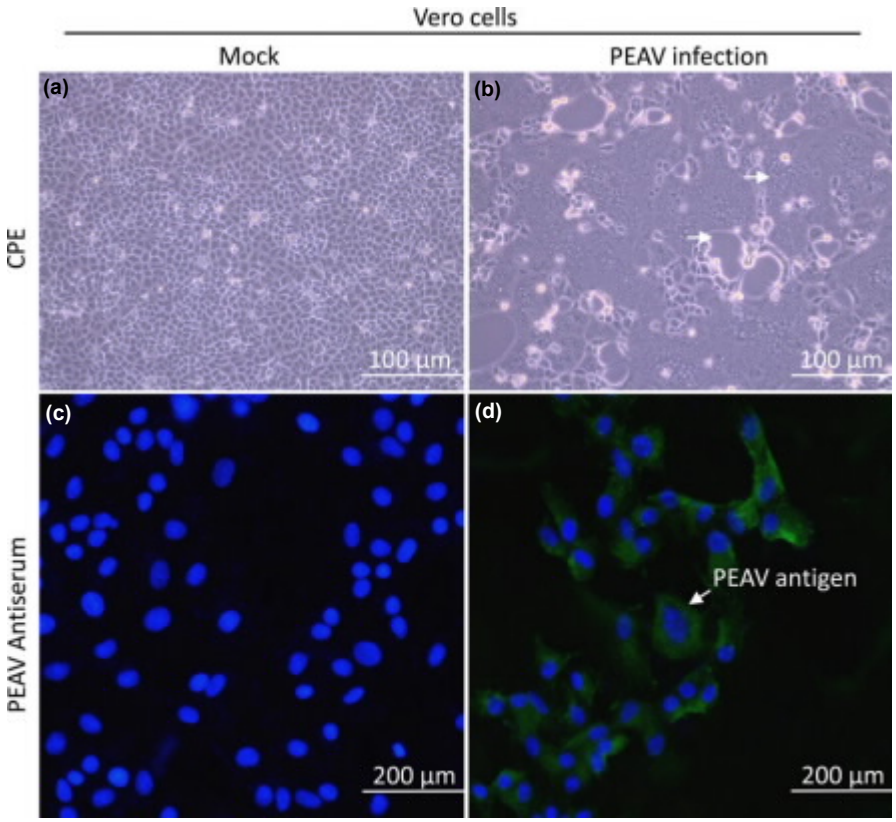

FIGURE 1 Cytopathic effects (CPE)and IFA staining on PEAV-inoculated Vero cells. (a) Mock-inoculated Vero cell culture showing normal cells. (b) PEAV-inoculated Vero cells at 1 d.p.i. showing syncytium and cells detachment (indicated by arrows). Vero cells were mock-inoculated (c) or inoculated with PEAV GDS04 (d). At 24 hr postinoculation, an immunofluorescence assay (IFA) was performed [Colour figure can be viewed at wileyonlinelibrary.com]

plasmid concentration for quantification. Briefly, the homogenates from serum, various tissues, and the supernatants of rectal swab from each piglet were centrifuged at 6,000× g for 5 min, respectively. Total RNA was prepared and used for cDNA synthesis as described above. Specific primers for the nucleocapsid (N) gene of PEAV (sense: 5′-GCACTTTTATTACCTTGGTA8′; antisense: 5′-GTAGCAGGTTCTTTGTTAC-3′), and probe (5′-FAM-TCCTCACGCAGATGCTCCTTTAMRA-3′) were designed according to reference sequence (GenBank, Accession no: MF167434.1) and synthesized by TaKaRa (Dalian, China). The real-time PCR assay was carried out with an Applied Biosystem 7500 Fast instrument (Life Technologies, USA). The PCR was performed in a 20-μl volume containing 1 μl of cDNA, 10 μl of Thunderbird Probe qPCR Mix, 0.04 μl 50× Rox reference dye (TOYOBO, Shanghai),0.2 μM of probe, and a 0.3 μM of each gene-specific primer. The thermal cycling parameters were as follows: 95°C for 20 s; 40 cycles of 95°C for 3 s, 60°C for 30 s. The standard curve was generated by construction of plasmids. Briefly, the n gene was amplified from PEAV GDS04 P12 strain using the specific primers as described above, and the PCR products were cloned into the pMD19-T (TaKaRa, Dalian). The known plasmid concentration was 10-fold serially diluted for generating a standard curve in each plate. The quantity of PEAV viral RNA in tested samples was calculated based on the cycle threshold (Ct) values for the standard curve.

2.9 | Histology and immunohistochemistry

At necropsy, tissue samples of heart, lung, spleen, liver, kidney, stomach, duodenum, jejunum, ileum, caecum, and colon of the piglets from the challenged and control groups were collected separately and routinely fixed in 10% formalin for 36 hr at room temperature (Hu, Jung, Vlasova,& Saif, 2016), and then dehydrated in graded ethanol, embedded in paraffin, cut in 5-μm sectioned, and mounted onto glass slides. Afterwards, the sections were deparaffinized, rehydrated, and stained with haematoxylin and eosin (H&E); the slides were examined and analysed with conventional light microscopy. Sections (5 μm) of formalin-fixed paraffin-embedded tissues were placed onto positively charged glass slides and the slides were air-dried for 120 min at 60°C. The tissue sections were deparaffinized, and then rinsed and incubated with target retrieval solution (Servicebio, China). After being blocked with 1% BSA (Solarbio, China), the sections were incubated with PEAV-specific mouse antisera (1:400) as the primary antibody for 12 hr at 4°C. They were then incubated with peroxidase-labelled goat anti-mouse IgG secondary antibody (Dako, Denmark) for 50 min at room temperature, and the samples were finally visualized with a 3, 3′-diaminobenzidine (DAB) chromogen kit (Dako, Denmark). Haematoxylin was used for counterstaining. Tissues of piglets from negative control groups were used as negative samples.

3 | RESULTS

3.1 | A strain of PEAV was isolated from an inoculated-newborn piglet with fresh excreta from ill newborn piglets

We attempted to isolate PEAV, a new bat-HKU2-like coronavirus from the positive samples since its first detection in China (Gong et

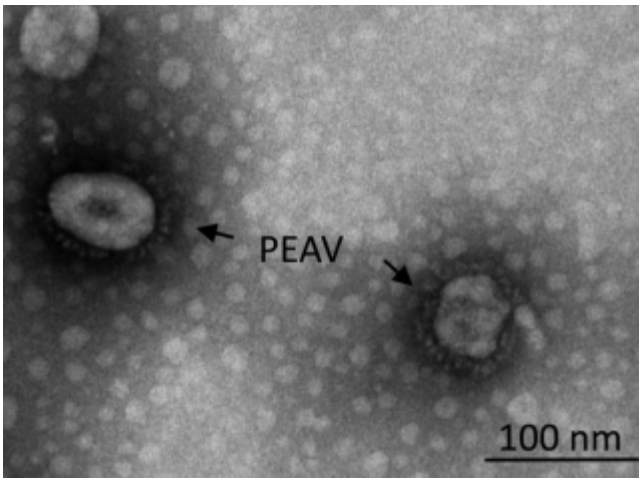

FIGURE 2 Electron micrographs of PEAV-inoculated Vero cells. Crown-shaped spikes of PEAV are visible (arrows). The sample was negatively stained with 3% phosphotungstic acid

al., 2017). As shown in Figure 1b, one inoculated cell monolayer with the supernatant from virus-infected cells of passage 10 (P10) showed visible CPE in the form of syncytium and detachment at 1 d.p.i. as compared with the control in Figure 1a. To confirm PEAV replication in Vero cells, viral RNA was extracted from the inoculated cells at 1 d.p.i. and tested by specific RT-PCR. This cell culture-passaged sample was positive for PEAV but negative for other porcine enteric coronaviruses (data not shown). PEAV from the first passage in Vero cells was named GDS04 (Gong et al., 2017). After blindly passaged in Vero cells for a total of 20 passages, the PEAV GDS04 could still be detected by specific RT-PCR (data not shown), indicating that the proliferation ability of the strain in Vero cells. Plaque-purified PEAV in Vero cells was further confirmed by IFA with PEAV-specific mouse antisera. As shown in Figure 1d, PEAV-specific immunofluorescence was detected in infected cells, as compared to the control (Figure 1c). To characterize the morphology and size of the virus particles, the PEAV GDS04 virus purified from infected Vero cells were examined with EM. Typical crown-shaped particles with spiky surface projections as in other coronaviruses were observed by negative staining on EM. The size of the viral particles was 80–160 nm in diameter (Figure 2). Taken together, these results suggest that a PEAV strain was successfully isolated from the intestinal contents of a newborn diarrheic piglet in China.

3.2 | Phylogenetic analysis of the s genes, n genes, and whole-genome of PEAV GDS04 P12

Since complete genome of the GDS04 was fully described (Gong et al., 2017), to further understand the origin of the virus, phylogenetic trees of complete s genes, n genes, and whole-genome of PEAV GDS04 strains together with other CoVs were constructed. Phylogenetic analysis of the s genes shows that the PEAV GDS04 strains along with four bat coronavirus HKU strains from Hong Kong, a BtRf-AlphaCoV strain from Beijing clustered in one group. Furthermore, the PEAV GDS04 strains, SADS-CoV, and SeACoV clustered into a subclade between bat coronavirus HKU strains and BtRf-AlphaCoV strain (Figure 3a). Consistent with the results of the s genes, phylogenetic analysis of the n genes and whole-genome of the PEAV GDS04 strains and other CoVs reveals that PEAV GDS04 strains, SADS-CoV, and SeACoV belong to the same subclade (Figure 3b&c). Therefore, these data suggest that the GDS04 strains were closely relative to SADS-CoV and SeACoV strains from Guangdong, China.

3.3 | Clinical manifestations of newborn piglets challenged with PEAV GDS04 P12

In order to determine whether PEAV GDS04 was the causative agent for diarrhoea, we experimentally infected newborn piglets with the isolated virus. Twelve newborn piglets inoculated with GDS04 P12 at a dose of 5×10^5 $TCID_{50}$/head via oral feeding showed mild diarrhoea from 1 to 4 d.p.i., and all developed severe watery diarrhoea, together with vomiting, and dehydration from 5 to 12 d.p.i., as compared with controls (Figure 4a–e), indicating a role of PEAV as an important causative agent for severe watery diarrhoea in newborn piglets. Furthermore, four piglets from group 2 as cohabitation controls also developed watery diarrhoea from 5 to 12 d.p.i. (Figure 4e). Since PEAV GDS04 caused severe watery diarrhoea in newborn piglets, we also recorded the mortality of newborn piglets in each group. As shown in Figure 5, in PEAV-inoculated groups, except that two piglets were necropsied at 7 d.p.i., all remaining 10 piglets died from 5 to 12 d.p.i. And the PEAV-inoculated piglets had 1, 1, 3 (+2 euthanized), 1, 1, 2, and 1 death (s) at 5, 6, 7, 8, 9, 10 and 12 d.p.i., respectively. In addition, 2/4 piglets from group 2 as cohabitation controls also died at 7 and 9 d.p.i. No piglets (6/6) died in control group except that two piglets were necropsied at 7 d.p.i. Taken together, these results suggest that PEAV GDS04 is highly pathogenic to the newborn piglets.

3.4 | Faecal shedding and virus distribution in newborn piglets challenged with PEAV GDS04 P12

Since PEAV GDS04 caused watery diarrhoea in newborn piglets, we explored the faecal viral shedding in PEAV-challenged piglets. As shown in Figure 6a, the PEAV RNA was detected by qRT-PCR in faecal swabs collected from orally inoculated piglets from 1 to 11 d.p.i., and peaked on 4 d.p.i. and kept up until 11 d.p.i. We also examined the faecal viral shedding in piglets from group 2 as cohabitation controls. PEAV RNA was detected in rectal samples collected from these piglets from 3 to 13 d.p.i. (Figure 6a), indicating that these piglets may be infected by the PEAV-challenged piglets. No PEAV RNA was detected in the negative control piglets during the study. To examine the distribution of the PEAV virus in different tissues in PEAV-challenged piglets, two piglets from each group were necropsied at 7 d.p.i. As shown in Figure 6b, the PEAV RNA was detected in all collected samples of duodenums, jejunums, ileums, caecum, and colons. The virus was also detected in 2/2 hearts, 2/2

(b & d) Watery diarrhoea (indicated by arrows) was observed at 3 and 7 d.p.i. with PEAV infection. (e) Average diarrhoea scores after PEAV infection [Colour figure can be viewed at wileyonlinelibrary.com]

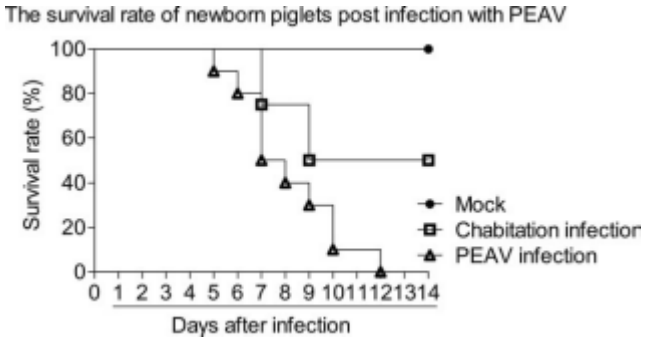

FIGURE 5 The survival rate of newborn piglets postinfection with PEAV GDS04 P12. The mortality of newborn piglets in each group was recorded from 1 to 14 d.p.i

livers, 2/2 spleens, 2/2 kidneys, 2/2 stomachs, and 1/2 lungs, but no viral RNA was detected in blood. No PEAV RNA was detected in the tissue samplesfrom the control piglets. Taken together, these results demonstrate that PEAV GDS04 strain could be widely distributed in different tissues, but mainly concentrated in the intestines of pig.

3.5 | Virus particles in jejunum of inoculated-PEAV piglets

To observe virus particles in vivo, the jejunum of piglets from each group was examined with EM. EM demonstrated that the virion without membrane in the vesicle (Figure 7b) and full virus particles in the intercellular space (Figure 7c) with typical crown-shape of

80–160 nm in diameter and spiky surface projections of CoV, indicating that PEAV GDS04 strain could replicate in the jejunum of pig. In addition, the virus-infected cells showed atrophied, ruptured cell morphology (Figure 7b&c). No virus particles or pathological lesions were detected in the jejunum from the control piglets (Figure 7a). Taken together, these results show that PEAV GDS04 could replicate and cause jejunum lesions in newborn piglets.

3.6 | Gross pathology, histopathology, and immunohistochemistry in newborn piglets infected with PEAV GDS04

To determine the gross pathological and histological changes in piglets infected with the PEAV GDS04 strain, two piglets from each group were necropsied at 7 d.p.i. Gross findings were similar in both piglets orally inoculated with PEAV GDS04. The whole intestinal tract, where yellow watery contents accumulated, were transparent, thin-walled, and gas-distended (Figure 8b). No lesions were observed in any other organs of the PEAV-challenged piglets (data not shown) or the organs in the negative control piglets (Figure 8a), indicating that intestinal tract is the target organ of PEAV infection. Microscopic lesions were also analysed. As shown in Figure 8h–l, abruption of intestinal villus was observed, whereas the intestinal in negative control was normal (Figure 8c–g). Consistent with the histopathological results, PEAV antigen was detected in the cytoplasm of the villous enterocytes of the PEAV-challenged piglets by immunohistochemical analysis (Figure 8o&p). Taken together, these results indicate that PEAV GDS04 could cause intestinal lesions in newborn piglets.

4 | DISCUSSION

The widely distributed CoVs could be isolated from a variety of animal hosts and products with animal origin (Felippe et al., 2010; Pan et al., 2012; Rihtaric et al., 2010; Stohlman et al., 1982; Tsunemitsu et al., 1995), as well as from human (Larson, Reed, & Tyrrell, 1980). Bats are thought to be the natural reservoir of a range of CoVs (Cui et al., 2007). The pathogenicity of five porcine CoVs has so far been confirmed (Doyle & Hutchings, 1946; Pensaert & de Bouck, 1978; Sasseville et al., 2002; Wesley et al., 1990; Woo et al., 2012). In February 2017, a new bat-HKU-like porcine coronavirus (PEAV) was detected by genomic analysis in swine herds (Gong et al., 2017). Although PEAV has been detected in piglets with severe diarrhoea (Gong et al., 2017), little information is known regarding the pathogenicity of PEAV strains in animals. In the present study, we reported that a PEAV strain was successfully isolated from a case of piglet diarrhoea in Guangdong, and showed high pathogenicity to

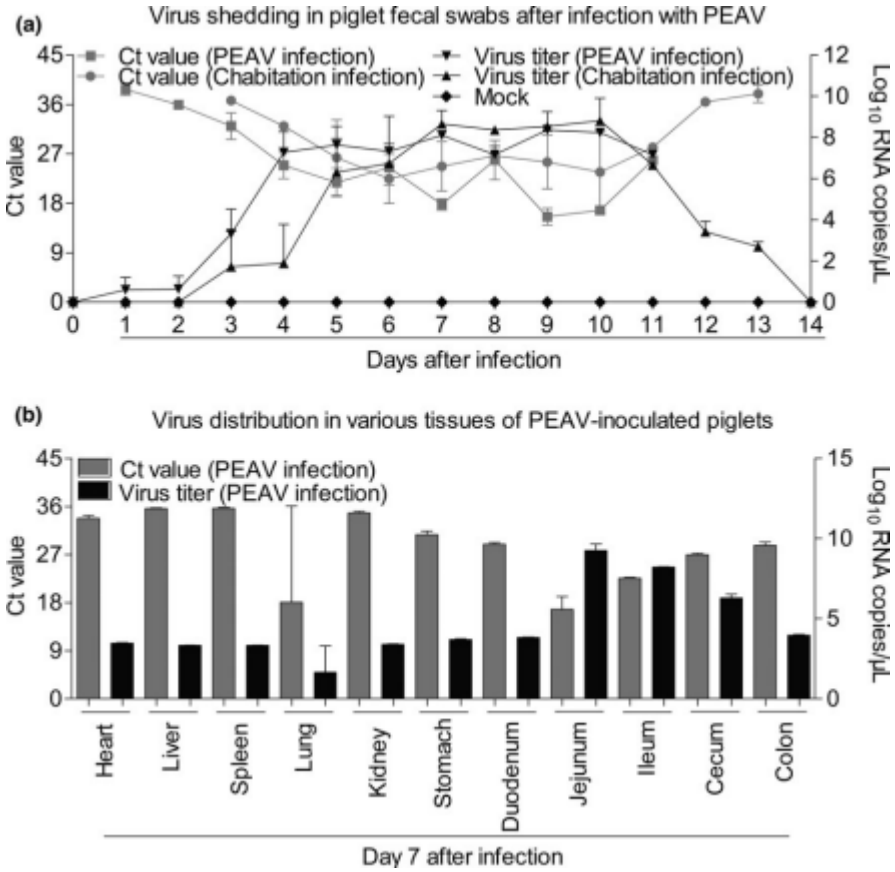

FIGURE 6 Virus shedding in rectal swabs and various tissues of PEAV-inoculated piglets. newborn piglets. This PEAV strain can be further used for virological and serological assay development, as well as vaccine development.

A stable African green monkey kidney cell line (Vero cells) (Rhim, Schell, Creasy, & Case, 1969) is commonly used to isolate CoVs like PEDV or bat coronavirus HKU2 (Lau et al., 2007; Lee et al., 2015). Since PEAV was first detected by genomic analysis in pigs (Gong et al., 2017), we attempted to isolate virus from PEAV-positive samples using Vero cells. The virus could only be isolated in circumstance of inoculation with fresh homogenate in piglets. The difficulty to isolate PEAV from positive samples might be associated with the fact that positive samples characterized by RT-PCR may contain noninfectious or low amount of virus. During virus isolation, the DMEM supplemented with 10 μg/ml trypsin performed better than 7 μg/ml in PEAV propagation with more evident CPE, which indicates that the amount of trypsin in Vero cells might also contribute to the successful PEAV isolation. CPE was firstly observed in inoculated Vero cells until the passage 10. After plaque purification and several passages, the viral titre reached 5.13×10^5 $TCID_{50}$/ml, showing that the PEAV GDS04 strain was highly replicative in Vero cells. The plaque-purified PEAV strain in Vero cells was further verified by IFA with PEAV-specific mouse antisera. The characteristic crown-like particles of the purified PEAV GDS04 strain was observed by EM. Although there were many PEAV-positive samples by genomic analysis, only GDS04 was isolated, indicating that the success rate of isolation PEAV strains was very low. Thus, further attempts are needed to improve PEAV isolation.

To determine the complete genome of P12 of GDS04 strain, we amplified and sequenced the complete genome of PEAV GDS04 P12 by RT-PCR. We found that PEAV GDS04 P12 strain (accession no. MH697599) shares 99.79% nucleotide identity with PEAV GDS04 strain (accession no. MF167434), and compared to the complete genome of the virus in the original small intestinal homogenate, the PEAV GDS04 P12 strain possesses 35 point mutations, a 1-nt deletion (A) in nt 77, a 3-nt deletion (GTA) in nt 24,790–24,792, a 1-nt deletion (A) in nt 27,071, a 1-nt deletion (T) in nt 27,081, a 1-nt deletion (A) in nt 27,089, a 3-nt insertion (TTG) in nt 4,554–4,556, 10-nt insertion (GACTAGAGCC) in nt 12483-12492, indicating that these mutations might be related to cellular adaptation. Based on the phylogenetic tree analysis of s genes, the PEAV strain GDS04 shares 36.23%–99.66% nucleotide identity with other 18 CoVs in GenBank. Notably, the PEAV GDS04 strains can be clustered into one clade with four bat coronavirus HKU strains from Hong Kong, a BtRf-AlphaCoV strain from Beijing, SADS-CoV strain from Guangdong, and SeACoV strain from Guangdong, indicating a close relationship of these strains. In addition, the PEAV GDS04 strains, SADS-CoV, and SeACoV clustered into a subclade, indicating that these three viruses might have similar origins. Consistent with the results of the s genes, phylogenetic analysis of the n genes and whole-genome of the PEAV GDS04 and other CoVs revealed that PEAV GDS04, SADS-CoV, and SeACoV belong to the same subclade. Previous studies have shown that the s gene, the most variable region in the CoV genomes, belongs to type I membrane glycoproteins family (Woo et al., 2010) and is involved in receptor binding and viral entry (Woo et al., 2010). Sequencing of s genes revealed that GDS04 had the smallest S protein among all coronaviruses (Gong et al., 2017). Compared to the s gene of the SeACoV and SADS-CoV strains, the PEAV GDS04 possesses 11 point mutations, 3 point mutations with SeACoV and SADS-CoV, respectively. Whether these unique variations contribute to the efficiency of viral replication and virulence needs to be further investigated.

We further investigated whether the PEAV GDS04 strain was responsible for causing clinical symptoms as severe diarrhoea and death in piglets. As a result, we infected 5-day-old newborn piglets with the PEAV GDS04 strain P12 via oral feeding. The sequential severe diarrhoea and vomiting in piglets by oral infection strongly suggest the pathogenicity of PEAV to the newborn piglets. Furthermore, PEAV RNA was detected from 1 to 11 d.p.i. in faecal of GDS04 challenged piglets, while no RNA was detected in the negative control piglets. Four piglets from group 2 as cohabitation contrast also developed profuse watery diarrhoea and viral shedding, suggesting the possibility of faecal–oral transmission of PEAV. Results from this study may help guide future PEAV experimental designs as the clinical diarrhoea and virus shedding patterns.

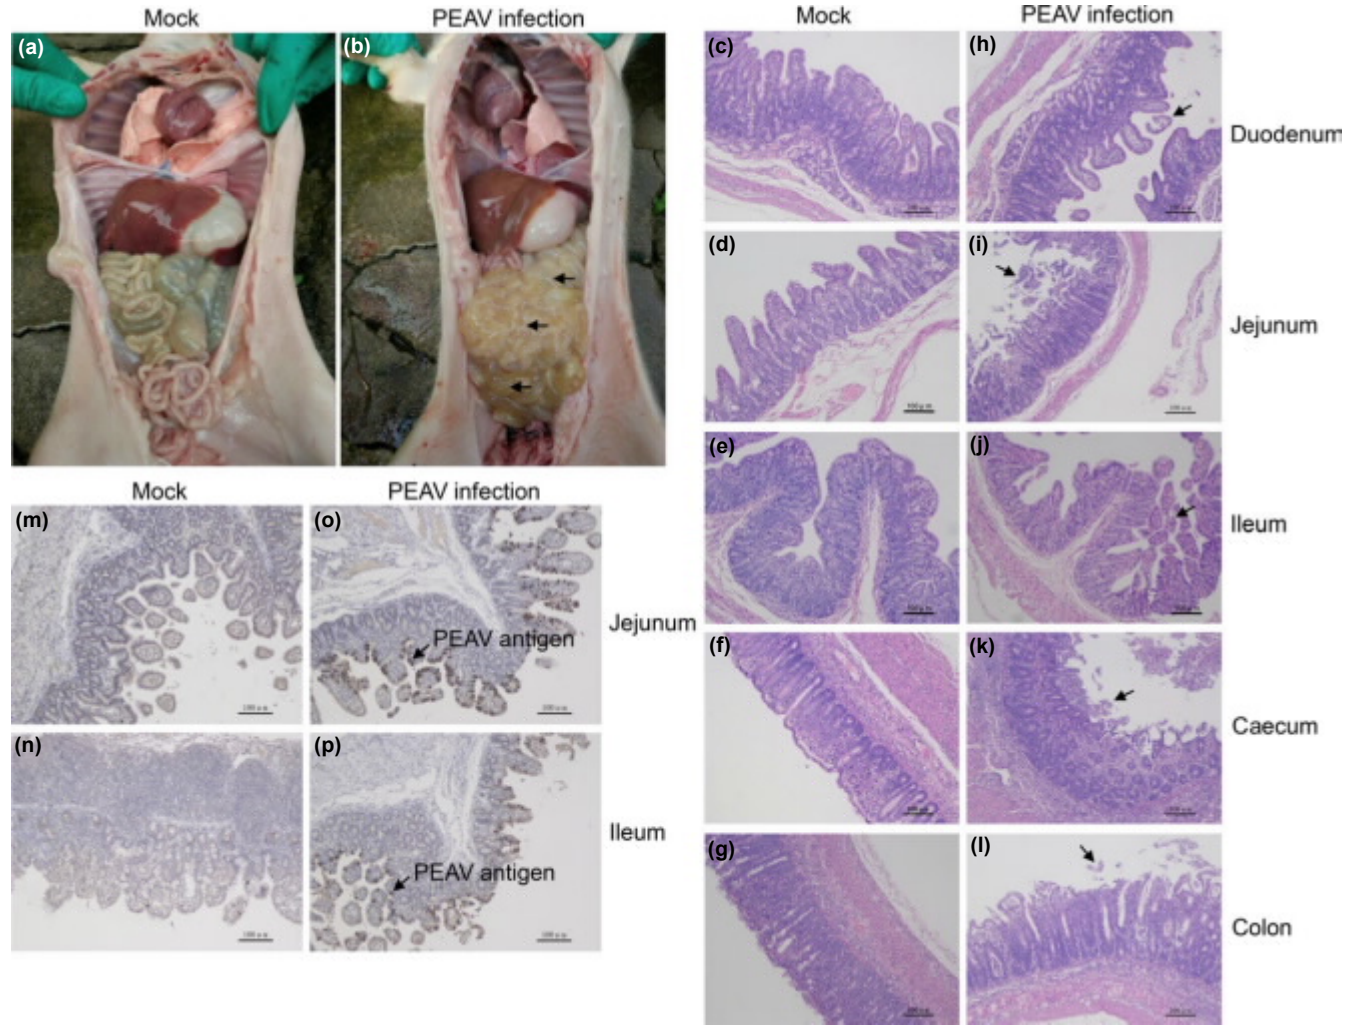

FIGURE 8 Intestinal changes in newborn piglets inoculated with PEAV strain GDS04 P12. (a) Macroscopic picture of a control piglet at 7 d.p.i. (b) Thin-walled intestinal tract (indicated by arrows) of a PEAV-challenged newborn piglets at 7 d.p.i. (c-g) Haematoxylin and eosin (H & E)-stained intestinal tissue section of a control piglet at 7 d.p.i. (h-l) H&E-stained intestinal tissue section of a PEAV-challenged piglet at 7 d.p.i. (Blunt intestinal villus was indicated by arrows). (m&n) Immunohistochemically stained jejunum or ileum tissue section of a control piglet at 7 d.p.i. (o&p) Immunohistochemically stained jejunum or ileum tissue section of a PEAV-challenged piglet at 7 d.p.i [Colour figure can be viewed at wileyonlinelibrary.com]

In addition, the viral RNA distribution in the PEAV-challenged piglets was also tested. The intestines contained higher levels of viral RNA copies compared with the other tissues, and no PEAV viral RNA was detected in the blood, indicating that PEAV might infect multiple organs in pigs, but the intestinal tract is the major target organ of PEAV. Furthermore, we confirmed that PEAV could replicate in pig intestines by EM. These results suggested that PEAV has similar infection process with other porcine CoVs like PEDV or PDCoV. Gross lesions by virus infection were obviously observed in the small intestines, caeca and colons of the 5-day-old piglets at necropsy at 7 d.p.i., similar to observations in PEDV or PDCoV infection (Chen et al., 2015; Lee et al., 2015). While microscopic lesions were observed in the jejunum and ileum infected by PDCoV in previous report (Chen et al., 2015), we found microscopic lesions distributed in the whole intestinal tract in GDS04 infected piglets, suggesting a more deteriorative effect by PEAV than that caused by PDCoV. What is more, no microscopic lesions were observed in any other organs of the PEAV-challenged piglets (data not shown), similar to observations in PDCoV infection (Chen et al., 2015). Consistent with the histopathological results, the PEAV antigen was detected in the cytoplasm of the villous enterocytes of challenged piglets by immunohistochemical analysis. This information is useful for choosing appropriate tissues for PEAV diagnostic investigations.

Since PEAV GDS04 caused severe watery diarrhoea in newborn piglets, we also recorded the mortality of newborn piglets from 1 to 14 d.p.i.. The pathogenicity of a SeACoV strain CH/GD/01/2017/P2 and SADS-CoV in neonatal piglets were described (Pan et al., 2017; Zhou et al., 2018). Results showed that SeACoV and SADS-CoV caused severe diarrhoea and vomiting in pigs of 3 days old. However, SeACoV infection did not cause fatality in piglets in 5 days (Pan et al., 2017), while 50% died after SADS-CoV infection within the same period (Zhou et al., 2018). When infected with PEAV

GDS04, one piglet died in dpi 5, and all PEAV-inoculated piglets and half piglets from cohabitation contrast died in 2 weeks, indicating that PEAV GDS04 strain and SADS-CoV were more pathogenic than SeACoV CH/GD/01/2017/P2. In addition, compared to the complete genome of the SeACoV CH/GD/01/2017/P2, the PEAV GDS04 P12 possesses82 point mutations, a 1-nt deletion (A) in nt 177, 10-nt insertion (GACTAGAGCC)in nt 12483-nt 12492, a 1-nt insertion (A) in nt 27068, a 1-nt insertion (T) in nt 27078, and a 1-nt insertion (A) in nt 27086, presenting a clue of different pathogenicity of the two strains. And compared to the complete genome of the SADS-CoV, the PEAV GDS04 P12 possesses41 point mutations, a 1-nt deletion (A) in nt 176, a 1-nt insertion (A) in nt 27067, a 1-nt insertion (T) in nt 27077, and a 1-nt insertion (A) in nt 27085. In addition, the PEAV strain GDS04 P12 shares 99.58%, 99.66% nucleotide identity with SeACoV and SADS-CoV, respectively, indicating that PEAV has more similarities with SADS-CoV than SeACoV. The details of genome comparison might also help explain the high mortality rate as high as 90% in piglets in PEAV-reported swine herds (Zhou et al., 2018). Together, all these results confirm that the PEAV GDS04 strain isolated in this study could cause enteric diseases and death in newborn piglets. However, there are still several important questions needed to be addressed. For instance, what is the prevalence of PEAV as a new CoV in herds? What are the molecular mechanisms of pathogenesis of PEAV infection? How to prepare effective vaccines against the PEAV? Elucidation of these questions will elevate our understandings of the pathogenicity of PEAV infection and help to develop better strategies to control PEAV.

In summary, we isolated a field strain of PEAV from the intestinal content of an inoculated-newborn piglet with fresh excreta from ill newborn piglets. Genomic analysis shows that the isolate manifests close relationship with SADS-CoV and SeACoV apart from several unique genetic characteristics. Remarkably, inoculation of newborn piglets with PEAV GDS04 P12 by oral feeding reproduced clinical symptoms, including vomiting, dehydration, and severe diarrhoea with a mortality of 100% in neonatal piglets. Collectively, these findings suggest that PEAV GDS04 is highly virulent in piglets.

5 | IMPORTANCE

In this work, a PEAV strain GDS04 was successfully isolated from a case of piglet diarrhoea in Guangdong, China. Newborn piglets orally challenged with PEAV GDS04 developed typical clinical symptoms as watery diarrhoea and high mortality, confirming PEAV is potential role of important pathogen in newborn piglets. The isolation and characterization would lay solid foundation for understanding this virus and the strain GDS04 can be further used for virological and serological assays, as well as vaccine development.

ABSTRACT The full-length genome sequence of a novel swine acute diarrhea syndrome coronavirus (SADS-CoV), CH/FJWT/2018, was determined, which was genetically most closely related to CN/GDWT/2017, recently discovered in Fujian, China. The indel sites of the spike (S) gene of CH/FJWT/2018 were most similar to those of bat-origin SADS-related coronaviruses.

Swine acute diarrhea syndrome coronavirus (SADS-CoV) belongs to the genus *Alphacoronavirus* in the family *Coronaviridae* and is an enveloped, positive-sense, single-stranded RNA virus (1). In January 2017, SADS-CoV was first discovered in suckling piglets with severe enteritis in South China after ruling out the presence of porcine epidemic diarrhea virus (PEDV), transmissible gastroenteritis virus (TGEV), porcine deltacoronavirus (PDCoV), and other known pathogens associated with piglet diarrhea (2–8). SADS-CoV had 95% nucleotide (nt) identity at the full-genome level with the previously reported bat-HKU2 strains (3, 4).

In this study, fecal and small intestinal samples (*n* ffi 168) collected from diarrheal piglets from seven farms in Fujian Province, China, in 2018 were tested for the presence of SADS-CoV based on reverse transcription-PCR (RT-PCR), as described previously (6). A SADS-CoV, designated CH/FJWT/2018, was identified, and this virus was isolated in Vero cell cultures according to the established protocol in the Key Laboratory for Animal Health of Jiangxi Province. To determine the complete genome sequence of CH/FJWT/2018, total RNA was extracted with TRIzol reagent (Invitrogen, USA) according to the manufacturer's instructions, and 36 sets of primers covering the complete genome of CH/FJWT/2018 were synthesized and then employed for RT-PCR. Each amplicon, including the 5= and 3= ends amplified by a Clontech SMARTer rapid amplification of cDNA ends (RACE) 5=/3= kit (TaKaRa, Japan), was sequenced with the Sanger sequencing method (Sangon Biotech, Ltd., China). The full-length genome sequence was then assembled and analyzed by Lasergene v7.10 (DNAStar, Inc., USA).

The complete genome sequence of CH/FJWT/2018 determined was 27,169 nt in length, excluding the 3= poly(A) tail. The genomic arrangement and corresponding nucleotide positions were as follows: open reading frame 1a (ORF1a), nucleotides 304 to 12456; ORF1b, nucleotides 12456 to 20489; spike gene, nucleotides 20486 to 23881; ORF3, nucleotides 23881 to 24570; envelope gene, nucleotides 24551 to 24778; membrane gene, nucleotides 24787 to 25476; and nucleocapsid gene, nucleotides 25488 to 26615. The results of a phylogenetic analysis using Molecular Evolutionary Genetics Analysis (MEGA) v7.0 (9), based on CH/FJWT/2018 and other reference sequences of SADS-CoVs retrieved from GenBank, showed that CH/FJWT/2018 had 99.6% nt identity with CN/GDWT/2017 (GenBank accession number MG557844), a swine-origin SADS-

CoV, and 98.9% nt identity with bat CoV HKU2 (EF203064) (10, 11), respectively. The complete genome sequence of CH/FJWT/2018 is 3 nt longer than that of HKU2. The mutations that occurred included a 3-nt (TTG) insertion between nucleotides 4554 and 4555 in the ORF1a gene, a 6-nt (GGCCTC) insertion between nucleotides 20504 and 20505, a 3-nt (GGC) deletion between nucleotides 22463 and 22465 in the spike (S) gene, and a 3-nt (GTA) deletion between nt 24773 and 24775 in the membrane (M) gene. Interestingly, the insertion/deletion patterns of CH/FJWT/2018 were more similar to those of bat-origin SADS-related coronaviruses (SADSr-CoVs) (6) than to those of swine-origin SADS-CoVs, suggesting that CH/FJWT/2018 might originate from bats. The findings determined in this study suggest that CH/FJWT/2018 was a novel SADS-CoV, and further study is required to address its biological properties, etiologies, and pathogenesis.

Data availability. The CH/FJWT/2018 sequence data have been deposited in GenBank under the accession number MH615810.

Real-time LAMP
Diagnosis

ABSTRACT

A novel swine acute diarrhea syndrome Coronavirus (SADS-CoV) that causes severe diarrhea in suckling piglets was identified in southern China in 2017. A simple and rapid detection test was developed for this virus using real-time RT-LAMP based on the conserved N gene of the virus. The method had a detection limit of 1.0×10^1 copies/μL with no cross-reactions with classical swine fever virus, porcine and respiratory syndrome virus NA, porcine and respiratory syndrome virus EU, transmissible gastroenteritis coronavirus, foot and mouth disease virus, porcine epidemic diarrhea virus (S-INDEL and non-S-INDEL), swine influenza virus subtype H1N1, porcine circovirus type 2, senecavalley virus, porcine parvovirus, porcine deltacoronavirus and rotavirus. This method was also reproducible. Twenty of 24 clinical samples were identified as SADS-CoV RNA-positive by the real-time RT-LAMP and the results were consistent with that of the real time RT-PCR method. This new method for detecting SADS-CoV is specific and sensitive for the detection of SADS-CoV.

1. Introduction

Outbreaks of diarrhea in newborn piglets occurred on a pig farm in Guangdong province of southern China in February 2017 (Gong et al., 2017). At that time, several pathogens were tested for these cases of diarrhea, including enteric coronaviruses porcine deltacoronavirus (PDCoV), porcine epidemic diarrhea virus (PEDV) and transmissible gastroenteritis virus (TGEV). However, all samples were negative for the presence of these three pathogens (Pan et al., 2017). In September 2017, a novel swine enteric alphacoronavirus (SeACoV) also named as bat-HKU2–like porcine coronavirus (PEAV) or swine acute diarrhea syndrome coronavirus (SADS-CoV) was identified in southern China (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018a,b). The mortality rate was more than 35% in swine that were less than 10 days old and caused serious economic losses to the swine industry (Pan et al., 2017). All affected pigs showed acute vomiting and severe watery diarrhea, similar to clinical signs caused by PEDV, TGEV and PDCoV. A reliable and simple diagnostic method for the surveillance of SADS-CoV was needed to distinguish between these viral pathogens.

Loop-mediated isothermal amplification (LAMP) is a simple isothermal method for in vitro nucleic acid amplification. The only equipment needed is a constant temperature heating block or water bath. In addition, the results of the reaction can be directly observed with the naked eye when performed in the presence of a fluorescent dye (Notomi et al., 2000; Yuan et al., 2014). In addition, the dye enables the use of a fluorescent detector that can be used to follow the progress of the reaction (real-time LAMP) (Oscorbin et al., 2016).

LAMP assays have been successfully used for other pathogens (de Souza et al., 2012; Kurosaki et al., 2017; Li et al., 2012; Zhao et al., 2011). In this study, a real time RT-LAMP assay was developed for rapid diagnosis of novel SADS-CoV.

2. Materials and methods

2.1. Virus strains and clinical samples

Clinical samples were collected from suckling piglets with diarrhea on commercial pig farms in Guangdong, China. All specimens were suspended in phosphate-buffered saline (PBS) and stored at -80 °C until use. The SADS-CoV virus strain was isolated from diarrheal pigs in Guangdong Province of China (Zhou et al., 2018a). Other porcine viruses were used to assess the specificity of the real-time LAMP method. Classical swine fever virus (CSFV) C strain, porcine respiratory and reproductive syndrome virus (PRRSV) JXA1-R vaccine strain (NA type), foot-and-mouth disease virus (FMDV) O/HB/HK99 vaccine strain, porcine circovirus type 2 (PCV2) LG vaccine strain and swine influenza virus H1N1 TJ vaccine strain, were obtained from Guangdong Animal Epidemic Prevention and Material Reserve Center (Guangzhou, China). Porcine epidemic diarrhea virus (PEDV) CV777 vaccine strain (non-S-INDEL), rotavirus (RV) NX vaccine virus and transmissible gastroenteritis virus (TGEV) Huadu vaccine strain were purchased from Harbin Weike Biological Technology (Harbin, China). PRRSV ZD-1 strain (EU type) was acquired from Prof. Zhijun Tian of Harbin Veterinary Research Institute, Chinese Academy of Agricultural Sciences. PEDV GD1 strain (S-INDEL), seneca valley virus (SVV) CH-01–2015 strain and porcine deltacoronavirus (PDCoV) CHN-GD16-03 strain were stored in our lab. Porcine parvovirus (PPV) vaccine virus were obtained from Qilu Animal Health Products CO.,LTD. (Jinan, China).

2.2. RNA extraction

Frozen fecal samples were thawed and centrifuged for 10 min at 10,000 × g. Total RNA was extracted from the supernatants using a TGUide Virus DNA/RNA Kit and T-Guide instrument according to the manufacturer's instructions (Tiangen, Beijing, China). RNA was eluted into RNAse-free ddH_2O and stored at - 80 °C until use.

2.3. Design of primers for the real-time RT-LAMP

The genome sequences of SADS-CoV (Accession numbers: MF167434.1, MF370205.1, MF094681, MF094682, MF094683, MF094684, MG557844.1) were retrieved from GenBank. Based on the N gene region of SADS-CoV, six real-time LAMP primers were designed using the software http://primerexplorer.jp/e/ and synthesized by Shanghai Sangon Biotech (Shanghai, China) (GenBank: MG557844.1, Swine acute diarrhea syndrome coronavirus isolate SADS-CoV/CN/GDWT/2017). The primers included two inner primers (SADS-FIP and SADS-BIP) and two outer primers (SADS-F3 and SADS-B3) (Table 1).

2.4. Construction of plasmids containing the N gene of SADS-CoV

Reverse transcription of SADS-CoV RNA templates was performed with random primers following the manufacturer's recommendations using a One Step Prime Script RT-PCR kit (Takara, Shanghai, China). The target fragment was amplified using primers SADS-F3 and SADS-B3 (Table 1). PCR amplification from SADS-CoV N gene (1128bp) were amplified using standard PCR conditions and cloned into pGEM T easy vector (Promega, Madison, USA) between T7 RNA polymerase and SP6 polymerase promoter. The pGEM T easy plasmid was in vitro transcribed (IVT) by RiboMax Large Scale RNA production system T7 (Promega, Madison, USA) according to the manufacturer's instructions. To remove plasmid DNA, 40 units RNase-free DNase (Promega, Madison, USA) enzyme was used. Trizol LS reagent (Invitrogen, Carlsbad, CA) was used for RNA isolation according to manufacturer's instructions. The RNA concentrations were measured by UV spectrophotometry and converted into copy numbers as previously described (Parida et al., 2011). All RNA templates of SADS-CoV N gene were stored at - 80 °C until use.

Table 1
Primers used to amplify the SADS-CoV N gene.

Primers' name	Sequence	Location in genome
SADS-F3	5′- CAGCCTTCTAACTGGCACT-3′	25707bp–25726bp
SADS-B3	5′- ACAGTCAGGTCTGGTGGTAA-3′	25884bp–25903bp
SADS-FIP	5′-CGTCAACAGCGACCCAATGCA-TCCTCACGCAGATGCTC-3′	(25786bp–25806bp) (25745bp–25762bp)
SADS-BIP	5′-AACTAGCCCCACAGGTCTTGGT-AACCCAAACTGAGGTGTAG-3′	(25814bp–25835bp) (25860bp–25879bp)
SADS-LB	5′- TCGCAATCGTAACAAAGAACCT-3′	25838bp–25859bp
SADS-LF	5′- CACCCTGAATCCGTTTCCTC-3′	25766bp–25785bp

Note: outer primers (SADS-F3 and SADS-B3); inner primers (SADS-FIP and SADS-BIP).
Loop primer (LF/LB).

2.5. Development of real-time RT-LAMP assay

The real-time RT-LAMP reaction was carried out in a 25 μL volume containing 2.5 μL 10 × Buffer (B0537S, New England Biolabs, Beverley, MA, USA), 0.2 mM outer primers (OF/OB), 1.6 mM inner primers (FIP/ BIP), 0.8 mM Loop primer (LF/LB), 1 μL Bst DNA polymerase (M5038 L, New England Biolabs), 3.5 μL dNTP Mix (D7373, Beyotime Biotechnology, Beijing, China), 4 μL betaine (BCBS087V, Sigma, St. Louis, MO USA), 0.5 μL SYTO 9 green fluorescent nucleic acid stain (S34854, Invitrogen), 0.5 μL AMV Reverse Transcriptase (M510 A Promega) and 2 μL RNA template. Amplification reactions were carried out at 63 °C for 60 min and a Thermostatic Fluorescence Detector (DEAOU-308C, Diao, Guangzhou, China) was used to monitor reaction progress. Non-template control was used in each reaction.

Specificity of the method was determined using RNA templates of SADS-CoV and other swine viral RNA samples including CSFV, TGEV, FMDV, PEDV (S-INDEL and non-S-INDEL), PRRSV NA and EU, PCV2, SVV, PPV, PDCoV, RV, and SIV H1N1. Ten-fold serial dilutions of N gene RNA templates were used to calculate the analytical sensitivity and assess assay reproducibility. The method was further evaluated using 24 clinical specimens from pigs with diarrhea that had been previously evaluated by a real-time RT-PCR assay (Zhou et al., 2018a). Vero cell nucleic acid was used as a mock control. Nuclease free water was used as a negative control. All reactions were carried out in triplicate.

3. Results

3.1. Specificity, sensitivity and reproducibility

Only samples that contained SADS-CoV were positive while there was no amplification of other tested viruses (Fig. 1). This indicated that the assay was highly specific for the detection of SADS-CoV.

To evaluate RT-LAMP sensitivity, the SADS-CoV N gene was in vitro transcribed from a cloned fragment. The detection limit of this assay is 1.0×10^1 copies / μL (Fig. 2). This indicated that the real-time LAMP assay was a sensitive method for SADS-CoV detection. To investigate the reproducibility of the reaction, different concentrations of the SADS-CoV N gene RNA at 1.0×10^8, 1.0×10^7, 1.0×10^6, 1.0×10^5, 1.0×10^4, 1.0×10^3, 1.0×10^2 and 1.0×10^1 copies/μL. Our results obtained from three experiments showed intra coefficients of variation were less than 2.5% and inter coefficients of variation were less than 6.8% (Supplementary Table 1). This indicated that the method was repeatable.

3.2. Clinical sample testing

Our laboratory has previously tested 24 clinical samples from pigs with diarrheal symptoms. The real time RT-PCR tests indicated that

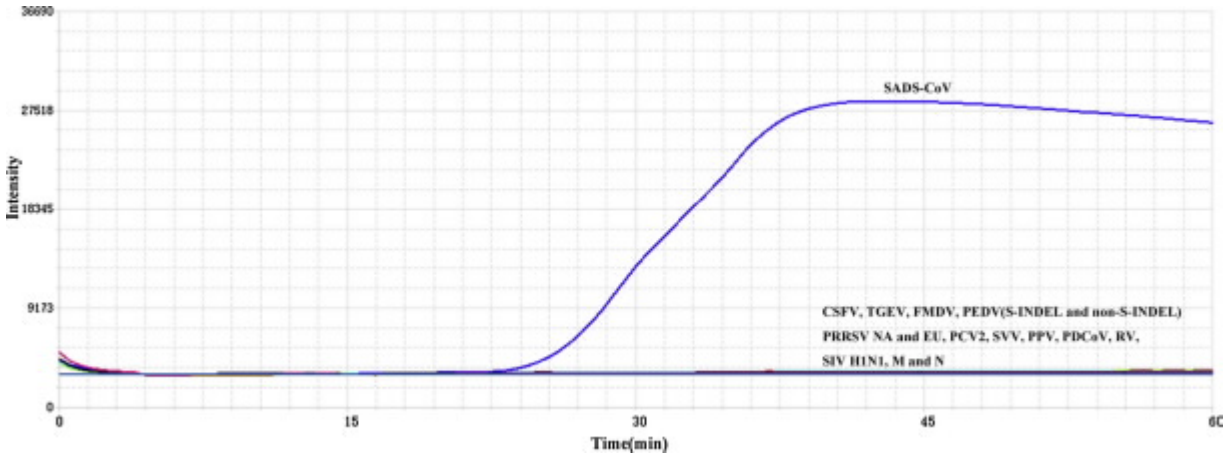

Fig. 1. Specificity of the real time RT-LAMP assay for SADV-CoV. The SADV-CoV RNA was amplified by the assay, but not other swine viruses including classical swine fever virus (CSFV), porcine and respiratory syndrome virus (PRRSV) NA and EU, transmissible gastroenteritis corona virus (TGEV), foot and mouth disease virus (FMDV), porcine epidemic diarrhea virus (PEDV) (S-INDEL and non-S-INDEL), porcine circovirus type 2 (PCV2), senecavalley virus(SVV), porcine parvovirus (PPV), porcine deltacoronavirus (PDCoV), rotavirus (RV), and swine influenza virus (H1N1). Vero cell nucleic acid was used a mock control (M). Nuclease free water was used as a negative control (N). The assay was repeated thrice.

twenty of these samples contained SADS-CoV (Zhou et al., 2018a). These 24 samples were again tested with the real-time RT-LAMP method. The real-time RT-LAMP assay could distinguish between the positive and negative samples (Fig. 3). Therefore, real-time LAMP was sufficiently accurate and reliable for the detection of SADS-CoV.

4. Discussion

SADS-CoV is a novel swine enteric alphacoronavirus identified in Guangdong province of China in 2017 (Gong et al., 2017; Pan et al., 2017). This disease has already caused huge economic losses in the Chinese swine industry. However, its detection was problematic since the disease symptoms are similar to other viruses (Jung et al., 2016; Pensaert and de Bouck, 1978; Stevenson et al., 2013). Although a TaqMan-based real-time RT-PCR assay had already been developed for SADS-CoV, this method required expensive equipment and supplies. Therefore, a simple and rapid method was needed for field studies of SADS-CoV infections. In this study, a real-time RT-LAMP assay was successfully developed using SADS-CoV N gene specific primers. The assay is suitable for SADS-CoV detection in less well-equipped laboratories.

LAMP technology is currently used for the nucleic acid detection of a number of animal pathogens (Niessen et al., 2013; Sahoo et al., 2016). The assay offers multiple advantages compared to conventional PCR including a shorter turnaround time (30–60 min) and a sensitivity 1–2 orders of magnitude higher (Huang et al., 2016; Yu et al., 2015). In the present study, the real-time RT-LAMP method was used to detect SADS-CoV and did not cross-react with other porcine pathogens. SADS-CoV N gene was specifically amplified with a detection limit of 1.0×10^1 copies/μL and had good reproducibility. The sensitivity of the LAMP assay is similar to real-time RT-PCR (Yu et al., 2015). In this study, the RT-LAMP correctly identified 20 out of 24 samples as positive, showing similar diagnostic sensitivity comparable to the real time RT-PCR. Together our data indicates that the real-time RT-LAMP assay was accurate and sensitive.

In conclusion, a novel real-time RT-LAMP method was developed for the detection of SADS-CoV in pigs. The assay was specific, sensitive and reproducible and will be helpful for the diagnosis, surveillance and pathogenesis studies of SADS-CoV infections.

Conflict of interest

Authors declare no competing interests.

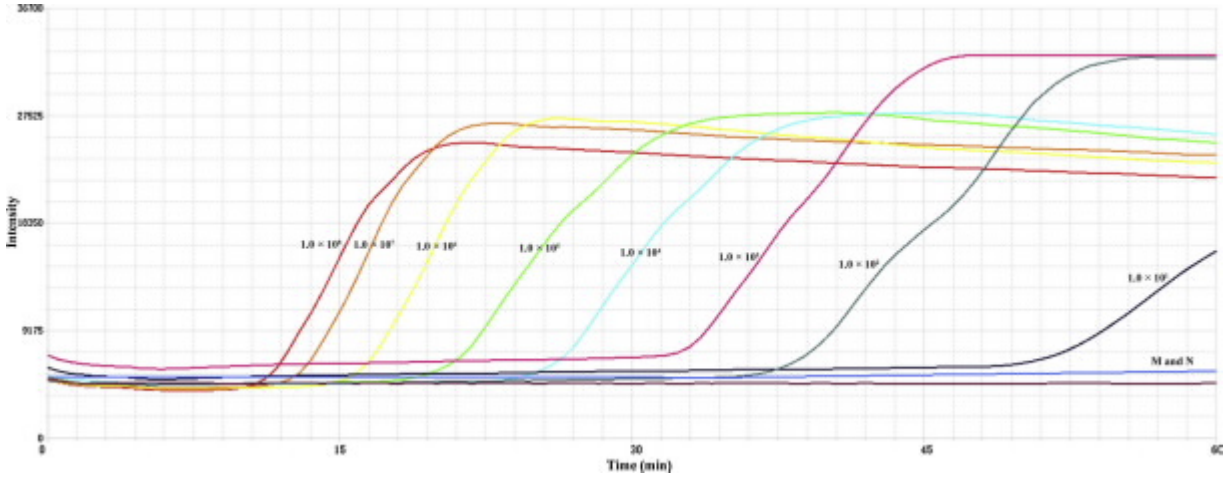

Fig. 2. Sensitivity of the real time RT-LAMP assay for SADS-CoV. Serial dilutions of in vitro transcribed copies of the cloned SADS-CoV N gene were tested in the assay. The detection limit of this assay was 1.0×10^1 copies. Vero cell nucleic acid was used a mock control (M). Nuclease free water was used as a negative control (N). The assay was repeated thrice.

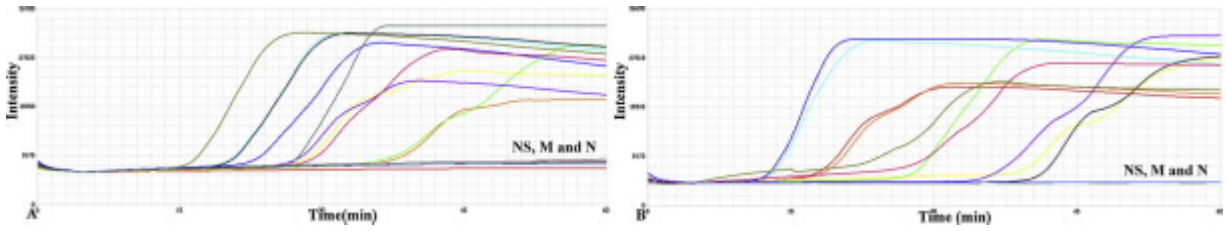

Fig. 3. Detection of the SADS-CoVRNA from clinical samples by real time RT-LAMP assay. (A) and (B), Amplification of 20 SADS-CoVpositive and 4 negative samplespreviously assayedusing real-time RT-PCRwere divided into two groups. NS, negative samples;M, mock control (vero cell nucleic acid), N, negative control (nuclease free water). Each group contained 10 positive samples, 2 negative samples, a mock control and a negative control. This assaywas repeated thrice.

ABSTRACT

Swine acute diarrhea syndrome coronavirus (SADS-CoV) is a novel coronavirus which was first reported in southern China in 2017. It can cause severe diarrhea disease in pigs. In order to detect this new emerging virus rapidly and reliably, a TaqMan-based real-time RT-PCR assay was established in this study. Specific primers and probe were designed and synthesized based on the conserved region within the N gene of the viral genome. Results showed that the lowest limit of detection was 3.0×10^1 copies/μL. This approach was specific for SADS-CoV, and there were no cross-reaction observed against other 15 swine viruses. It was 10 times more sensitive than the conventional PCR and gave higher SADS-CoV positive detection rate (70.69%, 123/174) than the conventional PCR (51.15%, 89/174) from clinical samples. These data indicated that the TaqMan-based real-time RT-PCR assay established here was an effective method with high sensitivity, specificity and reproducibility for faster and more accurate detection and quantification of SADS-CoV.

1. Introduction

Swine acute diarrhea syndrome coronavirus (SADS-CoV) is a newly discovered virus, which is an enveloped, positive and single-stranded sense RNA virus and belongs to the order Nidovirales, family Coronaviridae and genus Alphacoronavirus (Zhou et al., 2018; Pan et al., 2017; Woo et al., 2012). SADS-CoV can cause severe and acute diarrhea and rapid weight loss in piglets less than 6-day-old. From January 2017 to May, the outbreak of SADS-CoV has led to the death of almost 25,000 piglets in southern China and resulted in significant economic losses (data unpublished). Considering the clinical symptoms of this new emerging virus that are similar to those caused by other known swine enteric coronaviruese in China, there is an urgent need to establish a faster and reliable diagnostic technique for identification and quantification of SADS-CoV (Dong et al., 2015; Sun et al., 2016).

The real-time PCR using the fluorogenic probe system has been widely used to quantify virus nucleic acids in recent years (Li et al., 2011; Gava et al., 2015; Niu et al., 2016; Dall Agnol et al., 2017). Compared to the conventional PCR, it allows the accurate and reproducible quantitation of viral gene copies, and has advantages in rapidity, accuracy, reproducibility, and high sensitivity (Li et al., 2016; Fowler et al., 2016). So far, there is no diagnostic method have been established for the detection of SADS-CoV. In this study, a TaqMan-based real-time RT-PCR was designed for SADS-CoV diagnosis and quantification in clinical swine tissue samples.

2. Material and methods

2.1. Virus and samples collection

SADS-CoV virus used in this study was isolated from clinical samples with diarrheal symptoms from pig herds in Guangdong Province of China. Specimens from piglets with signs of severe diarrhea and high mortality were collected from February to August 2017 in four SADS-CoV positive farms.

2.2. Nucleic acid extraction and reverse transcription

Specimens were homogenized in phosphate-buffered saline (PBS) (20% w/v), and frozen and thawed three times, and then centrifuged

for 10 min at 10,000 × g. Viral nucleic acid was extracted following the manufacturer's recommendations of AxyPrep™ Body Fluid Viral DNA/RNA Miniprep Kit (Axygen Scientific, Inc). Reverse transcription was carried out according to the manufacturer's protocol of Prime Script™ RT Reagent Kit with gDNA Eraser (Takara, Dalian, China), the first step was performed in a total volume of 10 μL of a mixture containing 2 μL 5 × gDNA Eraser Buffer, 1 μL gDNA Eraser, 1 μL total RNA and 6 μL RNase Free dH2O at the condition of 42 ℃ for 2 min to remove residual genomic DNA, and then, ten microliters of mixture was used in a reaction volume of 20 μL containing 1 μL PrimeScript RT Enzyme Mix I, 1 μL RT Primer Mix, 4 μL 5 × PrimeScript Buffer 2, 4 μL RNase Free dH_2O, reactions were conducted with a program that included 37 °C for 15 min, 87 °C for 5 s. All DNA and cDNA templates were stored at - 80 °C until use.

2.3. Design of primers and probe for the real-time RT-PCR

The genome sequences of SADS-CoV (Accession number: MF094681-MF094684) were retrieved from GenBank. Conserved regions of the N gene were identified by nucleotide sequence alignments with MegAlign7.1.0 (DNAStar, USA). Primers and probe were selected and designed using Primer premers 5.0 to generate a 449 bp amplicon for plasmid and 155 bp real-time RT-PCR product. The probe was labeled with 5-carboxyflourescein(FAM) at the 5′-end and N, N, N' N'-tetramethyyl-6-carboxyrhodamine(TAMRA) at the 3′-end. Nucleotide information about primers and probe are summarized in Table 1.

2.4. Construction of standard plasmids DNA for the real-time RT-PCR

The target fragment was obtained with SADS-CoV-N-F/R by PCR and then cloned into pMD19-T vector (TaKaRa, Dalian, China). PCR product was transformed into DH5α Escherichia coli cells following the manufacture's recommendations (TaKaRa, Dalian, China) and purified by Plasmid Mini Kit 2 (Omega Bio-tek, USA). The positive recombinant plasmid was confirmed by sequencing (BGI, Shenzhen, China). Subsequently, the SADS-CoV plasmid (pSADS-CoV-N) was quantified by spectrophotometric analysis (NanoDrop ND-1000) and converted into copy number. The plasmid DNA was stored at - 80 ℃ in aliquots until use.

2.5. TaqMan-based real-time RT-PCR assay

The optimization of the real-time RT-PCR reaction components and cycling conditions was performed using DNA standards. Concentrations of primers, probe and cDNA were selected based on the greatest fluorescence obtained and the lowest threshold cycle. The optimized real-time RT-PCR assays were carried out in 20 μL reaction mixture containing 10 μL of Premix Ex Taq (Probe qPCR) (2×), 0.8 μL of qSADS-CoV-N-F (10 μM), 0.8 μL of qSADS-CoV-N-R (10 μM), 0.8 μL (10 μM) of probe, 1 μL of cDNA template, and 6.6 μL of ddH_2O. The PCR amplification was performed with a CFX96 Real-Time PCR Detection System (BIO-RAD) under the following conditions: 95 ℃ for 30 s for initial denaturation followed by 45 cycles of 95 ℃ for 5 s and 62 ℃ for 30 s. Ten-fold serial dilutions of pSADS-CoV-N, ranging from 10^9 to 10^2 copies/μL, were tested in five replicates with real-time RT-PCR to generate the standard curve.

Table 1
Primers and probe for SADS-CoV detection.

primers	Sequence(5′-3′)	amplicon
SADS-N-F	CAGGTCTTGGTGTTCGCAATCG	449 bp
SADS-N-R	ACCGTGCTGAACGAGGTCACT	
qSADS-N-F	CTGACTGTTGTTGAGGTTAC	155 bp
qSADS-N-R	TCTGCCAAAGCTTGTTTAAC	
probe	5, -FAM -TCACAGTCTCGTTCTCGCAATCA-TAMRA-3,	

2.6. Sensitivity and specificity of the real-time RT-PCR

The concentration of the plasmid DNA was 196.455 ng/μL, equivalent to 3.0×10^{10} copies/μL before dilution. To examine the detection limit of the real-time RT-PCR, plasmid DNA was diluted serially 10-fold with RNase Free ddH_2O (10^9–10^2 copies/μL) as templates. Briefly, conventional RT-PCR was performed by using 1 μL of diluted cDNA template and 10 μmol of primers in a 20 μL reaction volume with the following thermal profile: 50 °C for 30 min, 94 °C for 5 min, 35 cycles of 94 °C for 30 s, 55 °C for 30 s, 72 °C for 30 s and a final step of 72 °C for 5 min. And then the detection limit between the real-time RT-PCR and conventional PCR were compared.

The specificity of the TaqMan-based real-time RT-PCR assay was demonstrated with other porcine viruses, including classical swine fever virus (CSFV), foot-and-mouth disease virus (FMDV), porcine circovirus 3 (PCV3), porcine rotavirus (RV), porcine deltacoronavirus (PDCoV), porcine epidemic diarrhea virus (PEDV), porcine kobuvirus (PKV), porcine reproductive and respiratory syndrome virus (PRRSV), porcine sapelovirus (PSV), porcine bocavirus (PBoV), swine vesicular disease virus (SVDV), senecavalley virus (SVA), swine influenza virus (SIV), transmissible gastroenteritis virus (TGEV) and staphylococcus aureus, which were stored at our laboratory. Negative control (RNase Free ddH_2O) were also contained in the run.

2.7. Reproducibility of the real-time RT-PCR

Ten-fold serial plasmid dilutions ranging from 3.0×10^2 to 3.0×10^9 copies/μL were used to assess the coefficients of variation of the real-time RT-PCR. Intra-and inter-assay for Cq values were both included in three different times and quintuplicate.

2.8. Detection of the clinical tissues samples

In order to evaluate the real-time RT-PCR assay, a total of 174 clinical tissue samples with diarrheal symptoms, including heart, liver, spleen, lung, kidney, jejunum, ileum, duodenum, tonsil, lymphoglandulae mesentericae and lymphonodi abdominals were collected and quantified by the developed method. The samples amplified before 40 cycles and showed the typical amplification curves were considered to be SADS-CoV positive. Conventional PCR was preformed simultaneously.

3. Results

3.1. Standard curve and dynamic range

Ten-fold serial dilutions of DNA plasmids were used to establish a standard curve by plotting the logarithm of the plasmid copy number against the measured Cq values. The standard curve generated had a wide dynamic range of 10^9–10^2 copies/μL with a linear correlation (R^2) of 0.999 between the Cq value and the logarithm of the plasmid copy number (Fig. 1).

3.2. Specificity of the real-time RT-PCR

The real-time RT-PCR gave positive results for the standard plasmid of SADS-CoV strain (3.0×10^7 copies/μL) and negative results (Cq > 40) for other porcine viruses, including PEDV, PDCoV, RV, PRRSV, PKV, PSV, PBoV, FMDV, SVDV, SVA, SIV, CSFV, PCV3, TGEV, SA and negative control (RNase Free ddH_2O) (Fig. 2, Table 2).

3.3. Sensitivity of the real-time RT-PCR

To compare the sensitivity of the TaqMan-based real-time RT-PCR

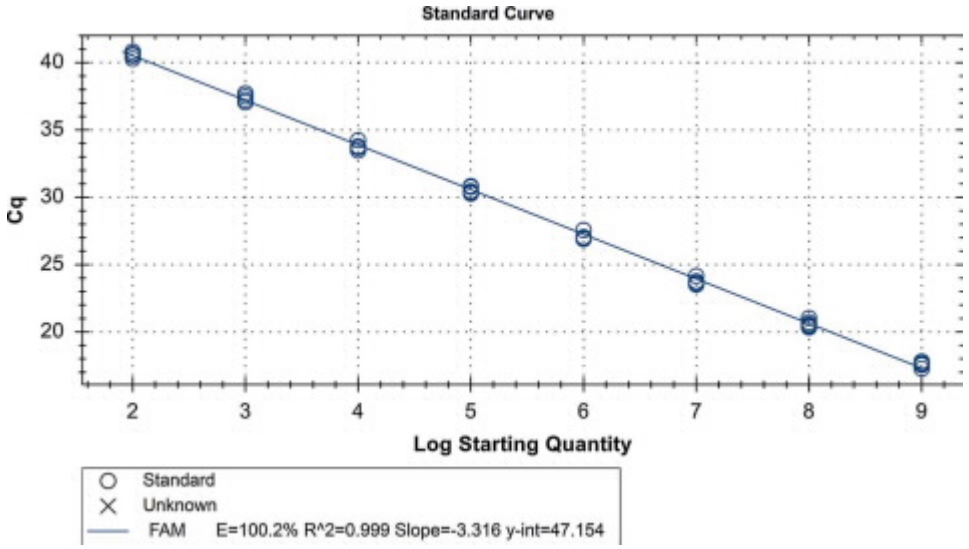

Fig. 1. Standard curve of TaqMan-based real-time RT-PCR assay. The assay was conducted using duplicated ten-fold serial dilutions (3.0×10^9–3.0×10^2 copies/μL) of the plasmid DNA; y = - 3.316x + 47.154.

and the conventional PCR, ten-fold serial dilutions of the plasmid pSADS-N were analyzed. The detection limits for the TaqMan-based real-time RT-PCR and the conventional PCR assays were 3.0×10^1 and 3.0×10^2 DNA copies/μL, respectively (Fig. 3).

3.4. Reproducibility of the TaqMan-based real-time RT-PCR assay

The coefficient of variation (C.V) in the intra-assay and inter-assay was evaluated. The intra-assay C.Vs of real-time PCR ranged from 0.31% to 1.93%, while the inter-assay C.Vs ranged from 0.14% to 1.86% (Table 3).

3.5. Detection of the clinical tissues samples

The developed TaqMan-based real-time RT-PCR assay was evaluated with 174 clinical samples. 123 out of 174 samples were positive for SADS-CoV by the TaqMan-based real-time RT-PCR. When these samples were detected by the conventional PCR, only 89 out of 174 (51.15%) were positive. The established technique increased the positive detection positive rated by 20%. Samples that were tested positively by the conventional PCR were also positive by the real-time RT-PCR. 34 samples were detected negatively by the conventional PCR, while using the TaqMan-based real-time RT-PCR, they were actually positive for SADS-CoV (Table 4).

Table 2
The samples' information of specificity assay for SADS-CoV Taqman-baes real-time RT-PCR. N/A: negative.

Number	Samples	Type	Cq Mean

4. Discussion

SADS-CoV is a newly identified virus in south China in 2017. Previous methods for the detection of this novel virus have relied on qualitative rather than quantitative PCR(Zhou et al., 2018; Pan et al., 2017; Gong et al., 2017). The conventional PCRis time-consuming, and it couldn't estimate the amount of viral gene copies, which could be crucial for virus diagnosis and correlations with clinical diseases (Mackay et al., 2002).

In this study, we described the development and validation of a TaqMan-based real-time RT-PCR assay for SADS-CoV diagnosis and quantification in 174 clinical samples from piglets affected by severe diarrhea in southern China. The hydrolysis probe employed in this assaywas located in the conservedregion within the N geneof the viral genome. Resultsshowed that the correlation coefficient of the standard curve in this study was 0.999, much closing to the R^2 of 1 in theory. No cross-reaction signals were observed for fifteen other porcine diseases. The lowest limit of detection was 3.0×10^{1} copies/μL, 10 times more sensitive than the conventional PCR.The intra-assay C.Vs were equal or lessthan 1.93% and the inter-assay C.Vswere equal or lessthan 1.86%, indicating the good reproducibility of this assay.The positive rate determined by the new technique was 70.69%, whereas that of the conventional PCR was merely 51.15%, further demonstrating the higher sensitivity of the former method. All these data showed that the TaqMan-basedreal-time RT-PCRapproach was reliable and sensitive.

In conclusion, the TaqMan-based real-time RT-PCRassay was established in present study for detection and quantification of SADS-CoV in pigs. Becauseof it remarkable sensitivity, reproducibility and rapidity compared to the conventional PCR,this assaymay not only help to resolve diagnosis investigation, but also help to provide knowledge on epidemiology and pathogenesis studies of SADS-CoV.

ABSTRACT

Outbreaks of severe diarrhea in neonatal piglets in Guangdong, China in 2017 resulted in isolation and discovery of a novel swine enteric alphacoronavirus (SeACoV) derived from the species *Rhinolophus bat coronavirus HKU2* (Vet Microbiol, 2017, 211:15-21). SeACoV was later referred to as swine acute diarrhea syndrome (SADS) CoV by another group (Nature, 2018, 556:255-258). The present study was set up to investigate potential species barriers of SADS-CoV *in vitro* and *in vivo*. We first demonstrated that SADS-CoV possesses a broad species tropism and is able to infect cell lines from diverse species including bats, mice, rats, gerbils, hamsters, pigs, chickens, nonhuman primates and humans. Trypsin contributes to, but is not essential for SADS-CoV propagation *in vitro*. Furthermore, C57BL/6J mice were inoculated with the virus via oral or intraperitoneal routes. Although the mice exhibited only subclinical infection, they supported viral replication and prolonged infection in the spleen. SADS-CoV nonstructural proteins and double-stranded RNA were detected in splenocytes of the marginal zone on the edge of lymphatic follicles, indicating active replication of SADS-CoV in the mouse model. We identified that splenic dendritic cells (DCs) are the major targets of virus infection by immunofluorescence and flow cytometry approaches. Finally, we demonstrated that SADS-CoV does not utilize known CoV receptors for cellular entry. The ability of SADS-CoV to replicate in various cells lines from a broad range of species and the unexpected tropism for murine DCs provide important insights into the biology of this bat-origin CoV, highlighting its possible ability to cross interspecies barriers.

43 **IMPORTANCE**

44 Infections with bat-origin CoVs (SARS-CoV and MERS-CoV) have caused severe illness
45 in humans after "host jump" events. Recently, a novel bat-HKU2-like CoV named swine acute
46 diarrhea syndrome CoV (SADS-CoV) has emerged in southern China, causing a lethal diarrhea
47 in newborn piglets. It is important to assess the species barriers of SADS-CoV infection since the
48 animal hosts (other than pigs and bats) and zoonotic potential are still unknown. An *in vitro*
49 susceptibility study revealed a broad species tropism of SADS-CoV, including various rodent
50 and human cell lines. We established a mouse model of SADS-CoV infection, identifying its
51 active replication in splenic dendritic cells, which suggests that SADS-CoV has the potential to
52 infect rodents. These findings highlight the potential cross-species transmissibility of SADS-CoV,
53 though further surveillance in other animal populations is needed to fully understand the ecology
54 of this bat-HKU2-origin CoV.

INTRODUCTION

The spread of zoonotic pathogens remains among the leading threats to global public health . Coronaviruses (CoVs) can infect a wide variety of animals and humans, resulting in several diseases with respiratory, enteric, and neurological pathologies of varying severity (1-4). Because of the various routes of infection and extensive phagocytosis in tissues, close contact between humans and animals provides potential scenarios for adaptive mutation and interspecies transmission (5).

The source of the severe acute respiratory syndrome (SARS)-CoV was traced to civets in animal markets and ultimately to bats, leading to more than 8,000 human infections and 774 deaths after its emergence in 2002 (5-7). The emergence of Middle East respiratory syndrome (MERS)-CoV in 2012 (2) resulted in more than 1,000 clinical cases with a mortality rate of 35%, making it the second marked threatening CoV of the 21st century (8, 9). Although camels can be infected with MERS-CoV, bats are also thought to be the original host of MERS-CoV (5). Both SARS-CoV and MERS-CoV originated in bats, illustrating the damage caused by CoVs during interspecies transmission events, and highlighting the need for increased global vigilance of CoV-associated disease (1, 5, 10).

In February 2017, outbreaks of severe diarrhea of suckling piglets occurred in swine herds in Guangdong Province, China (11). Clinical signs consisted of acute vomiting and watery diarrhea, but porcine viruses commonly associated with diarrhea including porcine epidemic diarrhea virus (PEDV), transmissible gastroenteritis virus (TGEV) and porcine deltacoronavirus (PDCoV) were not detected in any of the clinical samples (11). The new enteric pathogen of

commercial pigs that was isolated was finally identified as a new porcine CoV belonging to the species *Rhinolophus bat coronavirus HKU2* (11-13). Our research group tentatively designated this newly emerged virus as swine enteric alphacoronavirus (SeACoV) (11), and it was later named swine acute diarrhea syndrome (SADS)-CoV by Zhou *et al.* (14). It is also known by other names, such as porcine enteric alphacoronavirus (PEAV) (13). For purposes of unity, SADS-CoV is the name used to refer to this new virus in the current study. The expanded host range of bat-origin HKU2 to pigs indicates that bats play an important role in the ecology and evolution of SADS-CoV, though the mechanism of bat-to-swine transmission remains unclear. In view of the damage caused by SARS and MERS for both animal and public health, careful attention must be paid to the prevalence of CoV-associated disease among humans and domestic animals (15).

Therefore, there is an urgent need for more information on the details of SADS-CoV infection. It is critically important to assess potential species barriers of SADS-CoV transmission since the animal hosts (other than pigs and bats) and zoonotic potential are still unknown. In the present study, we demonstrated that SADS-CoV possesses a very broad species tropism *in vitro* and is able to infect cell lines from diverse species including rodents and humans. Furthermore, *in vivo* evidence from experimental infection of mice with SADS-CoV identified splenic dendritic cells (DCs) as the major site of SADS-CoV replication in mice. Finally, we demonstrated that SADS-CoV does not utilize known CoV protein receptors for cellular entry. These results present the possibility that rodents are among the susceptible hosts of SADS-CoV, highlighting the potential cross-species transmissibility of SADS-CoV.

101

102 **MATERIALS AND METHODS**

103 **Virus stocks and viral antibodies.** The SADS-CoV isolate CH/GD-01/2017 at passage 10
104 was used in all experiments and cultured in Vero cells (16). The virus was passaged serially using
105 the culture supernatant to infect fresh Vero cells at a multiplicity of infection (MOI) of 0.1, and
106 viral titers were determined in Vero cells by endpoint dilution as the 50% tissue culture infective
107 dose 50% ($TCID_{50}$). Rabbit polyclonal antibodies (pAb) against the membrane (M),
108 nucleocapsid (N) and the nonstructural protein 3 (Nsp3) acidic domain (AC) of SADS-CoV were
109 generated in-house, and validated in SADS-CoV-infected Vero cells (16). A mouse
110 anti-SADS-CoV-N pAb was also produced to allow double staining when mixed with the rabbit
111 pAb. A monoclonal antibody (MAb) against dsRNA (anti-dsRNA mAb J2, Cat# J2-1702,
112 SCICONS, Hungary) was used to specifically detect viral replication of SADS -CoV.

113 **Cell lines and cell culture.** Twenty-four cell lines derived from tissues of different species
114 were used (Table 1), including human (Huh-7, HepG2/C3A, 293T, A549 and HeLa), monkey
115 (Marc-145, Cos-7, BSC-40, Vero), swine [ST, PK15, LLC-PK1, IPEC-J2 (17)], bat [BFK (18),
116 Tb-1], canine (MDCK), mouse (NIH/3T3, RAW 264.7), hamster (BHK -21, CHO), rat (BRL-3A,
117 NRK-52E), chicken (DF-1) cell lines and a primary kidney cell line from Mongolian gerbils
118 (prepared in-house). The BFK cell line was a generous gift from Dr. Changchun Tu at the
119 Institute of Military Veterinary Medicine, Changchun, China. Each cell line was cultured in
120 Dulbecco's modified Eagle's medium (DMEM, Hyclone) supplemented wit h 10% (v/v) fetal
121 bovine serum (FBS, Biological Industries), 100 U/m1 penicillin and 100 U/ml streptomycin at

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

122 37 °C, 5% CO_2, and water-saturated humidity conditions.

123 To determine viral susceptibility, each cell line was cultured at 70% confluence in 12-well
124 plates with maintenance medium (MM) containing DMEM, 0.3% tryptose phosphate broth
125 (TPB), and 1% penicillin/streptomycin, or MM with addition of 5 μg/ml trypsin (MMT) (Sigma,
126 Cat#T7186-50TAB, St Louis, MO, USA). After washing with phosphate buffered saline (PBS),
127 cells were inoculated with SADS-CoV diluted in MM or MMT at an MOI of 0.01 for 2 h.
128 Non-attached viruses were removed by washing the cells three times with DMEM, and cell
129 monolayers were subsequently incubated in MM or MMT at 37 °C for 5 days. To determine the
130 effect of trypsin on viral entry, cell monolayers were infected by SADS-CoV in three conditions:
131 1) no trypsin treatment, infected with SADS-CoV diluted in MM, subsequently incubated in MM;
132 2) pre-trypsin treatment, inoculated with SADS-CoV diluted in MMT, subsequently incubated in
133 MM; and 3) double-trypsin treatment, inoculated with SADS-CoV in MMT, subsequently
134 incubated in MMT. Supernatants from cells were collected at 12, 24, 36, 48, 72, and 120 hours
135 post-infection (hpi) for one-step quantitative RT-PCR analysis. Cell cultures were examined for
136 cytopathic effects (CPE) and immunofluorescence assay at 48-72 hpi.

137 **Immunofluorescence assay (IFA) for cell line susceptibility.** Different cells infected with
138 SADS-CoV in 12-well plates were washed twice with PBS and fixed in 4% paraformaldehyde in
139 PBS and then permeabilized with 0.1% Triton X-100 in PBS. Cells were then incubated with the
140 rabbit anti-SADS-CoV-M pAb at 1:5000 dilution for 1 h at 37 °C, washed with PBS and stained
141 with the Alexa Fluor 488-conjugated goat anti-rabbit secondary antibody (Thermo Fisher
142 Scientific, USA) at 1:1000 dilution. After incubation for 1 h at 37 °C, the cells were washed with

143 PBS, stained with 4′,6-diamidino-2-phenylindole (DAPI) at 1:1000 dilution and visualized on a
144 fluorescence microscope.

145 **One-step quantitative RT-PCR analysis targeting the N gene.** The full-length SADS-CoV
146 N gene was inserted into an appropriately digested pET-28a vector using two unique restriction
147 sites, *Nde*I and *Xho*I, and then linearized with *Xho*I. The N gene was *in vitro* transcribed using
148 the T7 High Efficiency Transcription Kit (TransGen Biotech Co., LTD, Beijing China). Standard
149 curves were generated using dilutions of known quantity of N gene RNA to allow absolute
150 quantitation of SADS-CoV RNA copy numbers in samples.

151 Total RNA was extracted from culture supernatants or tissue homogenates using Trizol
152 (ThermoFisher Scientific, USA) following the manufacturer's instructions. SADS-CoV RNA
153 titer was determined by one-step qRT-PCR (TOYOBO Co., LTD) targeting the N gene with the
154 primers: 5'-CTAAAACTAGCCCCACAGGTC-3' and 5'-TGATTGCGAGAACGAGACTG-3',
155 and the probe FAM-GAAACCCAAACTGAGGTGTAGCAGG-TAMRA. Samples with a cycle
156 threshold value <35 were considered positive based upon validation data using the RNA
157 standards.

158 **Mouse infections, tissue harvest and viral load determination.** Wild-type C57BL/6J mice
159 (Jackson no. 000664) were purchased from the Model Animal Research Center of Nanjing
160 University and housed in animal facilities at the Zhejiang University under
161 specific-pathogen-free condition. For SADS-CoV infections, 6- to 8-week-old female and male
162 mice were inoculated with 5×10^5 $TCID_{50}$ (equal to 6×10^8 genome copies) of SADS-CoV, either
163 per oral infection (p.o.) with 25 μl inoculum (2×10^7 $TCID_{50}$/ml) or intraperitoneal infection (i.p.)

with 200 µl inoculum (2.5×10^6 $TCID_{50}$/ml). For viral load determination in specific tissues, mice were euthanized at 1, 3, 5, 7, 14, 21, and 28 days post-infection (dpi), and tissues were harvested including stomach, duodenum, jejunum, ileum, cecum, colon, mesenteric lymph nodes, spleen, kidney, liver, heart, lung, blood and feces. Tissues were weighed and homogenized in medium (DMEM contained 2% FBS) by bead beating using sterile zirconium oxide beads (Cat# ZrOB20 MidSci). Total RNA was extracted from tissue homogenates and tested by quantitative RT-PCR analysis targeting the SADS-CoV N gene, as described above. Blood samples were collected from the heart and serum was separated for virus-specific antibody detection.

Enzyme-linked immunosorbent assay (ELISA). SADS-CoV virus particles were purified from infected cell culture supernatants by sucrose density gradient centrifugation, and protein concentration was determined by the BCA Protein Assay kit (Beyotime Biotechnology, Shanghai, China). The optimal dilution of antigen was determined by square titration. The IgG antibodies contained in serum at a 1:100 dilution were detected in wells coated with purified SADS-CoV virus particles (6.25 ng/well) as antigen.

Histopathology, immunohistochemistry and immunofluorescence assay for murine spleen. Mice were infected i.p. with SADS-CoV and at 3 dpi, spleens were harvested and fixed in 4% paraformaldehyde for 24 h and embedded in paraffin. Tissue sections were then deparaffinized and rehydrated in three changes of xylene, 15 min each, dehydrated in two changes of pure ethanol for 5 min, followed by rehydration in an ethanol gradient of 85% and 75% ethanol. After washing in distilled water, tissues were subjected to hematoxylin and eosin staining for histopathological examinations.

185 For antigen retrieval, deparaffinized and rehydrated sections were immersed in sodium
186 citrate antigen retrieval solution (pH 6.0) and maintained at a sub-boiling temperature for 8 min,
187 let stand at 98 °C for 8 min and then incubated again at sub-boiling temperature for 7 min. After
188 allowing to cool to room temperature (RT) and washing three times with PBS (pH 7.4),
189 endogenous peroxidase was blocked by immersion in 3% hydrogen peroxide at RT for 30 min
190 and again washed with PBS. Tissue sections were blocked in 3% BSA at RT for 30 min, then
191 incubated with 1:500 dilution of each primary antibody (anti-dsRNA MAb, anti-SADS-CoV-M
192 pAb or anti-SADS-CoV-AC pAb) overnight at 4 °C. After washing slides three times with PBS
193 (pH 7.4), they were stained with appropriate secondary antibodies labeled with horseradish
194 peroxidase at RT for 50 min. Freshly prepared diaminobenzidine chromogenic reagent was added
195 and counterstained with hematoxylin, then dehydrated and visualized on a light microscope.
196 Spontaneous fluorescence quenching reagent (Wuhan servicebio technology Co., Ltd,
197 Wuhan, China) was added to the tissue sections and incubated for 5 min after antigen retrieval.
198 The sections were then washed in running water, followed with blocking and antibody staining
199 as described above. In addition, the primary antibody was supplement with a CD11c antibody
200 (Wuhan servicebio technology Co., Ltd, Wuhan, China) at a 1:200 dilution, then stained with
201 appropriate secondary antibodies. Finally, DAPI was added and sections were visualized on a
202 fluorescence microscope; nuclei labeled with DAPI appear blue, positive cells are green by
203 labeling with CD11/c or red by labeling with virus-specific antibody.
204 **Preparation of murine splenocytes and flow cytometry.** Mice infected with SADS-CoV
205 were euthanized at 3 dpi, and spleens were removed and placed in 5 ml complete DMEM. After

grinding the excised spleen through a 100-μm cell strainer using the plunger end of a 5-ml syringe, cells were washed with an excess of DMEM and centrifuged at 200 ×g for 5 min. After resuspending cells in 3 ml of red blood cell lysis buffer (Solarbio Life Sciences, Beijing, China) and incubation at RT for 10 min, 5 ml of DMEM was added and cells were passed through another strainer to remove clumps. After centrifugation at 200 ×g for 5 min, the supernatant was discarded and cells were resuspended in 10 ml fresh DMEM for cell counting and viability checks using trypan blue and a hemocytometer.

For flow cytometry, cultured cells were resuspended in Fc Block buffer (containing anti-mouse CD16 Fc Block Antibody at 1:500 dilution) and incubated on ice. Cells in Fc Block buffer were added to 96-well plates at 1×10^6 cells/well. After 30 min incubation, cells were centrifuged at 200 ×g for 10 min, the supernatant was discarded and pellets resuspended in 100 μl Cytofix/Cytoperm solution (Cytofix/Cytoperm Soln Kit; BD Biosciences, San Jose, CA, USA) to fix cells. After incubation on ice for 20 min protected from light , cells were centrifuged at 800 ×g for 5 min at 4 °C, supernatant was removed without disturbing cell pellets and cells were washed twice in 150 μl of 1x Perm/Wash buffer. After addition of 50 μl virus-specific primary antibody (anti-dsRNA MAb, anti-SADS-CoV-N pAb or anti-SADS-CoV-AC pAb) diluted in 1× Perm/Wash buffer with 3% BSA and incubation at 4 °C for 30 min, cells were centrifuged at 200 ×g for 10 min. Cells were washed twice in 150 μl of 1× Perm/Wash buffer followed by staining with appropriate secondary antibodies conjugated to Alexa Fluor 488 (Thermo Fisher Scientific, USA) at 4 °C for 30 min. After centrifuging at 800 ×g for 5 min at 4 °C and washing with 1× Perm/Wash buffer, pellets were resuspended in 0.2 ml FACS buffer and analyzed by flow

227 cytometry.

228 **Infection of splenocytes *in vitro*.** To detect replication of SADS-CoV in mouse splenic cells
229 *in vitro*, splenocytes were extracted from naïve mice, plated in 100- or 35-mm dishes and
230 infected with SADS-CoV at an MOI of 0.1. At 48 hpi, splenocytes were harvested and placed in
231 a 15-ml tube, centrifuged at 200 ×g for 10 min at 4 °C, and analyzed by flow cytometry as
232 described above. Infected mouse splenic cells in 35-mm dishes were detected by
233 immunofluorescence assay with anti-SADS-CoV-N antibodies, and infection supernatants were
234 collected at 0, 12, 24, 36, 48 and 72 hpi for one-step quantitative RT-PCR analysis.

235 **FACS analysis of splenocytes with cell marker staining.** Mice infected with SADS-CoV
236 were euthanized at 3 dpi, and splenocytes were prepared for flow cytometry by staining with
237 appropriate antibodies: anti-SADS-CoV-AC following secondary antibodies conjugated to Alexa
238 Fluor 647 (Thermo Fisher Scientific, USA); anti-CD19-FITC (eBioscience, Catalog no.4318813)
239 for B cells; anti-CD4-PE (eBioscience, Catalog no.4329629) for T cells; anti-CD11/c-PE-Cy7
240 (BD Bioscience, Catalog no.561022) for DCs; and anti-F4/80-PE/Cy5 (Biolegend, Catalog
241 no.123111) for macrophages. Stained cells were resuspended in 0.2 ml FACS buffer and
242 analyzed by flow cytometry.

243 **Production and transduction of S protein-pseudotyped lentiviruses.** Pseudovirions with
244 various CoV spike proteins were produced as described previously (19). Briefly, each of the
245 plasmids encoding TGEV, SARS-CoV, MERS-CoV, and mouse hepatitis virus (MHV) S proteins
246 were cotransfected into 293T cells with pLenti-Luc-green fluorescent protein (GFP) and psPAX2
247 plasmids (kindly provided by Dr. Zhaohui Qian, Chinese Academy of Medical Sciences &

248 Peking Union Medical College) at a molar ratio of 1:1:1 by using polyethylenimine (PEI). The
249 cells were fed with fresh medium in the next 24 h and the supernatant media containing
250 pseudovirions were then collected and centrifuged at 800 ×g for 5 min to remove debris. To
251 quantify S protein-mediated entry of pseudovirions, MDCK cells were seeded at about 25-30%
252 confluency in 24-well plates and transfected with either pAPN-Flag, hDPP4-Flag,
253 mCEACAM1a-Flag, hACE2-GFP (kindly provided by Dr. Zhaohui Qian) (19) or the control
254 backbone vector by using Lipofectamine 3000 (Thermo Fisher). The MDCK cells
255 overexpressing each receptor were inoculated with 500 µl of 1:1 diluted corresponding
256 pseudovirions at 24 h post-transfection. At 40 hpi, cells were lysed at room temperature with 110
257 µl of medium with an equal volume of Steady-Glo (Promega, Madison, WI). The cell lysates
258 were also used to confirm the expression of each receptor by using western blotting.
259 Transduction efficiency was monitored by quantitation of luciferase activity using a Modulus II
260 microplate reader (Turner Biosystems, Sunnyvale, CA). On the other hand, the MDCK cells
261 overexpressing each receptor were inoculated with SADS-CoV (MOI=1) at 24 h
262 post-transfection. IFA was performed to test for SADS-CoV susceptibility using anti-N pAb. The
263 replication competency of SADS-CoV in MDCK cells was further determined by a reverse
264 genetics system. Development of a DNA-launched SADS-CoV (SeACoV) infectious cDNA
265 clone (named pSEA) and rescue of SADS-CoV by transfection of cultured cells with pSEA
266 followed by passaging on Vero cells have been described recently by our lab (16).

267 **Ethics statement.** All animal experiments were performed in strict accordance with the
268 Experimental Animal Ethics Committee of Zhejiang University (approval no. ZJU20170026).

RESULTS

SADS-CoV can infect cell lines originating from various species. Previously, we reported that SADS-CoV was isolated in Vero cells supplemented with trypsin (11). Since exogenous trypsin is essential for propagation of PEDV isolates *in vitro* (20), likely by mediating activation of membrane fusion by S glycoprotein proteolysis (21), we were interesting to know whether it is also required for SADS-CoV growth in cell culture. A total of 24 cell lines originating in various tissues of humans and different animal species were tested for susceptibility to SADS-CoV treated with or without trypsin (Table 1). In brief summary of the results, 21 of the 24 cell lines showed significant susceptibility to SADS-CoV infection, defined by efficient viral replication, antigen expression and the appearance of CPE. The three cell lines that were not infected by SADS-CoV were MDCK, BFK and RAW 264.7.

First, CPE was examined by inverted light microscopy at 48 hpi, and scores are shown in Table 1. As the 293T, NIH/3T3, CHO, BRL-3A and NRK-52E cell lines were sensitive to trypsin, they couldn't be tested for SADS-CoV infection in MMT. Apart from that, CPE was visible in Vero, ST and BRL-3A cell lines without trypsin, and prominent CPE appeared or was enhanced with trypsin in Marc-145, Cos-7, BSC-40, Vero, ST, PK15, LLC-PK1 and BHK-21 cell lines (Table 1).

As some cells did not display CPE after SADS-CoV infection, all cell lines were subsequently tested for viral M protein expression by IFA (Fig. 1), revealing the same range as seen by CPE in the different cell lines (data not shown). Syncytia formation was prominent in

290 Huh-7, Vero and BHK-21 cells, whereas in MDCK, BFK and RAW 264.7 cells the antigen
291 expression was much less prominent than in the other cell lines (Figs. 1A, 1C and 1I). Most cell
292 lines tested showed evidence of productive infection as indicated by expression of the M protein,
293 while the inefficient antigen expression in Marc-145, LLC-PK1 and IPEC-J2 cells suggested
294 only a limited infection.

295 Next, viral load in the culture supernatants was detected over 5 dpi by quantitative RT-PCR
296 (Fig. 2A-2C). A higher mean viral load was detected by qRT-PCR after trypsin treatment in
297 HepG2, HeLa, Marc-145, Cos-7, BSC-40, Vero, LLC-PK1, IPEC-J2, BHK-21 and DF-1 cells.
298 Therefore, trypsin contributes to, but is not essential for SADS-CoV propagation in these cell
299 lines. There was no difference after trypsin treatment in the other cell lines, though Huh-7 and
300 Tb-1 cells had high levels of SADS-CoV RNA regardless of trypsin treatment.

301 The progressive release of infectious SADS-CoV into the culture medium of six
302 representative cell lines infected with SADS-CoV was determined by titration of supernatants in
303 Vero cells (Fig. 2D). Unlike in MDCK cells, SADS-CoV infection of HeLa, Vero, Tb-1,
304 BHK-21 and PK-15 cells was productive, with HeLa cells showing the greatest susceptibility
305 (Fig. 2D).

306 **Wild-type C57BL/6J mice can be infected by SADS-CoV via oral and intraperitoneal**
307 **routes.** With the observation that SADS-CoV could infect diverse rodent cell lines (from mice,
308 rats and hamsters as well as gerbil primary kidney cells), we hypothesized that mice may be
309 susceptible to SADS-CoV. To test this, we inoculated 6- to 8-week-old wild-type B6 mice with
310 5×10^5 $TCID_{50}$ of SADS-CoV by the p.o. or i.p. route and monitored them for 28 days for clinical

311 symptoms. The mice did not succumb to the infection nor did they develop diarrhea or
312 experience weight loss during the incubation period (data not shown).

313 To determine whether SADS-CoV infected the animals asymptomatically, tissue and fecal
314 samples from inoculated mice were collected at 1, 3, 5, 7, 14, 21 and 28 dpi to determine viral
315 growth kinetics and shedding. Analysis of tissue samples by qRT-PCR suggested that
316 SADS-CoV replicated modestly in the stomach early after i.p. or p.o. infection, declining and
317 reaching undetectable levels at 7 or 14 dpi and thereafter (Fig. 3A). A very limited viral
318 replication was observed in each region of the small intestine, with the ileum via i.p. infection
319 showing continuous and decent detectable viral RNA (Fig. 3B). In the large intestine, i.p.
320 infection also resulted in viral RNA loads slightly above the limit of detection at each time point
321 in the ceca, whereas it led to higher viral RNA levels at 1-3 dpi, and much lower viral RNA at
322 21-28 dpi in the colon compared to the p.o. route (Fig. 3C). However, this replication in the large
323 intestine did not translate into higher shedding, as hardly any viral genomes were detected even
324 at 1 dpi in the fecal samples collected from i.p.-infected mice (Fig. 3F). On the contrary,
325 significantly more virus was detected in the feces of p.o.-infected mice at 1 and 3 dpi, indicating
326 that i.p. inoculation does not lead to higher virus shedding.

327 Finally, SADS-CoV replicated more efficiently in the spleen following the i.p. route, with
328 significantly higher viral RNA loads at 21 dpi (Fig. 3D). More importantly, the virus was not
329 cleared from this tissue by 28 dpi in the i.p.-infected group and by 14 dpi in the p.o.-infected
330 group, suggestive of a SADS-CoV prolonged infection in the spleen independent of inoculation
331 route. In contrast to the spleen, only very low levels of viral RNA were detected in the local

lymphoid tissue of mesenteric lymph nodes (MLNs) at 1-3 dpi, and no virus was detectable at later time points (Fig. 3D). We also looked for virus in other extraintestinal sites including the heart, lungs, liver, kidneys and blood, but they were all negative or had extremely low levels (Fig. 3E). IgG antibody levels after 7 days detected by SADS-CoV virion-based ELISA showed that the i.p. route could effectively elicit host immune responses (Fig. 3G).

Splenocytes support SADS-CoV replication. With the mouse infection model described above, our next step was to determine the cell tropism of SADS-CoV *in vivo*. Thus, we performed immunohistochemistry (IHC) on sections of small and large intestine and spleen from mice infected i.p. with 5×10^5 $TCID_{50}$ of SADS-CoV at 3 dpi. A monoclonal antibody against dsRNA was used to identify cells that supported active virus replication, as dsRNA is an intermediate that only exists during intracellular viral replication. SADS-CoV dsRNA signals were observed in the splenic white pulp in the marginal zone on the edge of lymphatic follicles, and in the margins of the periarteriolar lymphocyte sheath (Fig. 4A). Staining of tissue sections from mock-infected mice were used as a control (Fig. 4B). In addition to dsRNA, we also used rabbit pAbs to detect expression of viral structural protein (M) or nonstructural protein (Nsp3-AC). At 3 dpi, anti-M or anti-AC staining was observed in the white pulp around the lymphatic nodules (Fig. 4C), similar to the localization of dsRNA staining (Fig. 4A). Tissue sections from SADS-CoV or mock-infected mice probed with preimmune sera were negative, indicating the specificity of the SADS-CoV antibody. Unfortunately, neither viral proteins (structural or nonstructural) nor dsRNA were detected in the intestine of infected mice, consistent with the detection of only very low levels of viral RNA in these tissues by qRT-PCR

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

353 (Fig. 3).

354 Next, SADS-CoV infection was quantified in the spleen using flow cytometry. We
355 inoculated B6 wild-type mice with 5×10^5 $TCID_{50}$ of virus either i.p. or p.o., and extracted the
356 bulk immune cells from the spleen of infected animals at 3 dpi. The flow cytometry method was
357 first validated in Vero cells infected with SADS-CoV at an MOI of 0.01 followed by staining
358 with pAb against the N or AC protein at 24 hpi (Fig. 4D). As the anti-AC pAb exhibited optimal
359 intracellular staining for viral signals (Fig. 4D), it was used to determine the percentage of
360 infected splenocytes. Approximately 1.5- and 2.5-fold increase of total splenocytes were positive
361 for virus replication after p.o. and i.p. inoculation, respectively (Fig. 4E, the left panel; Fig. 4F),
362 with a significant increase in the total number of AC-positive splenocytes in i.p.-infected mice
363 compared to p.o. (Fig. 4E, the right panel). This data is consistent with the significantly lower
364 viral loads in the spleen at 1 and 3 dpi in p.o.-inoculated mice (Fig. 3D), suggesting better virus
365 dissemination and replication and escape from mucosal immune clearance.

366 We then evaluated the growth characteristics of SADS-CoV in splenocytes by assessing
367 antigen production and replication kinetics *ex vitro*. Splenocytes were first extracted from naïve
368 mice, plated in 100 mm dishes and infected with 1×10^5 $TCID_{50}$ of SADS-CoV. We observed
369 clusters of infected cells that appeared to have been engulfed by phagocytes (Fig. 4G, the middle
370 panel), and the structural N protein was shown in the cytoplasm of infected cells by confocal
371 microscopy (Fig. 4G, the middle and right panels). The percentage of infected cells was
372 quantified by flow cytometry using anti-AC pAb, revealing that nearly 2-fold increase of the
373 splenocytes were positive for viral signals (Fig. 4H), very similar to the percentage of infection

Accepted Manuscript Posted Online

JVI

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

374 observed *in vivo*. To further characterize the growth kinetic of SADS-CoV in primary
375 splenocytes, cells were infected with 1×10^5 $TCID_{50}$ of SADS-CoV, and culture supernatants
376 were harvested at 0, 12, 24, 48 and 72 hpi. Active viral replication was confirmed, with a 1.5-log
377 time-dependent increase in genomic RNA equivalents, plateauing from 24 to 72 hpi (Fig. 4I).
378 This data suggests that although only ~2% of splenocytes were infected, these cells supported a
379 decent level of viral replication. Together, these results indicate that SADS-CoV productively
380 infects mouse splenocytes.

381 **Splenic DCs support SADS-CoV replication.** Splenocytes were harvested from
382 i.p.-infected mice at 3 dpi, and the extracted cells were co-stained with antibodies against
383 SADS-CoV-AC and each of four cell surface markers (anti-CD19 for B cells; anti-CD4 for T
384 cells; anti-$CD11/c^+$ for DCs and anti-$F4/80^+$ for macrophages) using flow cytometry (Fig. 5A).
385 The percentage of infected $CD11/c^+$ cells was significantly higher than the other cell subgroups,
386 indicating that DCs are the major targets of SADS-CoV infection in the spleen.

387 The phenotype was further confirmed by double-staining IFA with anti-dsRNA, anti-M or
388 anti-AC antibody plus anti-$CD11/c^+$ in splenic sections. As expected, dsRNA staining
389 overlapped with the CD11/c surface marker on the edges of lymphatic follicles (Fig. 5B),
390 whereas no viral signals were seen in the mock-infected control (Fig. 5C). Similar patterns of
391 co-staining were detected by M and AC antibodies (Fig. 5D). To gain insight into the relative
392 quantity of DCs compared to other undefined target cells, cells positive for dsRNA and CD11/c
393 were counted in 10-15 different microscope fields of spleens from 3 infected mice (Fig. 5E),
394 showing that 61.76% of SADS-CoV-infected cells were DCs (Fig. 5F).

395 **SADS-CoV does not utilize known CoV protein receptors for cellular entry.** To our
396 knowledge, these results reveal the most extensive cell tropism among known CoVs, suggesting
397 the functional receptor(s) for SADS-CoV is likely to be a very common molecule. In order to test
398 this hypothesis, it was first necessary to find a cell line that was refractory to infection only at the
399 internalization step. MDCK cells, which showed undetectable virus production in early infection
400 tests (Fig. 1 and Fig. 2), were chosen as a potential candidate. There are four known types of
401 functional CoV protein receptors, including angiotensin converting enzyme 2 (ACE2) for
402 SARS-CoV (22), dipeptidyl peptidase 4 (DPP4) for MERS-CoV (23), aminopeptidase N (APN)
403 for TGEV (24) and PDCoV (25, 26), and mouse carcinoembryonic antigen-related cell adhesion
404 molecule 1a (mCEACAM1a) for MHV (27). To test whether one of these molecules serves as the
405 SADS-CoV receptor, we attempted to inoculate non-susceptible MDCK cells overexpressing
406 porcine APN, human DPP4, mouse CEACAM1a, or human ACE2 with SADS-CoV, but none of
407 them allowed infection as staining with anti-SADS-CoV-N pAb was negative (Fig. 6A).
408 Meanwhile, the expression of each receptor in MDCK cells was confirmed by IFA (Fig. 6A) and
409 western blot analysis (Fig. 6B) using antibodies against the tags fused to the receptors. As
410 positive controls, we confirmed that lentiviruses pseudotyped with TGEV, SARS-CoV,
411 MERS-CoV or MHV spike (i.e., pseudoviruses) efficiently entered MDCK cells exogenously
412 expressing the respective receptors (Fig. 6C).

413 Next, we demonstrated that MDCK cells can confer SADS-CoV replication competency by
414 transfection of a SADS-CoV/SeACoV infectious cDNA clone established recently (16), as
415 simultaneous expression of Nsp3-AC and N proteins were clearly detected by IFA (Fig. 6D).

Moreover, passaging of supernatants from pSEA-transfected MDCK cells onto fresh Vero cells resulted in progeny SADS-CoV infection, as evidenced by expression of the N protein (Fig. 6E), indicating that MDCK cells can also support infectious SADS-CoV production without cell-to-cell spread. Therefore, SADS-CoV apparently does not utilize any of the known CoV receptors for cellular entry. The same conclusion was reached using HeLa cells overexpressing each of the four classical CoV receptors followed by SADS-CoV inoculation by Zhou et al (14); however, the HeLa cell line itself was most susceptible to SADS-CoV infection in the present study (Fig. 2D).

DISCUSSION

In order to assess the potential species barriers of SADS-CoV infection, a cell line susceptibility study was first conducted using 24 different cell lines. As SADS-CoV probably originated from a bat SADSr-CoV (14) derived from HKU2-CoV identified in *Rhinolophus sinicus* (Chinese horseshoe bats) (12), we commenced testing viral susceptibility in two available bat cell lines, BFK from *Myotis daubentonii* (18) and Tb-1 from *Tadarida brasiliensis*. Although BFK cells did not support SADS-CoV replication, it replicated efficiently in Tb-1 cells (Fig. 1A and Fig. 2), suggesting that other bat species in addition to horseshoe bats are likely susceptible to SADS-CoV infection.

Interestingly, SADS-CoV protein expression was detected in almost all of the rodent cells (hamster, gerbil, mouse and rat) including BHK-21, which is not susceptible to other known human CoVs such as SARS-CoV and MERS-CoV (28, 29) as well as three swine enteric CoVs,

Journal of Virology

JVI

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

437 PEDV, PDCoV and TGEV (25). Given the fact that SADS-CoV infects both primary and
438 passaged or primary cell lines originating from rodents, we hypothesized that rodents may be
439 susceptible to SADS-CoV infection. To explore this possibility, we challenged wild-type B6
440 mice with SADS-CoV by two different inoculation routes.

441 The challenged animals neither succumbed to infection nor manifested any signs of
442 gastroenteritis. In fact, experimental infection of neonatal piglets with a higher dose of purified
443 SADS-CoV in our laboratory only resulted in mild diarrheal signs or subclinical infection (11).
444 Also, there was a lack of robust viral replication in the intestines during infection, and no tissue
445 damage was detected throughout the intestines (Fig. 3B and 3C), reflecting the suboptimal
446 infection by SADS-CoV in immunocompetent wild-type mice. On the contrary, the virus had
447 more efficient replication within the spleen, reflected by a continuous detection of viral genomic
448 RNA in the immune cells at all time points over a 28-day period (Fig. 3D). The phenotype was
449 also consistent with the replication kinetics in extracted splenocytes *in vitro*, in which viral
450 genomic RNA peaked and plateaued at 72 hpi (Fig. 4G and 4I). This data collectively led to
451 speculation that SADS-CoV favors splenic cells over other tissues. The most logical explanation
452 for these tissue-specific discrepancies in virus replication is: i) target cells are more concentrated
453 in the spleen and more sporadic in the intestine; or ii) splenic immune cells have enhanced
454 expression of the unknown receptor(s) over intestinal cells. The animals were more susceptible
455 to i.p. infection, resulting in higher virus replication in the distal section of the small intestine,
456 large intestine and spleen, and perhaps a delayed clearance of viral infection in the cecum (Fig.
457 3B to 3E), suggesting the important role of mucosal immunity for controlling early infection in

Accepted Manuscript Posted Online

Journal of Virology

JVI

Journal of Virology

Downloaded from http://jvi.asm.org/ on October 22, 2019 at Columbia University Libraries

458 SADS-CoV in mice. It should be note that mice (C57BL/6J mice in this study) may not be the
459 optimal rodent species for SADS-CoV infection, as wild rats are more commonly seen in
460 Chinese pig farms. In addition, other transmission routes may be considered. Recently, PDCoV
461 has been shown to possibly spread via the respiratory route in addition to fecal-oral transmission
462 (30). Therefore, it will be interesting to try intranasal route for inoculation in rats or the other
463 rodent species to mimic SADS-CoV natural transmission in future studies.

464 More interestingly, we identified DCs to be the precise cell population that supported
465 SADS-CoV replication (Fig. 5). There have been a few reports of immune cell tropism for CoVs.
466 Macrophages are susceptible to MHV infection, representing the largest group of innate immune
467 cells that infiltrate the central nervous system after infection with neurotropic MHV strains (31).
468 In addition, based on the fact that SARS-CoV spike-pseudotyped HIV-based vectors can
469 efficiently transduce human DCs, Kobinger *et al*. hypothesized that SARS-CoV infection in
470 immature DCs contributes to viral pathogenesis (32). Yang *et al*. demonstrated that SARS-CoV
471 can infect myeloid DCs via S glycoprotein-associated cell entry, and DC infection mediated viral
472 transmission to other cells *in vivo* (33). These previous evidences support our present results,
473 showing that SADS-CoV can efficiently replicate in DCs.

474 Furthermore, this study gives us a novel inspiration that rodents may potentially serve as
475 susceptible hosts for SADS-CoV in addition to bats and pigs. Of note, the species *Rhinolophus*
476 *bat α-CoV HKU2*, including SADS-CoV, possesses unique S genes closely related to the
477 betacoronavirus (β-CoV), in a manner similar to some globally distributed rodent α-CoVs (11, 34,
478 35), implying an unknown evolutionary connection between the bat α-CoV HKU2 and rodents

479 α-CoVs. In the field conditions of China, direct contact between pigs and flying bats is a low
480 probability; however, rodents (especially rats) are frequently visible in the swine industry,
481 causing great nuisance due to feed loss. It is possible that as bats prey on insects near pig
482 facilities, they leave feces containing HKU2-like CoVs that contaminate pig feed, which is then
483 eaten by pig and rodents that subsequently become carriers of SADS-CoV. Rats and mice are
484 increasingly implicated as external vectors for a wide range of different pig pathogens, such as *L.*
485 *intracellularis* (36). Rodents not only spread pathogens, but also harm the practitioners of the
486 swine industry, as they are thought to be the major source of leptospirosis in pigs and piggery
487 workers (37). Future study on identifying SADS-CoV-positive samples in rodents near pig farms
488 are warranted to test this hypothesis.

489 In addition to rodents, we also measured the SADS-CoV susceptibility of cell lines from
490 humans, monkeys, chickens and dogs, revealing a remarkably broad spectrum of tropism (Table
491 1 and Fig. 1). As for the ability of SADS-CoV to grow efficiently in human cell lines, we should
492 not underestimate the risk that this bat-origin CoV may 'jump' from pigs to humans. It is
493 noteworthy that camel workers with high rates of exposure to camel nasal and oral secretions had
494 evidence of MERS-CoV infection (38). Considering that SARS-CoV and MERS-CoV originated
495 from bats and spread from one species to another through intermediate hosts (civets and camels,
496 respectively), SADS-CoV may pose a similar risk to human health through transmission from
497 pigs or other susceptible hosts.

498 The cell susceptibility study and testing of overexpression of four known CoV receptors in
499 non-susceptible MDCK cells (Fig. 6) demonstrated that SADS-CoV might use a new receptor

molecule that is conserved in bats, pigs, rodents, chickens, monkeys and humans, indicating a low barrier to cross-species transmission. This is in line with the unusual feature of SADS-CoV's apparently broad species tropism.

In summary, these results provide important insights into the ecology of this bat-origin CoV, highlighting the possibility of its jumping interspecies barriers and the potential role of rodents as susceptible hosts in the field. Identification of the unknown SADS-CoV cellular receptor and further surveillance of other animal populations are needed to fully understand the biology of SADS-CoV.

629 **Figure 1. Immunofluorescence assay showing susceptibility of different cell lines to**
630 **SADS-CoV infection.** Immunofluorescence assay of cells infected with SADS-CoV at an
631 MOI=0.01 was performed using rabbit anti-SADS-CoV-M polyclonal Ab (200× magnification)
632 and Alexa Fluor 488-conjugated anti-rabbit IgG as secondary antibody, with DAPI for
633 visualization of cell nuclei. Mock-infected cells were treated with the same procedures as
634 appropriate. Cells were tested from different species of origin, including: **(A)** Bats (BFK and
635 Tb-1); **(B)** Hamsters (CHO and BHK-21); **(C)** Mice (NIH/3T3 and RAW264.7); **(D)** Rats
636 (BRL-3A and NRK-52E); **(E)** Humans (Huh-7, HepG2, 293T, A549, and HeLa); **(F)** Monkeys
637 (Marc-145, Cos-7, BSC-40, and Vero); **(G)** Pigs (ST, PK15, LLC-PK1, and IPEC-J2); **(H)**
638 Chickens (DF-1); **(I)** Dogs (MDCK); and **(J)** Gerbil primary kidney cells.

639

640 **Figure 2. Growth of SADS-CoV in different cell lines through five days post-infection.** To
641 determine the effect of trypsin on SADS-CoV infection, each cell line was infected in three
642 conditions: **(A)** "No trypsin" treatment: inoculated with SADS-CoV diluted in maintenance
643 medium (MM) for 2 h, and subsequently replaced with MM; **(B)** "Pre-trypsin" treatment:
644 inoculated with SADS-CoV diluted in MM containing 5 μg/ml trypsin (MMT) for 2 h, and
645 subsequently replaced with MM; and **(C)** "Double-trypsin" treatment: inoculated with
646 SADS-CoV in MMT, and subsequently replaced with MMT. Infection supernatants were

collected at 12, 24, 36, 48, 72 and 120 hpi for viral load detection by a qRT-PCR assay targeting the viral N gene. Data is expressed as the mean viral load (log_{10} copies/µl) ± standard deviation (SD), and all experiments were performed in triplicate. The 293T, CHO, BRL-3A and NRK-52E cell lines did not survive in the presence of trypsin. **(D)** Infectious titers ($TCID_{50}$/ml) of SADS-CoV secreted from HeLa, Vero, Tb-1, BHK-21 PK-15 and MDCK cells were determined on Vero cells.

Figure 3. SADS-CoV infection of mice. C57BL/6J WT mouse were infected per orally (p.o; black) or intraperitoneally (i.p; red) with 5×10^5 $TCID_{50}$ of purified SADS-CoV. Viral loads in different tissue samples including **(A)** stomach, **(B)** small intestinal segments, **(C)** large intestinal segments, **(D)** lymphoid tissues, **(E)** the other organs (liver, kidney, heart and lung) and **(F)** feces collected at 1, 3, 5, 7, 14, 21, and 28 days post-infection (dpi) were determined by qRT-PCR; MLN: Mesenteric lymph nodes. Data are from three independent experiments, and each symbol represents titers from an individual sample (*: $p<0.05$). The limit of detection was 1×10^2 genome copies/mg. **(G)** SADS-CoV IgG antibodies were detected in serum samples collected at euthanasia, using an ELISA based on purified SADS-CoV virus particles.

Figure 4. SADS-CoV replication in mouse splenocytes. (A) Hematoxylin & eosin staining (HE) and immunohistochemistry (IHC) were performed on sections of spleen from intraperitoneally infected mice and **(B)** Mock-infected mice at 3 dpi, using anti-dsRNA antibodies to identify splenic cells that support active virus replication. **(C)** SADS-CoV infection could also be

Abstract

A new highly virulent swine acute diarrhoea syndrome coronavirus (SADS-CoV) emerged in Guangdong province in 2017 followed by fatal diarrhoea that involved the death of 24,693 piglets. And yet from May 2017 to January 2019, there were no new SADS cases arising in pig herds in Guangdong. In this study, we reported the recent diarrhoea outbreak of SADS-CoV in Southern China on February 2019. Intestinal samples collected from diarrhoeal piglets were detected for common swine virus and confirmed that SADS-CoV was responsible for the diarrhoea case. Meanwhile, serological investigation of sows' sera implied that SADS-CoV has existed in the farm and PEDV antibody may not directly contribute to the amplification of SADS-CoV. Homology and phylogenetic analysis of the whole genome showed that the re-emerging SADS-CoV strain shared high sequence identities with existing SADS-CoV strains and all strains clustered together in Alpha coronavirus. All in all, the report herein emphasized the re-emerging of SADS-CoV and highlights continuous monitoring for this virus.

KEYWORDS
phylogenetic analysis, re-emerging, SADS-CoV, Southern China

1 | INTRODUCTION

Swine acute diarrhoea syndrome (SADS) was first identified in South China in January 2017 as a disease causing high mortality in neonatal piglets (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). It is quickly demonstrated that the causative agent of SADS is a novel HKU2-related coronavirus, swine acute diarrhoea syndrome coronavirus (SADS-CoV) which originated from the same genus of horseshoe bats (*Rhinolophus*) as severe acute respiratory syndrome coronavirus (SARS-CoV), but the mechanism of transmission of bat-originated coronavirus in pigs needs further illumination (Cui, Li, & Shi, 2019; Zhou et al., 2018). Based on the analysis of genomes, SADS-CoV is classified into the genus *Alphacoronavirus* within the subfamily *Orthocoronavirinae* of the family *Coronaviridae* (Gong et al., 2017; Pan et al., 2017; Zhou et al., 2018). So far, besides porcine epidemic diarrhoea virus (PEDV), transmissible gastroenteritis virus (TGEV) and porcine deltacoronavirus (PDCoV), SADS-CoV is the fourth porcine enteric coronavirus that circulated in pigs in China (Dong et al., 2015; Xuan et al., 1984). A retrospective investigation showed that SADS-CoV emerged in China at least since August 2016 (Zhou et al., 2019). Li et al. (2018) reported one SADS-CoV strain that was isolated from fecal and small intestinal samples collected from Fujian province and suggested that SADS-CoV might have spread from Guangdong to Fujian province.

In the first outbreak of SADS-CoV occurring between January and May 2017, in order to reduce mortality in suckling pigs, the minced intestines from acutely infected piglets were filtered, centrifuged and inactivated before feeding back to pregnant sows to allow maternal antibodies to be obtained in neonatal piglets. Hence, after May 2017, the epidemic was controlled. And with a period of quiescence, SADS-CoV seemed to have disappeared from pig herds in South China. While on February 2019, there was a large-scale

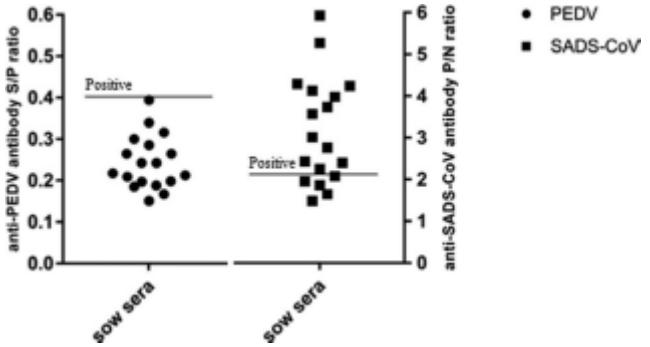

FIGURE 1 The results of ELISA test, *n* = 18 sows sera from outbreak farm. Detection of PEDV antibodies, sample S/P ratios ≥ 0.4 were considered positive. Detection of SADS-CoV antibodies, P/N ratios ≥ 2.1 were considered positive

outbreak of approximately 2000 piglets dying of diarrhoea in one farm, which was near the origin of the SADS pandemic in 2017. The extensive aetiological investigation for common swine viruses suggested that the causative agent of this recent diarrhoea outbreak was SADS-CoV. In this study, we compared the infections of piglets with the original and re-emerging SADS-CoV strains by clinical signs, epidemiological investigation, serological investigation and phylogenetic analysis. The results highlight the significance of SADS-CoV and the disease it causes.

At the beginning of the latest outbreak on February 2019, infected suckling piglets developed acute diarrhoea, vomiting and died after 2–6 days of the diarrhoea, which were consistent with the clinical signs reported in SAD-CoV outbreaking farms (Zhou et al., 2018). Two weeks after the onset, mortality did not increase due to the effective inactivated SADS-CoV vaccine which was propagated in vitro (data unpublished). Clinical small intestine samples were collected rapidly from piglets, and intestinal samples were homogenized, centrifuged and filtered for virus isolate. Viral nucleic acid was extracted using TRIzol reagent (Invitrogen, USA) according to the manufacturer's instruction. The potential swine viral pathogens were examined, including SADS-CoV, PEDV, PDCoV, porcine rotavirus (RV), TGEV, reovirus (REO), senecavirus A (SVA), foot and mouth disease virus (FMDV), porcine pseudorabies virus (PRV), porcine circovirus 2 (PCV2), porcine circovirus 3 (PCV3), porcine reproductive

and respiratory syndrome virus (PRRSV), porcine parainfluenza virus 1 (PPIV1), swine influenza virus (SIV), atypical porcine pestivirus (APPV), haemophilus parasuis (HPS), hog cholera (HC), porcine parvovirus (PPV), porcine bocavirus (PBoV), porcine sapelovirus (PSV) and porcine kobuvirus (PKV) by PCR or RT-PCR following the established protocol of Key Laboratory of Animal Health Aquaculture and Environmental Control. The extensive aetiological investigations for common swine viruses showed that only SADS-CoV was detected positively, which suggested that the causative agent of the most recent diarrhoea outbreak on February was SADS-CoV.

Furthermore, a total of 18 blood samples were simultaneously collected from healthy sows for serological investigation. Sera samples were obtained after coagulation and centrifugation (2,000 *g*, 10 min) and stored at −20°C until ELISA implemented. The PEDV antibody production was detected by means of commercial ELISA test kit (ZhenRui, China), of which, sample S/P ratios with ≥0.4 were considered positive and <0.4 were considered negative. And for SADS-CoV, ELISA was conducted following the modified procedures established in Key Laboratory of Animal Health Aquaculture and Environmental Control (P/N ≥ 2.1 considered positive). The absorbance at 450 nm wavelength was measured (Multiskan™ FC, Thermo Fisher). The results of ELISA assay revealed that all sera (100%) were negative for the PEDV and 13 of 18 (72.2%) were positive for SADS-CoV (Figure 1). In our previously clinical investigations, PEDV had caused prior outbreaks at most farms with SADS-CoV outbreaks (Zhou et al., 2018). It is possible that the presence of PEDV antibody may have somehow facilitated the amplification of the SADS-CoV. However, our results showed that PEDV antibodies were undetectable in all SADS-CoV antibody-positive sera samples, suggesting that it is SADS-CoV that caused the lethal infection in pigs on February 2019. Collectively, the re-emergence of SADS-CoV in pig herds in South China was confirmed by ELISA test and the association between PEDV and SADS-CoV infection requires further validation.

Subsequently, one SADS-CoV genome was amplified as previously described (Zhou et al., 2019). The novel SADS-CoV strain was named as SADS-CoV/CN/GDLX/2019 (accession number: MK651076). Sequence alignment and phylogenetic analysis were performed with Lasergene coresuite 10 (DNASTAR Inc.). Phylogenetic tree was constructed using the neighbour-joining method with MEGA 7.0 software (Kumar, Stecher, & Tamura, 2016). Bootstrap analysis was carried out on 1,000 replicate data sets

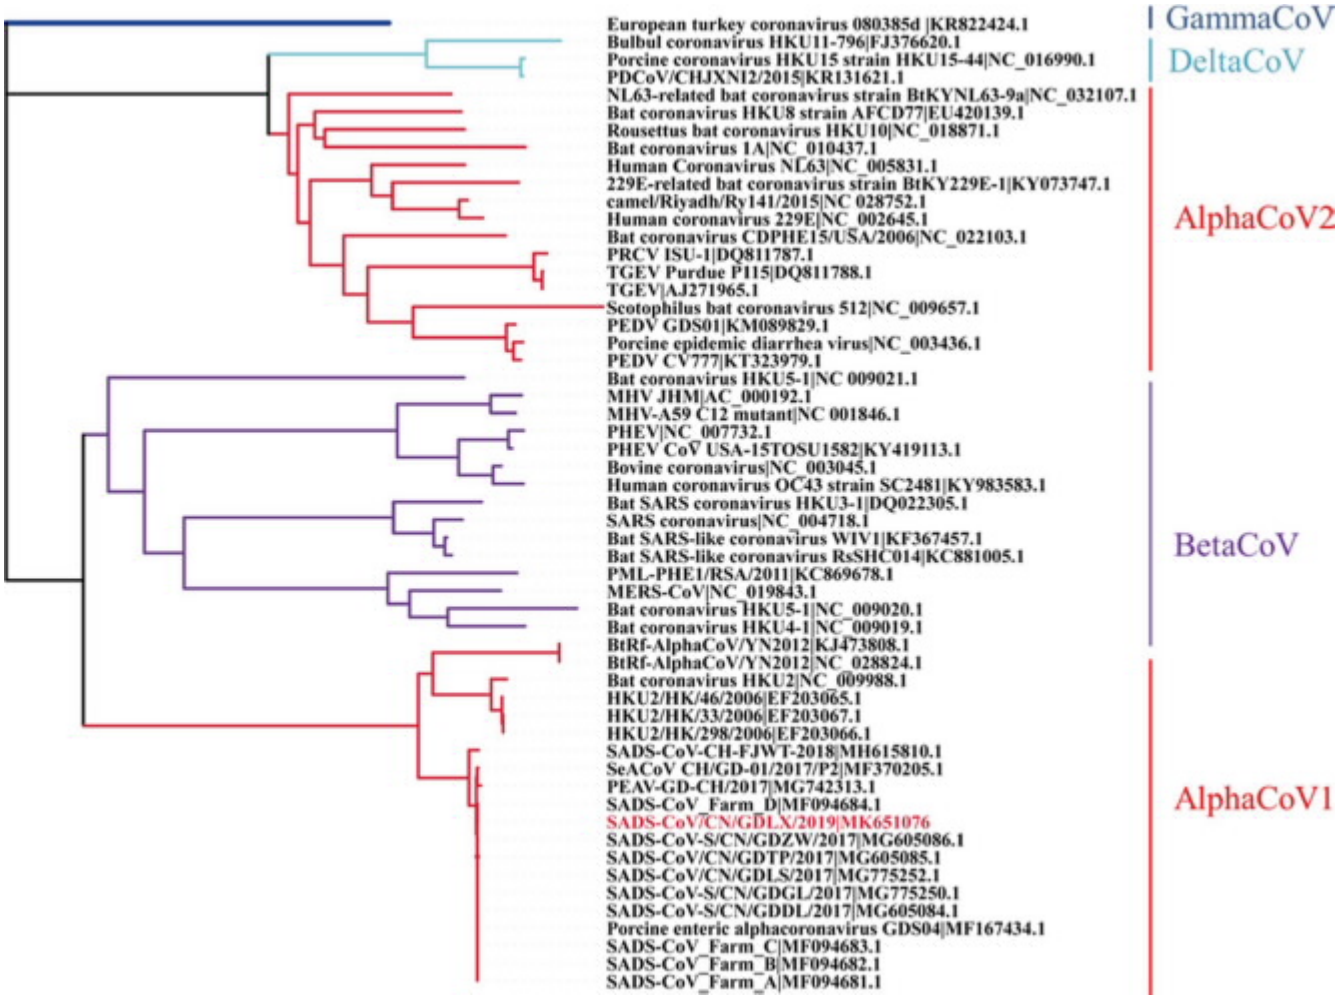

FIGURE 3 Phylogenetic analysis of the S gene of SADS-CoV and reference coronavirus species. The tree was constructed using MEGA 7.0 software with neighbour-joining methods and 1,000 replicate sets on bootstrap analysis [Colour figure can be viewed at wileyonlinelibrary.com]

(Felsenstein, 1985). For the whole genomes, sequence alignment results revealed that the nucleotide identities between SADS-CoV/CN/GDLX/2019 and previously reported SADS-CoV strains ranged from 99.3% to 100%. Moreover, the phylogenetic tree indicated that the novel SADS-CoV complete genome clustered together with other reported SADS-CoV strains and located in the Alpha coronavirus branch (Figure 2). Phylogenetic analysis based on S genes was also conducted, and the result showed that all SADS-CoV, bat HKU2 and BtRf-AlphaCoV strains were separated from other AlphaCoVs and clustered within BetaCoVs (Figure 3), which is consistent with previous studies (Pan et al., 2017; Xu et al., 2019; Zhou et al., 2019). Notably, the S gene of SADS-CoV/CN/GDLX/2019 had high identities of 99.2%–99.9% with other SADS-CoV strains detected in Guangdong and lowest identities of 97.5% with SADS-CoV-CH-FJWT-2018 reported from Fujian. Additionally, the comparative analysis of amino acids encoded by S gene revealed that the S protein of the novel strain had a two-amino-acid mutation (F306 and I882) compared with that of other SADS-CoV strains. It is well known that the S protein of coronavirus play an important role in cellular entry and determining the immunogenicity (Li, Frank, He, Peter, & Berend-Jan, 2016). In view of the lowest identities of Spike gene between the strains from Guangdong and Fujian, continuous monitoring of SADS-CoV genetic evolution is important for better understanding its epidemiology and establishing efficient strategies against its further circulating in pigs in China.

Here, we reported a new case of acute diarrhoea outbreak from a swine farm in Guangdong province on February 2019. Pathogenic and serologic analysis determined that SADS-CoV re-emerged in Guangdong and was responsible for the recent acute diarrhoea outbreak. Phylogenetic analysis based on whole genomes showed that SADS-CoV/CN/GDLX/2019 shared high nucleotide identities with previously reported SADS-CoV strains. Taken together, our study highlighted the significant threat of SADS-CoV and the potential outbreak of SADS epidemic in following months in Guangdong. Therefore, the persistent surveillance and vaccination countermeasures will be necessary to control the spread of SADS-CoV.

The Epidemiological Characteristics of an Outbreak of 2019 Novel Coronavirus Diseases (COVID-19) — China, 2020

The Novel Coronavirus Pneumonia Emergency Response Epidemiology Team

Abstract

Background: An outbreak of 2019 novel coronavirus diseases (COVID-19) in Wuhan, Hubei Province, China has spread quickly nationwide. Here, we report results of a descriptive, exploratory analysis of all cases diagnosed as of February 11, 2020.

Methods: All COVID-19 cases reported through February 11, 2020 were extracted from China's Infectious Disease Information System. Analyses included the following: 1) summary of patient characteristics; 2) examination of age distributions and sex ratios; 3) calculation of case fatality and mortality rates; 4) geo-temporal analysis of viral spread; 5) epidemiological curve construction; and 6) subgroup analysis.

Results: A total of 72,314 patient records—44,672 (61.8%) confirmed cases, 16,186 (22.4%) suspected cases, 10,567 (14.6%) clinically diagnosed cases (Hubei Province only), and 889 asymptomatic cases (1.2%)—contributed data for the analysis. Among confirmed cases, most were aged 30–79 years (86.6%), diagnosed in Hubei (74.7%), and considered mild (80.9%). A total of 1,023 deaths occurred among confirmed cases for an overall case fatality rate of 2.3%. The COVID-19 spread outward from Hubei Province sometime after December 2019, and by February 11, 2020, 1,386 counties across all 31 provinces were affected. The epidemic curve of onset of symptoms peaked around January 23–26, then began to decline, leading up to February 11. A total of 1,716 health workers have become infected and 5 have died (0.3%).

Conclusions: COVID-19 epidemic has spread very quickly taking only 30 days to expand from Hubei to the rest of Mainland China. With many people returning from a long holiday, China needs to prepare for the possible rebound of the epidemic.

Introduction

A cluster of pneumonia cases of unknown origin in Wuhan, China caused concern among health officials in late December 2019. On December 31, an alert was issued by the Wuhan Municipal Health Commission, a rapid response team was sent to Wuhan by the Chinese Center for Disease Control and Prevention (China CDC), and a notification was made to the World Health Organization (WHO) (*1*–*4*). Likely potential causes including influenza, avian influenza, adenovirus, severe acute respiratory syndrome coronavirus (SARS-CoV), and Middle East respiratory syndrome coronavirus (MERS-CoV) were ruled out. Epidemiological investigation implicated Wuhan's Huanan Seafood Wholesale Market, which was shut down and disinfected, and active case finding was initiated and vigorously pursued (*2*,*4*–*5*).

On January 7, 2020, the causative pathogen was identified as a novel coronavirus, and genomic characterization and test method development ensued (*2*–*6*). Now named 2019-nCoV, the virus is distinct from both SARS-CoV and MERS-CoV, yet closely related (*5*,*7*). Early cases suggested that COVID-19 (i.e. the new name for disease caused by the novel coronavirus) may be less severe than SARS and MERS. However, illness onset among rapidly increasing numbers of people and mounting evidence of human-to-human transmission suggests that 2019-nCoV is more contagious than both SARS-CoV and MERS-CoV (*3*,*8*–*11*).

On January 20, China's "*National Infectious Diseases Law*" was amended to make 2019-novel coronavirus diseases (COVID-19) a Class B notifiable disease and its "*Frontier Health and Quarantine Law*" was amended to support the COVID-19 outbreak response effort. Then, on January 23, the Chinese Government began to limit movement of people in and out of Wuhan, and two days later, it announced its highest-level commitment and mobilized all sectors to respond to the epidemic and prevent further spread of COVID-19. Characterization of the epidemiological features of COVID-19 is crucial for the development and implementation of effective control strategies. Here, we report the results of a descriptive, exploratory analysis of all cases found through February 11, 2020.

Method

Study Design

This study was a descriptive, exploratory analysis of all cases of COVID-19 diagnosed nationwide in China as of the end of February 11, 2020. As such, it in some respects uses a cross-sectional study design and hence, we have used the STROBE Guidelines (www.equator-network.org) to aid our thorough reporting of this observational study.

A public health emergency was declared, and a formal investigation began on December 31, 2019, supported by city (Wuhan Municipal Health Commission and Wuhan CDC), provincial (Health Commission of Hubei Province and Hubei Provincial CDC), and national (National Health Commission and China CDC) authorities and resources. This study was reviewed by the China CDC Institutional Review Board via a fast-track mechanism. Although individual informed consent was not required for this study, all data were handled as a deidentified set to protect patient privacy and confidentiality.

Data Source

By categorizing COVID-19 as a Class B notifiable disease, Chinese law required all cases to be immediately reported to China's Infectious Disease Information System. Entry of each case into the system was performed by local epidemiologists and public health workers who investigated and collected information on possible exposures. All case records contain national identification numbers, and therefore, all cases have records in the system and no records are duplicated. All data contained in all COVID-19 case records in the Infectious Disease Information System through the end of February 11, 2020 were extracted from the system as a single dataset and were then stripped of all personal identifying information. No sampling was done to achieve a predetermined study size and no eligibility criteria were used—all cases were included.

Variables

Patient characteristics were collected at baseline, meaning the time of diagnosis, epidemiological investigation, and entry into the Infectious Disease Information System. Patients were categorized as health workers for the occupation variable if they had active employment of any kind in a health facility (i.e., this category did not just include physicians and nurses). Patients were categorized as having a Wuhan-related exposure if they had recently resided in or visited Wuhan or if they had close contact with someone who had. The comorbid conditions variable was determined upon epidemiological investigation by patient self-reported medical history, which was not independently verified using medical records for all cases. The severity of symptoms variable was categorized as mild, severe, or critical. Mild included non-pneumonia and mild pneumonia cases. Severe was characterized by dyspnea, respiratory frequency ≥ 30/minute, blood oxygen saturation ≤93%, PaO_2/FiO_2 ratio <300, and/or lung infiltrates >50% within 24–48 hours. Critical cases were those that exhibited respiratory failure, septic shock, and/or multiple organ dysfunction/failure.

As some variables of interest (i.e., Wuhan-related exposure, comorbid condition, and case severity) are not required fields when creating records in the Infectious Disease Information System, some records have missing data for these variables.

For construction of epidemiological curves, date of onset was defined as the date on which patients self-reported the start of either fever or cough during epidemiological investigation. Cases were categorized as confirmed, suspected, clinically diagnosed (Hubei Province only), or asymptomatic. Confirmed cases were diagnosed based on positive viral nucleic acid test results on throat swab samples (some samples were tested retrospectively). Suspected cases were diagnosed clinically based on symptoms and exposures. Clinically diagnosed cases were suspected cases with lung imaging features consistent with coronavirus pneumonia. Asymptomatic cases were diagnosed based on positive viral nucleic acid test results but without any COVID-19 symptoms (e.g., fever, dry cough). The date of positive viral nucleic acid test result is used as onset date for asymptomatic cases

Analysis

For confirmed cases, demographic and clinical characteristics were summarized using descriptive statistics. Age distribution graphs were constructed using patient age at baseline for confirmed cases diagnosed in Wuhan, Hubei Province (including Wuhan), and China (including Hubei Province). Sex ratio (i.e., male:female [M:F] ratio) was also calculated. Case fatality rates were calculated as the total number of deaths (numerator) divided by the total number of cases (denominator), expressed as a percent. Observed time was summarized using person-days (PD) and

mortality was calculated as the number of deaths (numerator) divided by the total observed time (denominator), expressed per 10 PD.

For geo-temporal analysis, the county-level location of each case at time of diagnosis was used to build color-coded maps of China to indicate the numbers of cases in each province on December 31, 2019; January 10, 2020; January 31, 2020; and February 11, 2020. This analysis was performed using ArcGIS Desktop software (version 10.6; Esri; Redlands, California, USA).

The epidemiological curve for all cases was constructed by plotting the number of cases (y-axis) versus self-reported date of symptom onset (x-axis). Date of symptom onset for confirmed, suspected, clinically diagnosed, and asymptomatic cases were stacked to show total cases over time. The epidemiological curve for confirmed cases was also overlaid with the number of cases versus date of diagnosis to show the delay between onset of symptoms and diagnosis of disease.

Two subgroups were also analyzed separately using epidemiological curves: confirmed cases diagnosed outside of Hubei Province (with and without Wuhan-related exposure) and all cases diagnosed among health workers (confirmed, suspected, clinically diagnosed, and asymptomatic).

Results

Patients

A total of 72,314 unique records were extracted and data from all records were included in the analysis. Thus, all 72,314 individuals diagnosed with COVID-19 as of February 11, 2020, were included in the analysis. Among them, 44,672 cases (61.8%) were confirmed, 16,186 cases (22.4%) were suspected, 10,567 cases (14.6%) were clinically diagnosed, and 889 cases (1.2%) were asymptomatic.

Baseline characteristics of confirmed cases (n=44,672) are presented in Table 1. A majority were aged 30–69 years (77.8%), male (51.4%), farmers or laborers (22.0%), and diagnosed in Hubei Province (74.7%). Most patients reported Wuhan-related exposures (85.8%) and were classified as mild cases (80.9%).

TABLE 1. Patients, deaths, and case fatality rates, as well as observed time and mortality for n=44,672 confirmed COVID-19 cases in Mainland China as of February 11, 2020.

Abreviation: PD, person-days. -, not applicable.

* The Wuhan-related exposure variable, only includes a total of 37,269 patients and 919 deaths and these values were used to calculate percentages in the confirmed cases and deaths columns.

† The comorbid condition variable, only includes a total of 20,812 patients and 504 deaths and these values were used to calculate percentages in the confirmed cases and deaths columns.

§ The case severity variable, only includes a total of 44,415 patients and 1,023 deaths and these values were used to calculate percentages in the confirmed cases and deaths columns.

Deaths, Case Fatality Rates, and Mortality

As shown in Table 1, a total of 1,023 deaths have occurred among 44,672 confirmed cases for an overall case fatality rate of 2.3%. Additionally, these 1,023 deaths occurred during 661,609 PD of observed time, for a mortality rate of 0.015/10 PD.

The ≥80 age group had the highest case fatality rate of all age groups at 14.8%. Case fatality rate for males was 2.8% and for females was 1.7%. By occupation, patients who reported being retirees had the highest case fatality rate at 5.1%, and patients in Hubei Province had a >7-fold higher case fatality rate at 2.9% compared to patients in other provinces (0.4%). While patients who reported no comorbid conditions had a case fatality rate of 0.9%, patients with comorbid conditions had much higher rates—10.5% for those with cardiovascular disease, 7.3% for diabetes, 6.3% for chronic respiratory disease, 6.0% for hypertension, and 5.6% for cancer. Case fatality rate was also very high for cases categorized as critical at 49.0%.

Age Distribution and Sex Ratio

The age distribution of cases in Wuhan only, in Hubei Province overall, and in China overall are

presented in Figure 1. The proportion of confirmed cases 30–79 years of age at baseline (i.e., date of diagnosis) was 89.8% for cases in Wuhan city versus 88.6% in Hubei overall (which includes Wuhan) and 86.6% in China overall (which includes Hubei Province and all 30 other provincial-level administrative divisions, or PLADs). The male-to-female ratio was 0.99:1 in Wuhan, 1.04:1 in Hubei, and 1.06:1 in China overall.

Geo-Temporal Findings

On January 19, 2020, National Health Commission of the People's Republic of China confirmed that Guangdong Provincial CDC reported first imported cases of COVID-19, via the Chinese Infectious Diseases Reporting System. This was the first time COVID-19 had been reported outside of Hubei Province via the System. As of January 22, 2020, a total of 301 confirmed COVID-19 cases were reported from 83 counties in 23 provinces. On January 30, 2020, Xizang Autonomous Region (Tibet) reported its first confirmed COVID-19 case coming from Hubei Province. Thus, COVID-19 cases have been reported from all 31 PLADs (Figure 2).

As of February 11, 2020, a total 44,672 confirmed cases were reported from 1,386 counties of 31 provinces, autonomous regions, and municipalities and Hubei Province accounted for 74.7% (Figure 2E). Among them, 0.2% of cases had onset of illness before December 31, 2019 and all were from Hubei Province (Figure 2A); 1.7% had onset of illness during January 1–10, 2020, distributed in 113 counties of 22 PLADs and Hubei Province accounted for 88.5% (Figure 2B); 13.8% had onset of illness during January 11–20, 2020, distributed in 627 counties of 30 PLADs and Hubei Province accounted for 77.6% (Figure 2C); 73.1% had onset of illness during January 21–31, 2020, distributed in 1310 counties of 31 PLADs and Hubei Province accounted for 74.7% (Figure 2D).

Epidemiological Curve

Figure 3A shows the COVID-19 epidemic curve with number of cases plotted by date of patient onset of symptoms from December 8, 2019 to February 11, 2020. Confirmed, suspected, clinically diagnosed, and asymptomatic cases are stacked to show total daily cases by date of symptom onset. The inset shows that in December 2019 only 0–22 cases/day began to experience symptoms. The peak onset of symptoms for all cases overall occurred on February 1, 2020. Since then, onset of illness has declined.

Figure 3B shows the same COVID-19 epidemic curve for confirmed cases only with number of cases plotted by date of patients' onset of symptoms from December 8, 2019 to February 11, 2020. These data are overlaid with confirmed cases plotted by date of diagnosis to show the lag between the time patients fall ill and the time they actually are diagnosed and are reported to the Infectious Disease Information System. Although for confirmed cases onset of illness peaked around January 23–27, diagnosis of infection by nucleic acid testing of throat swabs did not peak until February 4.

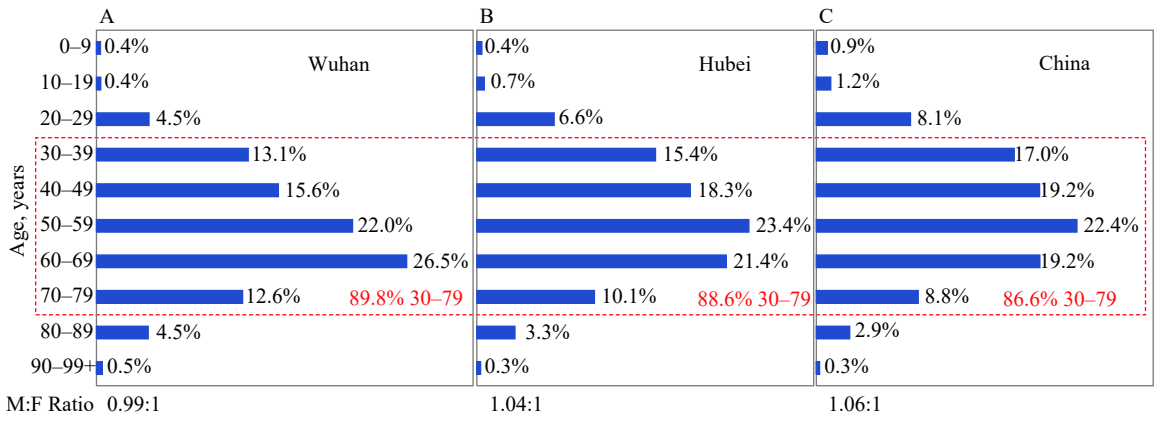

FIGURE 1. Age distribution and sex ratio of all confirmed COVID-19 cases in China through February 11, 2020. (A) patients diagnosed in the city of Wuhan only; (B) patients diagnosed in Hubei Province, which includes Wuhan as its capital city; and (C) patients diagnosed in China overall, including Hubei Province and all 30 other provincial-level administrative divisions (PLADs). Dashed red line highlights the proportion of patients in the 30–79 years age range. Sex ratio (i.e. male-to-female [M:F] ratio) is shown below each graph.

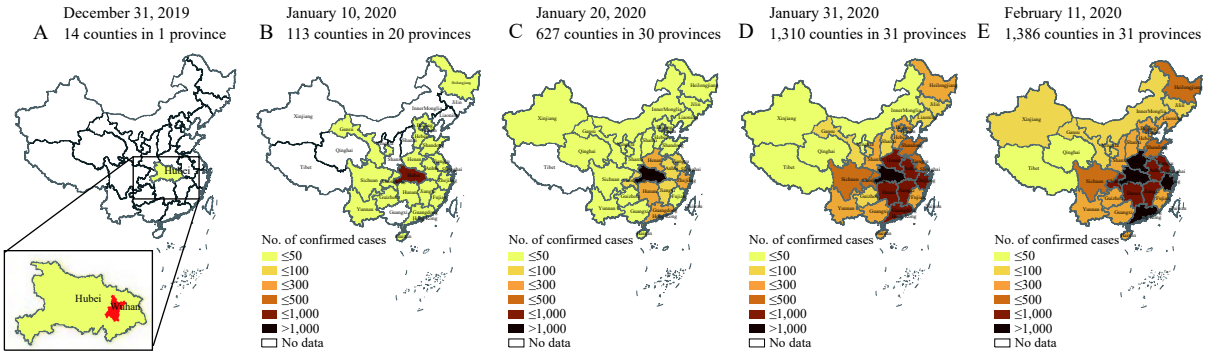

FIGURE 2. Geo-temporal spread of COVID-19 in China through February 11, 2020. (A) a total of 14 county-level administrative areas (hereafter counties) in Hubei Province only (inset) had reported cases as of December 31, 2019; (B) by January 10, 2020, 113 counties in 20 PLADs had reported cases with the highest prevalence still in Hubei Province; (C) nine days later, on January 20, 627 counties in 30 PLADs had reported cases and PLADs neighboring Hubei Province observed increasing prevalence; (D) by the end of January 31, 1,310 counties across all 31 PLADs were affected and prevalence in the central, south, and south-central regions had risen dramatically; (E) by the end of February 11, 1,386 counties nationwide were affected and prevalence in the south-central PLADs had risen to the level of Hubei.

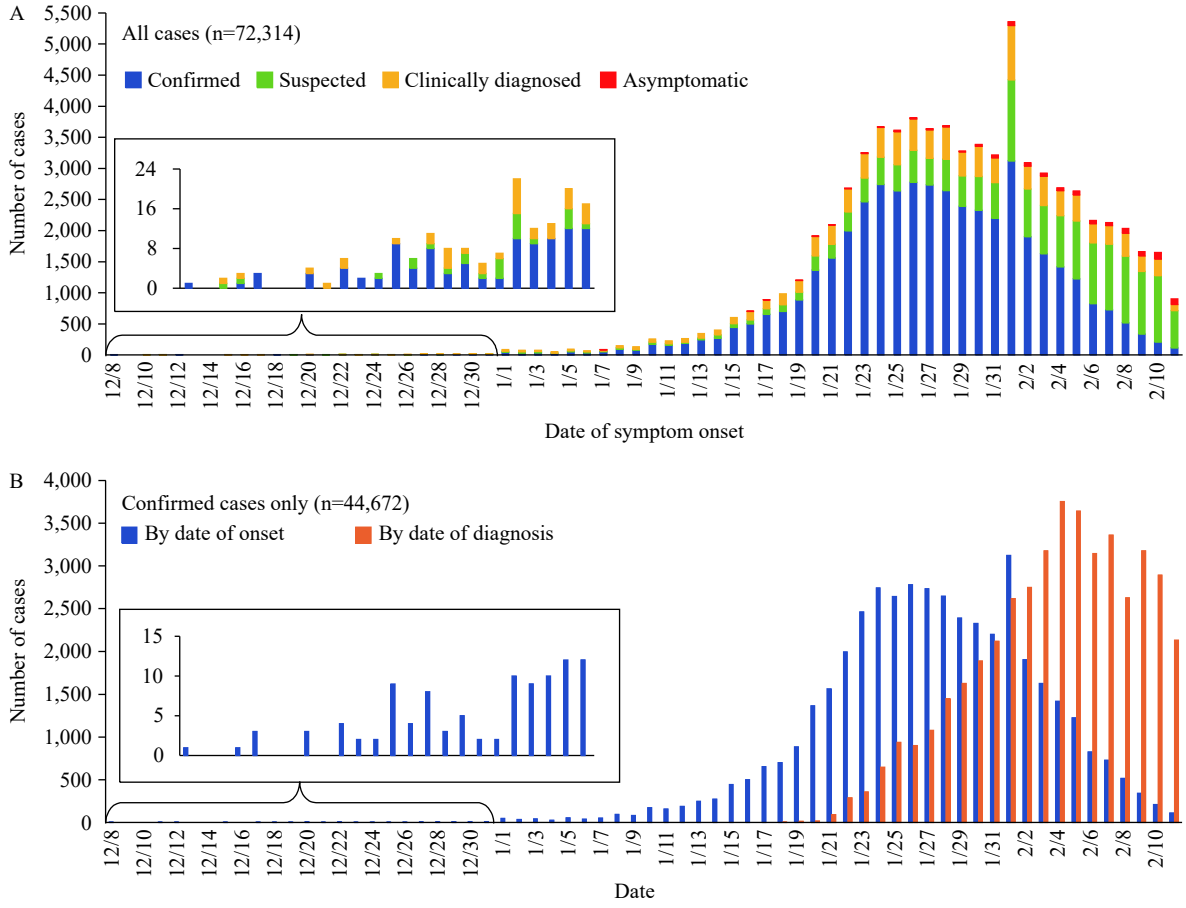

FIGURE 3. Epidemiological curves of COVID-19 in China through February 11, 2020. (A) the epidemiological curve shows the progression of illness in the outbreak over time from December 8, 2019 to February 11, 2020. A total of 72,314 cases are shown and confirmed cases (blue) are compared to suspected cases (green), clinically diagnosed cases (yellow), and asymptomatic cases (red). The inset shows a zoomed-in view of all days in December, when total daily count remained below 24 cases; (B) the epidemiological curve shows the progression of illness in the outbreak over time from December 8, 2019 to February 11, 2020 for confirmed cases only (blue). The number of cases diagnosed each day is also shown for confirmed cases only (orange). The inset shows a zoomed-in view of all days in December, when total daily count remained below 15 cases.

Subgroup Findings

Figure 4 shows the COVID-19 epidemic curve with the number of cases plotted by date of onset of symptoms from December 18, 2019 to February 11, 2020 for two subgroups—confirmed cases found outside of Hubei Province (Figure 4A) and all cases among health workers nationwide (Figure 4B). Peak timing of onset of symptoms among cases outside of Hubei Province occurred on January 27. Most of these cases (85.8%) reported having recently resided in or visited Wuhan or having had close contact with an infected individual from Wuhan. Peak timing of onset of symptoms among health worker cases occurred on February 1. In the 422 medical facilities serving COVID-19 patients, a total of 3,019 health workers have been infected (1,716 confirmed cases), and 5 have died.

Confirmed cases, case severity, and case fatality rates among health workers in different areas of China and different time periods are presented in Table 2. A total of 1,080 confirmed cases among health workers have been found in Wuhan, accounting for 64.0% of

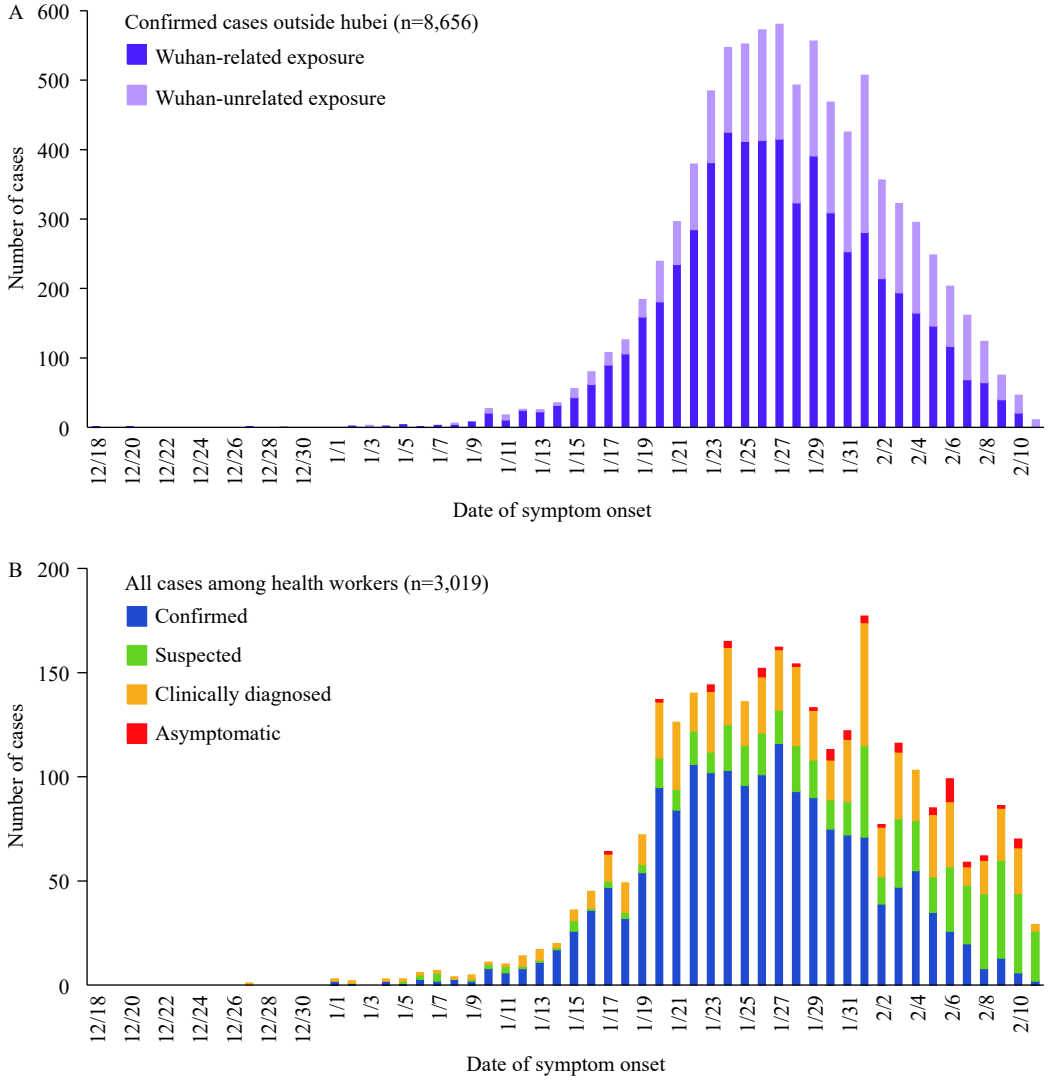

FIGURE 4. Subgroup epidemiological curves of COVID-19 in China through February 11, 2020. (A) subgroup analysis of confirmed cases discovered outside of Hubei Province only. The epidemiological curve shows the progression of illness in the outbreak over time from the onset of symptoms of the first case outside Hubei Province on December 18, 2019 through the end of February 11, 2020. Total confirmed cases outside Hubei Province, and Wuhan-related exposure (dark purple) versus Wuhan-unrelated exposure (light purple), are shown; (B) subgroup analysis of all cases among health workers only. The epidemiological curve shows the progression of illness in the outbreak over time from the onset of symptoms of the first health worker case on December 27, 2019 through the end of February 11, 2020. Total cases among health workers and confirmed (blue) versus suspected (green), clinically diagnosed (yellow), and asymptomatic (red) cases are shown.

national total. An additional 394 health worker cases (23.3%) were found in Hubei Province (excluding Wuhan), and 214 cases (12.7%) were found in the other 30 PLADs. The proportion of health worker cases that were severe or critical was 17.7% in Wuhan, 10.4% in Hubei Province, 7.0% in the remaining 30 PLADs, and 14.6% overall. The proportion of health worker cases in Wuhan classified as severe or critical declined from 38.9% in early January to 12.7% in early February. In China overall, the severe or critical cases among health workers also declined—from 45.0% in early January to 8.7% in early February.

Discussion

A main finding of this characterization and exploratory analysis of the first 72,314 cases of COVID-19 found in China in the 40 days between first recognition of the outbreak of pneumonia with unknown etiology on December 31, 2019 to the end of the study period on February 11, 2020 is that this novel coronavirus is highly contagious. It has spread extremely rapidly from a single city to the entire country within only about 30 days. Moreover, it has achieved such far-reaching effects even in the face of extreme response measures including the complete shutdown and isolation of whole cities, cancellation of Chinese New Year celebrations, prohibition of attendance at school and work, massive mobilization of health and public health personnel as well as military medical units, and rapid construction of entire hospitals.

In light of this rapid spread, it is fortunate that COVID-19 has been mild for 81% of patients and has a very low overall case fatality rate of 2.3%. Among the 1,023 deaths, a majority have been ≥60 years of age and/or have had pre-existing, comorbid conditions such as hypertension, cardiovascular disease, and diabetes. Moreover, the case fatality rate is surprisingly highest among critical cases at 49%, and no deaths have occurred among those with mild or even severe symptoms (Table 1).

A major contribution of our study is a first description of the COVID-19 epidemic curves. We interpret the overall curve (Figure 3A) as having a mixed outbreak pattern—the data appear to indicate a continuous common source pattern of spread in December and then from early January through February 11, 2020, the data appear to have a propagated source pattern. This mixed outbreak time trend is consistent with the working theory that perhaps several zoonotic events occurred at Huanan Seafood Wholesale Market in Wuhan allowed 2019-nCoV to be transmitted from a still-unknown animal into humans and, due to its high mutation and recombination rates, it adapted to become capable of and then increasingly efficient at human-to-human transmission (*3*,*8*).

The early days of the outbreak have been reminiscent of SARS and MERS, and indeed, the discovery that the causative agent was a closely-related, never-before-described coronavirus predicted potential for nosocomial transmission and so-called "super-spreader" events (*8*). Unfortunately, 2019-nCoV did indeed infect health workers in China via nosocomial transmission. Here we offer a first description of the 1,716 confirmed cases among health workers. Overall, they also display a likely mixed outbreak pattern—perhaps the data are characterized by a point source curve beginning in late December 2019, which

* CFR presented here was calculated as number of deaths (numerator) divided by total number of confirmed cases in the row (denominator), expressed as a percent.

was eclipsed by a higher magnitude continuous source curve beginning on January 20, 2020. To date, there is no evidence of a super-spreader event occurring in any of the Chinese health facilities serving COVID-19 patients. However, we do not know whether this is due to the nature of the virus itself or whether these events have been successfully prevented.

It is these authors' sincere hope and intent that this new analysis, on what has become a "public health emergency of international concern," (*12*) helps to inform health and public health workers preparing for or perhaps already experiencing COVID-19 in their populations. This study provides important insight into several crucial open questions on this epidemic and how to design strategies to effectively control it (*3*). For instance, the downward trend in the overall epidemic curve suggests that perhaps isolation of whole cities, broadcast of critical information (e.g., promoting hand washing, mask wearing, and care seeking) with high frequency through multiple channels, and mobilization of a multi-sector rapid response teams is helping to curb the epidemic.

China's response is certainly an echo of lessons learned during SARS and is a tribute to the work China and other low- and middle-income countries have been doing, with the much-needed help of international partners, over the past few decades to build infectious disease surveillance systems and public health infrastructure capable of catching outbreaks early and responding swiftly using evidence-based best practices. The 2019-nCoV and other coronaviruses may continue to adapt over time to become more virulent (*3*), and zoonosis is not going to stop. We must remain vigilant, hone our skills, fund our defenses, and practice our responses, and we must help our neighbors to do the same.

The very large number of cases included in our study was a major strength. Nevertheless, our study did have some important limitations. Firstly, a large proportion of cases included in our analysis (37%) were not confirmed by nucleic acid testing since this process is slow, labor intensive, and requires specialized equipment and skilled technicians. Yet all 72,314 cases were at least diagnosed clinically and investigated by trained epidemiologists. Secondly, some records did have missing data for a few important variables of interest—Wuhan-related exposure, comorbid conditions, and case severity—which limits our ability to draw conclusions from the data.

In conclusion, the present descriptive, exploratory analysis of the first 72,314 cases of COVID-19 reported through February 11, 2020 offers important new information to the international community on the epidemic in China. In particular, this analysis chronicles the extremely rapid spread of the novel coronavirus despite extreme efforts to contain it. However, important questions remain including identification of the animal reservoir, determination of infectiousness period, identification of transmission routes, and effective treatment and prevention methods including further test development, drug development, and vaccine development (*3*–*4*,*8*–*9*). As an international community, we must all be responsible partners in surveillance, communication, response, research, and implementation of evidence-based public health and clinical practice. The massive vigorous actions taken by the Chinese government have slowed down the epidemic in China and curbed spread to the rest of the world. Although the epidemic appears to be in decline in the lead up to February 11, 2020, we may yet face more challenges. Huge numbers of people will soon be returning to work and school after the extended New Year holiday. We need to prepare for a possible rebound of the COVID-19 epidemic in the coming weeks and months.

N95 Respirators vs Medical Masks for Preventing Influenza Among Health Care Personnel
A Randomized Clinical Trial

Perl, MD; for the ResPECT investigators

IMPORTANCE Clinical studies have been inconclusive about the effectiveness of N95 respirators and medical masks in preventing health care personnel (HCP) from acquiring workplace viral respiratory infections.

OBJECTIVE To compare the effect of N95 respirators vs medical masks for prevention of influenza and other viral respiratory infections among HCP.

DESIGN, SETTING, AND PARTICIPANTS A cluster randomized pragmatic effectiveness study conducted at 137 outpatient study sites at 7 US medical centers between September 2011 and May 2015, with final follow-up in June 2016. Each year for 4 years, during the 12-week period of peak viral respiratory illness, pairs of outpatient sites (clusters) within each center were matched and randomly assigned to the N95 respirator or medical mask groups.

INTERVENTIONS Overall, 1993 participants in 189 clusters were randomly assigned to wear N95 respirators (2512 HCP-seasons of observation) and 2058 in 191 clusters were randomly assigned to wear medical masks (2668 HCP-seasons) when near patients with respiratory illness.

MAIN OUTCOMES AND MEASURES The primary outcome was the incidence of laboratory-confirmed influenza. Secondary outcomes included incidence of acute respiratory illness, laboratory-detected respiratory infections, laboratory-confirmed respiratory illness, and influenzalike illness. Adherence to interventions was assessed.

RESULTS Among 2862 randomized participants (mean [SD] age, 43 [11.5] years; 2369 [82.8%]) women), 2371 completed the study and accounted for 5180 HCP-seasons. There were 207 laboratory-confirmed influenza infection events (8.2% of HCP-seasons) in the N95 respirator group and 193 (7.2% of HCP-seasons) in the medical mask group (difference, 1.0%, [95% CI, −0.5% to 2.5%]; $P = .18$) (adjusted odds ratio [OR], 1.18 [95% CI, 0.95-1.45]). There were 1556 acute respiratory illness events in the respirator group vs 1711 in the mask group (difference, −21.9 per 1000 HCP-seasons [95% CI, −48.2 to 4.4]; $P = .10$); 679 laboratory-detected respiratory infections in the respirator group vs 745 in the mask group (difference, −8.9 per 1000 HCP-seasons, [95% CI, −33.3 to 15.4]; $P = .47$); 371 laboratory-confirmed respiratory illness events in the respirator group vs 417 in the mask group (difference, −8.6 per 1000 HCP-seasons [95% CI, −28.2 to 10.9]; $P = .39$); and 128 influenzalike illness events in the respirator group vs 166 in the mask group (difference, −11.3 per 1000 HCP-seasons [95% CI, −23.8 to 1.3]; $P = .08$). In the respirator group, 89.4% of participants reported "always" or "sometimes" wearing their assigned devices vs 90.2% in the mask group.

CONCLUSIONS AND RELEVANCE Among outpatient health care personnel, N95 respirators vs medical masks as worn by participants in this trial resulted in no significant difference in the incidence of laboratory-confirmed influenza.

Health care personnel (HCP) who are routinely exposed to viral respiratory infections in the workplace[1] may transmit infection to others. It is widely recognized that HCP, as a group, incompletely adhere to infection prevention recommendations and practice standards. Inpatient respiratory protection studies suggest adherence rates vary from 10% to 84%.[2-4] While laboratory studies designed to achieve 100% intervention adherence have shown that N95 filtering facepiece respirators are more efficacious than medical masks at reducing exposure to aerosols,[5] comparative clinical effectiveness studies have been inconclusive.[3,4,6] Some experts argue that N95 respirators and medical masks are equivalent in clinical settings.[2,7] Pragmatic effectiveness trials are increasingly recognized as an essential component of medical evidence, in part because efficacy studies may overestimate effectiveness and true adherence.[8]

Disposable N95 respirators and medical masks are both worn by HCP for self-protection; however, these masks have different intended uses. N95 respirators are designed to prevent the wearer from inhaling small airborne particles,[9] must meet filtration requirements,[10] and fit tightly to the wearer's face, limiting facial seal leakage. Medical masks, frequently called surgical masks, are intended to prevent microorganism transmission from the wearer to the patient. Medical masks fit the face loosely and do not reliably prevent inhalation of small airborne particles. However, medical masks prevent hand-to-face contact and facial contact with large droplets and sprays.[11]

Clinical evidence is inconclusive regarding whether N95 respirators are more effective than medical masks for preventing viral respiratory infection among HCP, including influenza,[3,4,6,12] accounting for differing practices[2] and positions held by clinical,[7] public health,[13,14] and regulatory organizations.[15] The objective of this study was to compare[13] the effectiveness of N95 respirators vs medical masks worn by HCP in clinical practice for prevention of workplace-acquired influenza and other viral respiratory infections in geographically diverse, high-exposure, outpatient settings.

Key Points

Question Is the use of N95 respirators or medical masks more effective in preventing influenza infection among outpatient health care personnel in close contact with patients with suspected respiratory illness?

Findings In this pragmatic, cluster randomized clinical trial involving 2862 health care personnel, there was no significant difference in the incidence of laboratory-confirmed influenza among health care personnel with the use of N95 respirators (8.2%) vs medical masks (7.2%).

Meaning As worn by health care personnel in this trial, use of N95 respirators, compared with medical masks, in the outpatient setting resulted in no significant difference in the rates of laboratory-confirmed influenza.

Methods

Study Sites and Institutional Review Boards

The Respiratory Protection Effectiveness Clinical Trial (ResPECT) was approved by the human subjects research board at the National Institute for Occupational Safety and Health (protocol #10-NPPTL-05XP) and the institutional review boards (IRBs) at the 7 participating health systems, as previously described,[16] and approved or exempted by IRBs at the analysis and sample storage sites. All participants were permitted to participate for 1 or more years and gave written consent for each year of participation. Study intervention sites included outpatient settings at the Children's Hospital Colorado (Aurora), Denver Health Medical Center (Denver, Colorado), Johns Hopkins Health System (Baltimore, Maryland), Michael E. DeBakey Veterans Affairs (VA) Medical Center (Houston, Texas), VA Eastern Colorado Healthcare System (Denver), Washington DC VA Medical Center, and VA New York Harbor Healthcare System (New York). Sample storage and data analysis sites were the VA St Louis Healthcare System and St Louis University (St Louis, Missouri), University of Florida (Gainesville), University of Massachusetts (Amherst), and University of Texas Southwestern Medical Center (Dallas).

Design and Oversight

This cluster randomized, multicenter, pragmatic effectiveness trial[16] conducted between September 2011 and May 2015, with final follow-up on June 28, 2016, compared the effect of N95 respirators, used as recommended during the 2009 H1N1 pandemic,[13] and medical masks, used as recommended to prevent seasonal influenza[17,18] and other viral respiratory infections and illnesses, among HCP.[17] The investigators were blinded to the randomization until completion of the study and analysis. An independent data and safety monitoring board assessed the data. Additional details are included in Supplement 1, including the statistical analysis plan and the full protocol that was previously published in an abridged format.[16]

Participants and Setting

This trial was conducted in diverse outpatient settings serving adult and pediatric patients with a high prevalence of acute respiratory illness, including primary care facilities, dental clinics, adult and pediatric clinics, dialysis units, urgent care facilities and emergency departments, and emergency transport services.

All participants in a cluster worked in the same outpatient clinic or outpatient setting. A cluster randomized design was used to improve adherence and increase indirect effects associated with participants in a cluster using the same intervention. Participants were aged at least 18 years, employed at one of the 7 participating health systems, and self-identified as routinely positioned within 6 feet (1.83 m) of patients. Participants were full-time employees (defined as direct patient care for approximately ≥24 hours weekly) and worked primarily at the study site (defined as ≥75% of working hours). Exclusion criteria were medical conditions precluding safe participation or anatomic features that

Box 1. Criteria for Acute Respiratory Illness[a]

Signs
Coryza
Fever (temperature >37.8 °C)
Lymphadenopathy
Tachypnea (respiratory rate >25/min)
Symptoms
Arthralgias/myalgias/body aches
Chills
Cough
Diarrhea
Dyspnea
Fatigue
Headache
Malaise
Other gastrointestinal systems
Sore throat
Sputum production
Sweats
Vomiting/nausea

[a] An acute respiratory illness was defined as the presence of at least 1 sign or 2 symptoms listed, representing a change from baseline.

could interfere with respirator fit, such as facial hair or third-trimester pregnancy. Participants self-identified race and sex using fixed categories; these variables were collected because facial anthropometrics related to race and sex may influence N95 respirator fit.

Participants kept diaries that included signs and symptoms of respiratory illness, annual influenza vaccination status, and exposure to household and community members with respiratory illness. Participants also recorded their participation in aerosol-generating procedures and exposure to patients, coworkers, or both with respiratory illness daily. Participants were categorized for exposure risk by occupational roles.

Procedures, Interventions, and Group Allocation

Each year, participating sites were cluster randomized to have participants wear N95 respirators[13] or medical masks,[17,18] as previously described.[16] N95 respirator models studied were the 3M Corporation 1860, 1860S, and 1870 (St Paul, Minnesota) and the Kimberly Clark Technol Fluidshield PFR95-270, PFR95-274 (Dallas, Texas); medical mask models were the Precept 15320 (Arden, North Carolina) and Kimberly Clark Technol Fluidshield 47107 (Dallas, Texas).

Within each medical center, for each study year, pairs of clusters (clinics and other settings) were matched by the number of participants, health services delivered, patient population served, and additional personal protective equipment. One cluster was randomly assigned to the medical mask group and one to the N95 respirator group. Random allocation of clusters required using constrained randomization, a process that maintains random assignment and balance between groups.[19] Computer-generated random sequences of group assignments were generated by an individual not involved in the study implementation and data analyses. Random sequences of assignment assured that every participant in each season had an equal probability of being assigned to the N95 respirator and medical mask groups and allowed participants to switch groups between seasons. Occupational Safety and Health Administration–accepted fit testing[15] of N95 respirators was conducted annually for all study participants.

Participants were instructed to wear their assigned protective devices (ie, N95 respirators or medical masks) during the 12-week period (the intervention period) during which the incidence of viral respiratory illness and infections was expected to be highest that year, as predicted by the ALERT algorithm[20] developed for this trial. Participants were instructed to put on a new device whenever they were positioned within 6 feet (1.83 m) of patients with suspected or confirmed respiratory illness. Hand hygiene was recommended to all participants in accordance with Centers for Disease Control and Prevention guidelines.[13,17,18] Infection prevention policies were followed at each study site. Participants volunteered to participate for up to 12 weeks each intervention period, for a total of 48 weeks of intervention spanning 4 consecutive viral respiratory seasons.

Surveillance, Outcomes, and Measures of Effectiveness

Study personnel obtained swabs of the anterior nares and oropharynx[21] (FLOQSwabs UTM, Diagnostic Hybrids) from participants who self-reported symptoms of respiratory illness (**Box 1**). Symptomatic swabs were collected within 24 hours of self-report, and again if signs or symptoms persisted beyond 7 days. If symptomatic participants were not at work, samples were self-obtained using a structured process and shipped to the study laboratory. During each 12-week intervention period, 2 random swabs were obtained from all participants, typically while asymptomatic. Additionally, each year, paired serum samples obtained from all participants were assayed for influenza hemagglutinin levels before and after peak viral respiratory season.

The prespecified primary outcome was the incidence of laboratory-confirmed influenza, defined as detection of influenza A or B virus by reverse-transcription polymerase chain reaction[22] in an upper respiratory specimen collected within 7 days of symptom onset; detection of influenza from a randomly obtained swab from an asymptomatic participant; or influenza seroconversion (symptomatic or asymptomatic), defined as at least a 4-fold rise in hemagglutination inhibition antibody titers to influenza A or B virus between preseason and postseason serological samples deemed not attributable to vaccination. Individuals experiencing seroconversion were not required to have a detected symptomatic illness to meet the defined outcome. Influenza reagents used in the hemagglutination inhibition antibody assays were obtained from the International Reagent Resource Program, established by the Centers for Disease Control and Prevention.

© 2019 American Medical Association. All rights reserved.

Downloaded From: https://jamanetwork.com/ by a Health Services Research Library User on 02/27/2020

Secondary outcome measures were the incidence of 4 measures of viral respiratory illness and infection: (1) acute respiratory illness (Box 1) with or without laboratory confirmation; (2) laboratory-detected respiratory infection, defined as detection of a respiratory pathogen by polymerase chain reaction or serological evidence of infection with a respiratory pathogen during the study surveillance period(s), which was added to the protocol prior to data analysis; (3) laboratory-confirmed respiratory illness, identified as previously described,[23] defined as self-reported acute respiratory illness plus the presence of at least 1 polymerase chain reaction-confirmed viral pathogen (**Box 2**) in a specimen collected from the upper respiratory tract within 7 days of the reported symptoms and/or at least a 4-fold rise from preintervention to postintervention serum antibody titers to influenza A or B virus; and (4) influenzalike illness, defined as temperature of at least 100°F (37.8°C) plus cough and/or a sore throat, with or without laboratory confirmation.

Adherence to Group Assignment and Infection Prevention and Control Practices

Participants were reminded to adhere to protective device and hand hygiene instructions by signage posted at study sites, email, and by study personnel in person. Adherence to assigned devices were reported daily by participants as "always," "sometimes," "never," or "did not recall." In addition, study personnel observed participants' device-wearing behaviors as they entered and exited patient care rooms by conducting unannounced, inconspicuous visits to randomly selected study sites throughout the intervention period. However, to preserve patient confidentiality, monitors were not permitted to enter patient care rooms.

Statistical Analyses

Although we identified no standard definition of a "clinically significant difference," this study[16] was designed to detect a 25% relative reduction in the incidence of laboratory-confirmed influenza or respiratory illness, based on expert opinion, rather than an absolute reduction, which has been described in a previous study.[6] The total sample size required to provide 80% power to show a 25% reduction in the incidence of laboratory-confirmed influenza in the N95 respirator group compared with the medical mask group, with a type I error rate of .05, was 10 024 participant-sessions, and the sample size needed to provide 80% power to show a 25% reduction in the incidence of laboratory-confirmed respiratory illness was 5104 participant-seasons.

Comparative effects of the interventions were estimated for the primary and secondary outcomes by calculating odds ratios (ORs; for binary outcomes) and incidence rate ratios (IRRs; for count outcomes) between participant clusters randomly assigned to wear N95 respirators or medical masks. Laboratory-confirmed influenza was modeled using logistic regression and viral respiratory infection and illness outcomes were modeled using Poisson regression. Unadjusted and adjusted analyses (both prespecified) were conducted according to the statistical analysis plan (Supplement 2). The primary outcome was an adjusted analysis, as specified in the statistical analysis plan. Prespecified covariates used in adjusted analyses included age, sex, race, number of household members younger than 5 years, occupation risk level (defined as low, medium, or high), binary season-specific influenza vaccination status, the proportion of daily exposures to others with respiratory illness, categorical self-reported adherence to hand hygiene, and intervention group assignment. Prespecified adherence rates were calculated as the proportion of reports of adherence in each group reporting "always," "sometimes," "never," or "did not recall." Comparison of proportions between groups were done using χ^2 statistics and comparisons of binomial proportions. Analyses included random effects to account for correlation of outcomes at site-level and individual-level random effects to account for correlation of outcomes at the individual level for participants who participated for multiple seasons.

The primary analysis used available data on all randomized participants for the primary comparison of the intervention. A per-protocol analysis, conducted at the same time as the primary analysis, included only individuals who completed at least 8 weeks of study participation.

A sensitivity analysis was conducted using imputation to assign outcomes to participants who did not complete the study. Missing outcomes were imputed using standard multiple imputation techniques, creating multiple imputed data sets with no missing values for each analysis.[23] Details of this analysis are described in Supplement 2. Intervention group withdrawal rates and time to withdrawal were compared to assess for potential bias. In an additional sensitivity analysis, observed and self-reported exposures and adherence were compared using Pearson χ^2 tests. Mean workplace and household rates of exposure to respiratory illness were compared using mixed-effects logistic regression. For

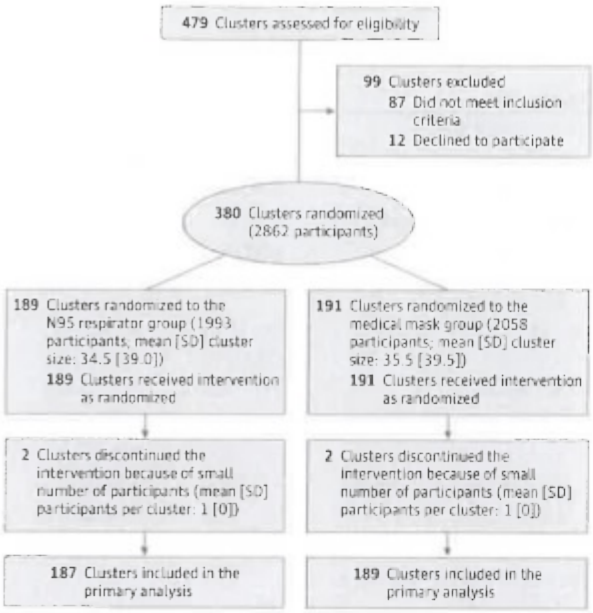
Figure 1. Study Site Enrollment, Randomization, Follow-up, and Analysis in a Study of the Effect of N95 Respirators vs Medical Masks for Preventing Laboratory-Confirmed Influenza Among Health Care Personnel



all calculations, a 2-sided type I error probability of .05 was used. Because of the potential for type I error due to multiple comparisons, findings for analyses of secondary end points should be interpreted as exploratory. All statistical analyses were performed in R version 3.3.3 (R Foundation).

Results

Participants

The study sites were randomized to provide 380 cluster-seasons of observation over 4 consecutive intervention periods. Of the 2862 participants, 1416 participated for more than 1 year or intervention period. Among 2862 unique randomized participants (mean [SD] age, 43 [11.5] years; 2369 [82.8%] women), 2371 completed the ResPECT protocol over the course of 48 weeks of intervention spanning 4 years. Among these individuals, 1446 participated in one 12-week intervention period, 723 participated in two 12-week intervention periods, and 693 participated in 3 or more 12-week intervention periods, accounting for 5180 HCP-seasons enrolled and randomized from 137 medical centers. Following randomization, 491 participants withdrew or were excluded because the cluster size was below a preestablished threshold of 2. Overall, 4689 HCP-seasons were included in the per-protocol analysis (2243 in the N95 respirator group and 2446 in the medical mask group; **Figure 1**). Some members of the primary analytic cohort did not complete all weeks of the study and were missing serological outcomes. Data were missing because of early withdrawal in 189 of 2512 participants (7.5%) in the N95 respirator group and 145 of 2668 (5.4%) in the medical mask group. In the per-protocol analysis, data were missing from 16 of 2243 participants (0.7%) in the N95 respirator group and 28 of 2446 (1.1%) in the medical mask group.

Baseline characteristics of the participants in the N95 respirator and medical mask groups were similar (**Table 1**). Daily workplace exposure to respiratory illness was reported 22.5% of the time in the N95 group and 21.6% of the time in the medical mask group, while weekly household exposure to respiratory illness was reported 3.6% of the time in the N95 respirator group and 3.4% of the time in the medical mask group (Table 1).

Illness Surveillance and Effectiveness

In the primary analysis, the incidence of laboratory-confirmed influenza infection events occurred in 207 of 2512 HCP-seasons (8.2%) in the N95 respirator group and 193 of 2668 HCP-seasons (7.2%) in the medical mask group, (difference, 1.0% [95% CI, −0.5% to 2.5%]; P = .18) (adjusted OR, 1.18 [95% CI, 0.95-1.45]).

Regarding secondary outcomes, there were 1556 acute respiratory illness events in the N95 respirator group (incidence rate [IR], 619.4 per 1000 HCP-seasons) vs 1711 in the medical mask group (IR, 641.3 per 1000 HCP-seasons) (difference, −21.9 per 1000 HCP-seasons [95% CI, −48.2 to 4.4]; P = .10; adjusted IRR, 0.99 [95% CI, 0.92-1.06]). There were 679 laboratory-detected respiratory infection events in the N95 respirator group (IR, 270.3 per 1000 HCP-seasons) vs 745 in the medical mask group (IR, 279.2 per 1000 HCP-seasons) (difference, −8.9 per 1000 HCP-seasons [95% CI, −33.3 to 15.4]; P = .47; adjusted IRR, 0.99 [95% CI, 0.89-1.09]) (**Table 2** and **Figure 2**). Overall, 371 laboratory-confirmed respiratory illness events occurred in the N95 respirator group (IR, 147.7 per 1000 HCP-seasons) vs 417 in the medical mask group (IR, 156.3 per 1000 HCP-seasons) (difference, −8.6 per 1000 HCP-seasons [95% CI, −28.2 to 10.9]; P = .39; adjusted IRR, 0.96 [95% CI, 0.83-1.11]). There were 128 influenzalike illness events in the N95 respirator group (IR, 51.0 per 1000 HCP-seasons) vs 166 in the medical mask group (IR, 62.2 per 1000 HCP-seasons) (difference, −11.3 per 1000 HCP-seasons [95% CI, −23.8 to 1.3]; P = .08; adjusted IRR, 0.86 [95% CI, 0.68-1.10]). Results were similar in the adjusted primary analysis and per-protocol analyses (Figure 2).

Intervention, Adherence, and Adverse Events

Adherence was reported on daily surveys 22 330 times in the N95 respirator group and 23 315 times in the medical mask group. "Always" was reported 14 566 (65.2%) times in the N95 respirator group and 15 186 (65.1%) times in the medical mask group; "sometimes," 5407 (24.2%) times in the N95 respirator group and 5853 (25.1%) times in the medical mask group; "never," 2272 (10.2%) times in the N95 respirator group and 2207 (9.5%) times in the medical mask group; and "did not recall," 85 (0.4%) times in the N95 respirator group and 69 (0.3%) times in the medical mask group. Participant-reported adherence could not be assessed in 784 participants (31.2%) in the N95 respirator group and 822 (30.8%) in the medical mask group (P = .84)

[a] Unless otherwise specified.

[b] Staff who have direct patient contact, such as clinical medical assistants and clinical technicians.

[c] Occupational risk based on direct patient contact, such as physical examination and/or performance of high-risk procedures (intubation, airway suctioning, nebulizer treatments, nasopharyngeal aspiration) for high risk, direct patient contact for medium risk, and no or minimal direct patient contact for low risk.

because of lack of response to surveys or lack of adherence opportunities (ie, participants did not encounter an individual with respiratory signs or symptoms).

Analyzed post hoc, participant adherence was reported as always or sometimes 89.4% of the time in the N95 respirator group and 90.2% of the time in the medical mask group. Additional details about adherence are included in Supplement 1. No serious study-related adverse events were reported. Nineteen participants reported skin irritation or worsening acne during years 3 and 4 at one study site in the N95 respirator group.

Per-Protocol Analysis and Sensitivity Analysis

Results of the per-protocol analysis can be seen in Figure 2. A sensitivity analysis assessed whether there was evidence for bias in self-reported outcomes based on group assignment. In a prespecified multiple-imputation analysis, the rates of laboratory-confirmed influenza infection events were 204 of 2243 HCP seasons (9.1%) in the N95 respirator group and 190 of 2446 HCP-seasons (7.8%) in the medical mask group. Quantitative data are available in Supplement 3.

Laboratory-confirmed influenza	6	13	52	52	55	51	94	77	207	193
Secondary Outcomes										
Acute respiratory illness	235	234	354	446	398	519	569	512	1556	1711
Laboratory-detected respiratory infection[b]	47	71	165	201	217	260	250	213	679	745
Laboratory-confirmed respiratory illness[b]	26	31	91	116	111	150	143	120	371	417
Influenzalike illness	13	10	30	45	22	50	63	61	128	166

[a] Influenza events were defined as the number of influenza infections attributed to the combination of polymerase chain reaction detection and hemagglutination inhibition assay serologies. Instances in which polymerase chain reaction and hemagglutination inhibition assay were both positive counted as 1 event.

[b] All respiratory viruses assayed, including influenza.

Discussion

In this pragmatic, cluster randomized trial that involved multiple outpatient sites at 7 health care delivery systems across a wide geographic area over 4 seasons of peak viral respiratory illness, there was no significant difference between the effectiveness of N95 respirators and medical masks in preventing laboratory-confirmed influenza among participants routinely exposed to respiratory illnesses in the workplace. In addition, there were no significant differences between N95 respirators and medical masks in the rates of acute respiratory illness, laboratory-detected respiratory infections, laboratory-confirmed respiratory illness, and influenzalike illness among participants. A sensitivity analysis suggested that the primary analysis reported was fairly robust to the missing outcome data with quantitative outcomes varying by less than 5%. This supports the finding that neither N95 respirators nor medical masks were more effective in preventing laboratory-confirmed influenza or other viral respiratory infection or illness among participants when worn in a fashion consistent with current US clinical practice.

Respiratory viruses are primarily transmitted by large droplets. Because a fraction of respiratory viruses may be transmitted by aerosol, N95 respirators have been presumed to provide better protection than medical masks against viral respiratory infections in health care settings.[2] However, definitive evidence of greater clinical effectiveness of N95 respirators is lacking. A well-designed trial[6] found the effectiveness of medical masks to be noninferior to N95 respirators, but the trial was stopped prematurely and was limited by small sample size. Two additional studies[3,4] (and a pooled analysis[12]) concluded that N95 respirators may be more effective than medical masks; however, these studies were limited by uncertain clinical significance of end points.[24] The current study was undertaken because of remaining uncertainty based on previous studies, which made it challenging for infection control clinicians to effectively implement respiratory protection programs in health care settings.[2,7,13,18,24,25]

This trial was designed to assess clinical effectiveness, taking into account many challenges of working in outpatient health care settings. This study had several strengths, including the pragmatic design; wide US geographic and climatic distribution; varied adult and pediatric outpatient settings, including emergency departments; and enrollment spanning 4 seasons of peak viral respiratory illness. Respiratory samples were obtained from symptomatic and asymptomatic participants to determine the incidence of viral respiratory infection, including individuals that were subclinical but still potentially transmissible. Influenza vaccination status information was collected. This trial was cluster randomized to avoid mixing of interventions in each clinic and clinical setting and to minimize cross-contamination from

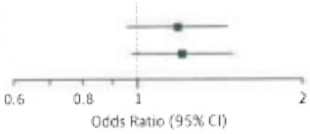
Figure 2. Primary and Secondary Outcomes of Influenza and Respiratory Illnesses and Adjusted Risk Estimates Among Health Care Personnel in the N95 Respirator Group vs the Medical Mask Group

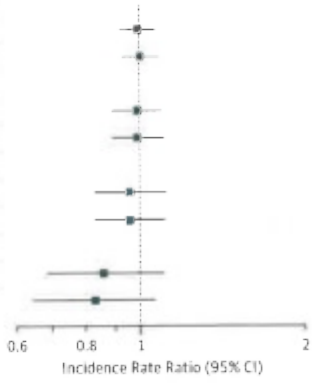
A Primary outcome

	N95 Respirator Events/Seasons	Medical Mask Events/Seasons	Incidence Rate Ratio (95% CI)
Laboratory-confirmed influenza			
ITT cohort	207/2512	193/2668	1.18 (0.95-1.45)
PP cohort	204/2243	190/2446	1.20 (0.97-1.48)



B All secondary outcomes

	N95 Respirator Events/Seasons	Medical Mask Events/Seasons	Incidence Rate Ratio (95% CI)
Acute respiratory illness			
ITT cohort	1556/2512	1711/2668	0.99 (0.92-1.06)
PP cohort	1512/2243	1656/2446	1.00 (0.93-1.08)
Laboratory-detected respiratory infection			
ITT cohort	679/2512	745/2668	0.99 (0.89-1.09)
PP cohort	664/2243	733/2446	0.99 (0.89-1.10)
Laboratory-confirmed respiratory illness			
ITT cohort	371/2512	417/2668	0.96 (0.83-1.11)
PP cohort	361/2243	406/2446	0.96 (0.83-1.11)
Influenzalike illness			
ITT cohort	128/2512	166/2668	0.86 (0.68-1.10)
PP cohort	121/2243	161/2446	0.83 (0.64-1.06)



The adjusted relative risks for the N95 respirator and medical mask groups for both the intention-to-treat (ITT) and per-protocol (PP) groups for the primary outcome and the other predetermined secondary outcomes. Values above 1 indicate higher relative odds or risk in the N95 respirator group compared with the medical mask group.

different HCP behaviors, conducted at 7 medical centers among frontline HCP in varied clinical settings with high exposure risk, and sufficiently powered to detect the predefined difference in laboratory-confirmed respiratory illness. Previous effectiveness studies[3,4,6,12,26-28] have met some, but not all, of these characteristics and have been inconclusive, contributing to the uncertainty and controversy among experts determining public health guidance, regulatory requirements, and health care delivery practices.[2,7,14,17,29] In the current study, findings were consistent across all laboratory-based outcomes and clinical syndromes. Results for the primary and secondary outcomes were in opposite directions (ie, one IRR was associated with increased risk and the other with decreased risk), although the differences were nonsignificant, further supporting a finding of no significant difference in the effectiveness of N95 respirators vs medical masks for prevention of influenza or other respiratory illness.

Limitations

This study has several limitations. First, the criteria for viral polymerase chain reaction testing may have missed participants who were infected but asymptomatic. Unrecognized infections may have increased the probability of finding no difference between interventions, even if a difference existed. Second, self-reporting of symptoms in daily diaries likely underestimated illness among HCP who often work while ill.[30] Third, despite being intentionally conducted as a pragmatic effectiveness trial,[8] incomplete participant adherence to assigned protective devices could have contributed to more unprotected exposures, increasing the probability of finding no difference between interventions even if a difference existed. However, participant-reported data indicates this did not differ by study group. Fourth, participants were not instructed to wear protective devices outside the workplace, which may have biased the results toward finding no difference between groups, although the rates of adherence did not differ by study group and household exposure was reported as much lower than workplace exposure. Fifth, only 2 N95 respirator and medical mask models were studied, limiting the ability to generalize about the protectiveness of other models. Sixth, the sample size required to definitively determine whether N95 respirators or medical masks are more effective for protection from laboratory-confirmed influenza in the health care setting required approximately 10 000 participant-seasons, which was not feasible with the available funding or resources. However, the morbidity and mortality associated with a wide range of viral respiratory infections, including novel and emerging pathogens, renders a secondary outcome in this study, laboratory-confirmed respiratory illness, important.

Conclusions

Among outpatient HCP, N95 respirators vs medical masks as worn by participants in this trial resulted in no significant difference in the incidence of laboratory-confirmed influenza.

Respiratory Protection of Health Care Personnel to Prevent Respiratory Viral Transmission

Thomas R. Talbot, MD, MPH; Hilary M. Babcock, MD, MPH

Influenza and other respiratory viruses continue to cause patient morbidity and mortality, including health care utilization for outpatient visits and inpatient and intensive care unit care. Occupational health and infection-prevention programs partner to prevent these infections among health care personnel (HCP) and their patients through a multifaceted approach that includes comprehensive strategies to achieve high rates of influenza vaccination, rational sick leave and attendance policies that do not reward coming to work while ill (presenteeism), early identification and isolation of possibly infected patients, and appropriate use of personal protective equipment (PPE). While influenza still gets the most attention, these efforts also protect HCP from other respiratory infections.

Related article page 824

Questions have been raised about the best PPE to limit HCP exposure to respiratory viral pathogens, leading to a debate between those who suggest use of medical masks and those who suggest use of particulate respirators. While official recommendations for most encounters still support the use of medical masks,[1] some concerns remain about the risk posed by the potential for small particle aerosol transmission of respiratory viruses, particularly influenza.[2] This risk has been demonstrated primarily in laboratory simulation settings[3,4] or inferred from transmission events occurring on airplanes[5] or despite PPE use.[6] As a result, particulate respirators, or even powered air-purifying respirators, have been suggested for improved protection.[7] Respirators provide filtration of smaller particles than medical masks, and the correct use of a fit-tested respirator also prevents particles of any size getting around the mask to the user's nose or mouth. However, it remains unclear if respirators provide benefits beyond medical masks in clinical settings. Prior studies attempting to address this important question have reached differing conclusions,[8-11] but have also used different study designs.

For many years, medical masks have been used to protect HCP from respiratory viral infections. In 2009, facing the first influenza pandemic in decades, "an abundance of caution" led to a recommendation for respirator use when caring for any patient infected with the emerging H1N1 pandemic influenza strain[12] until it was clear whether usual transmission routes had been altered in the new strain. The recommendation also recognized that a vaccine against the pandemic strain was not yet available and, therefore, HCP were more susceptible to infection in the event of exposure. Later, when it appeared that the transmission of pandemic H1N1 was not different from seasonal influenza, the recommendation for medical masks in most settings was reinstated. However, based on the same abundance of caution, respirators were (and are still) recommended for HCP when performing potentially aerosol-generating procedures (such as bronchoscopy), and the question of whether respirators would provide better protection during all encounters with patients infected with influenza and other respiratory virus infections has persisted.

To help address this question, in this issue of *JAMA*, Radonovich et al report the results of the ResPECT study,[13] a pragmatic, cluster randomized trial of medical masks vs respirators (fit-tested N95 masks) worn by HCP while within 6 feet (1.83 m) of a symptomatic patient. The study included HCP who worked in multiple outpatient settings, including adult and pediatric ambulatory clinics, dental practices, urgent care centers, hemodialysis units, emergency departments, and emergency medical services, over 4 seasons of peak respiratory viral illness. Participants self-reported symptoms of acute respiratory illness, which prompted polymerase chain reaction testing for a wide range of respiratory viruses. In addition, nares and oropharynx swabs were performed twice per participant per season, when participants were asymptomatic, and influenza hemagglutination inhibition titers were measured at the beginning and end of each season. Randomization to wear medical masks or N95 respirators was at the level of the cluster or clinical site and occurred anew each year so that no one site or participant used the same type of PPE for all 4 seasons. Analyses of prespecified clinically relevant outcomes occurred at the level of the participant-season, and were adjusted for age, race, sex, vaccination status, occupational exposure risk, self-reported hand hygiene adherence, and the number of children younger than 5 years at home.

The primary outcome was laboratory-confirmed influenza by either polymerase chain reaction or serology, for which the study was underpowered. The authors note that it would have required more than 10 000 HCP-seasons to have sufficient power for that outcome to detect the 25% relative reduction selected as the target, even though they did amass an impressive near 5000 HCP-seasons. Secondary outcomes included 4 other measures of respiratory illness among the participants: symptomatic acute respiratory illness with or without laboratory pathogen detection; influenzalike illness with or without influenza detection; acute respiratory illness with pathogen detection (laboratory-confirmed respiratory illness); and detection of a pathogen with or without reported symptoms (laboratory-detected respiratory infection).

Downloaded From: https://jamanetwork.com/ by a Health Services Research Library User on 02/27/2020

The study included 1993 participants in 189 clusters who were randomized to wear N95 respirators (accounting for 2512 HCP-seasons of observation) and 2058 participants in 191 clusters who were randomized to wear medical masks (2668 HCP-seasons of observation). For all outcomes, illness with or without laboratory detection of a pathogen and pathogen detection with or without reported symptoms, there were no statistically significant differences between participants wearing N95 respirators and those wearing medical masks. For the primary outcome of laboratory-confirmed influenza, 207 laboratory-confirmed influenza infection events (8.2% of 2512 HCP-seasons) occurred in the N95 respirator group and 193 (7.2% of 2668 HCP-seasons) occurred in the medical mask group (difference, 1.0%, [95% CI, −0.5% to 2.5%]; $P = .18$).

In many ways, the ResPECT study was specifically designed to address limitations of earlier studies. The cohorts that were randomized to use medical masks and N95 respirators were similar, with no significant between-group differences in job title, vaccination status, patient population served, smoking status, use of glasses or contact lenses, and presence of children at home, minimizing the risk of bias through differential exposure risk. The design included serologic testing for influenza hemagglutination inhibition titers and random polymerase chain reaction testing of asymptomatic participants to minimize the chances of missing asymptomatic or clinically mild infections. The symptoms used as criteria for an acute respiratory illness were broad and fairly nonspecific to avoid excluding participants with atypical presentations. The process developed for participants to self-collect samples decreased the risk of laboratory testing being missed because of timing or study staff access. The study included testing for other viruses in addition to influenza because influenza is not the only respiratory virus from which HCP need protection.

The study also had several limitations. One limitation was that the study was underpowered for its prespecified primary outcome. Laboratory-confirmed infections can be missed because of under-reporting of symptoms, limitations in specimen collection technique (self-collection), and delayed specimen collection (allowed up to 7 days after symptom onset). Inclusion of influenza hemagglutination inhibition testing mitigates the risk of missed infections somewhat, although only for influenza. Symptom-based outcomes are also problematic because most symptoms are not specific to the respiratory viral infections, potentially diluting the effectiveness of the intervention. To address these issues, the authors chose to include multiple outcomes, both symptom-based and laboratory-based. The finding of no difference across all of the reported outcomes is reassuring that medical masks provide comparable protection for HCP against respiratory viruses.

The ResPECT study did not directly address inpatient settings and particularly the appropriate protection for potentially aerosol-generating procedures. Although it seems unlikely that most basic principles of viral transmission differ between outpatient and inpatient settings, some differences may potentially affect transmission in inpatient settings, including higher viral burden among more symptomatic patient populations, a higher proportion of immunocompromised patients, and longer and closer interactions between HCP and patients while providing care (eg, bathing patients). It is unclear whether the effect of those possible differences would be affected by the use of respirators. For example, a 2008 study found that in usual use conditions (ie, wearing a mask while caring for possibly infected patients) there was no difference in outcomes between participants wearing medical masks vs N95 respirators in inpatient settings.[8] Additional pragmatic studies of HCP outcomes based on PPE use would still be helpful in these settings; however, such a study among inpatient HCP would require extensive funding support and likely would be quite expensive. Other studies defining changes in particle sizes and risk for pathogen transmission during patient procedures may also provide some guidance for those situations.[14]

Occasionally, the desire for an abundance of caution gets ahead of the available data and leads to changing recommended levels of protection just to be safe. These changes, which can be politically challenging to reverse, may not lead to better protection, but instead only create additional burdens on busy HCP and health care systems. The ResPECT trial provides useful data on appropriate protection against respiratory viral infections for HCP in outpatient settings. In addition to the findings reported in the current manuscript, the authors have previously noted through the ResPECT cohort the association between mandatory HCP influenza vaccination policies on vaccination rates and subsequent reductions in HCP symptomatic absenteeism.[15]

The pragmatic design of the ResPECT study reflects the conditions that many hospital epidemiologists are accustomed to: HCP may or may not wear the PPE they are supposed to, may or may not wear it correctly if they do wear it, and may self-report higher levels of adherence to hand hygiene and PPE use than noted by independent observers. Even though some may consider these elements of the study as weaknesses, these aspects increase the generalizability of the findings outside of a research study and provide reassurance to those making programmatic and policy decisions that, in outpatient settings under usual use conditions, there are no significant differences between medical masks and respirators for protection of HCP against respiratory viruses.

Evolving Priorities for Imaging Utilization Research
From Outputs to Outcomes

Deborah Levine, MD; Richard Duszak Jr, MD

In this issue of *JAMA*, Smith-Bindman et al[1] report findings from a study of advanced imaging utilization in 3 US integrated health care programs, in 4 US mixed-model insurance plans, and in individuals living in Ontario, Canada. Using electronic health record data from 2000 to 2016, the authors retrospectively characterized more than 135 million medical imaging examinations for 16 million to 21 million individuals annually, including segmenting utilization by both imaging mode and body region.

Related article page 843

Smith-Bindman et al found that among all adults, imaging rates increased significantly from 2000 to 2016 for all imaging tests other than nuclear medicine. For example, among older adults (aged ≥65 years) in US health care systems, rates of imaging with computed tomography (CT) in 2000 and 2016 were 204 per 1000 person-years compared with 428 per 1000 person-years, and in Ontario, were 161 per 1000 person-years compared with 409 per 1000 person-years. For magnetic resonance imaging (MRI), the US rates were 62 per 1000 person-years in 2000 and 139 per 1000 person-years in 2016, and the rates in Ontario were 13 per 1000 person-years in 2000 and 89 per 1000 person-years in 2016. For ultrasound, the rates in 2000 and 2016, respectively, were 324 per 1000 person-years and 495 per 1000 person-years in the United States and 332 per 1000 person-years vs 580 per 1000 person-years in Ontario. The notable exceptions to increased utilization were for nuclear medicine, which declined over time among older adults (from 94 per 1000 person-years in 2000 to 64 per 1000 person-years in 2016 in the United States and from 87 per 1000 person-years in 2000 to 74 per 1000 person-years in 2016 in Ontario) and for CT in children, which declined after 2009 in the United States and after 2006 in Ontario. Additional analyses also found a general slowing in the increase in imaging in the 3 to 5 years up to 2016.

The study findings are both interesting and provocative, but without information about discrete episodes of care, they are not immediately actionable. Without knowing who ordered this imaging (eg, physicians vs an expanding pool of nonphysician practitioners), for what indications (eg, new diagnoses or follow-up of incidental findings), and in what settings (eg, expanding emergency departments vs contracting outpatient imaging centers), more work will be necessary to translate this information into improved patient outcomes. In addition, with passage and implementation in the United States of the Affordable Care Act during the study interval, the contributing role of broader national policy on health care service utilization overall is unclear (for instance, it is not possible to determine whether the addition of a large previously underserved population to health systems may, at least in part, have contributed to these findings).

Nonetheless, utilization research remains important in guiding meaningful health policy, and imaging is associated with both substantial cost and some risk. Such work informs ongoing research and guidelines to optimize imaging

ABSTRACT

Enhanced vascular permeability in the lungs can lead to pulmonary edema, impaired gas exchange, and ultimately respiratory failure. While oxygen delivery, mechanical ventilation, and pressure-reducing medications help alleviate these symptoms, they do not treat the underlying disease. Mechanical activation of transient receptor potential vanilloid 4 (TRPV4) ion channels contributes to the development of pulmonary vascular disease, and overexpression of the high homology (HH) domain of the TRPV4-associated transmembrane protein CD98 has been shown to inhibit this pathway. Here, we describe the development of an adeno-associated virus (AAV) vector encoding the CD98 HH domain in which the AAV serotypes and promoters have been optimized for efficient and specific delivery to pulmonary cells. AAV-mediated gene delivery of the CD98 HH domain inhibited TRPV4 mechanotransduction in a specific manner and protected against pulmonary vascular leakage in a human lung Alveolus-on-a-Chip model. As AAV has been used clinically to deliver other gene therapies, these data raise the possibility of using this type of targeted approach to develop mechanotherapeutics that target the TRPV4 pathway for treatment of pulmonary edema in the future.

INTRODUCTION

Pulmonary edema is a life-threatening condition characterized by abnormal accumulation of intravascular fluid in alveolar air spaces and interstitial tissues of the lungs due to vascular leakage across the alveolar-capillary barrier.[1–4] Currently, there are no specific therapies to improve vascular permeability, and clinical management relies on providing supportive measures, including diuretics, vasoactive medications, maintenance of adequate nutrition, hemodynamic monitoring, and mechanical ventilation if necessary.[1] While mechanical ventilation is usually required for the survival of patients with severely compromised lung function, these artificial breathing motions can be detrimental and further compromise the pulmonary vascular barrier as a result of overinflation of the alveoli, a form of "barotrauma" called ventilator-induced lung injury.[5] Thus, a major challenge in pulmonary medicine is to identify molecular targets unique to lung cells that, if blocked, could prevent the increase in pulmonary vascular permeability, particularly that induced by mechanical distortion.

Transient receptor potential vanilloid 4 (TRPV4) is a promising target for the treatment of pulmonary edema due to its mechanosensitive nature,[6] along with its roles in regulating endothelial permeability,[7] epithelial barrier function,[8] lung myogenic tone,[9] and lung vascular remodeling in response to hypoxia.[10–12] TRPV4 ion channels can be activated within 4 ms after mechanical forces are transmitted across cell surface receptors, and mechanical activation of these channels, such as associated with breathing motions or vascular pressure, has been shown to contribute to pulmonary edema progression.[6,13] While chemical inhibitors of TRPV4 channel activity are known and have been shown to prevent pulmonary vascular leakage,[13,14] TRPV4 plays a ubiquitous role and is involved in the regulation of diverse bodily functions, including control of serum osmolarity,[15–22] nociception,[23–26] bone formation and remodeling,[27–30] and bladder tone.[31–34] Therefore, to reduce adverse effects and dose-limiting toxicities from off-target effects of systemic administration of TRPV4 inhibitors,[35] we explored the possibility of developing a more selective inhibitor of pulmonary vascular leakage that preferentially targets the mechanical signaling mechanism by which physical forces activate TRPV4. We have previously shown that mechanical forces that activate TRPV4 are transferred to it from integrin b1 via the transmembrane protein CD98.[6] In addition, overexpression of the high homology (HH) domain of CD98 by transfection exerted a dominant negative effect that specifically inhibited mechanical, but not chemical, activation of TRPV4.[36] However, developing this mechanotransduction-targeted approach into a therapeutic strategy requires a more clinically relevant delivery method.

Adeno-associated virus (AAV) vectors have been used for delivery of gene therapies in the clinic because they provide many advantages, including favorable safety profiles, tailorable tissue tropism, and long-term gene expression,[37] and their efficacy has been demonstrated in wide-ranging clinical trials, from hemophilia B[38] to Parkinson's disease.[39] Thus, we set out to explore whether AAV gene delivery vectors can be used to deliver a gene encoding the CD98 HH domain to demonstrate the feasibility of targeting this mechanotransduction pathway as a way to inhibit pulmonary vascular leakage. We first investigated how AAV serotype and different promoters affect the efficiency of AAV-mediated gene transfer to human pulmonary alveolar epithelial cells (HpAECs) and human primary lung microvascular endothelial cells (HpMVECs) and optimized the transduction efficiency of AAV for these cells. The delivery of the CD98 HH domain with the optimized vectors inhibited mechanical strain-induced activation of TRPV4-dependent responses, including calcium influx and cell realignment. As a proof-of-concept in a more complex biomimetic model, we demonstrated that selective inhibition of mechanical signaling through TRPV4 also suppressed pulmonary barrier leakage in a human Lung Alveolus Chip (Alveolus Chip) that has been previously shown to model multiple human pulmonary diseases with high fidelity, including pulmonary edema and pulmonary thrombosis.[13,40,41]

RESULTS

Optimization of AAV vectors for pulmonary cell transduction

Different serotypes of AAV have been reported to have differential tissue-targeting tropisms.[42–45] While no AAV vectors have been specifically optimized to target human lung alveolar epithelial cells or microvascular endothelial cells, AAV2.5T and AAV2/2 have been previously reported to have enhanced targeting efficiency to human lung airway cells[46] and other types of human endothelial cells,[47,48] respectively. AAV2.5T is an AAV chimera resulting from the combination of AAV2 (aa1-128) and AAV5 (aa129-725) with one point mutation (A581T),[40] while AAV2/2 has the AAV2 genome packaged in an AAV2 capsid.[49] Thus, we first screened these two AAV vectors using recombinant EYFP-expressing constructs and compared their transduction efficiency in HpAECs and HpMVECs. These primary donor-derived cells contain mixed populations, with HpAECs being composed of both type I and type II alveolar epithelial cells and HpMVECs containing pulmonary endothelial cells from both blood and lymphatic sources.

When added to HpAECs differentiated under air-liquid interface (ALI) culture conditions in Transwells, AAV2.5T (MOI ¼ 10 000) exhibited the highest gene delivery efficiency, with 60%–70% being transduced and stable expression sustained for at least 5 days after transduction, whereas only 4%–8% of these alveolar cells were transduced with AAV2/2 [Fig. 1(a)]. Conversely, a higher (25–30%) transduction efficiency was achieved in HpMVECs with AAV2/2 (MOI ¼ 10 000), and this expression was again sustained for at least 5 days, while only 8%–10% of these endothelial cells were transduced with AAV2.5T [Fig. 1(b)]. When these results in primary respiratory cells were benchmarked against the more commonly investigated human umbilical vein endothelial cells (HUVECs), a high gene transfer efficiency of approximately 70% for AAV2/2 (MOI ¼ 10 000) was observed after 3 days, which is consistent with previous literature results.[48] AAV2.5T was less efficient; however, it still achieved a relatively high transduction efficiency of 45% in HUVECs [Fig. 1(c)].

To further optimize transgene expression, a panel of luciferase-expressing vectors was constructed with several commonly used constitutive promoters (CMV, EF1a, and CASI), and their luciferase activities were compared two days after transduction. While the serotype affects the percentage of cells transduced, once a cell is transduced, it is the promoter that determines the amount of gene expression. From initial testing, it was found that AAV2.5T (MOI ¼ 7000) transduction of HpAECs resulted in stronger transgene expression using either EF1a or CASI promoters, while CMV, the most common promoter used in previous AAV studies, had the lowest gene expression with levels less than 1% of the other promoters [Fig. 1(d)]. Moreover, comparable results were obtained in a second type of human lung alveolar epithelial cells (A549 cells) [Fig. 1(e)]. Again, EF1a and CASI yielded the highest levels of expression, with CASI driving approximately 4-fold higher levels than EF1a. An additional commonly used promoter, CAG, was also investigated with the A549 cells, and although the activity levels were on par with EF1a, it did not result in an improvement over levels observed with EF1a or CASI [Fig. 1(e)].

We therefore proceeded to engineer EYFP-expressing AAV vectors using EF1a and CASI promoters. As we found that AAV2.5T can transduce HpMVECs as well as HpAECs under baseline conditions (albeit at approximately 3-fold lower efficiency) [Fig. 1(b)], we investigated whether integrating EF1a or CASI promoters into this vector could improve this efficiency. When transduced with these new EYFP-expressing AAV2.5T vectors, we found that the two promoters resulted in almost identical transgene expression in HpAECs (MOI ¼ 10 000) when analyzed by flow cytometry 3 days after transduction [Fig. 1(f)]. Interestingly, similar to what we observed in A549 cells, the CASI promoter was 3-fold stronger than the EF1a promoter in HpMVECs (MOI was increased to 30 000 to counterbalance the lower

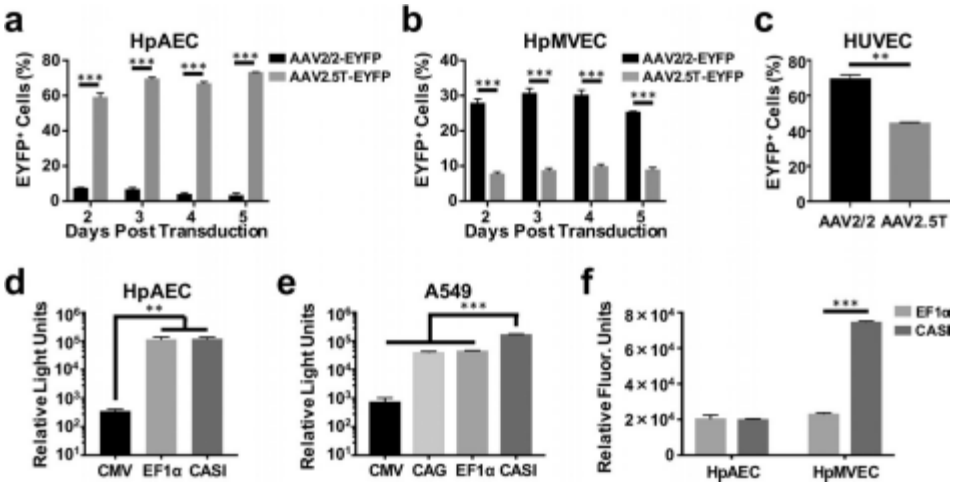

FIG. 1. AAV serotype and promoter affect viral transduction efficiency and transgene expression, respectively. AAV2/2 and AAV2.5T that carry EYFP genes were added to HpAECs (a), HpMVECs (b), or HUVECs (c) at MOI 10 000. Cells were collected 2–5 days after transduction, and the percentage of EYFP-positive cells was analyzed using flow cytometry ($n = 2$, $p < 0.01$, and $p < 0.001$). AAV2.5T-luciferase with different promoters was added to A549 (d) and HpAECs (e) at MOI 7000. Cells were collected at day two of transduction to measure luciferase activity ($n = 3$, $p < 0.01$, and $p < 0.001$). (f) AAV2.5T-EYFP with promoters EF1α and CASI was added to HpAECs and HpMVECs at MOI 10 000 and 30 000, respectively. Cells were collected at day three, and the relative fluorescent units of EYFP-positive cells were analyzed by flow cytometry ($n = 2$, $p < 0.001$).

efficiency observed in our initial studies). Due to the combination of the stronger promoter and the higher MOI used, higher EYFP expression in HpMVECs was found, despite lower transduction efficiency of AAV2.5T for these cells relative to HpAECs. Based on these results, the CASI promotor was used for all subsequent studies.

Disruption of mechanotransduction with AAV-mediated CD98 HH domain delivery

Mechanical activation of TRPV4 ion channels has been implicated in enhanced vascular permeability and pulmonary edema,[13,14] and overexpression of the CD98 HH domain by transfection with CD98 HH can inhibit the force transfer from b1-integrin to TRPV4 that mediates this response.[36] As the CD98 HH domain exerts its dominant negative effects on the cytoplasmand transmembrane delivery of large proteins is difficult to pursue clinically, we investigated whether our engineered AAV vectors with high transduction efficiency in human lung cells could be leveraged to deliver the CD98 HH domain and specifically inhibit TRPV4-mediated mechanotransduction.

Regulation of endothelial cell reorientation under cyclic mechanical strain is mediated by mechanical activation of TRPV4,[50] and thus, we used this as an initial readout of mechanotransduction inhibition. Under baseline conditions, approximately 70% of these endothelial cells and their actin cytoskeleton realigned perpendicular to the direction of the applied mechanical strain (15% cyclic strain, 1 Hz) when cultured on flexible extracellular matrix (ECM)-coated culture substrates [Figs. 2(a) and 2(b)]. In contrast, when AAV2.5T vectors encoding the CASI promotor and both the CD98 HH domain and the fluorescent marker EYFP (AAV2.5T-EYFP-CD98HH) were constructed and transduced (MOI ¼ 10 000) in HpMVECs, this strain-induced cell realignment was almost completely prevented, whereas transduction of the control AAV2.5T-EYFP vector had no detectable effect [Figs. 2a and 2(b)].

We then examined the effect of transduction of HpMVECs with AAV2.5T-EYFP-CD98HH on mechanical strain-induced activation of TRPV4-dependent calcium influx, which mediates the cellular reorientation response.[50] We did not observe an effect of CD98 HH overexpression on the resting level of the Ca^{2+} concentration in the cytosol. Furthermore, individual cells that expressed higher levels of CD98 HH (quantified by the level of EYFP expression) displayed complete inhibition of mechanically activated calcium signaling, as measured by quantifying Rhod-3 calcium dye influx [Figs. 2(c) and 2(d)]. Overexpression of CD98 HH did not interfere directly with the TRPV4 function, as the addition of the TRPV4 chemical agonist GSK1016790A was able to stimulate calcium influx in these cells (supplementary Fig. S1). Thus, overexpression of the CD98 HH domain through delivery by an AAV vector allows for specific suppression of TRPV4-dependent mechanical signaling pathways in human lung endothelial cells.

Inhibition of pulmonary vascular leakage in a human Lung Alveolus Chip

An experimental model that has been shown to mimic pulmonary vascular leakage and edema development with high fidelity in vitro is the human Lung Alveolus Chip, a 2-channel microfluidic culture device lined with alveolar epithelial cells cultured under ALI, which are interfaced with underlying endothelial cells while experiencing simulated breathing motions and fluid flow mimicking the in vivo alveolar microenvironment.[13,51] While the original Lung Chip utilized A549 lung alveolar epithelial cells and HUVECs, we used an improved model that contains primary HpAECs and HpMVECs[40,41] in our studies to more directly explore whether AAV vectors encoding the CD98 HH domain could serve as potential mechanotherapeutics for treatment of pulmonary edema in humans.

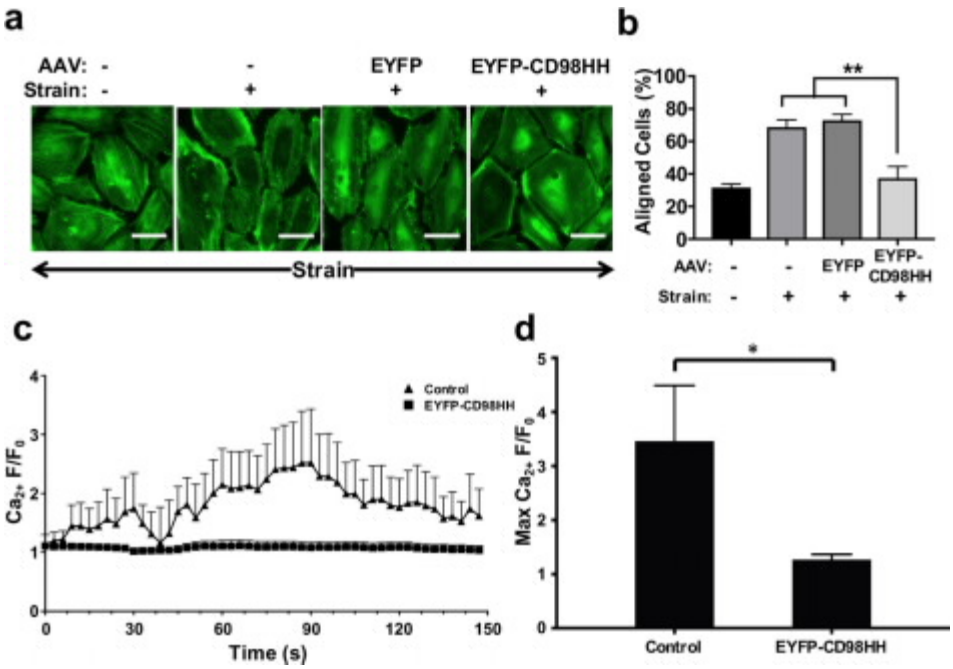

FIG. 2. AAV-mediated expression of CD98 HH disrupts cyclic strain-induced cell realignment and calcium response in human pulmonary endothelial cells. (a) Fluorescence images of HpMVECs stained for F-actin after one day of exposure to 15% cyclic strain (1 Hz) in the horizontal direction; cells were transduced with or without AAV2.5T (MOI 10 000) 2 days earlier (bar, 50 l m). (b) Percentage of cells with actin filaments aligned at 90° 6 30° with respect to the direction of cyclic strain (p < 0.01). (c) Relative change in cytosolic calcium (Ca_{2p} F/F_0) in Rhod-3-loaded HUVECs overexpressing high (bottom) or low (top) levels of CD98 HH in response to static strain (12% for 15 s, arrow). (d) Average maximum relative change in cytosolic calcium (Max Ca_{2p} F/F0) in cells described in c (p < 0.05).

We first elucidated how the route of delivery influences gene expression in the primary human lung epithelium and endothelium by comparing AAV administration through either the airway or circulatory channels. After culturing the cells on the Alveolus Chip and allowing them to mature following established protocols and timelines[40] [supplementary Fig. S2(a)], we infused a droplet of medium containing either AAV2.5T-EYFP (MOI ¼ 10000) to the apical, epithelial channel or AAV2/2-EYFP (MOI ¼ 10000) to the basal endothelium-lined channel, while exposing the cultures continuously to cyclic strain (10%, 0.2 Hz) to mimic breathing motions. After delivery of the vectors and restoration of the ALI, the entire Alveolus Chip was fed by flowing medium through the endothelium-lined vascular channel to mimic pulmonary capillary perfusion in vivo. When we fixed the chips 6 days later and analyzed EYFP expression using confocal microscopy, we observed that gene expression levels were high and sustained for at least 6 days (Fig. 3). Delivery by the apical route was more efficient, with transduction of both HpAECs (12%) and HpMVECs (3%) compared to delivery by the basal route where only transduction of HpMVECs (4%) was achieved. We therefore only administered the vectors apically in subsequent studies.

Fluid accumulation in the lung alveoli and airways is known to result in the loss of lung surfactant, increased permeability of the alveolar–capillary interface, and decreased lung compliance in vivo,[52] which can influence mechanical signals conveyed across the ECM and integrins that feedback to further promote pulmonary edema. To model this physiologically relevant physical stimulus, we infused the apical channel with medium for 4 h under static conditions on day 8 of Alveolus Chip maturation. For these studies, we used chips that had electrodes embedded into the top and bottom of the channels[53,54] [Fig. 4(a)], which allowed us to carry out transepithelial electrical resistance (TEER) measurements to quantitatively assess the pulmonary barrier function in real-time. Studies of Alveolus Chip maturation over time confirmed that the TEER chips can sense to changes in barrier integrity. We measured a rise in TEER values on day 5, which is consistent with a significant improvement in the barrier function after the lung epithelium was placed under an ALI, which has been previously shown to promote epithelial differentiation [supplementary Fig. S2(b)]. The TEER levels and hence the barrier were also maintained for at least 2 days after cyclic mechanical strain (10%) was initiated 2 days after shifting the cells to an ALI [supplementary Fig. S2(b)].

After perfusing the epithelial channel with medium, alone, with AAV2.5T-EYFP-CD98HH, or with the control vector AAV2.5T-EYFP (all MOI ¼ 50 000), while maintaining perfusion through the vascular channel, the ALI was restored to the epithelial channel and cyclic strain application was reinitiated. An increase in vascular leakage through the pulmonary barrier was detected by the following day in response to this physical perturbation, as indicated by a decrease in TEER values by 200–225 Ohms (X) compared to control chips that did not experience fluid immersion [Fig. 4(b); supplementary Fig. S3]. In general, TEER values were 800–1000 X at maturity, which is in line with what was previously measured for airway epithelial cells that form a pseudostratified epithelium (2000 X).[53] Importantly, transduction of the cells with AAV-EYFP-CD98HH encoding the CD98 HH domain significantly inhibited this compromise of the pulmonary barrier function ($p < 0.01$), while the AAV-EYFP control had no protective response [Fig. 4(b)]. It is important to note that fluorescence microscopic imaging of EYFP expression [Fig. 4(c)] and flow cytometry analysis [Fig. 4(d)] revealed that only 30% of HpAECs and 10% of HpMVECs were successfully transduced with the AAV vectors under these conditions. Thus, the scale of this protective response is notable given that only a subset of cells expressed the CD98 HH domain.

In addition to the TEER measurements, ZO-1 and VE-cadherin immunofluorescence staining studies were performed for the epithelial

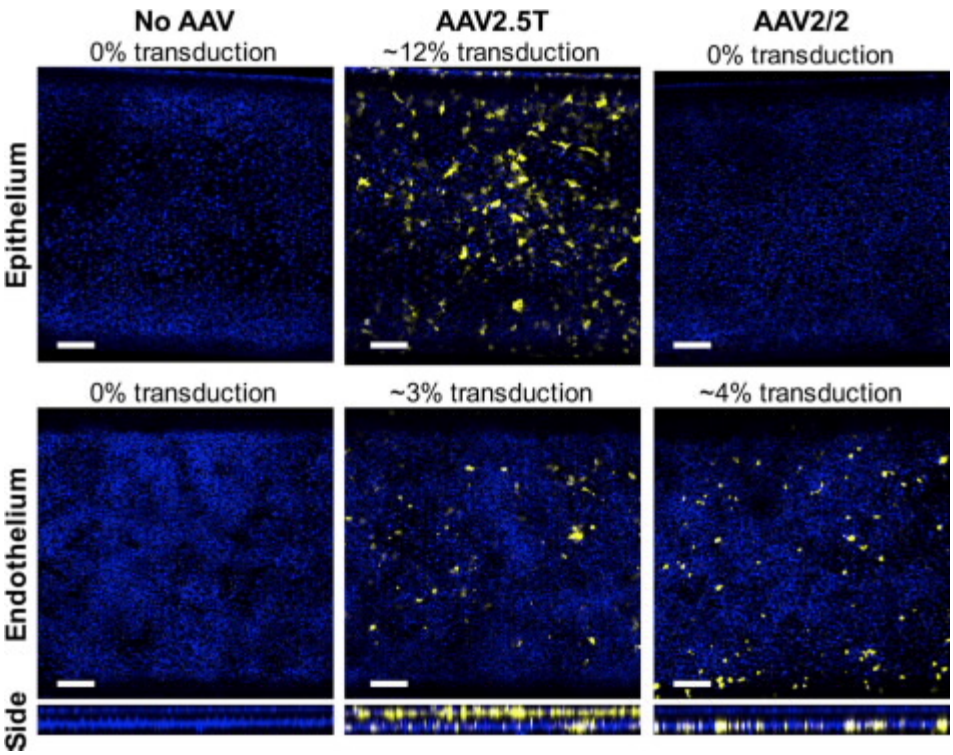

FIG. 3. AAV transduction efficiency in Alveolus Chip AAV-EYFP transduction efficiencies was investigated when AAV2.5T-EYFP (MOI ¼ 10000) was delivered to HpAECs in the top channel of the chip compared to when AAV2/2-EYFP (MOI ¼ 10000) was delivered to HpMVECs in the bottom channel of the human Alveolus Chip (left, control; middle, AAV2.5T-EYFP; right, AAV2/2-EYFP). Confocal images were taken at day 6 of AAV transduction.

and endothelial cells, respectively. For the medium alone and AAV2.5T-EYFP groups, occasional small breaks in cell-cell junctions could be detected, confirming the low-level injury induced by fluid submersion that was measured by TEER [Fig. 4(e)]. Interestingly, although the initial injury was to the epithelium, there was evidence of crosstalk between the two cell populations as previously described,[41] as there were detectable disruptions in the endothelial junctions as well as those in the epithelium [Fig. 4(e)]. Most importantly, fluorescence imaging independently validated that overexpression of CD98 HH protects against this disruption of cell-cell junctions [Fig. 4(e)], which helps to explain its ability to suppress the development of pulmonary vascular leakage as detected by TEER [Fig. 4(b)].

DISCUSSION

AAV2 is the most commonly used viral vector and was first utilized in Phase I/II clinical trials to target a human lung disease (cystic fibrosis).[55,56] These studies established safety profiles for AAV2 in humans, but they did not accomplish therapeutic goals due to the low level of gene transfer in lung epithelial cells. Different serotypes of AAV have different tropisms, and it was later discovered that AAV5, rather than AAV2, binds preferentially to the apical surfaces of airway epithelia.[57] Additionally, AAV5-mediated expression has been reported to persist for at least 12 months in mouse lungs without inducing inflammatory, mechanical, or morphometric changes in the lungs.[58,59]

Here, we demonstrated that AAV2.5T (MOI ¼ 10 000) reached 60% transduction of fully differentiated HpAECs. We further optimized AAV2.5T performance by using the CASI promoter to enhance transgene expression, which increased by more than 100-fold compared to that of the original CMV promoter. Based on previous reports that AAV2 is able to transduce HUVECs and brain endothelial cells,[47,48] we also constructed an endothelium-specific AAV2/2-EYFP vector with a CASI promoter that was able to achieve 30%–60% transduction efficiency in two different types of human endothelial cells (HpMVECs and HUVECs).

We then explored whether we could selectively inhibit TRPV4 mechanotransduction by targeting expression of the CD98 HH domain as a therapeutic for pulmonary vascular disease. Using the optimized AAV vectors, we investigated whether the delivery of CD98 HH could be used to rescue the compromised pulmonary barrier function in a human Lung Alveolus Chip, which has been previously shown to model multiple physiological and pathophysiological features of the human lungs, including pulmonary edema.[13,41] Permeability of the alveolar-capillary interface can be measured in vitro by quantifying the passage of fluorescent tracers or directly measuring TEER, as we have previously demonstrated in previous studies using various Organ Chips, including Lung Chips.[13,53,60] We used TEER measured with embedded electrodes to monitor barrier integrity over time because the TEER method is much more sensitive than the tracer approach (supplementary Fig. S4), and the use of tracer compounds for barrier function measurements can affect transport processes and barrier integrity, especially in Alveolus Chips where the ALI would have to be disrupted for extended periods.[61]

Importantly, by using TEER measurements in the Alveolus Chip, we were able to detect disruption of the pulmonary barrier when the ALI was submerged in liquid medium for 4 h, which is believed to result in a mild mechanical injury due to changes in lung surface tension and compliance.[52] While AAV delivery of EYFP had no effect,

(b) Lung barrier permeability reported as changes in TEER in response to mechanical flooding of the apical chamber on day 8 ($p < 0.01$; Control, $n = 5$; DMEM, $n = 9$; AAV2.5T-EYFP, $n = 9$; AAV2.5T-EYFP-CD98HH, $n = 10$). (c) Fluorescence micrographs of AAV transduction efficiency of primary epithelial and endothelial cells 3 days after apical delivery for 4 h (MOI = 50000), displaying EYFP signals from transduced cells (yellow) and DAPI counterstaining (blue) (bar, 200 μm). (d) Percent of cells transduced as quantified by flow cytometry ($n = 3$). (e) Immunostaining of primary epithelial and endothelial cells for ZO-1 (top) and VE-cadherin (bottom), respectively, to visualize cell-cell junctions 3 days after exposure to mechanical flooding and 10% cyclic strain (bar, 20 μm; arrows indicate the breaks in cell-cell junctions).

significant protection (> 65%) against barrier disruption was conferred when the cells were transduced with CD98 HH. The magnitude of recovery is especially remarkable given that less than 30% of the lung cells were transduced with the AAV vectors based on flow cytometric analysis. The MOI of 50 000 that was used was at the upper limit of the maximum achievable AAV concentration. It would be an interesting avenue for the future to investigate if enhanced therapeutic efficacy could be achieved as AAV serotypes with greater affinity for pulmonary cells are engineered or discovered.

There are chemical inhibitors of TRPV4 activity that are currently in Phase II clinical trials for treatment of pulmonary edema in humans,[62] which demonstrates the clinical relevance of this target. However, TRPV4 can mediate a plethora of cellular responses, many of which are activated by chemical signals as well as mechanical cues. Thus, it is important to note the significance of the potential to deliver the CD98HH domain as a highly precise mechanotherapeutic inhibitor that uncouples mechanical activation of TRPV4 from its chemical activation. Using this approach, our results demonstrate that we can minimize the damage to the endothelial-epithelial barrier that occurs from fluid immersion of the airways without affecting TRPV4's chemical signaling function.

Mechanotherapeutic approaches are especially important in the case of patients with acute respiratory distress syndrome (ARDS), who require ventilator support, as fluid accumulation coupled to the stress from the mechanical ventilation can contribute to massive alveolar collapse and perpetuate pulmonary injury.[63] By targeting the

© Author(s) 2019

mechanotransduction mechanism that leads to TRPV4 activation in patients on respirators, rather than generically blocking all TRPV4 channel activity, this exacerbation of injury could potentially be avoided without also introducing the possibility of triggering other adverse events from off-target effects of a generalized channel inhibitor. This targeted mechanotherapeutic design strategy also has the potential to protect against additional mechanical injuries that can be induced by other rescue therapies, such as extracorporeal membrane oxygenation (ECMO).[64] As similar TRPV4-dependent calcium signaling and mechanotransduction have been demonstrated in other cell types (e.g., bovine capillary endothelial cells and human dermal microvascular endothelial cells),[6] it should be possible to extend this mechanotherapeutic design approach to other cell types and applications. Additionally, one caveat of the present study is that TRPV4 may not be the only channel whose mechanical activation is blocked by CD98 HH; however, this suggests the possibility of identifying other non-chemical inhibitors of such channels, which could lead to additional mechanotherapeutics with greater specificity than direct channel blockers.

METHODS

Plasmids and recombinant AAV vector production

Ethics approval was not required. The tested promoters were obtained from the following sources: cytomegalovirus immediate-early promoter (CMV) from pAAV-CMV-luciferase (University of California, Berkeley), chicken b-actin promoter coupled with CMV early enhancer (CAG) from AAV pCAG-FLEX-EGFP-WPRE as a gift from Hongkui Zeng (Addgene Plasmid #51502),[65] human elongation factor 1a (EF1a) from pAAV-EF1a-EGFP (Wyss Institute at Harvard University), and the CASI promoter, which consists of a CMV enhancer, a chicken b-actin promoter, and a ubiquitin enhancer region,[66] from pAAV-CASI-Luc2 (Ragon Institute of MGH, MIT, and Harvard). Luciferase and EYFP genes were cloned into the AAV backbone plasmids with different promoters. As described previously,[66,67] to generate recombinant AAV vectors carrying the transgenes (supplementary Fig. S5), HEK293T cells (ATCC) were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and 100 U ml^{-1} penicillin, and the cells were co-transfected with a three-plasmid system: the coding region containing the backbone plasmid, the helper plasmid pHELP (Applied Viromics), and the seed vector pAAV2.5T (University of California, Berkeley) or pAAV2/2 (Massachusetts Eye and Ear) at a ratio of 1:4:8 using the BioT transfection reagent (Bioland Scientific). The culture supernatant was collected, pooled, and filtered through a 0.2 l m filter, and then a 40% polyethylene glycol (PEG) in 2.5 M NaCl solution was added to the supernatant at a volume ratio of 1:4 and gently mixed at 4 ! C overnight to precipitate the AAV. The precipitated virus was spelleted at 4000 g for 30 min and resuspended in 10 ml of DMEM. To remove the PEG residue and concentrate the virus, the solution was loaded onto 100 kDa MWCO centrifugal filters (Millipore) and spun at 3220 g at 4 ! C until 1 ml of retentate remained. Fresh DMEM was added to the filter, and this process was repeated two more times. The final virus solution was about 2 ml total and stored at " 80 ! C.

Cell culture

HpAECs and HpMVECs (Cell Biologics) were expanded in tissue culture flasks coated with 0.1% (w/v) gelatin (Sigma) using complete human epithelial/endothelial cell medium (Cell Biologics), respectively, with the FBS concentration reduced to 5% (v/v) for the epithelial cells. HUVECs (Lonza) were cultured in endothelial growth medium supplemented with 5% (v/v) FBS and growth factors (EGM-2; Lonza), while A549 cells (ATCC) were cultured in DMEM/F12 (Gibco) with 10% (v/v) FBS and 1% (v/v) penicillin/streptomycin. The cells were all maintained in an incubator at 37 ! C and 5% CO_2.

AAV transduction in vitro

For plate assays, HpMVECs, HUVECs, and A549 cells were seeded in 6- or 24-well plates, while HpAECs were cultured in 12- or 24-well Transwell plates, treated with 1 l M dexamethasone for 2 days, and introduced to ALI for 4 days before AAV transduction. For chip assays, chips were also allowed to mature at ALI for 4 days (2 days strain) before AAV transduction (see the chip culture section below). AAV vectors were diluted with DMEM and added to cells at MOI ranging from 7000 to 50 000 at 37 ! C for 4 h. After removing the virus solution, epithelial cells were washed once with fresh medium before being returned to ALI, while endothelial cells were replaced with fresh medium, and then the cells were cultured for the desired time.

Flow cytometry

Sample cells were collected by trypsinization and washed with DPBS. After fixing with 2% paraformaldehyde (Electron Microscopy Sciences), cells were stored in 100% methanol at " 20 ! C for future analysis. On the day of analysis, cells were removed from methanol, washed once with wash buffer (DPBS with 1% normal goat serum and 5 mM NaN_3), and finally analyzed in wash buffer using a BD LSRFortessa™ flow cytometer.

Luciferase assay

Two days after AAV transduction, cells were washed with DPBS once and lysed with Glo Lysis Buffer (Promega) at room temperature for five minutes. After transferring to a 96-well plate, the cell lysate was mixed with the Bright-Glo™ Luciferase Assay Reagent (Promega) at a 1:1 volume ratio. Luminescence was then measured using a microplate reader (BioTek).

Cell realignment and calcium imaging for CD98 HH overexpression experiments

HpMVECs and HUVECs were seeded on collagen IV-coated 6-well UniFlex plates (for cell realignment) or StageFlexer membranes (for calcium imaging) (Flexcell) and transduced 24 h after seeding with AAV2/2-EYFP, AAV2/2-EYFP-CD98HH, or nothing (MOI ¼ 10000). 1 day post transduction, cells were exposed to uniaxial cyclic strain (15% strain, 1 Hz) for a further 24 h before fixation with 4% paraformaldehyde. F-actin was stained with Alexa Fluor 647 phalloidin (Invitrogen; diluted 1:40) and visualized by confocal microscopy. The percentage of cells aligned 90 ! 6 30 ! with respect to the direction of cyclic strain was determined using ImageJ. For calcium imaging, cells were loaded with Rhod-3 calcium dye according to the manufacturer's recommendations, mounted on a StageFlexer device, and imaged using Zeiss Axio Imager 2 during and following 12% static strain for 15 s. 100 cells per membrane were sorted based on EYFP expression into five distinct, equally spaced bins, and analysis was

∀ Author(s) 2019

performed comparing intensities from group 5 (high expressers) to group 2 (low expressers). For the group with the TRPV4 chemical agonist GSK1016790A (Tocris), 100 nM GSK1016790A was added 100 s after the start of imaging to induce calcium signaling.

Confocal imaging

Cells were fixed with 4% paraformaldehyde for 15 min at room temperature and permeabilized with 0.1% Triton X-100 for 5 min. After blocking with 10% goat serum and 0.1% Triton X-100 in DPBS, HpAECs were immunostained with a primary mouse anti-ZO-1 monoclonal antibody (Invitrogen; 1:200) and a secondary goat anti-mouse IgG1 Alexa Fluor 647 (Invitrogen; 1:1000), while HpMVECs were stained with a primary mouse anti-VE-cadherin antibody (BD Biosciences; 1:200) and a secondary goat anti-mouse IgG1 Alexa Fluor 594 (Invitrogen; 1:1000) in an incubation buffer consisting of DPBS with 1% goat serum and 0.1% Triton X-100. Nuclei were stained with 4′,6-diamidino-2-phenylindole (DAPI) in DPBS for 5 min (0.5 μg ml^{-1}). AAV transduction was visualized by EYFP. Images were obtained using a Zeiss TIRF/LSM710 confocal microscope and analyzed using ImageJ (NIH) and Imaris (Bitplane).

Chip cell culture

For microfluidic chip cell culture, polydimethylsiloxane (PDMS) chips (Emulate) or TEER chips (see below) were first treated for extracellular matrix (ECM) immobilization using a sulfosuccinimidyl 6-(4′-azido-2′-nitrophenylamino)hexanoate (sulfo-SANPAH) crosslinker (ThermoFisher Scientific). To do so, channels were sequentially washed with 70% ethanol, water, and 50 mM HEPES pH 8.0 before incubation with 0.5 mg/ml sulfo-SANPAH in 50 mM HEPES and pH 8.0 with 0.5% DMSO. The sulfo-SANPAH was then photoactivated with a 36 W UV lamp (NailStar) for 30 min. The channels were washed with 50 mM HEPES, pH 8.0 followed by three additional washes with ice-cold Dulbecco's phosphate-buffered saline (DPBS) before incubation with an ECM coating solution (100 μg ml^{-1} human collagen type I (Advanced BioMatrix), 50 μg ml^{-1} human fibronectin (Corning), and 50 μg ml^{-1} laminin nonapeptide [EMD Millipore)] overnight at 4 °C. The following day, the channels were washed once with respective media before seeding of HpAECs (passage 4) and HpMVECs (passage 5) to the apical and basal channels, respectively. Cell seeding was accomplished by first incubating the basal channel with HpMVECs (4 × 10^6 cells ml^{-1}), flipping the devices upside-down, and incubating the chips for 30 min to allow cell attachment. The chips were then returned upright, HpAECs (4 × 10^6 cells ml^{-1}) were introduced to the apical channel, and the devices were cultured in an incubator overnight. The following two days, endothelial growth medium was replaced in the basal channels and 1 μM dexamethasone in epithelial growth medium was introduced in the apical channels to promote tight junction formation and surfactant production.[13,40,68] ALI was then established by removing the medium from the apical channels, and the basal channels were subjected to continuous perfusion at 60 μl h^{-1} using a peristaltic pump (Ismatec). The perfusion medium for longer-term survival of the cells[40] was composed of phenol red-free endothelial medium without endothelial cell growth supplement (ECGS) and with reduced FBS (0.4%), reduced EGF (0.01%), and additional $CaCl_2$ (1 mM). After 2 days at ALI, physiological breathing motion was initiated by applying vacuum suction to the side chambers of the devices to implement cyclical strain (10% strain, 0.2 Hz).

TEER chip fabrication

Stretchable polydimethylsiloxane (PDMS) microfluidic chips integrated with electrodes for measuring transepithelial electrical resistance (TEER) were fabricated following protocols similar to those reported in the literature.[53] In brief, two parallel microchannels served as the air and microvascular channels (800 μm and 200 μm height, respectively; 1 mm width, and 16.7 mm length in the overlapping region), with a 50 μm PDMS membrane in between allowing for epithelial/endothelial cell-cell interactions through 7 μm pores. Electrodes were positioned above and below the channels to allow for a 4-point impedance measurement [see Fig. 4(a)].

TEER measurements

A PGstat128N potentiostat/galvanostat (Autolab) was used to record four-point impedance spectra in galvanostatic mode over the two-week culture period. The TEER chips were first allowed to equilibrate to room temperature for at least 10 min prior to any measurements. For chips at ALI, 40 μl of room temperature perfusion medium was briefly introduced to the apical channels for the 2 min TEER measurement time before the immediate removal of the medium after each measurement. For each chip, impedance spectra were obtained from 10 Hz to 100 kHz. In the high frequency range (> 10 kHz), the impedance curves are dominated by the resistance of the medium, whereas in the low frequency range (< 100 Hz), the impedance is dominated by the TEER.[61] Therefore, reported TEER data were calculated by subtracted medium resistance at 100 kHz from TEER measured at 21.2 Hz.

Statistical Analysis

All values are expressed as the mean ± standard error of the mean (SEM). All experiments were repeated at least 3 times. Statistical comparisons were performed using Student's *t*-test for experiments with two conditions or ANOVA for experiments with more than two conditions using GraphPad Prism.

SUPPLEMENTARY MATERIAL

See the supplementary material for figures of the response of CD98 overexpressing cells to a TRPV4 chemical agonist, Alveolus Chip maturation over time, and the AAV transgene vector map.

ACKNOWLEDGMENTS

This study was supported by the National Institute for Health research Grant (No. RO1-EB020004 to D.E.I.) and fellowship (No. F32-HL146070), and Wyss Institute for Biologically Inspired Engineering at Harvard University. We thank David V. Schaffer (University of California, Berkeley) for providing pAAV2.5T, Luk H. Vandenberghe and Ru Xiao (Massachusetts Eye and Ear) for providing pAAV2/2, Alejandro Balazs (Ragon Institute of MGH, MIT, and Harvard) for providing pAAV-CASI-Luc2, and George M. Church and Noah Davidsohn (Wyss Institute at Harvard University) for providing pAAV-EF1a-EGFP. We thank Thomas Ferrante for assistance with microscopy and Carlos F. Ng and Elizabeth L. Calamari for assistance with TEER chip fabrication.

Reconstituting Organ-Level Lung Functions on a Chip

Dongeun Huh,[1,2] Benjamin D. Matthews,[2,3] Akiko Mammoto,[2] Martín Montoya-Zavala,[1,2] Hong Yuan Hsin,[2] Donald E. Ingber[1,2,4]*

Here, we describe a biomimetic microsystem that reconstitutes the critical functional alveolar-capillary interface of the human lung. This bioinspired microdevice reproduces complex integrated organ-level responses to bacteria and inflammatory cytokines introduced into the alveolar space. In nanotoxicology studies, this lung mimic revealed that cyclic mechanical strain accentuates toxic and inflammatory responses of the lung to silica nanoparticles. Mechanical strain also enhances epithelial and endothelial uptake of nanoparticulates and stimulates their transport into the underlying microvascular channel. Similar effects of physiological breathing on nanoparticle absorption are observed in whole mouse lung. Mechanically active "organ-on-a-chip" microdevices that reconstitute tissue-tissue interfaces critical to organ function may therefore expand the capabilities of cell culture models and provide low-cost alternatives to animal and clinical studies for drug screening and toxicology applications.

One of the causes of the high cost of pharmaceuticals and the major obstacles to rapidly identifying new environmental toxins is the lack of experimental model systems that can replace costly and time-consuming animal studies. Although considerable advances have been made in the development of cell culture models as surrogates of tissues and organs for these types of studies (1), cultured cells commonly fail to maintain differentiation and expression of tissue-specific functions. Improved tissue organization can be promoted by growing cells in three-dimensional extracellular matrix (ECM) gels (2); however, these methods still fail to reconstitute structural and mechanical features of whole living organs that are central to their function. In particular, existing model systems do not recreate the active tissue-tissue interface between the microvascular endothelium and neighboring parenchymal tissues where critical transport of fluids, nutrients, immune cells, and other regulatory factors occur, nor do they permit application of dynamic mechanical forces (e.g., breathing movements in lung, shear in blood vessels, peristalsis in gut, tension in skin, and the like) that are critical for the development and function of living organs (3).

Microscale engineering technologies first developed to create microchips, such as microfabrication and microfluidics, enable unprecedented capabilities to control the cellular microenvironment with high spatiotemporal precision and to present cells with mechanical and biochemical signals in a more physiologically relevant context (4–7). This approach has made it possible to microfabricate models of blood vessels (8, 9), muscles (10), bones (11), airways (12), liver (13–16), brain (17, 18), gut (19), and kidney (20, 21). However, it has not yet been possible to engineer integrated microsystems that replicate the complex physiological functionality of living organs by incorporating multiple tissues, including active vascular conduits, and placing them in a dynamic and mechanically relevant organ-specific microenvironment.

To provide the proof of principle for a biomimetic microsystems approach, we developed a multifunctional microdevice that reproduces key structural, functional, and mechanical properties of the human alveolar-capillary interface, which is the fundamental functional unit of the living lung. This was accomplished by microfabricating a microfluidic system containing two closely apposed microchannels separated by a thin (10 μm), porous, flexible membrane made of poly(dimethylsiloxane) (PDMS). The intervening membrane was coated with ECM (fibronectin or collagen), and human alveolar epithelial cells and human pulmonary microvascular endothelial cells were cultured on opposite sides of the membrane (Fig. 1A). Once the cells were grown to confluence, air was introduced into the epithelial compartment to create an air-liquid interface and more precisely mimic the lining of the alveolar air space. The compartmentalized channel configuration of the microdevice makes it possible to manipulate fluid flow, as well as delivery of cells and nutrients, to the epithelium and endothelium independently.

During normal inspiration, intrapleural pressure decreases, causing the alveoli to expand; this pulls air into the lungs, resulting in stretching of the alveolar epithelium and the closely apposed endothelium in adjacent capillaries (Fig. 1B). We mimicked this subatmospheric, pressure-driven stretching by incorporating two larger, lateral microchambers into the device design. When vacuum is applied to these chambers, it produces elastic deformation of the thin wall that separates the cell-containing microchannels from the side chambers; this causes stretching of the attached PDMS membrane and the adherent tissue layers (Fig. 1A, right versus left). When the vacuum is released, elastic recoil of PDMS causes the membrane and adherent cells to relax to their original size. This design replicates dynamic mechanical distortion of the alveolar-capillary interface caused by breathing movements.

These hollow microchannels were fabricated by soft lithography in conjunction with a new method that uses chemical etching of PDMS (22) to form the vacuum chambers. Fabrication begins with alignment and permanent bonding of a 10-mm-thick porous PDMS membrane (containing 10-μm-wide pentagonal pores) and two PDMS layers containing recessed microchannels (Fig. 1C). A PDMS etching solution composed of tetrabutyl-

ammonium fluoride and N-methylpyrrolidinone is then pumped through the side channels (Fig. 1D). Within a few minutes, PDMS etchant completely dissolves away portions of the membrane in the side channels, creating two large chambers directly adjacent to the culture microchannels. The entire integrated device is only 1 to 2 cm in length, with the central channels only millimeters in width (Fig. 1E), and thus, it is fully amenable to high-density integration into a highly multiplexed microdevice in the future.

Reconstitution of a functional alveolar-capillary interface. When human alveolar epithelial cells and microvascular endothelial cells were introduced into their respective channels, they attached to opposite surfaces of the ECM-coated membrane and formed intact monolayers composed of cells linked by continuous junctional complexes containing the epithelial and endothelial junctional proteins, occludin and vascular endothelial cadherin (VE-cadherin), respectively (Fig. 2A). These cells remained viable for prolonged periods (>2 weeks) after air was introduced into the epithelial microchannel and the alveolar cells were maintained at an air-liquid interface (fig. S1). Addition of air to the upper channel resulted in increased surfactant production by the epithelium (Fig. 2B and fig. S1), which stabilizes the thin liquid layer in vitro as it does in whole lung in vivo, such that no drying was observed. This was also accompanied by an increase in electrical resistance across the tissue layers (Fig. 2C) and enhanced molecular barrier function relative to cells cultured under liquid medium (Fig. 2D). These differences in barrier integrity and permeability likely result from strengthening of intercellular junctions in air-liquid interface culture (12), and from the observed changes in pulmonary surfactant production that can influence alveolar-capillary barrier function (23). Moreover, the low level of protein permeability (2.1%/hour for fluorescently labeled albumin) exhibited by cells cultured at the air-liquid interface (Fig. 2D) closely approximated that observed in vivo (1 to ~2%/hour) (24). It should be noted that although we mimic the alveolar microenvironment by generating an air-liquid interface in contact with the apical surface of epithelium in our microdevice, there is likely a large variation in the microscale properties of this interface in vivo. Thus, it would be difficult to interpret these results in any way other than functional measures at this time. Our results clearly show that the epithelial cells not only remained viable but also increased their surfactant production, enhanced their structural integrity, and restored normal barrier permeability in this biomimetic microsystem.

The microfluidic device was then integrated with computer-controlled vacuum to produce cyclic stretching of the tissue-tissue interface to mimic physiological breathing movements (movie S1). The level of applied strain ranged from 5% to 15% to match normal levels of strain observed in alveoli within whole lung in vivo, as previously described (25). Vacuum application generated uniform, unidirectional mechanical strain across the channel length, as demonstrated by measured displacements of fluorescent quantum dots immobilized on the PDMS membrane (Fig. 2E and movie S2). Membrane stretching also resulted in cell shape distortion, as visualized by concomitant increases in the projected area and length of the adherent cells in the direction of applied tension (Fig. 2F and movie S3).

The permeability of the alveolar-capillary barrier to fluorescent albumin remained unchanged during cyclic stretching over 4 hours with physiological levels of strain (5 to ~15%) or after preconditioning with 10% strain for varying amounts of time (fig. S1). Application of physiological cyclic strain (10% at 0.2 Hz) also induced cell alignment in the endothelial cells in the lower compartment (fig. S2 and movie S4) and, hence, mimicked physiological responses previously observed in cultured endothelium and in living blood vessels in vivo (26, 27). Cyclic stretching caused some pulsatility in the fluid flow, but this unsteady effect was negligible due to the small channel size and low stretching frequency (see SOM text). Thus, this microdevice extends far beyond previously described cell stretching systems by permitting the application of cyclic stretch and fluid shear stress to two opposing cell layers

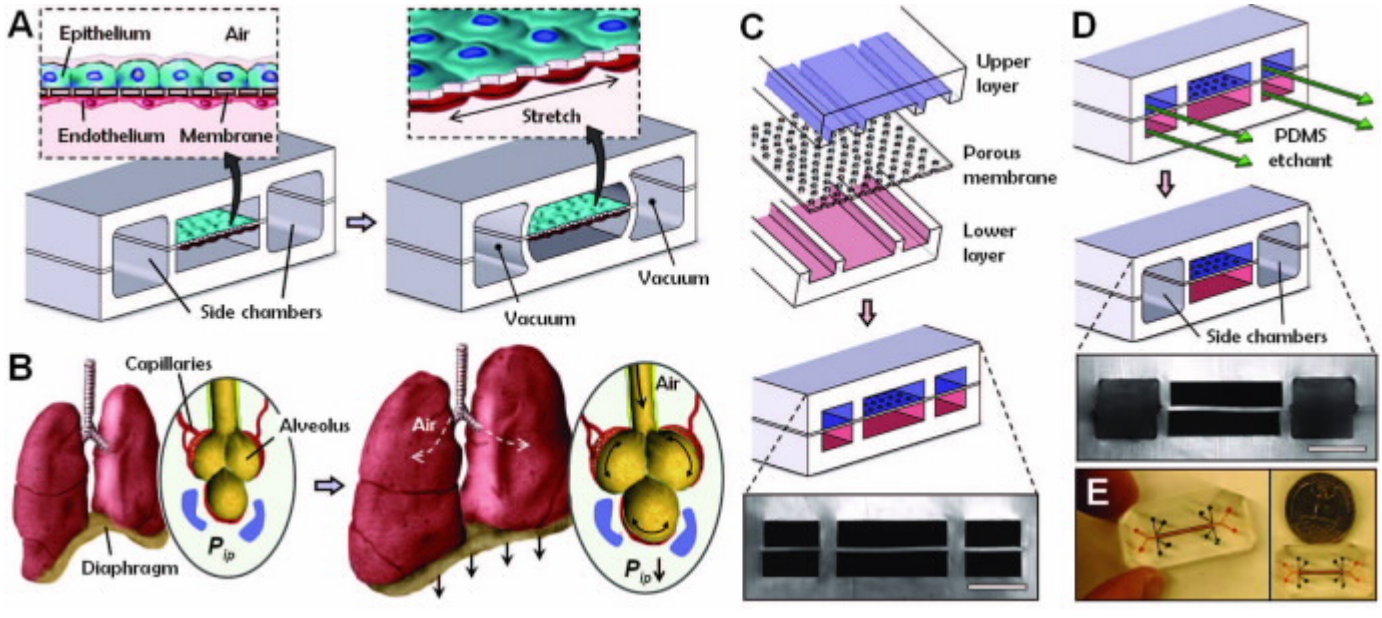

Fig. 1. Biologically inspired design of a human breathing lung-on-a-chip microdevice (A) The microfabricated lung mimic device uses compartmentalized PDMS microchannels to form an alveolar-capillary barrier on a thin, porous, flexible PDMS membrane coated with ECM. The device recreates physiological breathing movements by applying vacuum to the side chambers and causing mechanical stretching of the PDMS membrane forming the alveolar-capillary barrier. (B) During inhalation in the living lung, contraction of the diaphragm causes a reduction in intrapleural pressure (P_{ip}), leading to distension of the alveoli and physical stretching of the alveolar-capillary interface (C) Three PDMS layers are aligned and irreversibly bonded to form two sets of three parallel microchannels separated by a 10-mm-thick PDMS membrane containing an array of through-holes with an effective diameter of 10 mm. Scale bar, 200 mm. (D) After permanent bonding, PDMS etchant is flowed through the side channels. Selective etching of the membrane layers in these channels produces two large side chambers to which vacuum is applied to cause mechanical stretching. Scale bar, 200 mm. (E) Images of an actual lung-on-a-chip microfluidic device viewed from above.

separated by a permeable and flexible ECM, while simultaneously enabling analysis of tissue barrier permeability and transport.

Recapitulation of whole-organ responses. We then explored whether this microsystem could recapitulate more complex integrated organ-level responses observed in whole living lung, such as pulmonary inflammation, by incorporating blood-borne immune cells in the fluid flowing through the vascular channel. Pulmonary inflammatory responses involve a highly coordinated multistep cascade including epithelial production and release of early-response cytokines, activation of vascular endothelium through up-regulation of leukocyte adhesion molecules [e.g., intercellular adhesion molecule-1 (ICAM-1)], and subsequent leukocyte infiltration into the alveolar space from the pulmonary microcirculation (28–30). Because cytokines are produced by cells of the lung parenchyma, we simulated this process by introducing medium containing the potent proinflammatory mediator, tumor necrosis factor–a (TNF-a), into the alveolar microchannel in the presence of physiological mechanical strain and examined activation of the underlying microvascular endothelium by measuring ICAM-1 expression.

TNF-a stimulation of the epithelium substantially increased endothelial expression of ICAM-1 within 5 hours after addition (Fig. 3A and fig. S3), whereas physiological cyclic strain had no effect on ICAM-1 expression. The activated endothelium also promoted firm adhesion of fluorescently labeled human neutrophils flowing in the vascular microchannel, which do not adhere to the endothelium without TNF-a stimulation (Fig. 3B and movies S5 and S6). Real-time, high-resolution, fluorescent microscopic visualization revealed that soon after adhering, the neutrophils flattened (fig. S3) and migrated over the apical surface of the endothelium until they found cell-cell junctions, where they underwent diapedesis and transmigrated across the capillary-alveolar barrier through the membrane pores over the period of several minutes (Fig. 3C and movie S7). Phase-contrast microscopic visualization on the opposite side of the membrane revealed neutrophils crawling up through the spaces between neighboring cells and emerging on the surface of the overlying alveolar epithelium (Fig. 3D), where they remained adherent despite active fluid flow

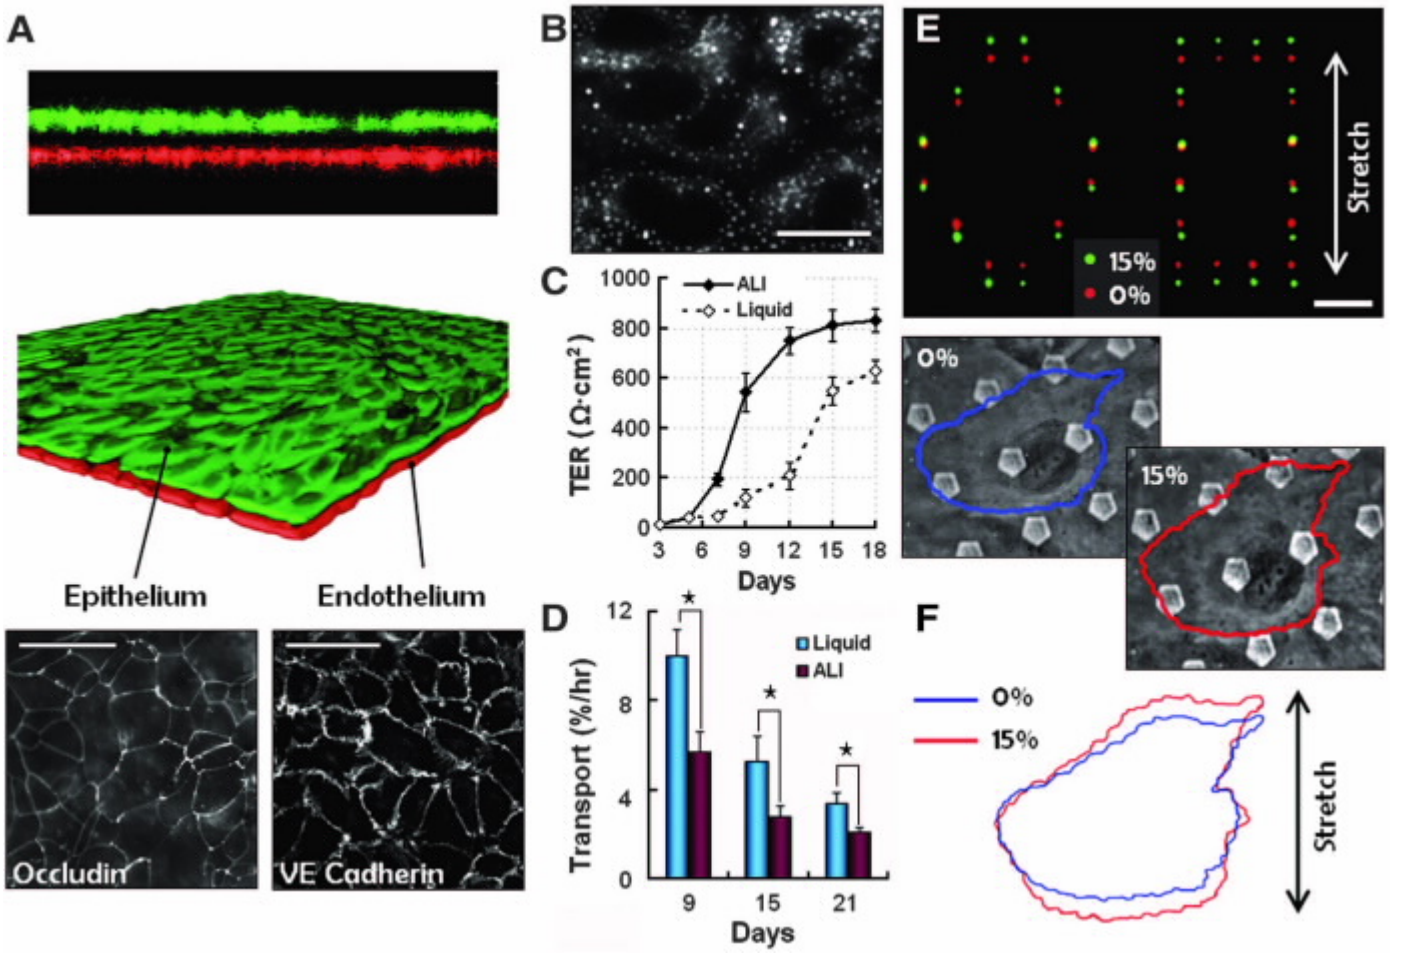

Fig. 2. On-chip formation and mechanical stretching of an alveolar-capillary interface. (A) Long-term microfluidic coculture produces a tissue-tissue interface consisting of a single layer of the alveolar epithelium (epithelium, stained with CellTracker Green) closely apposed to a monolayer of the microvascular endothelium (endothelium, stained with CellTracker Red), both of which express intercellular junctional structures stained with antibodies to occludin or VE-cadherin, separated by a flexible ECM-coated PDMS membrane. Scale bar, 50 mm. (B) Surfactant production by the alveolar epithelium during air-liquid interface culture in our device detected by cellular uptake of the fluorescent dye quinacrine that labels lamellar bodies (white dots). Scale bar, 25 mm. (C) Air-liquid interface (ALI) culture leads to a greater increase in transbilayer electrical resistance (TER) and produces tighter alveolar-capillary barriers with higher TER (>800 Ω·cm^2), as compared with the tissue layers formed under submerged liquid culture conditions. (D) Alveolar barrier permeability, measured by quantitating the rate of fluorescent albumin transport, is significantly reduced in ALI cultures compared with liquid cultures (*$P < 0.001$). Data in (C) and (D) represent the mean ± SEM from three separate experiments. (E) Membrane stretching–induced mechanical strain visualized by the displacements of individual fluorescent quantum dots that were immobilized on the membrane in hexagonal and rectangular patterns before (red) and after (green) stretching. Scale bar, 100 mm. (F) Membrane stretching exerts tension on the cells and causes them to distort in the direction of the applied force, as illustrated by the overlaid outlines of a single cell before (blue) and after (red) application of 15% strain. The pentagons in the micrographs represent microfabricated pores in the membrane. Endothelial cells were used for visualization of cell stretching.

and cyclic stretching. Similar adhesion and transmigration of neutrophils were observed in response to alveolar stimulation with other proinflammatory cytokines, such as interleukin-8. These sequential events successfully replicate the entire process of neutrophil recruitment from the microvasculature to the alveolar compartment, which is a hallmark of lung inflammation.

We also demonstrated that this system could mimic the innate cellular response to pulmonary infection of bacterial origin. Living Escherichia coli bacteria constitutively expressing green fluorescent protein (GFP) were added to the alveolar microchannel. The presence of these pathogens on the apical surface of the alveolar epithelium for 5 hours was sufficient to activate the underlying endothelium, as indicated by capture of circulating neutrophils and their transmigration into the alveolar microchannel. Upon reaching the alveolar surface, the neutrophils displayed directional movement toward the bacteria, which they then engulfed over a period of a few minutes (Fig. 3E and movies S8 and S9), and the phagocytic activity of the neutrophils continued until most bacteria were cleared from the observation area. We specifically excluded the air-liquid interface in the experiments shown in Fig. 3 because inflammatory cytokines are produced by the epithelial tissue, and alveoli often become filled with fluid exudate during early stages of lung infections. These results show that this bioinspired microdevice can effectively recapitulate the normal integrated cellular immune response to microbial infection in human lung alveoli. It also can be used to visualize these cellular responses in real time by high-resolution microscopic imaging during mechanical stimulation, which has been difficult in most existing cell stretching systems.

Identification of novel mechanosensitive responses to nanoparticulates. We also explored the potential value of this lung-on-a-chip system for toxicology applications by investigating the pulmonary response to nanoparticulates delivered to the epithelial compartment. Despite the widespread use of nanomaterials, much remains to be learned about their risks to health and the environment (31–33). Existing toxicology methods rely on oversimplified in vitro models or lengthy and expensive animal testing.

When nanoparticles are delivered to the alveoli of the lung in an aerosol, they are deposited in a thin fluid layer supported by surfactant on the surface of the epithelium. To mimic delivery of airborne nanoparticles into the lung using our microdevice, we injected nanoparticle solution into the alveolar microchannel and then gently aspirated the solution to leave a thin liquid layer containing nanoparticles covering the epithelial surface. When alveolar epithelial cells were exposed for 5 hours to 12-nm silica nanoparticles that are commonly used to model the toxic effects of ultrafine airborne particles (34–36), the underlying endothelium in the microvascular channel became activated and exhibited high levels of ICAM-1 expression (Fig. 4A). Although physiological breathing movements (~10% cyclic strain) had no effect on ICAM-1 expression on their own, mechanical stretching significantly augmented endothelial expression of ICAM-1 induced by the silica nanoparticles (Fig. 4A). Moreover, this effect was sufficient to induce endothelial capture

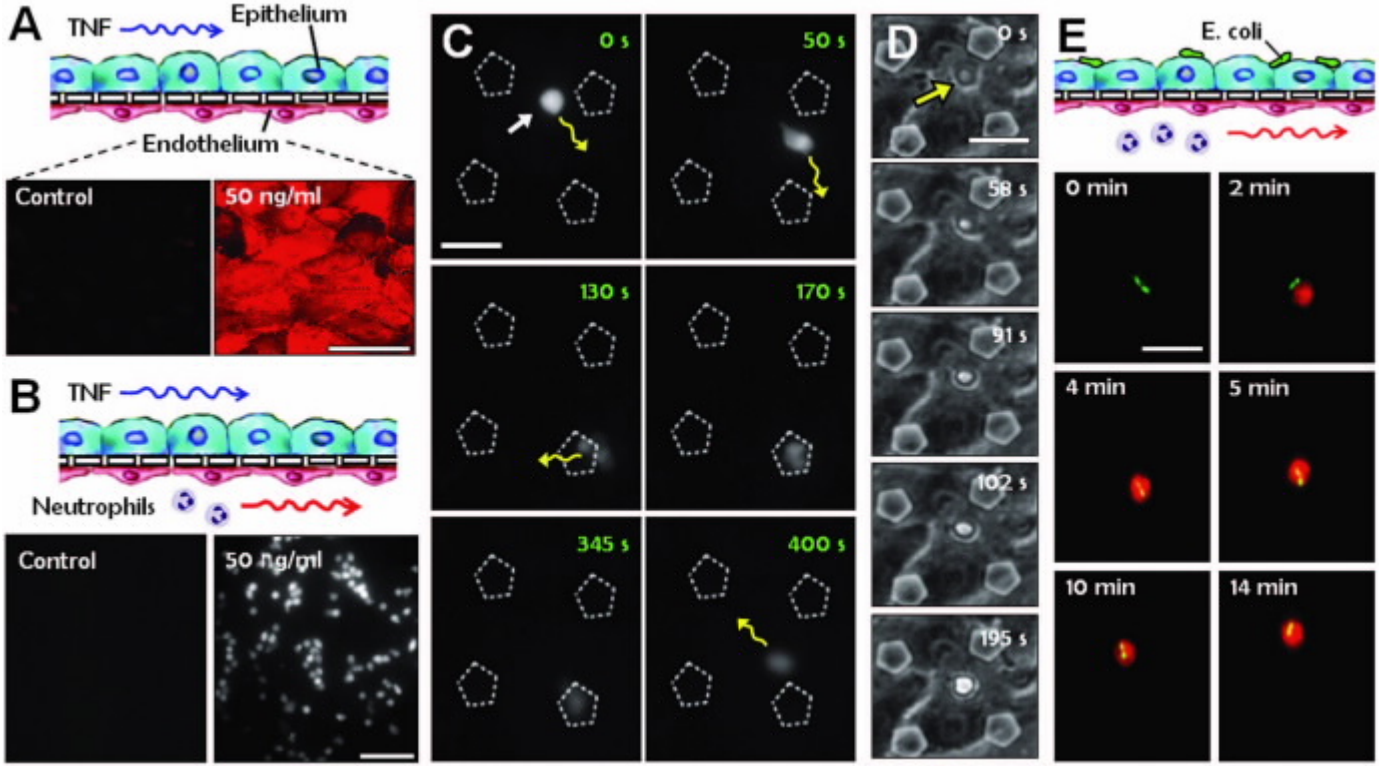

Fig. 3. Reconstitution and direct visualization of complex organ-level responses involved in pulmonary inflammation and infection in the lung-on-a-chip device. (A) Epithelial stimulation with TNFα (50 ng/ml) up-regulates ICAM-1 expression (red) on the endothelium; controls show lack of ICAM-1 expression in the absence of TNFα treatment. Cells were stretched with 10% strain at 0.2 Hz in both cases. (B) Fluorescently labeled human neutrophils (white dots) adhere avidly to the activated endothelium within 1 min after introduction into the vascular channel. (C) Time-lapse microscopic images showing a captured neutrophil (white arrow) that spreads by firm adhesion and then crawls over the apical surface of the activated endothelium (not visible in this view; direction indicated by yellow arrows), until it forces itself through the cell-cell boundary within about 2 min after adhesion (times indicated in seconds). During the following 3 to 4 min, the neutrophil transmigrates through the alveolar-capillary barrier by passing through a pentagonal pore in the PDMS membrane, and then it moves away from the focal plane, causing it to appear blurry in the micrographs. (D) Phase-contrast microscopic images show a neutrophil (arrow) emerging from the apical surface of the alveolar epithelium at the end of its transmigration over a period of ~3 min; thus, complete passage takes approximately 9 min in total. (E) Time-lapse fluorescence microscopic images showing phagocytosis of two GFP-expressing E. coli (green) bacteria on the epithelial surface by a neutrophil (red) that transmigrated from the vascular microchannel to the alveolar compartment. Scale bar, 50 mm in (A) and (B), 20 mm in (C) to (E).

of circulating neutrophils (Fig. 4A) and to promote their transmigration across the tissue-tissue interface and their accumulation on the epithelial surface (fig. S4).

Nanoparticles have been previously shown to induce lung inflammation by stimulating pulmonary epithelial cells to produce proinflammatory cytokines and by causing endothelial cells to express ICAM-1 and recruit circulating leukocytes (31–33, 37). However, our results extend this observation by providing evidence to suggest that breathing motions might greatly accentuate the proinflammatory activities of silica nanoparticles and contribute substantially to the development of acute lung inflammation. This finding also could be relevant for the design of artificial lung motions in positive-pressure lung ventilator devices, which can sometimes induce dangerous inflammatory responses in the clinic. This effect of mechanical stress would never have been detected in conventional culture models based on static cultures, including Transwell culture systems, that fail to incorporate mechanical force regimens.

Next, various nanomaterials were added to the alveolar microchannel, and the cellular oxidative stress response was quantitated by measuring intracellular production of reactive oxygen species (ROS) using microfluorimetry (31). When the ultrafine (12 nm) silica nanoparticles were added to the alveolar epithelium in the absence of mechanical distortion, there was little or no ROS production. However, when the cells were subjected to physiological levels of cyclic strain (10% at 0.2 Hz), the same nanoparticles induced a steady increase in ROS production that increased by a factor of more than 4 within 2 hours (Fig. 4B), and this response could be inhibited with the free radical scavenger *N*-acetylcysteine (NAC) (fig. S5). ROS levels in the underlying endothelium also increased by a factor of almost 3 over 2 hours, but initiation of this response was delayed by about 1 hour compared with the epithelium (fig. S5). Experiments with carboxylated Cd/Se quantum dots (16 nm) produced similar results (fig. S6), whereas cyclic strain alone had no effect on ROS even when applied for 24 hours (fig. S7). Nanomaterial-induced ROS production also increased in direct proportion to the level of applied strain (Fig. 4C). In contrast, exposure of alveolar epithelial cells to 50-nm superparamagnetic iron nanoparticles under the same conditions only exhibited a small transient increase in ROS production (Fig. 4D).

Indeed, this mechanical strain–induced oxidative response appeared to be specific for the silica nanoparticles and carboxylated quantum dots, because it was not induced by treatment with various other nanomaterials, including single-walled carbon nanotubes, gold nanoparticles, polystyrene nanoparticles, or polyethylene glycol–coated quantum dots (fig. S8 and table S1). On the other hand, we found that longer exposure to silica nanoparticles alone for 24 hours induced similar

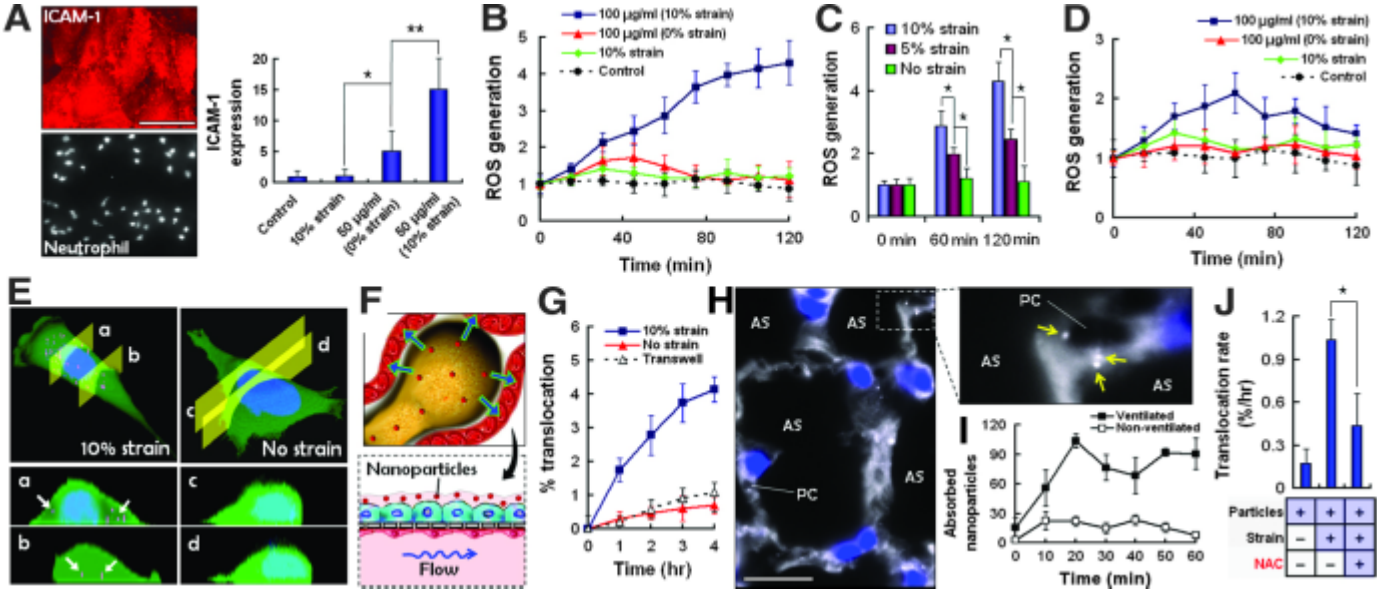

Fig. 4. Microengineered model of pulmonary nanotoxicology. (A) Ultrafine silica nanoparticles introduced through an air-liquid interface overlying the alveolar epithelium induce ICAM-1 expression (red) in the underlying endothelium and adhesion of circulating neutrophils (white dots) in the lower channel. Scale bar, 50 mm. Graph shows that physiological mechanical strain and silica nanoparticles synergistically up-regulated ICAM-1 expression (*$P < 0.005$; **$P < 0.001$). (B) Alveolar epithelial cells increase ROS production when exposed to silica nanoparticles (100 mg/ml) in conjunction with 10% cyclic strain (square) ($P < 0.0005$), whereas nanoparticles (triangle) or strain (diamond) alone had no effect on intracellular ROS levels relative to control cells (circle). ROS generation was normalized to the mean ROS value at time 0. (C) The alveolar epithelium responds to silica nanoparticles in a strain-dependent manner (*$P < 0.001$). (D) Addition of 50-nm superparamagnetic nanoparticles produced only a transient elevation of ROS in the epithelial cells subjected to 10% cyclic strain ($P < 0.0005$). (E) Application of physiological mechanical strain (10%) promotes increased cellular uptake of 100-nm polystyrene nanoparticles (magenta) relative to static cells, as illustrated by representative sections (a to d) through fluorescent confocal images. Internalized nanoparticles are indicated with arrows; green and blue show cytoplasmic and nuclear staining, respectively. (F) Transport of nanomaterials across the alveolar-capillary interface of the lung is simulated by nanoparticle transport from the alveolar chamber to the vascular channel of the lung mimic device. (G) Application of 10% mechanical strain (closed square) significantly increased the rate of nanoparticle translocation across the alveolar-capillary interface compared with static controls in this device (closed triangle) or in a Transwell culture system (open triangle) ($P < 0.0005$). (H) Fluorescence micrographs of a histological section of the whole lung showing 20-nm fluorescent nanoparticles (white dots, indicated with arrows in the inset at upper right that shows the region enclosed by the dashed square at higher magnification) present in the lung after intratracheal injection of nebulized nanoparticles and ex vivo ventilation in the mouse lung model. Nanoparticles cross the alveolar-capillary interface and are found on the surface of the alveolar epithelium, in the interstitial space, and on the capillary endothelium. PC, pulmonary capillary; AS, alveolar space; blue, epithelial nucleus; scale bar, 20 mm. (I) Physiological cyclic breathing generated by mechanical ventilation in whole mouse lung produces an increase by a factor of more than 5-fold in nanoparticle absorption into the blood perfusate when compared to lungs without lung ventilation ($P < 0.0005$). The graph indicates the number of nanoparticles detected in the pulmonary blood perfusate over time, as measured by drying the blood (1 ml) on glass and quantitating the number of particles per unit area (0.5 mm^2). (J) The rate of nanoparticle translocation was significantly reduced by adding NAC to scavenge free radicals (*$P < 0.001$).

high levels of ROS production even in the absence of mechanical strain (fig. S7), confirming findings of past pulmonary nanotoxicology studies that analyzed the effects of ultrafine silica nanoparticles in static cell cultures (34). Taken together, these data suggest that physiological mechanical stresses due to breathing might act in synergy with nanoparticles to exert early toxic effects or accelerate nanoparticle toxicity in the lung.

Mechanical strain enhanced cellular uptake of nanoparticulates in the alveolar epithelium and underlying endothelium. For example, confocal microscopic analysis revealed that the number of fluorescent nanoparticles (100 nm in diameter) or their aggregates present within the intracellular compartment of alveolar epithelial cells was much greater for the first hour after exposure when cells were subjected to physiological breathing movements (Fig. 4E). More than 70% of cells within mechanically active epithelium and endothelium internalized nanoparticles, whereas this fraction was lower by a factor of 10 in the absence of strain (fig. S9).

Modeling nanoparticle transport from alveoli into the lung vasculature. Increasing in vivo evidence suggests that nanomaterials introduced into the alveolar space have the capacity to cross the alveolar-capillary barrier and enter the pulmonary circulation, potentially affecting other organs and causing systemic toxicity (31, 33). When we introduced fluorescent nanoparticles (20 nm in diameter) into the alveolar microchannel and monitored nanoparticle translocation across the alveolar-capillary barrier in air-liquid interface culture by measuring the fraction of particles retrieved from the underlying microvascular channel by continuous fluid flow (Fig. 4F), we observed only a low level of nanoparticle absorption under static conditions. The level was similar to that measured with a static Transwell culture system containing a rigid, porous, ECM-coated membrane lined with opposing layers of alveolar epithelium and capillary endothelium (Fig. 4G). In contrast, there was an increase by more than a factor of 4 in nanoparticle transport into the vascular compartment when our microdevice experienced physiological breathing motions (10% strain at 0.2 Hz) (Fig. 4G). This was striking given that transport of fluorescent albumin remained unchanged under similar loading conditions (fig. S1). Thus, strain-induced increases in nanoparticle absorption across the alveolar-capillary barrier are not due to physical disruption of cell-cell junctions and simple convective transport. Instead, they more likely result from altered transcellular translocation or from a change in paracellular transport that somehow selectively permits passage of these nanoparticulates while restricting movement of small molecules, such as albumin. The presence of an air-liquid interface on the epithelial surface did not appear to produce substantially higher mechanical stresses or change nanoparticle absorption across the alveolar-capillary barrier in our microdevice. An air-liquid interface has been previously shown to exert higher stress on cells (12, 38); however, those studies focused mainly on the deleterious effects of a moving air-liquid interface (e.g., as might occur with a mucus plug), which generates much larger forces that are more relevant to small-airway closure and reopening.

To determine the physiological relevance of these observations, we conducted similar studies in a whole mouse lung ventilation-perfusion model, which enables intratracheal injection of nebulized nanoparticles and monitoring of nanoparticle uptake into the pulmonary vasculature ex vivo (fig. S10). When 20-nm nanoparticles were injected into whole breathing mouse lung, they were delivered into the deep lung, and histological analysis revealed that they reached the surface of the alveolar epithelium, as well as the underlying interstitial space and microvasculature (Fig. 4H). These findings confirm that these nanoparticles are retransported across the alveolar-capillary barrier in vivo, as we observed in vitro. When we monitored the number of absorbed nanoparticles collected from the pulmonary venous circulation after nanoparticle injection into the whole perfused lung, we found that nanoparticle transport from the alveoli into the microvasculature was significantly increased in the presence of cyclic breathing in vivo (Fig. 4I), just as we observed in the lung mimic device in vitro (Fig. 4G). Similar studies carried out with Transwell systems that represent the state of the art for in vitro analysis of tissue barrier permeability only exhibited low levels of nanoparticle translocation (Fig. 4G).

This mechanical force–induced increase in nanoparticle translocation was reduced significantly when the cells were incubated with the antioxidant NAC (Fig. 4J). This finding implies that elevated intracellular production of ROS due to a combination of mechanical strain and nanoparticle exposure might be responsible for the observed increase in barrier permeability to these nanoparticles. We also found that preconditioning of endothelial cells with physiological levels of shear stress (15 dyne/cm^2) slightly increased the rate of nanoparticle translocation in the presence of mechanical stretch (fig. S11), presumably due to a shear-induced increase in endothelial permeability, as previously demonstrated by others (39). Taken together, these results highlight the advantages of our microengineered device over existing in vitro model systems and provide evidence that the inherent mechanical activity of the living lung may contribute substantially to the transport of airborne nanoparticulates from the alveolar space into the bloodstream.

Biomimetic microsystems as replacements for animal testing. Development of cell-based biochips that reproduce complex, integrated organ-level physiological and pathological responses could revolutionize many fields, including toxicology and development of pharmaceuticals and cosmetics that rely on animal testing and clinical trials. This human breathing lung-on-a-chip microdevice provides a proof of principle for this novel biomimetic strategy that is inspired by the integrated chemical, biological, and mechanical structures and functions of the living lung. This versatile system enables direct visualization and quantitative analysis of diverse biological processes of the intact lung organ in ways that have not been possible in traditional cell culture or animal models.

There are still differences between our lung mimic device and the alveolar-capillary barrier in vivo (e.g., barrier thickness, cellular composition, lack of alveolar macrophages, and changes in air pressure and flow), and the transformed lung cells used in our study might not fully reproduce the responses of native alveolar epithelial cells. However, our data clearly demonstrate that this biomimetic microsystem can reconstitute multiple physiological functions observed in the whole breathing lung. Specifically, the lung mimic device reconstitutes the microarchitecture of the alveolar-capillary unit, maintains alveolar epithelial cells at an air-liquid interface, exerts physiologically relevant mechanical forces to the entire structure, and enables analysis of the influence of these forces on various physiological and pathological lung functions, including interactions with immune cells and pathogens, epithelial and endothelial barrier functions, and toxicity and absorption of nanoparticulates across this critical tissue-tissue interface. Existing in vitro mechanical stimulation models fail to offer any of these integrated capabilities, and the fact that our system allows one to study all of these complex physiological phenomena in a single device makes it even more novel. Moreover, this microdevice represents an innovative and low-cost screening platform that could potentially replace in vivo assays or substantially improve the outcome of animal and clinical studies, by enhancing the predictive power of in vitro or in silico computational models.

Microengineering approaches developed in this research also might offer new opportunities to more accurately model critical tissue-tissue interfaces and specialized physical microenvironments found in other organs, such as the gut, kidney, skin, and bone marrow, as well as in human cancers. These biomimetic microsystems are miniaturized (Fig. 1E) and can be easily multiplexed and automated. Hence, with simplified designs and careful choice of biocompatible device materials, they might be useful for high-throughput analysis and screening of cellular responses to drugs, chemicals, particulates, toxins, pathogens, or other environmental stimuli relevant to pharmaceutical, cosmetic, and environmental applications. Furthermore, these microengineering approaches might open the possibility of integrating multiple miniaturized organ model systems into a single device to recapitulate interactions between different organs and enable more realistic in vitro assays of the whole body's response to drugs and toxins (19, 40, 41).

REPORTS

4D Electron Tomography

Oh-Hoon Kwon and Ahmed H. Zewail*

Electron tomography provides three-dimensional (3D) imaging of noncrystalline and crystalline equilibrium structures, as well as elemental volume composition, of materials and biological specimens, including those of viruses and cells. We report the development of 4D electron tomography by integrating the fourth dimension (time resolution) with the 3D spatial resolution obtained from a complete tilt series of 2D projections of an object. The different time frames of tomograms constitute a movie of the object in motion, thus enabling studies of nonequilibrium structures and transient processes. The method was demonstrated using carbon nanotubes of a bracelet-like ring structure for which 4D tomograms display different modes of motion, such as breathing and wiggling, with resonance frequencies up to 30 megahertz. Applications can now make use of the full space-time range with the nanometer-femtosecond resolution of ultrafast electron tomography.

For nearly a century, the determination of three-dimensional (3D) structures of a crystalline specimen, with redundancy in the repeating units of the architecture, has primarily depended on x-ray and electron-based methods. Recently, with the combination of electron microscopy techniques and fast computation methods, electron tomography has become a powerful tool for 3D structural determination of nanoscopic noncrystalline materials (1, 2) and biological assemblies such as viruses, bacteria, and cells (3–5). Historically, several initial advances were made (5), but the first examples of the approach were published with different variants in the 1960s: reconstruction of 3D biostructures (of high symmetry) from one or more projections (6, 7), reconstruction of an asymmetric protein structure from a sufficient number of projections (8), and average reprojection calculated from a tilt series of images (9). However, decades of advances in computation methods were required to bring the field into the state of the art in high-resolution electron tomography with applications in many fields (10–12), which include the impressive methods of energy-filtering for mapping a specific element or site (13–16) and the use of the high-angular annular dark field (HAADF) for suppressing the diffraction contrast of crystalline materials (17, 18). In all of these studies, the tomograms obtained are those of a static object representing the time-averaged equilibrium state of the structure.

To visualize the dynamics, the dimension of time must be integrated into any electron tomogram that spans a whole tilt series. Furthermore, the time resolution in every step must be high enough to capture the motion of the object, ideally reduced to the atomic scale. This simultaneous real-space and real-time resolution can be obtained using ultrafast electron microscopy (UEM) (11, 19). However, in UEM a snapshot represents a time frame of the 2D projection of the object under investigation, making invisible the spatial information in the dimension along the optical axis of the microscope. This is because of the large focus depth in the specimen.

Here, we report the development of 4D electron tomography. The tomograms are reconstructed from nearly 4000 projections for a whole series of tilt angles and time steps. The methodology is demonstrated in the imaging of multiwalled carbon nanotubes (MWNTs), with the time resolution being independent of the video camera response time of milliseconds, thus enabling the visualization of non-equilibrium, fleeting structures on the femtosecond to millisecond time scale. For the nanotubes, the 4D tomograms in a movie display the mechanical motions and morphological dynamics of the object, a

small airway-on-a-chip enables analysis of human lung inflammation and drug responses *in vitro*

Kambez H Benam[1,8], Remi Villenave[1,8], Carolina Lucchesi[1,7], Antonio Varone[1,7], Cedric Hubeau[2], Hyun-Hee Lee[3], Stephen E Alves[3], Michael Salmon[3], Thomas C Ferrante[1], James C Weaver[1,4], Anthony Bahinski[1], Geraldine A Hamilton[1,7] & Donald E Ingber[1,4–6]

here we describe the development of a human lung 'small airway-on-a-chip' containing a differentiated, mucociliary bronchiolar epithelium and an underlying microvascular endothelium that experiences fluid flow, which allows for analysis of organ-level lung pathophysiology *in vitro*. exposure of the epithelium to interleukin-13 (il-13) reconstituted the goblet cell hyperplasia, cytokine hypersecretion and decreased ciliary function of asthmatics. small airway chips lined with epithelial cells from individuals with chronic obstructive pulmonary disease recapitulated features of the disease such as selective cytokine hypersecretion, increased neutrophil recruitment and clinical exacerbation by exposure to viral and bacterial infections. With this robust *in vitro* method for modeling human lung inflammatory disorders, it is possible to detect synergistic effects of lung endothelium and epithelium on cytokine secretion, identify new biomarkers of disease exacerbation and measure responses to anti-inflammatory compounds that inhibit cytokine-induced recruitment of circulating neutrophils under flow.

The development of new therapeutics for chronic respiratory diseases such as asthma and chronic obstructive pulmonary disease (COPD), which pose a huge public health burden[1], has been hindered by the inability to study organ-level complexities of lung inflammation *in vitro*. Although hospitalization and mortality due to these diseases are often consequences of exacerbations triggered by pathogens[2,3], there is currently no way to study these processes in human lung outside of the clinical setting. Animal models of asthma and COPD exist; however, their clinical relevance is questionable because the anatomy, immune system and inflammatory responses of animal lungs differ greatly from those in humans[4–6]. For example, mucin-producing cells, which are central to the development of asthma, are less frequent in the respiratory trees of mice and rats than in those of humans[6]. Neutrophils, which increase in number dramatically in the lungs of patients with COPD and severe asthma[7–9], constitute only 10–25% of circulating leukocytes in mice, whereas they represent 50–70% in humans[5]. Because many animal models do not accurately predict drug activities in humans, the pharmaceutical and biotechnology industries strive to replace or minimize the use of animal models for drug testing whenever possible[10].

Airway inflammatory diseases have been modeled *in vitro* using cultures of primary or immortalized human epithelial cells, sometimes positioned at an air-liquid interface to induce epithelial differentiation[11], or using cocultures of airway epithelium and tissue-resident immune cells (for example, macrophages or dendritic cells)[12]. However, lung inflammation is mediated by organ-level responses involving complex tissue-tissue interactions between the lung airway epithelium and the underlying microvascular endothelium that modulate immune reactions to respiratory pathogens and allergens[13–15] and alter the vascular cell adhesion molecular machinery that recruits circulating immune cells, such as neutrophils. This is important because neutrophil accumulation in the lung is associated with enhanced severity of airflow limitation in people with COPD[7], and it has a critical role in severe asthma as well[8]. Unfortunately, it is not possible to study complex interactions among airway epithelium, endothelium and circulating neutrophils using existing *in vitro* lung models because most fail to recapitulate normal functional coupling between epithelium and endothelium, and none enables analysis of the recruitment of circulating immune cells under active fluid flow. The latter point is crucial because neutrophil adhesion to inflamed endothelium involves initial E-selectin–mediated rolling along the luminal surface of endothelium, which is followed by firm adhesion to ICAM-1 (ref. 16), and this dynamic shear stress–dependent response cannot be studied in a physiologically relevant way using static cell cultures.

Advances in microsystems engineering have recently made it possible to create biomimetic microfluidic cell-culture devices, known as organs-on-chips, that contain continuously perfused microchannels lined by living human cells and which recapitulate the multicellular architectures, tissue-tissue interfaces, physicochemical microenvironments and vascular perfusion of the body[17], potentially offering new opportunities for disease

modeling and drug-efficacy assessment[18]. We previously used this approach to successfully reconstitute the alveolar-capillary interface of the human lung air sac and associated inflammatory responses *in vitro*[19,20]. Here we adapted this approach to micro engineer a human lung small airway-on-a-chip that supports full differentiation of a columnar, pseudostratified, mucociliary bronchiolar epithelium composed of cells isolated from healthy individuals or people with COPD and underlined by a functional microvascular endothelium.

results

on-chip reconstitution of a functional small airway

To construct the human small airway-on-a-chip, we used soft lithography to create a microfluidic device made of poly(dimethylsiloxane) (PDMS) containing an upper channel with a height and width of 1 mm (similar to the radius of a human bronchiole) separated from a parallel lower microvascular channel (0.2 mm high × 1 mm wide) by a thin (100 μm), porous (0.4 μm pores), polyester membrane coated on both sides with type I collagen (**Fig. 1a**). We cultured primary human airway epithelial cells (hAECs) on top of the membrane until confluent with medium flowing (60 μl h^{-1}) in both channels. To trigger the differentiation of lung airway epithelial cells, we removed the apical medium after 5 d and introduced air to create an air-liquid interface (ALI). We added retinoic acid (1 μg ml^{-1}) to the medium flowing in the lower channel to prevent the development of a squamous phenotype. Three to five weeks later, we seeded primary human lung microvascular endothelial cells on the opposite side of the porous membrane and cultured them at the same flow rate until confluent to create a tissue-tissue interface (**Fig. 1a,b**).

Immunofluorescence confocal microscopic analysis showed that these culture conditions resulted in the formation of a pseudostratified, mucociliary airway epithelium on one side of an extracellular matrix–coated membrane and a planar microvascular endothelium on the opposite side (**Fig. 1c–f**, **Supplementary Fig. 1a** and **Supplementary Videos 1** and **2**). The epithelial cells were linked by a continuous band of ZO1-containing tight junctions along the lateral borders of their apical surfaces (**Fig. 1d**), whereas endothelial cells were joined by adherens junctions containing PECAM-1 (**Fig. 1e**). The epithelium formed from cells isolated from the small airway epithelium of lungs from both healthy humans (**Fig. 1f,g** and **Supplementary Video 2**) and people with COPD (**Supplementary Fig. 1a**) contained many ciliated epithelial cells as well as mucus-producing goblet cells, club cells (**Supplementary Fig. 1b**) and basal cells with proportions strikingly similar to those found in normal human lung (**Table 1**). Immunodetection of tight junctions was accompanied by the formation of a robust epithelial barrier that restricted the passage of fluorescent inulin (4 kDa) and dextrans (10 and 70 kDa) between the parallel channels during analysis

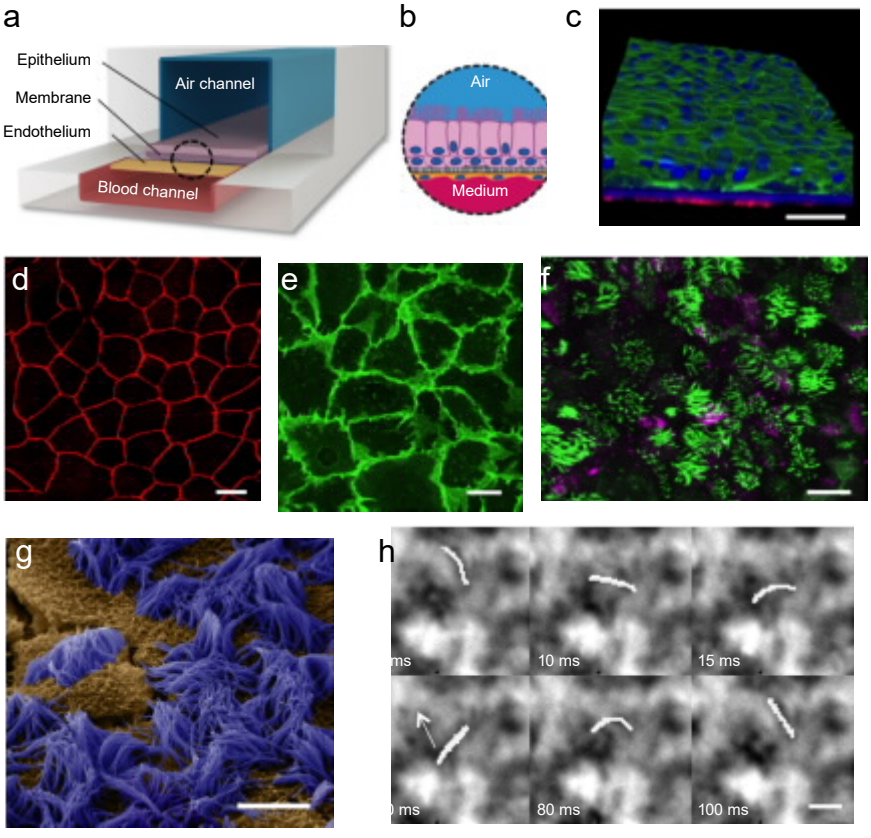

Figure 1 | The human small airway-on-a-chip. (**a**) Schematic diagram of a cross-section through the small airway-on-a-chip. The dashed circle highlights the area depicted in **b**. (**b**) Diagram of the tissue-tissue interface that forms on-chip, showing differentiated airway epithelium (pink cells) cultured on top of a porous collagen-coated membrane at an air-liquid interface in the upper channel and the endothelium below (orange cells) with flowing medium that feeds both tissue layers. (**c**) A 3D reconstruction showing fully differentiated, pseudostratified airway epithelium formed on-chip by cultured hAECs (green, F-actin) with human pulmonary microvascular endothelial cells (red, F-actin) on the opposite side of the membrane. Blue denotes DAPI-stained nuclei; scale bar, 30 μm. (**d**) The differentiated human small airway epithelium exhibited continuous tight junctional connections on-chip, as demonstrated by ZO1 staining (red). Scale bar, 20 μm. (**e**) The human (lung blood microvascular) endothelial monolayer formed on-chip also contained continuous adherens junctions between adjacent cells, as indicated by PECAM-1 staining (green). Scale bar, 20 μm. (**f**) Well-differentiated human airway epithelium formed on-chip using hAECs derived from healthy donors demonstrating the presence of high numbers of ciliated cells labeled for β-tubulin IV (green) and goblet cells stained with anti-MUC5AC (magenta). Scale bar, 20 μm. (**g**) Scanning electron micrograph of cilia (blue) on the apical surface of the differentiated airway epithelium formed on-chip (nonciliated cells are in brown). Scale bar, 10 μm. (**h**) Sequential frames of a video of the apical surface of differentiated epithelium recorded over 100 ms showing cilia beating at a frequency of ~10 Hz. A single cilium is highlighted in white in each frame; time stamps and the white arrow indicate the duration and direction of one forward and return stroke (**Supplementary Video 4** shows the full recording). Scale bar, 5 μm (applies to all images in panel). All images are representative of three to six independent experiments performed on cells from three to six different donors.

table 1 | Comparison of structure and function between living human airway and human small airway-on-a-chip

	human airway	small airway-on-a-chip
Cell type		
Ciliated cells (%)	~30	~20–30
Goblet cells (%)	~10–15	~10–20
Club cells (%)	~11–44	~25
Basal cells (%)	~6–30	~20
Cilia		
Structure	9 + 2 structure	9 + 2 structure
Length	~6 μm	~6 μm
Beating frequency	9–20 Hz	9–20 Hz
Transport velocity	40–150μm s^{-1}	40–100μm s^{-1}

Human airway cell composition characteristics and properties of pulmonary cilia were obtained from other publications[21,23,48,49].

over 24 h, mimicking the barrier function of living lung mucosa (**Supplementary Fig. 1c**). Electron microscopic analysis of the normal lung small airway-on-a-chip confirmed that the cilia on the apical surface of the polarized epithelium had the same structure (9+2 microtubule organization) and length (~6 μm) (**Supplementary Fig. 1d**) as healthy cilia found in living human lung *in vivo*[21,22]. High-speed microscopic imaging confirmed that these cilia beat actively at a frequency of 9–20 Hz (**Fig. 1h** and **Supplementary Video 3**), which again is nearly the same as that observed in human airways[21,23] (**Table 1**). Moreover, when we measured mucociliary transport by introducing fluorescent polystyrene microbeads into the top channel, we observed rapid coordinated movement of the beads along the surface of the epithelium (**Supplementary Video 4**) as a result of active synchronized cilia beating; again, the particle velocity measured (50–100μm s^{-1}) was nearly identical to that observed in healthy human lung airways (**Table 1**). Thus, the human lung small airway-on-a-chip effectively recapitulated many of the structures and functions of healthy lung bronchioles and sustained them for weeks *in vitro*.

modeling asthma and lung inflammation on-chip

IL-13 has a pivotal role in asthma, as it is necessary and sufficient to induce all features of allergic asthma in animal models of the disease[24]. IL-13 has a direct effect on human airway epithelium[25] and participates in airway inflammation, goblet cell hyperplasia and mucus hypersecretion, as well as subepithelial fibrosis and airway hyper-responsiveness[24]. When we treated the small airway-on-a-chip with IL-13 (100 ng ml^{-1}) for 8 d, we observed a significant increase in the number of goblet cells (**Fig. 2a,b**), in line with other *in vitro* models[26]; higher production and secretion of the inflammatory cytokines G-CSF and GM-CSF into the vascular channel, as measured in the fluid effluent at days 2 and 8, respectively (**Fig. 2c**); and a decrease in cilia beating frequency (**Fig. 2d**) similar to that observed in the airway mucosa of individuals with asthma[27–29].

As mucosal inflammation and its exacerbation by viral infections are major components of both asthma and COPD, and because it has been challenging to recapitulate these clinically relevant responses *in vitro*, we analyzed the effects of exposing the airway epithelium to the viral mimic polyinosinic-polycytidylic acid (poly(I:C)) (10 μg ml^{-1}). Poly(I:C) is an analogue of the double-stranded RNA that is produced in infected cells during viral replication by respiratory viruses[30]. The synthetic nature of our engineered lung airway model enabled us to analyze both independent and collective responses of the lung epithelium and endothelium to poly(I:C) challenge, which is not possible in human subjects. Stimulation with poly(I:C) for 3 h triggered a proinflammatory response in the chips similar to that in human subjects with acute severe asthma exacerbations[8], including large increases in the basal secretion of RANTES, IL-6 and interferon-γ–inducible protein 10 (IP-10) (**Fig. 2e**) that were threefold to sixfold higher when underlying endothelium was present relative to when the endothelium was absent. This effect seemed to be specific for these cytokines in that removal of the endothelium had no effect on the secretion

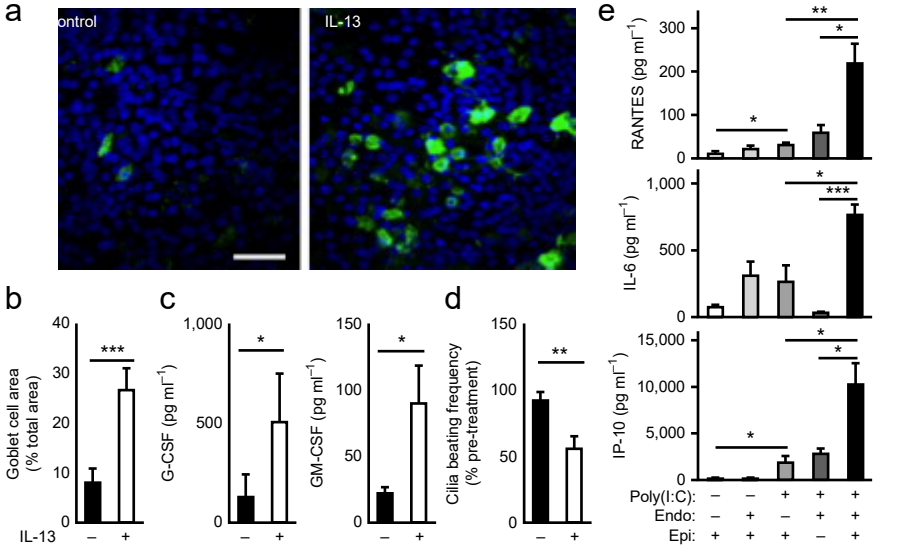

Figure 2 | Modeling asthma and lung inflammation on-chip. (**a**) Immunofluorescence micrographic views of differentiated airway epithelium cultured on-chip for 4–6 weeks at the air-liquid interface in the absence (left) or presence (right) of IL-13 showing epithelium stained for the goblet cell marker MUC5AC (green) and with DAPI (blue). Scale bar, 50 μm (applies to both views); images are representative of three independent experiments performed on cells from three different donors. (**b**–**d**) Total culture area covered by goblet cells (**b**), production of the cytokines G-CSF and GM-CSF (**c**) and cilia beating frequency (**d**) under the conditions described in **a**. Data represent mean and s.e.m. (compared to unstimulated controls) of cells from three healthy donors, with one or two biological replicates per donor; for goblet cell analysis, three to five representative areas per condition were used for quantification; $n = 3–8$. (**e**) Production of the cytokines RANTES, IL-6 and IP-10 by the small airway-on-a-chip with (+) or without (−) a differentiated bronchiolar epithelium (Epi), an umbilical vein endothelium (Endo) or both in the presence or absence of poly(I:C) (10 μg ml^{-1}) stimulation; data represent mean and s.e.m. (compared to unstimulated epithelium or stimulated coculture) of cells from three or four healthy donors, with one biological replicate per donor; $n = 3–4$. Significance determined by unpaired Student's *t*-test; * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$.

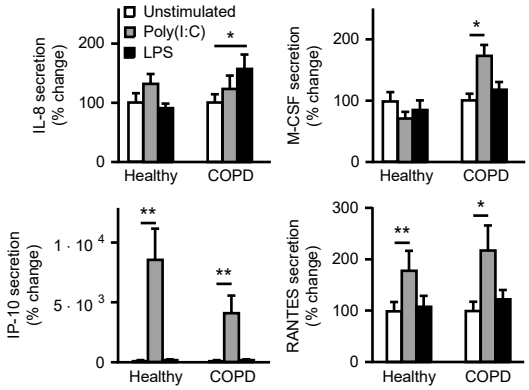

Figure 3 | Modeling COPD exacerbations in the small airway-on-a-chip. The graphs show effects on production of the cytokines IL-8, M-CSF, IP-10 and RANTES by Toll-like receptor stimulation with LPS (10 μg ml^{-1}) or poly(I:C) (10 μg ml^{-1}) in small airway chips lined by 3–5-week-old hAECs obtained from either healthy or COPD subjects (all the COPD subjects had a history of smoking). Note that Toll-like receptor activation by these simulants of bacterial and viral infection significantly induced IL-8 and M-CSF release only in COPD chips, whereas IP-10 and RANTES release increased in both healthy and COPD epithelia (unpaired Student's *t*-test; * $P < 0.05$, ** $P < 0.01$). Data represent mean and s.e.m. (compared to unstimulated controls) of cells from four different healthy and four different COPD donors, with one to three biological replicates (chips) per donor; $n = 5–10$. The variability between biological replicates for a given donor was minimal (s.e.m. <5% of mean).

of GRO-α or IL-8 (**Supplementary Fig. 2a**). We found that this effect was synergistic, as stimulated endothelial cells alone secreted similar or lower levels of cytokines compared with the isolated epithelium (**Fig. 2e**). Notably, although previous studies have investigated airway epithelium homeostasis using cocultures of endothelium and lung basal cells[31,32], inflammatory responses in fully differentiated human small airway epithelium have not been demonstrated previously *in vitro*. In addition, poly(I:C) induced upregulation of E-selectin and VCAM-1 expression in the underlying endothelium (**Supplementary Fig. 2b**); these proteins are crucial for the initial adhesion and rolling of neutrophils under flow in microvessels in inflamed living tissues[33]. In fact, this upregulation resulted in enhanced adhesion, rolling and total recruitment of circulating human neutrophils in the small airway chip when primary human neutrophils were flowed through the lower channel under physiological flow and shear stress (1 dyn cm^{-2}) (**Supplementary Video 5**).

Thus, these findings reveal intrinsic cross-talk between human epithelium and endothelium during poly(I:C)-induced inflammation and corroborate past animal studies suggesting that the pulmonary endothelium contributes significantly to viral-induced inflammation by acting as a central regulator of the cytokine storm[15]. Also, when we compared responses to poly(I:C) stimulation in bronchiolar versus bronchial epithelial cells, we found that the two types of cells displayed nearly identical secretion of inflammatory cytokines (**Supplementary Fig. 2c**).

Modeling COPD exacerbation on-chip

As pathogenic infections are a major cause of COPD exacerbation in patients, we next explored whether the lung small airway-on-a-chip could be used to model these inflammatory responses *in vitro*. We stimulated small airway chips lined by either normal or COPD epithelial cells with the viral mimic poly(I:C) or with lipopolysaccharide endotoxin (LPS), which is a bacterial wall–derived component that stimulates cytokine production and has been widely used to simulate bacterial infection *in vitro*[34]. We analyzed secretion of the cytokine M-CSF because it promotes the differentiation and survival of macrophages, and we studied the production of IL-8 because it attracts neutrophils; these are two major immune cell types that accumulate in the airway tissue of individuals with COPD[35,36]. Stimulation with LPS and poly(I:C) respectively upregulated the secretion of IL-8 and M-CSF in the COPD chips, but these infection mimics did not produce any significant change in chips lined by healthy airway epithelial cells (**Fig. 3**). These results are consistent with findings from past studies showing that bronchial epithelial spheroids from subjects

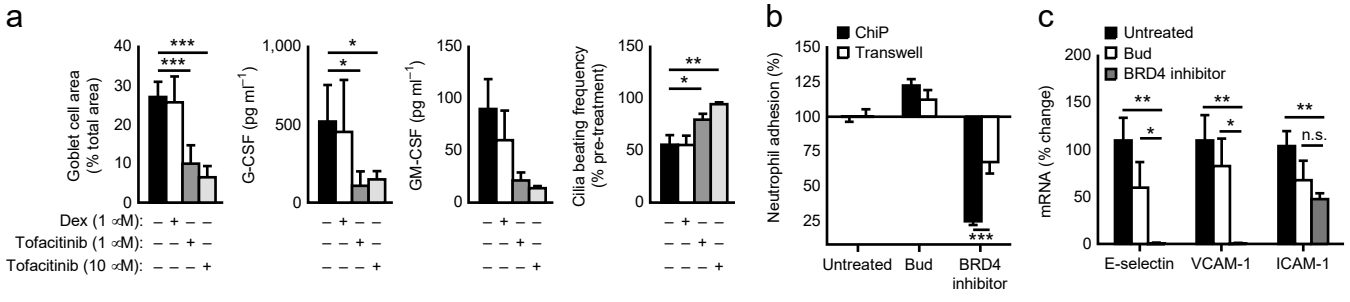

Figure 4 | Pharmacological modulation of IL-13 induced asthmatic phenotype and COPD exacerbation–associated inflammation in the small airway chip. (**a**) Total area covered by goblet cells, effects on production of the cytokines G-CSF and GM-CSF, and cilia beating frequency after exposure of the epithelium to IL-13 with or without dexamethasone (Dex) or tofacitinib for 8 d (skewed cytokine data were log transformed before comparison; data represent mean and s.e.m. (compared to IL-13–treated condition) of cells from three healthy donors, with one or two biological replicates per donor; for goblet cell analysis, three to five representative areas per condition were used for quantification; $n = 3–9$). (**b**) Neutrophil-adhesion results compared with neutrophil-recruitment data obtained when similar studies were carried out in static Transwell cultures. Data represent mean and s.e.m. (chip versus Transwell) of cells from two to four different COPD donors, with one to four biological replicates per donor and three to ten independent fields of view per chip or Transwell; $n = 15–59$. Bud, budesonide; BRD4, bromodomain-containing protein 4. (**c**) Effects of (10 nM) budesonide and (500 nM) BRD4 inhibitor on expression of genes encoding the endothelial cell adhesion molecules E-selectin, VCAM-1 and ICAM-1, compared to the untreated (0.1% DMSO) group, as measured using real-time PCR; human pulmonary blood microvascular cells were studied (n.s., not significant; data represent mean and s.e.m. of cells from one of the donors studied, in three or four biological replicates per condition; $n = 3–4$). Significance determined by unpaired Student's *t*-test; * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$; n.s., not significant.

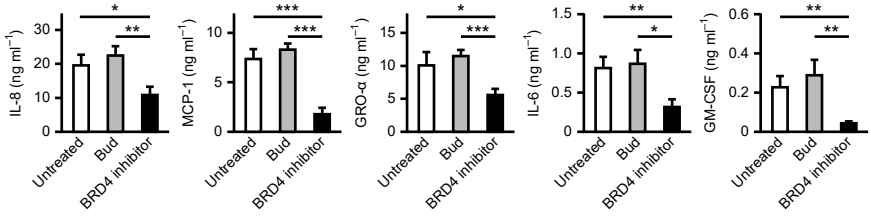

Figure 5 | Therapeutic modulation of inflammatory cytokine and chemokine production in the COPD small airway chip. Analysis of the effects of budesonide (Bud) and BRD4 inhibitor on the secretion of IL-8, MCP-1, GROα, IL-6 and GM-CSF into the microvascular channel of chips lined by COPD epithelium cultured at the air-liquid interface for 3–5 weeks when challenged with poly(I:C) (unpaired Student's *t*-test; * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$; data represent mean and s.e.m. (compared to untreated controls) of cells from three different COPD epithelial and two different lung blood microvascular endothelial cell donors, with one to four biological replicates per donor, $n = 6–8$).

with COPD exhibit greater LPS-induced IL-8 release than those from healthy controls[37], and the enhanced levels of M-CSF that we detected might partly explain the accumulation of macrophages observed in the lungs of people with COPD[9]. In contrast, stimulation with poly(I:C) produced large increases in secretion of the cytokines IP-10 and RANTES in both healthy and COPD chips (**Fig. 3**). These results are consistent with the finding that serum IP-10 is an excellent clinical marker for acute viral exacerbations in COPD patients[2]. Our finding that M-CSF levels specifically increased only in poly(I:C)-treated small airway chips (**Fig. 3**) suggests that M-CSF could be a new biomarker for COPD exacerbations induced by respiratory viruses.

evaluation of therapeutic responses in small airway chips

Having established these microfluidic models of human asthmatic and COPD airways, we then asked whether this new *in vitro* method could be useful for drug discovery. As IL-13 signals through the JAK-STAT pathway, we investigated whether tofacitinib, a potent inhibitor of JAK1, -2 and -3 used for patients with rheumatoid arthritis[38], could reverse the IL-13–induced phenotype. When we exposed normal airway epithelium on-chip to IL-13 to produce asthmatic changes in the epithelium and then treated with high doses of tofacitinib (1 and 10 μM) to inhibit JAK signaling, we observed suppressed goblet cell hyperplasia, decreased secretion of G-CSF and GM-CSF, and restoration of normal cilia beating frequency (**Fig. 4a**). In contrast, when similar chips exposed to IL-13 were treated with the corticosteroid dexamethasone, it was found to be ineffective, which is consistent with the clinical finding that although patients with moderate to severe asthma receive dexamethasone inhalation therapy, they often fail to respond to the treatment[39]. These results also validate recent reports suggesting that immunosuppressant JAK inhibitors may represent potential new therapeutics for allergic airway diseases[40].

To test the breadth and robustness of our platform, we also explored whether we could use the human small airway-on-a-chip model of COPD exacerbation by microbial infection to identify pharmacological agents able to suppress the associated inflammation, specifically by inhibiting the recruitment of neutrophils circulating under flow. When we treated COPD epithelial cells that had been stimulated with poly(I:C) on-chip with the glucocorticoid drug budesonide, there was no significant change in neutrophil adhesion (**Fig. 4b**), which again is consistent with the drug's noted lack of activity in many COPD patients[41]. We then tested a new experimental anti-inflammatory drug, 2-methoxy-N-(3-methyl-2-oxo-1,2-dihydroquinolin-6-yl) benzenesulfonamide[42], which is a bromodomain-containing protein 4 (BRD4) inhibitor of NFκB signaling. We chose this drug because it belongs to an emerging class of new anti-inflammatory drugs that were recently shown to alleviate lung inflammation in an LPS-challenged mouse model[43]. When the BRD4 inhibitor was added to the inflamed human small airway chip, it suppressed neutrophil adhesion under flow by almost 75% (**Fig. 4b**). However, when we tested these same drugs on similarly differentiated airway epithelium maintained with an underlying endothelium in static Transwell cultures, we found that the inhibitory effect of the BRD4 inhibitor on neutrophil recruitment was reduced by one-third, whereas the results obtained with budesonide were similar (**Fig. 4b**). This differential response to the BRD4 inhibitor under static versus dynamic flow conditions suggests that its mechanism of action might involve preferential inhibition of early adhesion and rolling responses that are required for initiation of the neutrophil-recruitment cascade because they occur only under dynamic flow conditions[44]. In fact, our studies showed that treatment of inflamed endothelial cells with the BRD4 inhibitor resulted in a more than 50-fold reduction in expression levels of E-selectin and VCAM-1, as well as a 50% reduction in ICAM-1, whereas budesonide treatment did not significantly decrease the expression of either of these vascular cell adhesion molecules (**Fig. 4c**).

Consistent with its ability to suppress neutrophil adhesion, the BRD4 inhibitor also proved greatly superior to the corticosteroid in downregulating expression of the genes encoding IL-8, MCP-1, GRO-α and IL-6 in human lung microvascular endothelial cells (**Supplementary Fig. 3**), as well as suppressing secretion of these cytokines into the lower microvascular channel (**Fig. 5**). These are important findings because these cytokines are key chemoattractants for neutrophils *in vivo*. The BRD4 inhibitor also significantly suppressed the production of GM-CSF (**Fig. 5**), which is a neutrophil chemokine that enhances the functionality of neutrophils[45], in addition to supporting bone marrow cell proliferation and the survival of granulocytic precursors. Although budesonide slightly decreased the expression of selected cytokine genes (**Supplementary Fig. 3**), it did not significantly suppress cytokine secretion (**Fig. 5**), which is the most critical determinant of the inflammatory response; these findings again mimic results from animal models of COPD and lung inflammation[43,46]. Thus, reconstitution of the COPD inflammatory phenotype on-chip not only enabled testing for the efficacy of new experimental therapeutics but also allowed dissection of the mechanism of drug action at the molecular level in a human organ context *in vitro*.

discussion

Although attempts have been made in the past to culture human airway epithelium in microfluidic devices along with endothelium and fibroblasts[47], the small airway-on-a-chip described here achieved greater robustness and fidelity in mimicking the

structure and functions of the human lung airway, as well as in modeling of pulmonary diseases and recapitulation of lung inflammatory responses *in vitro*. Because the organ-on-chip approach essentially represents 'synthetic biology' at the organ level, we also were able to independently control and vary virtually all system parameters, including the presence or absence of different cell types, vascular flow conditions and soluble factors, while simultaneously analyzing human organ-level responses in real time with molecular-scale resolution. This microengineered lung small airway-on-a-chip model also faithfully recapitulated *in vivo* organ-level responses to therapy, and thus it offers a powerful complement to animal models for both analyzing human pathophysiology and carrying out preclinical drug evaluations (more details can be found in the **Supplementary Discussion**).

online methods

Device fabrication. We created the upper and lower layers of the microfluidic device (**Fig. 1a**) by casting PDMS pre-polymer on molds prepared using stereolithography (Fineline, USA). Curing (10:1 PDMS base to curing agent, wt/wt) was carried out overnight at 60 °C to produce devices containing two adjacent parallel microchannels (top channel, 1,000 μm wide × 1,000 μm high; bottom channel, 1,000 μm wide × 200 μm high; length of overlapping channels, 16.7 mm), which were used to form the airway lumen and the microvascular channel, respectively. The channels were separated by a thin (~1 mm) semiporous polyester membrane (0.4 μm pores) that was purchased from Maine Manufacturing (USA). The membrane was laser cut, plasma treated using Plasma Etcher PE-100 (Plasma Etch, USA) with one cycle of 50 watts of oxygen gas (15 standard cm^3 min^{-1}) for 15 s, sandwiched between the carefully aligned top and bottom channels, and treated with ultraviolet light in a UVO-Cleaner (Model 342, Jelight, USA) for 30 min before a collagen coating was applied.

Microfluidic cell culture. Primary hAECs obtained from commercial suppliers (Promocell, Germany; Lonza, USA; and Epithelix, Switzerland) were expanded in 75-cm^2 tissue culture flasks using airway epithelial growth medium (BEBM; catalog no. CC-3171) supplemented with growth factors and/or supplements (BulletKit Supplements; Lonza) until 70–80% confluent. We isolated the lung epithelial cells, on the basis of information provided by the vendors, by dissecting airways from whole lungs or lung biopsies, subjecting them to enzymatic digestion and subsequently culturing them in a selective growth medium. The age and sex of healthy and COPD donors are presented in **Supplementary Table 1**. All of the COPD subjects whose epithelial cells were studied in the experiment described in **Figure 3** had a history of smoking. Cells were randomly checked with a mycoplasma biochemical detection kit (Lonza, USA) and were found to be negative.

Before cell culture, the porous membrane of the device was coated on both sides with rat tail collagen type I (300 μg ml^{-1}; Corning, USA) at 37 °C for 24 h. The hAECs were then trypsinized and seeded onto the collagen-coated porous membrane in the upper channel of the device at a concentration of 2×10^6 to 10×10^6 cells ml^{-1} (2×10^5 to 5×10^5 cells cm^{-2}, or 4×10^4 to 10×10^4 cells per chip) and allowed to attach under static conditions. Three hours later, the cell monolayer was washed with fresh medium, and the cultures were maintained in a submerged state until fully confluent (typically 4–5 d after seeding) under constant flow (60 μl h^{-1}) using an IPC-N series peristaltic pump (Ismatec, Switzerland). The chips were cultured in an incubator containing 5% CO_2 and 16–18% O_2 at 85–95% humidity.

When cultures were confluent, the apical medium was removed and an ALI was generated to trigger differentiation. The hAECs were maintained at the ALI for 3–5 weeks with a constant flow of growth medium in the bottom channel, which was sufficient to support epithelial cell viability and function for weeks in culture. The apical surface of the epithelium was rinsed once weekly with growth medium to remove debris. To control for variability in our studies, we ensured that all cultures reached a similar level of morphological and functional differentiation before we carried out any experiments. In our initial characterization studies, we determined that the primary human epithelial cells formed a stable and terminally differentiated ciliated epithelium within 3–5 weeks after being placed under an ALI, as defined using noninvasive microscopic imaging to confirm the formation of a confluent epithelial layer expressing actively beating surface cilia, and chips that failed to reach this standard by 5 weeks were discarded. We did not observe any notable difference in the differentiation responses of cells from different donors in our studies. Mucociliary transport was visualized using 1-μm-diameter fluorescent microbeads (Life Technologies, USA) diluted in phosphate-buffered saline (PBS), injected in the upper channel of a fully differentiated small airway-on-a-chip and imaged using a high-speed Hamamastu ORCA-Flash 4.0 camera mounted on a Zeiss AxioObserver Z1 microscope. For permeability measurements we flowed inulin (4 kDa)–FITC, dextran (10 kDa)–Cascade blue or dextran (70 kDa)–Texas red diluted in growth medium (100 μg ml^{-1}) at 60 μL h^{-1} in the top channel for 24 h and measured the fluorescence intensity of medium flowing out of the top and bottom channels in three individual small airway chips. The apparent permeability was calculated using the following formula:

$$P_{app} = \frac{J}{A \times \Delta C}$$

where P_{app} is the apparent permeability, J is the molecular flux, A is the total area of diffusion, and ΔC is the average gradient (~1 because of the low flow rate).

Once differentiation of the hAECs was accomplished, human lung microvascular endothelial cells (Lonza; purchased as 'lung blood microvascular' endothelial cells before the supplier switched to the 'lymphatic + vascular' mix) were used for analysis of neutrophil adhesion and rolling, drug-efficacy testing and experiments involving COPD chips. We performed flow cytometric analysis and confirmed that our endothelial cells were >98% pure blood microvascular endothelial cells free of cells expressing lymphatic antigens (lymphatic vessel endothelial receptor 1 and podoplanin). Human umbilical vein endothelial cells (Angioproteomie, USA, or Lonza) were used for synergistic cytokine secretion studies; both types of endothelial cells were seeded onto the lower side of the porous membrane through the bottom channel at a density of 2×10^7 cells ml^{-1} (2×10^5 cells cm^{-2} or 4×10^4 cells per chip). Endothelial cells were seeded in Lonza EBM-2 endothelial cell basal growth medium (catalog no. CC-3156) supplemented with EGM-2MV SingleQuot Kit growth factors and/or supplements under static conditions with the chip oriented upside down to allow cell adhesion to the undersurface of the porous membrane. Two hours later, flowing of growth medium (60 μL h^{-1}) was resumed until cells were fully confluent (usually 3–6 d after seeding). We found no significant difference in the cell densities in the epithelial and endothelial layers when we compared epithelium cultured alone to that cultured in the presence of endothelium.

Immunofluorescence microscopy. For immunofluorescence staining, we washed cells by flowing PBS through the top and bottom channels, fixed them with 4% paraformaldehyde (Electron Microscopy Sciences, USA) for 15 min without flow, and washed them gently by flowing additional PBS before storing them at 4 °C until use. The cells cultured on-chip

doi:10.1038/nmeth.3697

were washed again with PBS, permeabilized with 0.2% Triton X-100 (Sigma) in PBS for 2 h and exposed to blocking buffer composed of PBS containing 1% BSA (Sigma) and 5% FBS (Life Technologies, USA) for 30 min at room temperature. Cultures were stained for ciliated cells (anti–β-tubulin IV, 1:100, clone ONS.1A6; Genetex, Taiwan), goblet cells (anti-Mucin5AC, clone H-160, Santa Cruz Biotechnology, USA), basal cells (anti-Cytokeratin 5, Abcam, USA), tight junctions (anti-ZO1, clone 1A12; Life Technologies, USA) or PECAM-1 (clone WM-59; eBioscience, USA). When cell-adhesion molecules were stained on endothelial cells, the cells were not permeabilized to visualize surface antigens. In all studies, antibodies diluted in blocking buffer were introduced in the channels and incubated for 1 h at room temperature or overnight at 4 °C, and cultures were washed with PBS three times each for 5 min at room temperature. Secondary antibodies (Life Technologies, USA) were incubated for 45 min at room temperature and washed three times with PBS. In some studies, TO-PRO-3 (Life Technologies, USA) was used to label nuclei after secondary antibody staining. Devices were then cut using a razor blade, and membranes were delicately lifted from the PDMS and mounted on microscopy slides in mounting medium (Vectashield; Vector Laboratories) with or without DAPI. Fluorescence imaging was carried out using confocal laser-scanning microscopy (SP5 X MP DMI-6000, Germany). Image processing and three-dimensional *Z*-stack reconstruction were done using Imaris (Bitplane, Switzerland) and ImageJ software (downloaded from http://imagej.nih.gov/ij/). When two primary antibodies of the same species were used, the Zenon antibody labeling kit (Life Technologies, USA) was used to preconjugate the antibodies separately before addition to fixed cells. For IL-13 experiments, cultures were treated with IL-13 (Peprotech, USA), dexamethasone (Sigma-Aldrich, USA) or tofacitinib; fixed after 8 d of treatment; and stained for MUC5AC and DAPI. Tofacitinib was purchased commercially (CP-690550, Selleckchem, USA) and was not obtained from Pfizer, and the doses were optimized in-house. We quantified goblet cell hyperplasia by measuring the percentage of the projected area covered by goblet cells in three to five different fields for each condition.

Scanning and transmission electron microscopy. For electron microscopic analysis, the porous membranes supporting the cell cultures were excised from the devices with a razor blade, and cells were fixed with 2.5% glutaraldehyde (Electron Microscopy Sciences, USA) in 1% sodium cacodylate (Sigma) for 1 h at room temperature. Fixed cells were rinsed with 1% sodium cacodylate and post-fixed with 1% osmium tetroxide (Electron Microscopy Sciences, USA) in 1% sodium cacodylate for 90 min in a fume hood. Cells were dehydrated sequentially in ethanol gradients; rinsed in hexamethyldisilazane; air-dried overnight in a desiccator at room temperature; and then mounted on a conductive carbon support, coated with gold and imaged with a VEGA II scanning electron microscope (Tescan, Czech Republic).

For transmission electron microscopy, fixed cells were embedded in Taab 812 resin (Marivac Ltd., Nova Scotia, Canada) and incubated at 60 °C for 1 d. Samples were cut in 80-nm sections with a Leica ultracut microtome, picked up on 300-mesh formvar-carbon–coated copper grids, stained with 0.2% lead citrate, and viewed and imaged under a Philips Technai BioTwin Spirit electron microscope.

Analysis of ciliated, goblet and basal cells and of mucociliary transport. Cilia beating frequency was measured using a high-speed Hamamatsu ORCA-Flash 4.0 camera mounted on a Zeiss AxioObserver Z1 microscope. The epithelium was washed with warm PBS before analysis to avoid mucus accumulation and slowing of cilia beating. High-speed videos of beating cilia were recorded at approximately 200 frames per second and played at 10 frames per second for 1 s to allow manual counting. Four to five random areas of each chip were counted, and cilia-beating frequencies were averaged for each condition. For IL-13 treatment experiments, cilia beating frequency was recorded and measured after 8 d of treatment ($n = 3$–4 chips). Epithelial cell types were quantified as previously described[50]. Briefly, for ciliated cells and basal cells, fully differentiated epithelia from three small airway chips were trypsinized, centrifuged (1,000 *g*, 2 min), air-dried for 1 h at room temperature, fixed with 100% ice-cold acetone, rinsed with PBS, stained for β-tubulin IV (ciliated cell marker) or Cytokeratin 5 (basal cell marker) and counterstained with DAPI. Ciliated cells and basal cells were counted in ten fields per chip, and percentages were calculated. For goblet cells, fully differentiated epithelia from four chips were fixed with 4% paraformaldehyde and stained for MUC5AC (goblet cell marker). We quantified goblet cells by measuring the percentage of the projected area covered by MUC5AC staining in five different fields for each condition. We evaluated mucociliary transport by measuring the displacement of 1-μm polystyrene fluorescent beads diluted in PBS and introduced in the top channel of the small airway chip for 1 s as shown in **Supplementary Video 4**

Gene expression analysis. Total RNA was extracted from differentiated epithelial or endothelial cells *in situ* on-chip with the RNeasy mini kit (Qiagen, USA). The RNA was incubated with DNase I (Qiagen, USA) for 15 min at room temperature to remove residual contaminating genomic DNA, enzyme heat-inactivated at 65 °C for 5 min, and then reverse transcribed into cDNA using the SuperScript Reverse Transcriptase III kit (Invitrogen, USA). We primed cDNA synthesis by mixing 1 μl of oligodT (50 μM) and 1 μl of dNTP mix (10 mM) with up to 500 ng total RNA. Real-time PCR was carried out using a CFX-96 real-time PCR system (Bio-Rad, USA). Reactions contained 1 μl of cDNA, 10 μl of 2× universal SYBR Green Supermix (Bio-Rad, USA), 3 μl of each forward and reverse primer (300 nM final concentration), and 2 μl of molecular biology-grade water, and results were quantified using the $2^{-\Delta\Delta Ct}$ method[51]. Primers were either designed using the online Primer3 application (http://frodo.wi.mit.edu/primer3/) or used from previous reports[52], and sequences are presented in **Supplementary Table 2**

Analysis of chemokines and cytokines. The effluent of flowing medium was analyzed for a panel of cytokines and chemokines (IL-8, IP-10, RANTES, IL-6, M-CSF, G-CSF, GM-CSF and GRO) using custom Milliplex assay kits (Millipore, USA). Analyte concentrations were determined according to the manufacturer's instructions using a LuminexFlexMap 3D system coupled with Luminex XPONENT software (Luminex, USA). For endothelium depletion experiments, basal secretions were collected for each condition, and amounts of RANTES, IL-6 and IP-10 were measured at 24 h after poly(I:C) (InvivoGen, USA) treatment. For Toll-like receptor stimulation experiments, COPD and healthy

© 2016 Nature America, Inc. All rights reserved.

epithelia were challenged with LPS (10 μg ml^{-1}) or poly(I:C) (10 μg ml^{-1}) for 1 h, and amounts of secreted IL-8, M-CSF, IP-10 and RANTES were measured 24 h after treatment. For COPD drug studies, in chips containing cocultures of differentiated COPD epithelium and microvascular pulmonary endothelium, the endothelial cells were treated with 10 nM budesonide (Sigma), 500 nM BRD4 inhibitor (provided by Pfizer) or 0.1% DMSO diluent (Sigma) under flow (60 μL h^{-1}) through the vascular channel for 24 h before poly(I:C) (10 μg ml^{-1}) was delivered into the airway channel for 6 h. The vascular effluents were then collected for cytokine and chemokine analysis.

Analysis of neutrophil adhesion. Neutrophils were isolated from fresh human blood by two-step gradient sedimentation. The peripheral blood mononuclear cells were removed from the polymorphonuclear cell population using Ficoll (Stem Cell Technologies, Canada) density centrifugation, and then the polymorphonuclear cells were isolated using a modified Percoll (Sigma) protocol[53]. Flow cytometry analysis for CD15 and CD16 expression confirmed that the purity of the neutrophil population was >93%. Isolated neutrophils were then live-stained for 30 min at 37 °C using CellTracker red or Hoechst (Life Technologies, USA), resuspended in RPMI medium containing 10% FBS (vol/vol) (Life Technologies, USA) and used within 3 h for recruitment and adhesion assays in chips. The chips were flipped upside down, and neutrophils (1 × 10^{7} cells ml^{-1}) were flowed (2.7 ml h^{-1}; 1 dyn cm^{-2}) through the microvascular channel of the device to mimic the physiological hemodynamic conditions in human postcapillary venules[33]. After 10 min, unbound neutrophils were washed away by flowing cell-free RPMI–10% FBS medium for 5 min, and micrographs of four or five random areas were taken for subsequent counting; we carried out quantification by counting attached neutrophils using ImageJ (http://imagej.nih.gov/ij/) and CellProfiler (http://www.cellprofiler.org) software. For experiments using Transwells, the inserts were placed upside down, and 50 μl of neutrophil suspension (1 × 10^{7} cells ml^{-1}) was added gently to endothelium on the undersurface of each insert and incubated for 10 min at 37 °C. The inserts were then reverted to the upright position in cell culture medium for 5 min to remove unbound neutrophils and subsequently imaged and analyzed as chips. Micrographs of three to ten random areas were taken to count adherent neutrophils.

Statistical analysis. All results and error bars are presented as mean and s.e.m. Data were analyzed with an unpaired Student's *t*-test using Graphpad Prism (GraphPad Software Inc., San Diego, CA, USA) or Excel software (Microsoft, USA). Differences between groups were considered statistically significant when $P < 0.05$. Variability between biological replicates (for example, in **Fig. 3**) for a given donor was minimal (s.e.m. < 5% of mean).

The convalescent sera option for containing COVID-19

Arturo Casadevall[1] and Liise-anne Pirofski[2]

[1]Department of Molecular Microbiology and Immunology, Johns Hopkins School of Public Health, Baltimore, Maryland, USA. [2]Division of Infectious Diseases, Department of Medicine, Albert Einstein College of Medicine, Bronx, New York, USA.

As of early 2020, humanity is confronting a pandemic in severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). SARS-CoV-2 causes coronavirus disease, abbreviated as COVID-19. At the time of this writing, SARS-CoV-2 is spreading in multiple countries, threatening a pandemic that will affect billions of people. This virus appears to be a new human pathogen. Currently there are no vaccines, monoclonal antibodies (mAbs), or drugs available for SARS-CoV-2, although many are in rapid development and some may be available in a short time. This Viewpoint argues that human convalescent serum is an option for prevention and treatment of COVID-19 disease that could be rapidly available when there are sufficient numbers of people who have recovered and can donate immunoglobulin-containing serum.

Passive antibody therapy

Passive antibody therapy involves the administration of antibodies against a given agent to a susceptible individual for the purpose of preventing or treating an infectious disease due to that agent. In contrast, active vaccination requires the induction of an immune response that takes time to develop and varies depending on the vaccine recipient. Thus, passive antibody administration is the only means of providing immediate immunity to susceptible persons. Passive antibody therapy has a storied history going back to the 1890s and was the only means of treating certain infectious diseases prior to the development of antimicrobial therapy in the 1940s (1, 2). Experience from prior outbreaks with other coronaviruses, such as SARS-CoV-1, shows that such convalescent sera contain neutralizing antibodies to the relevant virus (3).

In the case of SARS-CoV-2, the anticipated mechanism of action by which passive antibody therapy would mediate protection is viral neutralization. However, other mechanisms may be possible, such as antibody-dependent cellular cytotoxicity and/or phagocytosis. Possible sources of antibody for SARS-CoV-2 are human convalescent sera from individuals who have recovered from COVID-19, mAbs, or preparations generated in certain animal hosts, such as genetically engineered cows that produce human antibody (4). Although many types of preparations are or will soon be under development, the only antibody type that is currently available for immediate use is that found in human convalescent sera (Figure 1). As more individuals contract COVID-19 and recover, the number of potential donors will continue to increase.

A general principle of passive antibody therapy is that it is more effective when used for prophylaxis than for treatment of disease. When used for therapy, antibody is most effective when administered shortly after the onset of symptoms. The reason for temporal variation in efficacy is not well understood but could reflect that passive antibody works by neutralizing the initial inoculum, which is likely to be much smaller than that of established disease (5). Another explanation is that antibody works by modifying the inflammatory response, which is also more easily achieved during the initial immune response, a stage that may be asymptomatic (6). As an example, passive antibody therapy for pneumococcal pneumonia was most effective when administered shortly after the onset of symptoms, and there was no benefit if antibody administration was delayed past the third day of disease (7).

For passive antibody therapy to be effective, a sufficient amount of antibody must be administered. When given to a susceptible person, this antibody will circulate in the blood, reach tissues, and provide protection against infection. Depending on the antibody amount and composition, the protection conferred by the transferred immunoglobulin can last from weeks to months.

Historical precedents

In the early twentieth century convalescent sera was used to stem outbreaks of viral diseases such as poliomyelitis (8), measles (9, 10), mumps (11), and influenza (12). A retrospective meta-analysis of eight studies on the use of convalescent sera involving 1703 patients during the 1918 H1N1 influenza virus pandemic suggested that those who received serum had lower mortality (13). Although the efficacy of convalescent sera varied with the virus and the study, there was consensus at the time that this intervention was useful, and it was used in numerous outbreaks. It is noteworthy that historically, convalescent sera were developed and used in many cases without the means to measure antibody titers or knowledge about viral serotypes, and in clinical studies that did not meet modern criteria for randomization or blinding.

More recently, convalescent serum was used during viral epidemics. In the 2009–2010 H1N1 influenza virus pandemic, convalescent serum antibody preparations obtained by apheresis were used to treat individuals with severe H1N1 2009 infection requiring intensive care (14). Serum-treated individuals manifested reduced respiratory viral burden, serum cytokine responses, and mortality (14). Convalescent serum was also used in the 2013 West African Ebola epidemic. A small nonrandomized study in Sierra Leone revealed significantly longer survival for those treated with convalescent whole blood relative to those who received standard treatment (15). Two patients transferred to the United States and treated with a combination of convalescent serum and an experimental drug also survived (16). There is anecdotal evidence from the H5N1 (17, 18) and H7N9 (19) avian flu out-

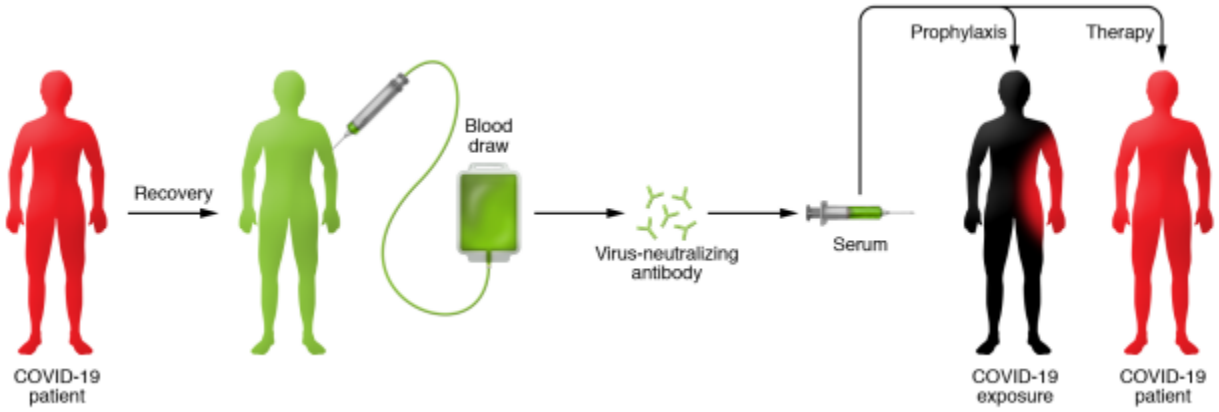

Figure 1. Schematic of the use of convalescent sera for COVID-19. An individual who is sick with COVID-19 and recovers has blood drawn and screened virus-neutralizing antibodies. Following identification of those with high titers of neutralizing antibody, serum containing these virus-neutralizing antibodies can be administered in a prophylactic manner to prevent infection in high-risk cases, such as vulnerable individuals with underlying medical conditions, health care providers, and individuals with exposure to confirmed cases of COVID-19. Additionally, convalescent serum could potentially be used in individuals with clinical disease to reduce symptoms and mortality. The efficacy of these approaches is not known, but historical experience suggests that convalescent sera may be more effective in preventing disease than in the treatment of established disease.

breaks that use of convalescent sera was effective, with all patients surviving.

Although every viral disease and epidemic is different, these experiences provide important historical precedents that are both reassuring and useful as humanity now confronts the COVID-19 epidemic.

Experience with the use of convalescent sera against coronavirus diseases

In the twenty-first century, there have been two other epidemics with coronaviruses that were associated with high mortality, SARS in 2003 and Middle East respiratory syndrome (MERS) in 2012. The SARS epidemic was contained, but MERS became endemic in the Middle East and triggered a secondary major outbreak in South Korea. In both outbreaks, the high mortality and absence of effective therapies led to the use of convalescent serum. The largest study involved the treatment of 80 patients with SARS in Hong Kong (20). Patients treated before day 14 had improved prognosis defined by discharge from hospital before day 22, consistent with the notion that earlier administration is more likely to be effective (20). In addition, those who were PCR positive and seronegative for coronavirus at the time of therapy had improved prognosis (20). There is also some anecdotal information on the use of convalescent serum in seriously ill individuals. Three patients with SARS in Taiwan were treated with 500 mL convalescent serum, resulting in a reduction in serum virus titer, and each survived (21). Three patients with MERS in South Korea were treated with convalescent serum, but only two of the recipients had neutralizing antibody in their serum (22). The latter study highlights a challenge in using convalescent sera, namely, that some who recover from viral disease may not have high titers of neutralizing antibody (23). Consistent with this point, an analysis of 99 samples of convalescent sera from patients with SARS showed that 87 had neutralizing antibody, with a geometric mean titer of 1:61(3). This suggests that antibody declines with time and/or that few patients make high-titer responses. It is also possible that non-neutralizing antibodies are produced that contribute to protection and recovery, as described for other viral diseases (24–26). There are reports that convalescent serum was used for therapy of patients with COVID-19 in China during the current outbreak (27). Although few details are available from the epidemic in China and published studies involved small numbers of patients, the available information suggests that convalescent serum administration reduced viral load and was safe.

Risks and benefits

COVID-19 convalescent sera can be used for either prophylaxis of infection or treatment of disease. In a prophylactic mode, the benefit of convalescent serum administration is that it can prevent infection and subsequent disease in those who are at high risk for disease, such as vulnerable individuals with underlying medical conditions, health care providers, and those with exposure to confirmed cases of COVID-19. Passive antibody administration to prevent disease is already used in clinical practice. For example, patients exposed to hepatitis B and rabies viruses are treated with hepatitis B immune globulin (HBIG) and human rabies immune globulin (HRIG), respectively. In addition, passive antibody is used for the prevention of severe respiratory syncytial virus (RSV) disease in high-risk infants. Until recently, a polyclonal hyperimmune globulin (RSV-IG) prepared from samples of donors with high serum titers of RSV neutralizing antibody was used, but these preparations have now been replaced by palivizumab, a humanized murine mAb. Used therapeutically, convalescent serum would be administered to those with clinical disease in an effort to reduce their symptoms and mortality. The efficacy of these approaches cannot be inferred without carrying out a controlled clinical trial. Based on the historical experience with antibody administration, it can be anticipated that antibody administration would be more effective in preventing disease than in the treatment of established disease (12).

Risks of passive administration of convalescent sera fall into two categories, known and theoretical. Known risks are

those associated with transfer of blood substances, which include inadvertent infection with another infectious disease agent and reactions to serum constituents, including immunological reactions such as serum sickness. With modern blood banking techniques that screen for blood-borne pathogens and match the blood type of donors and recipients, the risks of inadvertently transferring known infectious agents or triggering transfusion reactions are low. However, convalescent sera used in a therapeutic mode would likely be administered to individuals with pulmonary disease, in whom plasma infusion carries some risk for transfusion-related acute lung injury (TRALI) (28), and this should be a consideration in the risk-benefit assessment. The theoretical risk involves the phenomenon of antibody-dependent enhancement of infection (ADE). ADE can occur in several viral diseases and involves an enhancement of disease in the presence of certain antibodies. For coronaviruses, several mechanisms for ADE have been described, and there is the theoretical concern that antibodies to one type of coronavirus could enhance infection to another viral strain (29). It may be possible to predict the risk of ADE of SARS-CoV-2 experimentally, as proposed for MERS (29). Since the proposed use of convalescent sera in the COVID-19 epidemic would rely on preparations with high titers of neutralizing antibody against the same virus, SARS2-CoV-2, ADE may be unlikely. The available evidence from the use of convalescent sera in patients with SARS1 and MERS (30), and anecdotal evidence from its use in 245 patients with COVID-19 (27), suggest it is safe. Nevertheless, in convalescent serum trials, caution and vigilance to identify any evidence of enhanced infection will be required.

Another theoretical risk is that antibody administration to those exposed to SARS-CoV-2 may prevent disease in a manner that attenuates the immune response, leaving such individuals vulnerable to subsequent reinfection. In this regard, passive antibody administration before vaccination with respiratory syncytial virus was reported to attenuate humoral but not cellular immunity (31). This concern could be investigated as part of a clinical trial by measuring immune responses in those exposed and treated with convalescent sera to prevent disease. If the risk proved real, these individuals could be vaccinated against COVID-19 when a vaccine becomes available.

Given that historical and current anecdotal data on use of convalescent serum suggest it is safe in coronavirus infection, the high mortality of COVID-19, particularly in elderly and vulnerable persons, suggests that the benefits of its use in those at high risk for or with early disease outweigh the risks. However, for all cases where convalescent serum administration is considered, a risk-benefit assessment must be conducted to assess individual variables. These considerations were invoked recently with the decision to use mAbs in the treatment of Ebola virus disease (32)

Deployment and proposed use

To deploy convalescent serum administration for COVID-19 the following six conditions must be met: (i) availability of a population of donors who have recovered from the disease and can donate convalescent serum; (ii) blood banking facilities to process the serum donations; (iii) availability of assays, including serological assays, to detect SARS-CoV-2 in serum and virological assays to measure viral neutralization; (iv) virology laboratory support to perform these assays; (v) prophylaxis and therapeutic protocols, which should ideally include randomized clinical trials to assess the efficacy of any intervention and measure immune responses; and (vi) regulatory compliance, including institutional review board approval, which may vary depending on location. Ideally, the use of convalescent serum would involve multiple centers, follow randomized control protocols, and have a single center as a governing body. Each of these conditions should be available in developed areas affected by COVID-19. At least one pharmaceutical company, Takeda, is gearing up to generate antibody preparations against SARS2-CoV-2 from COVID-19 convalescent sera (33). Producing highly purified preparations containing a high titer of neutralizing antibodies against SARS2-CoV-2 is preferable to convalescent sera given that these are safer and have higher activity. Unfortunately, such preparations will not be available for many months, whereas locally produced convalescent sera could be available much sooner.

We anticipate that once the necessary regulatory permissions are in place, individuals who recover from COVID-19 can be approached to donate blood for serum preparation or antibody isolation through apheresis. Recovery from COVID-19 will be assessed clinically, and such individuals must be shown to free of SARS-CoV-2, including in their blood by appropriate viral nucleic acid screening. Donated blood products will be screened for infectious agents according to current blood banking practices, and individual sera will be studied for specific antibody content and neutralizing activity to SARS-CoV-2. Depending on the volumes needed and the neutralizing activity of donated convalescent sera, these could be pooled or used individually, and preparations for clinical use would be treated for pathogen attenuation. At this time, we do not know what an effective neutralizing titer would be in a susceptible individual given passive antibody therapy for prophylaxis, and determining this parameter would be part of the study design. Similarly, we do not know what doses would be effective therapeutically. We do know that when convalescent serum was used to prevent measles or mumps the amounts used were in the order of 10–40 cc (10, 11) In contrast, when convalescent serum was used to treat severe disease in soldiers with 1918 influenza, the amounts given were in the hundreds of milliliters (34). These older studies claimed efficacy even though convalescent serum was given without any knowledge of neutralizing titers. Those experiences suggest that even small amounts of antibody may prevent and/or treat infection. Hence, we can anticipate that effective prophylactic doses would be much smaller than therapeutic doses. This makes sense, since the infecting inoculum is likely to be much smaller than the viral burden during severe disease.

COVID-19 convalescent sera could be used to treat individuals with early symptoms and prevent disease in those exposed. Today, nurses, physicians, and first responders exposed to known cases of COVID-19, some of whom have developed disease, are being quarantined, which threatens to collapse the health care system. It is anticipated that convalescent serum will prevent SARS-CoV-2 infection in those to whom it is administered. If this is established, indi-

viduals who receive convalescent sera may be able to avoid a period of quarantine. This could allow them to continue their critical function as health care providers. Convalescent sera could also be used to prevent disease among family members caring for COVID-19 patients at home. Clearly, the use of convalescent serum would be a stopgap measure that could be used in the midst of the current epidemic. However, even local deployment will entail considerable coordination between different entities, such as infectious disease specialists, hematologists, blood banking specialists, and hospital administrators. Hence, as we are in the midst of a worldwide pandemic, we recommend that institutions consider the emergency use of convalescent sera and begin preparations as soon as possible. Time is of the essence.

MATERIAL TRANSFER AGREEMENT
[THE AGREEMENT IS NOT FOR USE WITH HUMAN MATERIALS]

MTA ID: MO-12665
Date: 02/21/2020

Provider:
The University of North Carolina at Chapel Hill
Office of Technology Development
100 Europa Drive, Suite 430
Chapel Hill, NC 27517-4105
Provider Scientist: Dr. Ralph Baric

Coordinator:
Wuhan Institute of Virology
44 Xiao Hong Shan
Wuhan, Hubei 430071
China
Coordinator scientist: Dr. Zheng-Li Shi

Recipient: Sun Yat-sen University, 132 Wai Huan Dong Road, Guangzhou, China

Recipient Scientist: Xiaojun Xia

Material: transgenic mice expressing human angiotensin converting enzyme 2 from lung cell specific promotors
Purpose: Pathogenesis study of bat SARS-like coronavirus.
Fee: $0

In response to the Recipient's request for the Material the Provider asks that the Recipient agree to the following before the Recipient receives the Material:

1. The above referenced Material (and any progeny, unmodified derivatives, including any Material incorporated in substances/in modifications created by Recipient) is the property of the Provider and is made available as a service to the research community.
2. THIS MATERIAL IS NOT FOR USE IN HUMAN SUBJECTS.
3. The Material will be used for teaching or not-for-profit research purposes only.
4. The Material will not be further distributed to others without the Provider's written consent. The Recipient shall refer any request for the Material to the Provider.
5. The Recipient agrees to acknowledge the source of the Material in any publications reporting use of it. The Recipient agrees to acknowledge the provider scientist and coordinator scientist as the coauthors in the first publication.
6. Any Material delivered pursuant to this Agreement is understood to be experimental in nature and may have hazardous properties. THE PROVIDER MAKES NO REPRESENTATIONS AND EXTENDS NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED. THERE ARE NO EXPRESS OR IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR

Donna M. Ambrosino, MD

EDUCATION AND TRAINING:

1970 - 1974	AB, Harvard University, Cambridge, Massachusetts
1974 - 1977	MD, Dartmouth Medical School, Hanover, New Hampshire

Postdoctoral Training
Internship and Residencies:

1977 - 1978	Intern in Pediatrics, Dartmouth-Hitchcock Medical Center, Hanover, New Hampshire
1978 - 1979	Resident in Pediatrics, Dartmouth-Hitchcock Medical Center, Hanover, New Hampshire

Clinical and Research Fellowships:

1979 - 1980	Clinical Fellow in Infectious Diseases, Dana-Farber Cancer Institute, Beth Israel Hospital, Children's Hospital Medical Center, Boston, Massachusetts
1980 - 1982	Research Fellow in Infectious Diseases, Dana-Farber Cancer Institute, Children's Hospital Medical Center, Boston, Massachusetts

WORK EXPERIENCE:

2019-Present	Co-founder ClearSite Antibodies LLC
2016- 2019	CEO, Nosocomial Vaccine Company, Rockville MD
2014 - 2019	Chief Medical Officer, ClearPath Vaccines Company, Rockville, MD
2012 - 2014	Chief Medical Officer, Visterra Inc, Cambridge MA
1998 - 2011	CEO, MassBiologics, Professor of Pediatrics, University of Massachusetts Medical School
1992	Associate Professor in Pediatrics, Children's Hospital and Dana- Farber Cancer Center, Harvard Medical School
1986	Assistant Professor in Pediatrics, Children's Hospital and Dana- Farber Cancer Center, Harvard Medical School
1982	Instructor in Pediatrics, Children's Hospital and Dana-Farber Cancer Center, Harvard Medical School

LICENSURE AND CERTIFICATION:

1982 - 2017	Massachusetts License Registration No. 47141
1981	American Board of Pediatrics

AWARDS AND HONORS:

1974	Summa Cum Laude, Biology, Harvard University
1974	Phi Beta Kappa, Harvard University
1974	Class Officer and Marshall, Harvard University
1977	M.D. Honors, Dartmouth Medical School, Hanover, New Hampshire
1977	Head Marshall Medical School Class, Dartmouth Medical School, Hanover, New Hampshire
1983	Young Investigator Award, Infectious Disease Society of America
1992	Elected to Harvard Medical School Faculty Council
1995	Nominated as Outstanding Physician Mentor, Harvard Medical School
2006	Manuel Carballo Governor's Award for Excellence in Public Service

Keywords:
Animal models
Influenza virus
Universal influenza vaccine

abstract

Animal models that can recapitulate the human immune system are essential for the preclinical development of safe and efficacious vaccines. Development and optimization of representative animal models are key components of the NIAID strategic plan for the development of a universal influenza vaccine. To gain insight into the current landscape of animal model usage in influenza vaccine development, NIAID convened a workshop in Rockville, Maryland that brought together experts from academia, industry and government. Panelists discussed the benefits and limitations of the field's most widely-used animal models, identified currently available and critically needed resources and reagents, and suggested areas for improvement based on inadequacies of existing models. Although appropriately-selected animal models can be useful for evaluating safety, mechanism-of-action, and superiority over existing vaccines, workshop participants concluded that multiple animal models will likely be required to sufficiently test all aspects of a novel vaccine candidate. Refinements are necessary for all current model systems, for example, to better represent special human populations, and will be facilitated by the development and broader availability of new reagents. NIAID continues to support progress towards increasing the predictive value of animal models.

1. Introduction

Seasonal influenza infects millions, causing thousands of hospitalizations and deaths each year. While even healthy people can get very sick, infection can present particularly serious problems for young children, the elderly, pregnant women and people with certain medical conditions such as asthma and heart disease. In addition to supporting research to improve seasonal influenza vaccines, the National Institute of Allergy and Infectious Diseases (NIAID), part of the National Institutes of Health (NIH), is working to prepare for a potential pandemic influenza threat. This effort includes the development of a universal influenza vaccine that ideally provides long-lasting protection against both seasonal and pandemic strains. As emphasized in NIAID's ''Pathway to a Universal Influenza Vaccine" workshop [1] and strategic plan [2], the use of animal models is essential for understanding mechanisms of vaccine-mediated protection against influenza. Animal models are also important for pre-clinical testing and down-selection of universal influenza vaccine candidates. However, there is a need to improve existing animal models or develop novel animal models that more accurately represent influenza immunity in humans, with an emphasis on increasing the predictive value of models for evaluating novel universal influenza vaccines. A workshop organized by the EDUFLUVAC Consortium, a European Union-funded project coordinated by the European Vaccine Initiative, convened on June 23–24, 2016 to discuss the current knowledge and future perspectives for testing broadly reactive influenza vaccines in animal models [3]. From that workshop, several key recommendations were made to the influenza community, including the need for harmonized and standardized pre-clinical models for evaluation of new influenza vaccines. To build upon these discussions, NIAID hosted a workshop on August 7–8, 2018 entitled, ''Optimization of Animal Models to Better Predict Influenza Vaccine Efficacy (VE)". Approximately 100 U.S.and international scientists from academia, industry, and government convened in Rockville, Maryland to review the benefits and limitations of current influenza animal models, address the availability of and need for critical resources and reagents, and establish the steps required

to address current shortcomings. Anthony S. Fauci, Director of NIAID, provided opening remarks and re-iterated NIAID's commitment to universal influenza vaccine research and development, including research on improving animal models.

The workshop commenced with a keynote presentation by Kanta Subbarao, Director of the World Health Organization (WHO) Collaborating Centre for Reference and Research on Influenza at The Peter Doherty Institute for Infection and Immunity in Melbourne, Australia, who conveyed considerations for improving the predictive value of animal models in efficacy studies of influenza vaccines and biologics. Most importantly, she stressed that an appropriate animal model should be selected based on the specific research question. Dr. Subbarao noted that animal models are critical for studying pandemic viruses and performing pre-clinical testing of therapeutics and vaccines, particularly those directed at strains with pandemic potential. However, current animal models cannot completely recapitulate infection in humans due to several key differences. First, animals are immunologically naïve while humans experience multiple exposures/infections with influenza in their lifetime. This type of acquired immunity is difficult to model in animals. Vaccine preparations used in animals can differ from those used in clinical trials, and challenge infections in animals often use a high dose of virus. Finally, it is difficult to extrapolate the specifics of dose sparing in animal models to humans. To advance current influenza animal models, recommendations include: 1) improving the similarity of animal models to humans by genetic engineering; 2) considering infection history and coinfection status; 3) incorporating controlled variability through methods such as genetic crosses and including both female and male animals as well as those with a diverse microbiome; and 4) identifying biomarkers and correlates of protection through iterative comparative studies between animals and humans.

The workshop was composed of four animal model sessions and two panel discussions. For each animal model session, the utility and limitations of each model were addressed with respect to: (1) examining pre-existing immunity and sequential vaccination/-exposure; (2) estimating influenza vaccine efficacy in humans; (3) ability to stratify vaccine candidates for further evaluation in later stage human challenge studies and clinical trials; (4) availability of immunological reagents for the animal model including antibodies that recognize, activate, or deplete specific immune cell populations; methods for cytokine/chemokine detection; major histocompatibility complex (MHC) tetramers; and (5) cost and other limitations (e.g., space). For the first panel discussion, representatives from NIAID, U.S. Food and Drug Administration (FDA), Biomedical Advanced Research and Development Authority (BARDA), and industry were invited to engage the participants in a discussion of the utility of pre-clinical models for informing influenza vaccine candidate prioritization. To conclude the workshop, a final panel discussion summarized the need for optimized and/or complementary influenza animal models to better predict influenza vaccine efficacy.

2. Mouse and hamster models

Mouse models have been used extensively in mechanistic studies of influenza infection, as well as for the pre-clinical evaluation of vaccine candidates. Despite the advantages of reproducibility, ease of genetic manipulation, controlled environment factors, availability of reagents, and relatively low cost, it was agreed that standard laboratory mice also have limitations related to studying various aspects of influenza. Such limitations include, but are not limited to, the lack of genetic heterogeneity of inbred mouse lines; the need to adapt seasonal influenza virus strains to cause sufficient replication and virulence in mice; the difference of respiratory tract anatomy and influenza receptor distribution between mice and humans; the shorter life span is not optimal for studying long-lasting immune responses; and that mice are not optimal for studying influenza transmission. The session's presentations highlighted recent efforts to overcome some of these limitations.

To date, most mouse studies have been conducted in a limited number of inbred strains, allowing researchers to control for genetic variability. However, each mouse strain only represents one individual genotype; thus, these do not model more complex populations like humans. One way to overcome this issue is to use genetically diverse mouse reference populations, such as the Collaborative Cross (CC). The CC is a collection of recombinant inbred lines derived from initial random crosses of eight genetically-diverse inbred founder strains which include three wild-derived strains [4]. These mice capture 90% of the known genetic variation present in the genome of standard laboratory mice and their genetic diversity is comparable to that of humans. With their diverse genotypes, the CC mice display an increased range of phenotypes compared to standard laboratory strains, and extreme phenotypes have been identified that provide a unique opportunity to pinpoint underlying genetic causes for susceptibility or resistance to pathogens. Mark Heise, Professor of Genetics at the University of North Carolina-Chapel Hill, detailed his work using the CC mice and their genetic derivatives in a non-mouse-adapted influenza A virus (IAV, 2009 H1N1) infection model. Heise and colleagues conducted quantitative trait loci (QTL) mapping and narrowed down the genetic intervals associated with disease phenotype and immune function. They identified candidate genes and discovered novel cell populations that may be involved in the immune response against IAV [5]. In the context of vaccine research, the CC also provides a valuable tool for identifying genes that regulate the breadth and durability of vaccine-induced immune responses as well as gene networks that regulate adjuvant activity, discoveries which will allow for the development of new models for testing vaccine efficacy and safety.

In addition to inherited differences, researchers have noticed that non-heritable parameters like environmental factors can shape the immune system and lead to variations in immune response. While laboratory mice are often housed in a pathogen-free environment and their immune cells are largely "naïve", humans generally have much more antigen experience resulting in more differentiated immune cells. Growing evidence indicates that this difference diminishes the translational ability of mice to mimic human immune responses. In his presentation, Ryan Langlois, Assistant Professor at the University of Minnesota, summarized recent advances in research using "dirty" mice and discussed his work using these mice for influenza infection studies. A dirty mouse colony can be generated by natural microbiome transmission between animals through either co-housing or transfer of fomites as well as by deliberate infection with pathogens that model those which commonly infect humans (such as MHV68, murine cytolomegalovirus and Heligmosomoides polygyrus) [6]. The reconstitution of laboratory mice with a complex microbiome has a profound impact on the cell composition of the innate and adaptive immune systems as well as blood cytokine and antibody profiles, and results in altered immune responses to infection and vaccination [6–8]. The immune signatures of dirty mice resemble those of healthy adult humans more closely than standard laboratory mice. Therefore, it is plausible that dirty mice may serve as improved mouse models to add new dimensions in immunology research and vaccine discovery. While researchers are enthusiastic about the dirty mouse concept and its potential, establishing and maintaining such a colony is challenging [9]. Concerns have also been raised by the scientific community regarding the reproducibility of experiments using dirty mice generated by natural

transmission. The requirement and/or feasibility of standardization of a complex microbiome remains debatable. However, it is well documented that humans have diverse microbial experience that varies among individuals. Even monozygotic twin studies in humans indicate that environmental/epigenetic influences drive a significant degree of human variation in many immune system measurements [10]. Perhaps results that hold true among a majority of diverse dirty mice, including those in different colonies, will be most likely to be recapitulated among diverse humans.

Yoshihiro Kawaoka, Professor of Virology at the University of Wisconsin- Madison, noted that when looking for an animal model to better predict influenza vaccine efficacy, considerations should include efficacy evaluation methods, availability of reagents to measure immune response, susceptibility of the model to recent human influenza viruses, pre-existing immunity, practicality (e.g., husbandry and economics) and feasibility of genetic manipulation. Given these factors, Dr. Kawaoka suggested that hamsters may provide a better animal model than mice for influenza research [11]. First, replication of human influenza viruses in hamsters can occur without adaptation, and alpha 2–6 sialic acid expression in the respiratory system is similar to that of humans [11]. Second, hamsters live longer than mice which provides an opportunity to study sequential infections. Third, hamsters reproduce quickly and the process of establishing inbred lines is faster than in mice. Finally, hamster genomic and transcriptomic information is available, and gene-targeting techniques have been established that enable gene manipulation [12–14]. Dr. Kawaoka concluded that hamsters are an excellent model for evaluating influenza vaccine efficacy and that more reagents need to be developed to increase their use.

3. Ferret models

Ferrets are used extensively in influenza research to model pathogenesis and viral transmission and are also used in efficacy studies of vaccines and therapeutics. Ferrets are an attractive model of influenza infection because they are susceptible to human strains of the virus and several clinical symptoms of influenza infection in ferrets resemble those observed in humans [1]. Additionally, there are similarities between ferrets and humans in lung anatomy, cell biology and sialic acid receptor distribution. Limitations to the ferret model include the lack of species-specific reagents and standardized assays. Availability also may become a limitation, as demand for ferrets may outpace the available supply from the few ferret sources that currently exist. In this session, presentations highlighted promising work in ferret models of influenza.

John Engelhardt, Professor and Chair of the Department of Anatomy and Cell Biology at the University of Iowa, presented his work manipulating the ferret genome to investigate the effects of cystic fibrosis on the lung and pancreas [15]. These genetic approaches provide the opportunity to interrogate the contributions of different gene products to influenza pathogenesis and immunity. Further, advances in genetic engineering in ferret zygotes using CRISPR/Cas9have allowed for the generation of gene knock-out lines [16,17], knock-in lines harboring human mutations [18], and transgenic ferrets carrying a dual-fluorescent Cre reporter system flanked by integrase sites to enable rapid engineering of additional transgenic ferret models [17,19]. Such gene editing approaches may also be useful for generating in vitro airway models allowing more rapid screening of relevant influenza targets, prior to engineering a transgenic ferret model.

Scott Hensley, Associate Professor of Microbiology at the University of Pennsylvania, discussed his work on understanding prior exposure and pre-existing immunity in ferrets. Most ferrets used for influenza virus research have not been previously exposed to influenza, while humans have typically been infected or vaccinated with influenza by 3 or 4 years of age. Initial childhood influenza exposures can leave life-long immunological imprints that shape the specificity of influenza virus antibody responses over the lifespan [20]. Dr. Hensley showed that naïve ferrets and humans produce antibodies of different specificities after exposure to the same influenza strain. Importantly, he showed that ferrets that are previously exposed to older seasonal influenza virus strains produce antibodies that have similar specificities to human antibodies, which suggests that differences in antibody specificity can be linked to prior exposure to influenza virus. This extends beyond influenza infections and suggests that responses to influenza vaccination are also driven by prior exposure to influenza viruses.

Stacey Schultz-Cherry, Full Member (Professor) in the Department of Infectious Diseases and Deputy Director of the WHO Collaborating Centre for Studies on the Ecology of Influenza in Animals and Birds at St Jude Children's Research Hospital, presented ongoing work from a global collaboration aimed at developing validated reagents and assays to improve understanding of ferret innate and adaptive immune responses [21]. With support from NIAID's Centers of Excellence for Influenza Research and Surveillance (CEIRS),Dr. Schultz-Cherry is leading a team working to develop influenza and ferret-specific reagents including antibodies, recombinant proteins, and primers/probes. A repository of ferret lung, spleen, trachea, mediastinal lymph nodes, blood, peripheral blood mononuclear cells, single cell suspension, and paraffin-embedded tissues has been developed to support reagent validation (Supplementary Tables 1–5). Primary cell lines from ferrets including fibroblast, respiratory epithelial cells (nasal, tracheal, alveolar), and soft palate cells also have been established. Reagents developed by the CEIRSnetwork are freely available for distribution. For a complete list of influenza ferret reagents and tissues, see http://www.niaidceirs.org/resources/ceirs-reagents/ . Dr. Schultz-Cherry also summarized the work being done by her laboratory and others to develop models for pregnant, immunocompromised, and diet-induced obese ferrets [21]. These models will allow investigation of influenza infection and vaccination in groups at higher risk for influenza infection-related complications.

4. Swine models

Amy Vincent, Research Veterinary Medical Officer at the USDA National Animal Disease Center, provided an overview of the swine model for influenza [22]. Swine are a natural host for influenza infections, and they experience clinical signs similar to humans when infected with endemic swine influenza strains. With the exception of H1N1pdm09, human seasonal and avian influenza strains do not readily infect or cause disease in swine without adaptive changes. For example, several avian influenza and human seasonal viruses, including H3N2 viruses, do not readily infect swine or cause lung lesions, and the mechanisms of adaptation and establishment of these human lineage influenza viruses in swine populations are not well-understood. Swine share many physiological and anatomical similarities to humans including tracheobronchial tree structure, physiology, and lung size [23–28]. Despite many commonalities between the human and swine immune systems, swine have different immune cell populations (e.g. large populations of cr T cells and CD4 + CD8 + double-positive T cells).

Currently, researchers are developing more broadly protective, durable influenza vaccines for veterinary use and these efforts also could inform universal influenza vaccine development in humans. Renukaradhya J.Gourapura, Professor in the Department of Veterinary Preventative Medicine , Food Animal Health Research Program in the Ohio Agricultrual Research and Development Center at the

Ohio State University, discussed three separate intranasal nanoparticle vaccine formulations to evaluate mucosal responses and immune correlates of cross-protective influenza immunity in swine [29–31] . He also described the growing availability of swine-specific reagents and immunological tools as well as ongoing international efforts to develop the Swine Immune Toolkit, a collaborative activity between U.S. and U.K. veterinary immunologists to generate new immune reagents, mAbs, new assays for swine immune markers, and protocols to better understand immune pathways important in swine infection and vaccination [32,33] .

Inbred pigs provide an additional tool to elucidate immunological responses to influenza infection and vaccination. The large inbred Babraham pig is 85%homozygous across its genome, including across the pig MHC (referred to as the swine leukocyte antigen [SLA]) class I and II regions [34] . Elma Tchilian, Head of Mucosal Immunology at the Pirbright Institute, presented studies using the inbred Babraham pig to characterize local lung cellular immune responses after aerosol delivery of the novel single cycle influenza vaccine, S-FLU, followed by influenza challenge [35,36] . These studies utilized newly-developed immunological tools in swine models, including long-term in vitro T cell cultures and peptide SLA tetramers, to identify influenza T cell epitopes and track antigen-specific CD8+ T cell responses after immunization with S-FLU or influenza infection [37] . Other studies presented during the session demonstrated the feasibility of the swine model to evaluate the effectiveness of candidate influenza vaccines to disrupt transmission.

During discussions, there was consensus that the swine model has the potential to be a valuable tool in evaluating universal influenza vaccines for both clinical and agricultural use. Due to their long life-spans, swine could serve as a good model for evaluating the duration of influenza immune responses and protection against both natural exposure and vaccine-induced immunity. Dr. Vincent also highlighted the potential value of using swine as a model for studying vaccine safety due to the ability to screen influenza vaccine candidates for their potential to induce vaccine-associated enhanced respiratory disease (VAERD). Previous studies showed that VAERD occurs in swine vaccinated with adjuvanted whole-inactivated virus that are subsequently challenged with an antigenically mismatched virus of the same subtype (i.e., H1 or H3) [38] . Although VAERD has not been reported in humans, workshop participants pointed to an overall need for better animal models for vaccine safety studies.

Logistical challenges of the swine model were also discussed. Both outbred and inbred swine models are commercially available and range in size from micro-minipigs (~20 kg) and mini pigs (~40 kg) to traditional sizes (ranging from ~10–100 kg). Recent studies have indicated the genome, distribution of receptors, and sensitivity to influenza infection are roughly equivalent across these swine models [39] . Due to the specialized facilities and technically skilled personnel needed to conduct influenza research in swine, panelists confirmed that these studies can be cost-prohibitive. Studies requiring large animal BSL-3 facilities will likely be inaccessible for many investigators; however, most studies are done at BSL-2 for endemic swine, human seasonal, and non-HPAI avian strains. Another challenge is finding sources of pigs that are negative for influenza virus and antibodies. Panelists strongly encouraged those interested in working with swine not to be deterred by these challenges, noting that agricultural labs are often willing to collaborate to test new vaccine candidates in this model.

5. Non-human primate models

Douglas Reed, Associate Professor of Immunology at the University of Pittsburgh, briefly outlined the history of non-human primate (NHP) influenza model development, which has largely settled on the use of healthy adult rhesus and cynomolgus macaques. He noted that although these NHP species typically develop mild clinical signs following infection with seasonal influenza viruses, they poorly model human infection with H5N1 avian strains. Nearly all NHP influenza models employ intranasal or intratracheal challenge which, due to differences in sialic receptor expression, favors upper respiratory tract infection. The inability to adequately model H5N1 infection in NHPs could be due to the fact that seasonal flu strains preferentially infect the upper respiratory tract, while H5N1 avian strains mainly deposit in the lower respiratory tract. Dr. Reed and colleagues undertook a project to improve the NHP avian flu infection model by inducing a lower respiratory tract infection through small particle aerosol challenge [40] . This study demonstrated that small particle aerosol challenge of cynomolgus macaques with an H5N1 avian strain results in a severe acute infection defined by fever, depressed respiration, evidence of cytokine storm, and rapid uniform lethality. Further studies using varying particle size and prolonging the disease course are needed to refine this model to better simulate human infection with H5N1.

Todd Suscovich, Research Specialist at the Ragon Institute of MGH, MIT and Harvard, spoke about the potential of systems serology approaches to identify immunologic correlates and mechanisms of humoral protection when traditional measures, such as antibody titers and neutralization, are inadequate predictors of protective immunity. He noted that the ability of a vaccine to elicit a high neutralizing titer, although generally accepted as a major indicator of protective efficacy, does not often adequately predict protection. The systems serology approach can be used to comprehensively characterize polyclonal antibody responses through network analysis of antibody features and Fc-mediated functional profiles elicited by a vaccine. This approach offers a potentially powerful tool to compare antibody profiles between different vaccine groups or populations, including between NHPs and humans. A few noted caveats include the limited information available on Fc effector function for NHP species other than rhesus and cynomolgus macaques, key differences in IgG conservation across subclasses, and Fcc receptor diversity in macaques compared with humans.

Kathleen Engelman, Program Director at the University of Massachusetts Medical School, described the NIH-funded NHP Reagent Resource Program [41] which seeks to facilitate the optimal use of NHP models in biomedical research. This resource provides GMP-grade antibodies to academic investigators for use in NHP studies requiring in vitro diagnostics, reference reagents for immune assays, and to selectively block or deplete immune effector function to better characterize immune responses to pathogenic agents or vaccines. This resource has developed antibody platforms including engineered antibodies that can finely modulate immune effector function, bispecific antibodies, and modifications to immunoglobulin glycosylation to enhance effector function. Dr. Engelman indicated that the resource currently features rhesus macaque reagents, but also highlighted NHPRR efforts to develop antibody resources specific for several species of New World primate.

Meeting participants agreed that there are multiple advantages offered by NHP models such as respiratory architecture, susceptibility to infection in the absence of uniform lethality, and the availability of technologies to track upper and lower respiratory tract infection over time in the same animal. Participants noted that there are more immunological reagents available for NHPs than for any species other than mice, allowing for a more profound characterization of immune responses to infection or vaccination. In addition, the lifespan of these animals permits evaluation of age-diverse infection models from neonate to elderly that may more

closely approximate human infection/vaccination in these age groups. Despite these advantages, there are a few important drawbacks that must be considered, in particular cost, availability and care requirements. The purchase price for NHPs is substantially greater than for other relevant models: up to five times higher than swine, more than ten times higher than ferrets and more than one-hundred times higher than small rodent species. Due to current demand, locating and acquiring NHPs of appropriate size, age, and immune status has become increasingly difficult and can present limitations to study design and delays in study initiation. Finally, NHPs have care requirements that exceed those of smaller model species. For example, stress reduction through social housing and enrichment activities is critical to the well-being of NHP species, but can place demands on facility capacity and staff capability that many institutions cannot meet. Participants acknowledged that investigation of viral transmission is warranted in the NHP model, as is further evaluation of the aerosol challenge model.

6. Panel 1 discussion

Following in-depth discussions on the attributes and challenges of each animal model, workshop participants then considered pre-clinical animal models more broadly in the context of influenza vaccine development. Specifically, they discussed how animal models could be optimized to better predict vaccine safety and efficacy, and how this information could be used to inform the prioritization and down-selection of promising candidates.

Hana Golding, Chief of the FDA Laboratory of Retrovirus Research, FDA Center for Biologics Evaluation and Research, reminded workshop participants that the FDA will evaluate new universal influenza vaccine candidates following the same general pathway used for all vaccines. Vaccines must demonstrate safety and efficacy in clinical trials, and researchers must consider similarities between the immune responses measured in their animal model and those of humans. Therefore, product characterization and formulation should be similar to those for the intended human vaccine product. The FDA will additionally consider the following questions: Will the dosing and administration protocol be the same? Will the formulation need to change between animal and human studies? Does an adjuvant work the same in animals as predicted in humans? How does the time interval differ between animal models and optimal immune responses in humans? Dr. Golding also noted that although animal models are available to evaluate general safety concerns, a gap remains in the ability to use current animal models to predict potential rare adverse effects. Finally, new assays measuring biological activities of antibodies will require bridging between animals and humans. In vitro and in vivo assays should be selected carefully to ensure pre-clinical data will accurately inform clinical findings.

Armen Donabedian, Scientific Technical Advisor and Chief of the Vaccine Advanced Development Branch, Influenza and Emerging Diseases Division of BARDA, described BARDA's mission and role in universal influenza vaccine development. BARDA assists in pandemic preparedness by supporting the advanced development and licensure of medical countermeasures against chemical, biological, radiological, and nuclear (CBRN) threats. For influenza vaccines, BARDA must balance investments between efforts to improve the speed and scalability of vaccine manufacturing and efforts to support clinical development of improved, broadly-protective vaccines that could be deployed during a pandemic. BARDA is most interested in animal models that can accurately identify candidates ready and suitable for advanced development. Dr. Donabedian highlighted the opportunity to develop a standardized data package to aid in the prioritization of candidates. The package could include data on safety, efficacy, formulation and mechanism of action. Useful information could also include data on the protection of vaccinated animal models against a defined panel of viruses representing circulating contemporary strains as well as those with pandemic potential. Head-to-head comparisons showing improved benefits of a candidate over other licensed vaccines is also of interest. Like Dr. Golding, Dr. Donabedian emphasized that efficacy data in animal models should reflect the vaccine regimen and route of inoculation proposed for clinical use, and he reemphasized the value of animal models in defining correlates of protection and predicting how candidates will perform in advanced clinical trials.

Mario Barro, Associate Vice President and Head of FluNXT Advanced Research at Sanofi Pasteur, provided an industry perspective. Sanofi Pasteur has established an independent unit called FluNXT to develop advanced analytics and computational structural biology-based approaches for vaccine R&D. FluNXT is using these techniques to integrate clinical and pre-clinical data from animal models to better elucidate complex findings in human immune responses. Individual responses to standard of care vaccination are diverse, and it is important to define precise targets for future vaccine improvements. Their iterative approach allows for refinement of translational studies and better connects animal findings to observations from human subjects.

Although workshop participants agreed that using animal models to predict rare adverse effects is a significant challenge, panelists stated that animal models can be used to identify some safety concerns early in development. For example, tissue tropism can be defined during the early stages of vaccine development. Participants agreed that vaccine development efforts are based on careful risk/benefit considerations and that animal models need to be optimized to help understand these trade-offs. Adjuvants also are an area of opportunity for further animal model development. Adjuvants need to demonstrate a true added benefit to a vaccine formulation and must be tested with the specific vaccine candidate that will eventually be considered for licensure. However, depending on the mode of action and the presence, distribution and specificity of the corresponding innate immune receptor, some adjuvants may not exert the same biological and immunological activities in specific animal model, so care must be taken in both adjuvant and animal model selection to improve predictability of benefit/risk in humans. Influenza animal models also are needed to better understand risks and benefits in specific populations such as pregnant women and immunocompromised individuals.

There was general agreement that any candidate considered for advanced development needs to show clear superiority to licensed vaccines to garner funder and investor interest. However, concern was raised over the possibility that animal models might falsely down-select promising candidates. Dr. Barro responded that, for this reason, it is important to integrate and examine all the available data to assess the full picture. A more holistic evaluation can also help the community to understand why certain approaches may not be superior in certain animal models, to pinpoint where and why candidates are likely to fail, and to design studies to understand and address those findings.

7. Summary

The second panel discussion, led by representatives from each of the animal model sessions, summarized the benefits and limitations of existing influenza animal models, which are noted in each of the animal model sessions above and summarized in a recent comprehensive review on animal models for influenza viruses [42] . The panel concluded by summarizing the ongoing tool development and model refinement efforts for each of the influenza

Table 1
Ongoing tool development & model refinement for existing influenza animal models.

Animal	Ongoing tool development and model refinement
Mice	ff Use of transgenic tools to "humanize" mice by adding human host or immune genes ff Use of CC mice to introduce genetic diversity within inbred mouse lines [5] ff Reconstitution of laboratory mice with a complex microbiome ("dirty" mice)
Hamsters	ff Use of transgenic tools to "humanize" hamsters by adding human host or immune genes ff Use of Syrian hamsters for pathogenicity studies of recent H3N2 viruses and other influenza strains [11]
Ferrets	ff Use of transgenic tools to "humanize" ferrets by adding human host or immune genes ff Concentrated efforts to generate immune reagents [43] ff Development of models for pregnant, immunocompromised, and diet-induced obese ferrets [21]
Swine	ff Use of transgenic tools to "humanize" pigs by adding human host or immune genes ff International efforts to develop a 'Swine Immune Toolkit' that provides new immune reagents, mAbs, assays, and protocols for swine health, vaccine and disease studies for widespread use by the community [32,33] ff Use of the MHC homozygous inbred Babraham pig as a model to characterize local lung cellular immune responses to influenza [34,44]
NHPs	ff Variation of aerosol particle size during infection of cynomolgus macaques to better simulate human infection with H5N1 [40] ff Generation and provision of GMP-grade antibodies for use in NHP studies requiring in vitro diagnostics, reference reagents for immune assays, and to selectively block or deplete immune effector function to better characterize immune responses to pathogenic agents or vaccines [41]

animal models that were discussed at length during the workshop (Table 1).

To conclude the workshop, Alan Embry, Chief of the Respiratory Diseases Branch at NIAID re-emphasized the value of animal models in furthering the development of universal influenza vaccines, a key component of NIAID's universal influenza vaccine strategic plan [2]. He emphasized the importance of: (1) considering the strengths and weaknesses of each model; (2) considering the specific research questions being addressed; (3) assessing the role of pre-existing immunity and the effect of sequential vaccination/infection in animal models; (4) performing iterative studies between humans and animals to evaluate immune mechanisms and improve predictive value of models; and (5) utilizing more than one animal model to address all aspects of a novel vaccine candidates. As an outcome of this workshop, NIAID has published a funding opportunity to solicit applications that aim to improve existing animal models or develop novel animal models that more accurately represent influenza immunity in humans, with an emphasis on increasing the predictive value of models for evaluating novel universal influenza vaccines (https://grants.nih.gov/grants/guide/pa-files/PAR-19–248.html, https://grants.nih.gov/grants/guide/pa-files/PAR-19–247.html). Additionally, NIAID supports the development of validated reagents and assays to improve understanding of ferret innate and adaptive immune responses through a number of resources, including the CEIRSnetwork [21] (Supplementary Tables 1–5), BEI Resources Repository (https://www.niaid.nih.gov/research/bei-resources-repository), and the NIH Tetramer Core Facility (http://tetramer.yerkes.emory.edu/). Lastly, NIH supports the development and refinement of animal models for studying human disease through targeted funding opportunities. Such targeted funding opportunities can be located on NIAID's funding opportunities website (https://www.niaid.nih.gov/grants-contracts/find-funding-opportunity) as well as the NIH Office of Research Infrastructure Programs website (https://orip.nih.gov/funding-opportunities-list), and include PAR-19-247 and PAR-19-248, Research Projects to Improve the Predictive Value of Animal Models in Recapitulating Human Immunity to Influenza Infection and Vaccination.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper. This report is the summary of the collective views from the meeting participants and does not necessarily reflect the views of NIAID.

Assessing the Risks Posed by SARS CoV-2 in and via North American Bats
A Rapid Decision and Risk Assessment

Introduction to Expert Elicitation for an Expert Panel

Introduction

The novel betacoronavirus, SARS-CoV-2, that has caused a pandemic disease in humans, arose from a mammalian host, possibly Old-World bats in the family *Rhinolophidae*; the closest known virus discovered in wildlife was found in a horseshoe bat (*Rhinolopus affinis*) from Yunnan province in China (Zhou et al. 2000). No SARS-related betacoronaviruses have yet been identified in New-World bats, but a different type of betacoronavirus has been identified in a New-World bat from Mexico (Anthony et al. 2013). This raises an important question about whether North and South American bats could be vulnerable to infection with SARS-CoV-2, via contact with humans, which in turn raises questions about whether there may be reciprocal spread to humans via a bat reservoir. This inquiry is designed to be a rapid assessment of the risk of transmission of SARS-CoV-2 from humans to North American bats, the management contexts in which this risk might be relevant, and an assessment of possible mitigation actions that may be implemented by those who come into contact with bats or their habitats.

Justification for an expert elicitation

Ideally, we would obtain parameter estimates from empirical data and associated mathematical models. Because these information are unavailable and time is of the essence for decision makers, we aim to use an expert panel to elicit parameter values with associated uncertainty, using techniques of expert judgment that utilize best available scientific information, account for uncertainty, and reduce bias (Morgan 2014, Sutherland and Burgman 2015).

Expert elicitation is a formal, structured process of obtaining expert judgment for specific questions. An expert is someone who possesses substantive information on a particular topic that is not widely known by others. We know that experts have knowledge, often privileged knowledge, that accrues as a result of their research and experience, even about processes for which data have not been collected. The question is how to extract that knowledge accurately and precisely. Expert judgment is a quantitative expression of an expert's belief based on knowledge and experience; it is an informed belief. Expert elicitation can provide improved information over single-expert inquiry when a diverse group of experts is asked to provide estimates, using a facilitated approach with discrete opportunities for information sharing, provision of estimates, and review of summarized information (Martin et al. 2012). Expert elicitation, when conducted with the same level of rigor as the collection and use of empirical data, can result in reliable predictions (e.g., O'Hagan et al. 2006, Speirs-Bridge et al. 2010, Runge et al. 2011, Martin et al. 2012, Adams-Hosking et al. 2016).

An expert elicitation is governed by specific protocols to avoid inherent biases resulting from cognitive traps. These cognitive traps are shortcuts, or heuristics, that serve us well for simple decisions but result in biased estimates for more complex tasks (O'Hagan 2019). These biases include:

- Availability bias (experts will be influenced by evidence or events that are easily recalled)
- Anchoring bias (experts fail to consider possible values far from an initial estimate)
- Overconfidence (experts tend to underestimate their uncertainty, and make forecasts that are too narrow)
- Representativeness bias (a tendency to think of probabilities related to readily-available examples)
- Motivational bias (an innate desire to further our own interests)

When the number of experts is limited, we would additionally be concerned about small-sample bias.

There are additional biases that arise through the behavior of groups. To some extent, these can be collectively referred to as "groupthink", the tendency for groups to converge too quickly on consensus estimates or decisions and to ignore or forget divergent views that are held my members of the group. In this way, groups of experts can be collectively overconfident, or even biased.

So, the methodological challenge of expert judgment is to reliably extract the desired information from each member of a group of experts, without falling into the cognitive and behavioral biases that can undermine such an exercise. The best practices in an expert judgment approach have evolved by considering this challenge, testing approaches via experiments, and recommending a set of protocols for conducting an expert elicitation.

Steps in an elicitation

We are using a protocol based on a modified Delphi method called the IDEA protocol (Hanea et al. 2017), with the four-point elicitation method (Speirs-Bridge et al. 2010). There are six steps in the process:

1) Select experts
2) Calibrate experts (seed questions and sharing available information)
3) Elicitation of parameter values (4-point method)
4) Summary, review, and discussion (aimed at reducing linguistic uncertainty – relating to the instructions – and sharing insights, not to reach consensus)
5) Experts revise their initial values (if desired)
6) Aggregate information across experts

Steps 3-6 comprise a modified Delphi approach (described below).

Selection of experts

Experts are individuals with specific subject-matter experience and knowledge. Experts should have relevant expertise which may come from formal training and be demonstrated by professional accomplishments such as peer-reviewed publications, familiarity with and

knowledge of the system or related systems, willingness to participate fully and impartially in an elicitation process, and good interpersonal and communication skills (Ayyub 2001, Fazey et al., 2006).

Groups of experts have been found to perform as well (in terms of providing information close to the true empirically observed data) as more specific experts (e.g., Burgman et al. 2011). The expert panel should be diverse – possessing knowledge of North American bats, zoonotic disease, and possible mitigation strategies; representing multiple institutions, specialization, and gender. The optimal number of experts for a structured elicitation is between 5 and 12, with decreasing marginal benefit after 12 experts (Hogarth 1978, Hemming et al. 2018).

Calibration questions

Before starting the elicitation concerning the questions of interest, we will provide the expert panel a chance to practice the elicitation methods. We will provide questions that are known (i.e., we have identified values from the literature, but are unlikely to be known precisely by experts). We use these questions to ensure that the instructions are understood by experts, and to allow experts a chance to calibrate their estimates of uncertainty.

Three questions are listed below (see accompanying spreadsheet < BatEE Practice Questions v2.xlsx>). For each question, we ask experts to provide four responses: an estimate that represents your view of the lowest reasonable value; an estimate of the highest reasonable value; an estimate that represents the best central value; and your confidence that the true value lies within the low and high values that you have provided. We have attached a spreadsheet in which you can enter these values; the spreadsheet automatically calculates a probability distribution that represents your uncertainty, as immediate feedback about whether your responses reflect your expert belief. This is a "closed book" exercise (we ask that you do not check this information in books or online). Please return your answers to us; we will use them to provide feedback to the group about your individual and collective accuracy and precision; as a means of allowing you to calibrate your thinking process prior to the elicitation for the questions of central importance.

The calibration questions are:

1) What is the mean forearm length (in centimeters) of an adult little brown bat (*Myotis lucifugus*)?

2) What is the average number of subsequent white-nose syndrome infections resulting from a single infected little brown bat (i.e., R_0)?

3) In a population that has already experienced decline due to WNS, out of 100 adult female little brown bats, how many would you expect to breed in a given year?

Elicitation of parameters using a modified Delphi approach

To generate empirical estimates of each parameter, we use a '4-point' elicitation method. This approach has been shown to reduce overconfidence in experts (Speirs-Bridge et al. 2010) and can generate a quantitative estimate from experts who may be uncomfortable providing estimates. We derive a median and credible interval for each parameter from the following four questions:

1) Realistically, what is the lowest reasonable value for the parameter?
2) Realistically, what is the highest reasonable value for the parameter?
3) Realistically, what is the most likely reasonable value (i.e., your best estimate) for the parameter?
4) How confident are you that the true value is between the lowest and highest values you provided?

We then assume that the most likely value is the median value, and combine the upper and lower estimates and the reported confidence to generate a credible interval.

Experts provide their estimates anonymously, and summaries are provided that maintain anonymity, to avoid biases associated with group thinking and dominant personalities. Experts are encouraged to discuss the information during a facilitated discussion of the summarized data, after which experts have the opportunity to revise any of their estimates.

The modified Delphi sequence (independent-group-independent) is important to preserve the unique insights help by individuals while at the same time allowing the benefit of wisdom to be shared. By asking experts to perform the first estimate independently, their own personal views are captured. By allowing the expert to share and discuss their initial estimates, we can explore whether there is residual linguistic uncertainty that needs to be corrected and we can allow insights to be shared across experts. By allowing the final estimates to be made independently, we guard against dominant voices in the group and retain the diversity of insights among the experts.

Aggregation of information across experts

Following the elicitation, we will aggregate the results to produce a single probability distribution that represents an estimate, with uncertainty, for each parameter. To do this, we will first transform the four-point elicitation results into a probability distribution for each expert. We will then average these probability distributions across experts, with equal weighting. (There are involved methods for weighting experts based on sets of calibration questions, but we are both skeptical of these methods and limited on time).

Consider a wildlife biologist engaged in research, survey, monitoring, or management (RSM) who is actively shedding SARS-CoV-2 virus (CoV+), performing their routine activities in the absence of any new restrictions, regulations, or protocols.

Q3

3. If the RSM biologist is **not in an enclosed space but is within a 6-foot proximity** of 100 little brown bats (and does not handle them), how many of those bats will be exposed to a sufficient viral dose that they could become infected?

		logit(x)
What is the lowest reasonable estimate?		Error: must be between 0 and 100
What is the highest reasonable estimate?		Error: must be between 0 and 100
What is your central estimate?		Error: must be between 0 and 100
How confidence are you that the true mean is between your low and high estimates?		**Error: Confidence should be >50**
(Confidence should be a number between 50 and 100)		

Assume: logit-normal uncertainty distribution

Consider your response to question 1, regarding exposure through handling by RSM scientists. The new guidance and protocols consist of: restriction of fieldwork to people without symptoms and without contact with someone who had symptoms of COVID-19 in the last 14 days; proper training and compliance protocols for the use of PPE; proper use of Tyvek or other dedicated clothing; proper use of an N95 respirator; and proper use of gloves for handling bats. In these questions, please assume that the biologists have proper training, have access to PPE, and are using it appropriately.

Q9

9. By what proportion should this exposure probability be multiplied if the new guidance and protocols are put into place? (Note that a proportion of 1 means there would be no change in exposure probability; a proportion of less than 1 would indicate a reduction in exposure probability; and a proportion of greater than 1 would indicate an increase in exposure probability as a result of such guidance.)

		ln(x)
What is the lowest reasonable estimate?		Error: proportion must be >0
What is the highest reasonable estimate?		Error: proportion must be >0
What is your central estimate?		Error: proportion must be >0
How confidence are you that the true mean is between your low and high estimates?		**Error: Confidence should be >50**
(Confidence should be a number greater than 50 and less than 100)		

Assume: log-normal uncertainty distribution

Consider your response to question 3, regarding exposure through proximity in an *un*enclosed space by RSM scientists. The new guidance and protocols consist of: restriction of fieldwork to people without symptoms and without contact with someone who had symptoms of COVID-19 in the last 14 days; proper training and compliance protocols for the use of PPE; proper use of Tyvek or other dedicated clothing; proper use of an N95 respirator; and proper use of gloves for handling bats. In these questions, please assume that the biologists have proper training, have access to PPE, and are using it appropriately.

Q11

11. By what proportion should this exposure probability be multiplied if the new guidance and protocols are put into place?

		ln(x)
What is the lowest reasonable estimate?		Error: proportion must be >0
What is the highest reasonable estimate?		Error: proportion must be >0
What is your central estimate?		Error: proportion must be >0
How confidence are you that the true mean is between your low and high estimates?		Error: Confidence should be >50
(Confidence should be a number greater than 50 and less than 100)		

Assume: log-normal uncertainty distribution

Open-ended response. Are there reasons to believe that the proportional change in the handling and proximity exposure probabilities for wildlife rehabilitators (WR) and wildlife control operators (WC), owing to the same protocol guidance, would be different than for scientists involved in research, survey, and management (RSM)? Explain.

Q13

13. What is R_0 for SARS-CoV-2 in little brown bats during the active season? That is, for each infected little brown bat, how many other little brown bats would become infected with the virus? Note that R_0 can be less than 1, in which case you can think of it as the probability that an infected bat will infect one other bat, or it can be greater than 1, in which case each infected bat infects more than one other bat. Note that the spreadsheet calculates from your responses (in cell D13) the probability that R_0 is greater than 1.

		ln(x)
What is the lowest reasonable estimate?		Error: R0 must be >0
What is the highest reasonable estimate?		Error: R0 must be >0
What is your central estimate?		Error: R0 must be >0
How confidence are you that the true mean is between your low and high estimates?		**Error: Confidence should be >50**
(Confidence should be a number between 50 and 100)

Abstract

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) causes the recent COVID-19 public health crisis. Bat is the widely believed original host of SARS-CoV-2. However, its intermediate host before transmitting to humans is not clear. Some studies proposed pangolin, snake, or turtle as the intermediate hosts. Angiotensin-converting enzyme 2 (ACE2) is the receptor for SARS-CoV-2, which determines the potential host range for SARS-CoV-2. On the basis of structural information of the complex of human ACE2 and SARS-CoV-2 receptor-binding domain (RBD), we analyzed the affinity to S protein of the 20 key residues in ACE2 from mammal, bird, turtle, and snake. Several ACE2 proteins from Primates, Bovidae, Cricetidae, and Cetacea maintained the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. The simulated structures indicated that ACE2 proteins from Bovidae and Cricetidae were able to associate with SARS-CoV-2 RBD. We found that nearly half of the key residues in turtle, snake, and bird were changed. The simulated structures showed several key contacts with SARS-CoV-2 RBD in turtle and snake ACE2 were abolished. This study demonstrated that neither snake nor turtle was the intermediate hosts for SARS-CoV-2, which further reinforced the concept that the reptiles are resistant against infection of coronavirus. This study suggested that Bovidae and Cricetidae should be included in the screening of intermediate hosts for SARS-CoV-2.

KEYWORDS

ACE2, Bovidae, Cricetidae, intermediate host, SARS-CoV-2

1 | INTRODUCTION

Coronavirus disease 2019 (COVID-19), which was first reported in Wuhan, Hubei province, China, has caused over 80 422 human infections and more than 2984 deaths (as of 4 March 2020) in China.[1,2] The confirmed cases outside China are increasing, which raised major global concern. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was identified to be the pathogen of COVID-19. SARS-CoV-2 has joined SARS-CoV and Middle East respiratory syndrome-related coronavirus (MERS-CoV) as another coronavirus that causes severe respiratory disease and human death.[3,4]

The specificity of the interaction between virus and receptor determines its host range for the virus. Spike protein (S) of SARS-CoV-2 has attracted great attention because of its role in receptor binding. Angiotensin-converting enzyme 2 (ACE2) binds to the receptor-binding domain (RBD) of SARS-CoV-2 S protein and functions as a receptor for SARS-CoV-2.[5,6] The origin of SARS-CoV-2 is considered as bat.[6] However, the intermediate host is unknown. Some studies suggest that pangolin is involved in the evolution of SARS-CoV-2.[7,8] Others suggested that snake and turtles are potential intermediate hosts for SARS-CoV-2.[9,10] In this study, we compared the key amino acids (AAs) in ACE2 from different species for the binding ability to RBD. On the basis of

 © 2020 Wiley Periodicals, Inc.

potential interaction between S protein and ACE2, it was speculated that SARSCoV-2 preserved the ability to infect Bovidae and Cricetidae but not snake or turtle.

2 | METHODS

2.1 | Sequence analysis of ACE2

A total of 93 ACE2 protein sequences were selected from 85 mammals, 4 birds, 3 turtles, and 1 snake. These ACEs with their corresponding species are listed as follows: hACE2: Homo sapiens (BAB40370.1), RhiACE2: Rhinopithecus roxellana (XP_010364367.2), MacmACE2: Macaca mulatta (NP_001129168.1), MuseACE2: Mustela erminea (XP_032187679.1), CamdACE2: Camelus dromedarius (XP_031301717.1), PlACE2: Procyon lotor (XP_031301717.1), PcACE2: Paguma larvata (AAX63775.1), RmACE2: Rhinolophus macrotis (ADN93471.1), RfACE2: Rhinolophus ferrumequinum (BAH02663.1), RsACE2: Rhinolophus sinicus (ADN93472.1), RlACE2: Rousettus leschenaultii (BAF50705.1), SsACE2: Sus scrofa (NP_001116542.1), MpfACE2: Mustela putorius furo (BAE53380.1), RatACE2: Rattus norvegicus (Q5EGZ1), MmACE2: Mus musculus (Q3URC9), ClfACE2: Canis lupus familiaris (J9P7Y2), FcACE2: Felis catus (A0A384DV19), MjACE2: Manis javanica (XP_017505752.1), RpACE2: Rhinolophus pearsonii (ABU54053.1), PvACE2: Pteropus vampyrus (XP_011361275.1), PoaACE2: Pongo abelii (NP_001124604.1), EcACE2: Equus caballus (F6V9L3), BtACE2: Bos taurus (Q58DD0), PtACE2: Pan troglodytes (A0A2J8KU96), OraACE2: Ornithorhynchus anatinus (F7FDA2), OvaACE2: Ovis aries (W5PSB6), PanACE2: Papio Anubis (A0A096N4X9), LaACE2: Loxodonta africana (G3T6Q2), SsdACE2: Sus scrofa domesticus (A0A220QT48), EeACE2: Erinaceus europaeus (A0A1S3APE5), OcACE2: Oryctolagus cuniculus (G1TEF4), NpACE2: Nyctereutes procyonoides (B4XEP4), VvACE2: Vulpes vulpes (A0A3Q7-RAT9), PhcACE2: Phodopus campbelli (C7ECU7), MaACE2: Mesocricetus auratus (C7ECV1), CjACE2: Callithrix jacchus (F7CNJ6), SusACE2: Suricata suricatta (XP_029786256.1), HgACE2: Heterocephalus glaber (A0A0N8EUX7), DoACE2: Dipodomys ordii (A0A1S3GHT7), ItACE2: Ictidomys tridecemlineatus (XP_005316051.3), CpACE2: Cavia porcellus (XP_023417808.1), CgACE2: Cricetulus griseus (A0A061HZ66), ChACE2: Capra hircus (A0A452EVJ5); BibtACE2: Bos indicus x Bos taurus (A0A4W2H3A1), BmACE2: Bos mutus (L8I4I4), NlACE2: Nomascus leucogenys (G1RE79); CsACE2: Chlorocebus sabaeus (A0A0D9RQZ0); MfACE2: Macaca fascicularis (A0A2K5X283); PpACE2: Pan paniscus (A0A2R9BKD8); CaACE2: Cercocebus atys (A0A2K5KSD8); MnACE2: Macaca nemestrina (A0A2K6D1N8); MalACE2: Mandrillus leucophaeus (A0A2K5ZV99); TsACE2: Tarsius syrichta (A0A1U7TY97); PrcACE2: Propithecus coquereli (A0A2K6GHW5); UmACE2: Ursus maritimus (A0A452TT30); OgACE2: Otolemur garnettii (H0WMI5); SbbACE2: Saimiri boliviensis boliviensis (A0A2K6SBD4); CciACE2: Cebus capucinus imitator (A0A2K5PYM0); GggACE2: Gorilla gorilla gorilla (G3QWX4); AnACE2: Aotus nancymaae (A0A2K5DQI6); ChaACE2: Chlorocebus aethiops (Q1LZX8); AmACE2: Ailuropoda melanoleuca (G1MC42); VuACE2: Vombatus ursinus (A0A4X2M679); UaACE2: Ursus americanus (A0A452R1Z9); UahACE2: Ursus arctos horribilis (A0A3Q7TE16); PmACE2: Physeter macrocephalus (A0A2Y9S5T9); LvACE2: Lipotes vexillifer (A0A340Y3Y6); BasACE2: Balaenoptera acutorostrata scammoni (A0A452CBT6); DlACE2: Delphinapterus leucas (A0A2Y9M9H3); TtACE2: Tursiops truncatus (A0A2U4AJL3); NaaACE2: Neophocaena asiaeorientalis asiaeorientalis (A0A341BCI8); CuACE2: Callorhinus ursinus (A0A3Q7N3M7); NsACE2: Neomonachus schauinslandi (A0A2Y9GEI9); TmlACE2: Trichechus manatus latirostris (A0A2Y9E393); ElkACE2: Enhydra lutris kenyoni (A0A2Y9KLV0); ClACE2: Chinchilla lanigera (C7ECU0); MdACE2: Monodelphis domestica (F6WXR7); LpACE2: Lynx pardinus (A0A485NF12); PaACE2: Pipistrellus abramus (C7ECT9); MbACE2: Myotis brandtii (S7N573); DrACE2: Desmodus rotundus (K9INV8); RhpACE2: Rhinolophus pusillus (E2DHI9); RaACE2: Rhinolophus alcyone (A0A0N7IQX6); RlACE2(2): Rhinolophus landeri (A0A0P0IB69); MylACE2: Myotis lucifugus (G1PXH7), GgACE2: Gallus gallus (F1NHR4), ApACE2: Anas platyrhynchos (R0LHX5), MgACE2: Meleagris gallopavo (G1NPB8), CaaACE2: Cathartes aura (A0A091MDI4), OhACE2: Ophiophagus hannah (V8NIH2), CpbACE2: Chrysemys picta bellii (XP_023964517.1), CmACE2: Chelonia mydas (XP_007070561.1); and PsACE2: Pelodiscus sinensis (XP_006122891.1). On the basis of known 20 key sites in human ACE2 interacting with SARSCoV-2 RBD,[11] we analyzed whether these sites were conserved on other ACE2 proteins. Phylogenetic and molecular evolutionary analysis of ACE2 protein was conducted using molecular evolutionary genetics analysis version X (MEGA-X).[12] Phylogenetic tree was generated with Jones-Taylor-Thornton evolutionary model using a maximum-likelihood method.

2.2 | Structure simulation of ACE2-RBD complex

On the basis of the structure of hACE2 with SARSCoV-2 S RBD (PDB: 6LZG), the structure of SARSCoV-2 S and ACE2 from Bos taurus, Cricetulus griseus, Pelodiscus sinensis, and Ophiophagus hannah were simulated by SWISSMODEL online server[13] and analyzed by Chimera software version 1.14.[14]

3 | RESULTS

3.1 | Sequence alignment of ACE2

According to the recently resolved structure of the complex of human ACE2 and SARSCoV-2 RBD, there are 20 key AAs in hACE2 for interacting with RBM.[11] We analyzed those AAs of ACE2 protein from a list of mammals, birds, turtles, and snake, as shown in Table 1. Next, a phylogenetic tree for mammalian ACE2 proteins was constructed by MEGA-X software. There were 16 primates ACE2, 5 Bovidae ACE2, 2 Cricetidae ACE2, and 3 Cetacea ACE2 (Table 1 and Figure 1A), possessing at least 90% (18/20) critical AAs. Pangolin ACE2 preserved only 70% (14/20) AAs. Nearly half of the key residues in turtles (CpbACE2, CmACE2, and PsACE2) and snake (OhACE2) were changed (Table 1). ACE2 from Aves, including Gallus gallus, Anas platyrhynchos, Meleagris gallopavo, and Cathartes aura, only matched 10 to 11 AAs (Table 1).

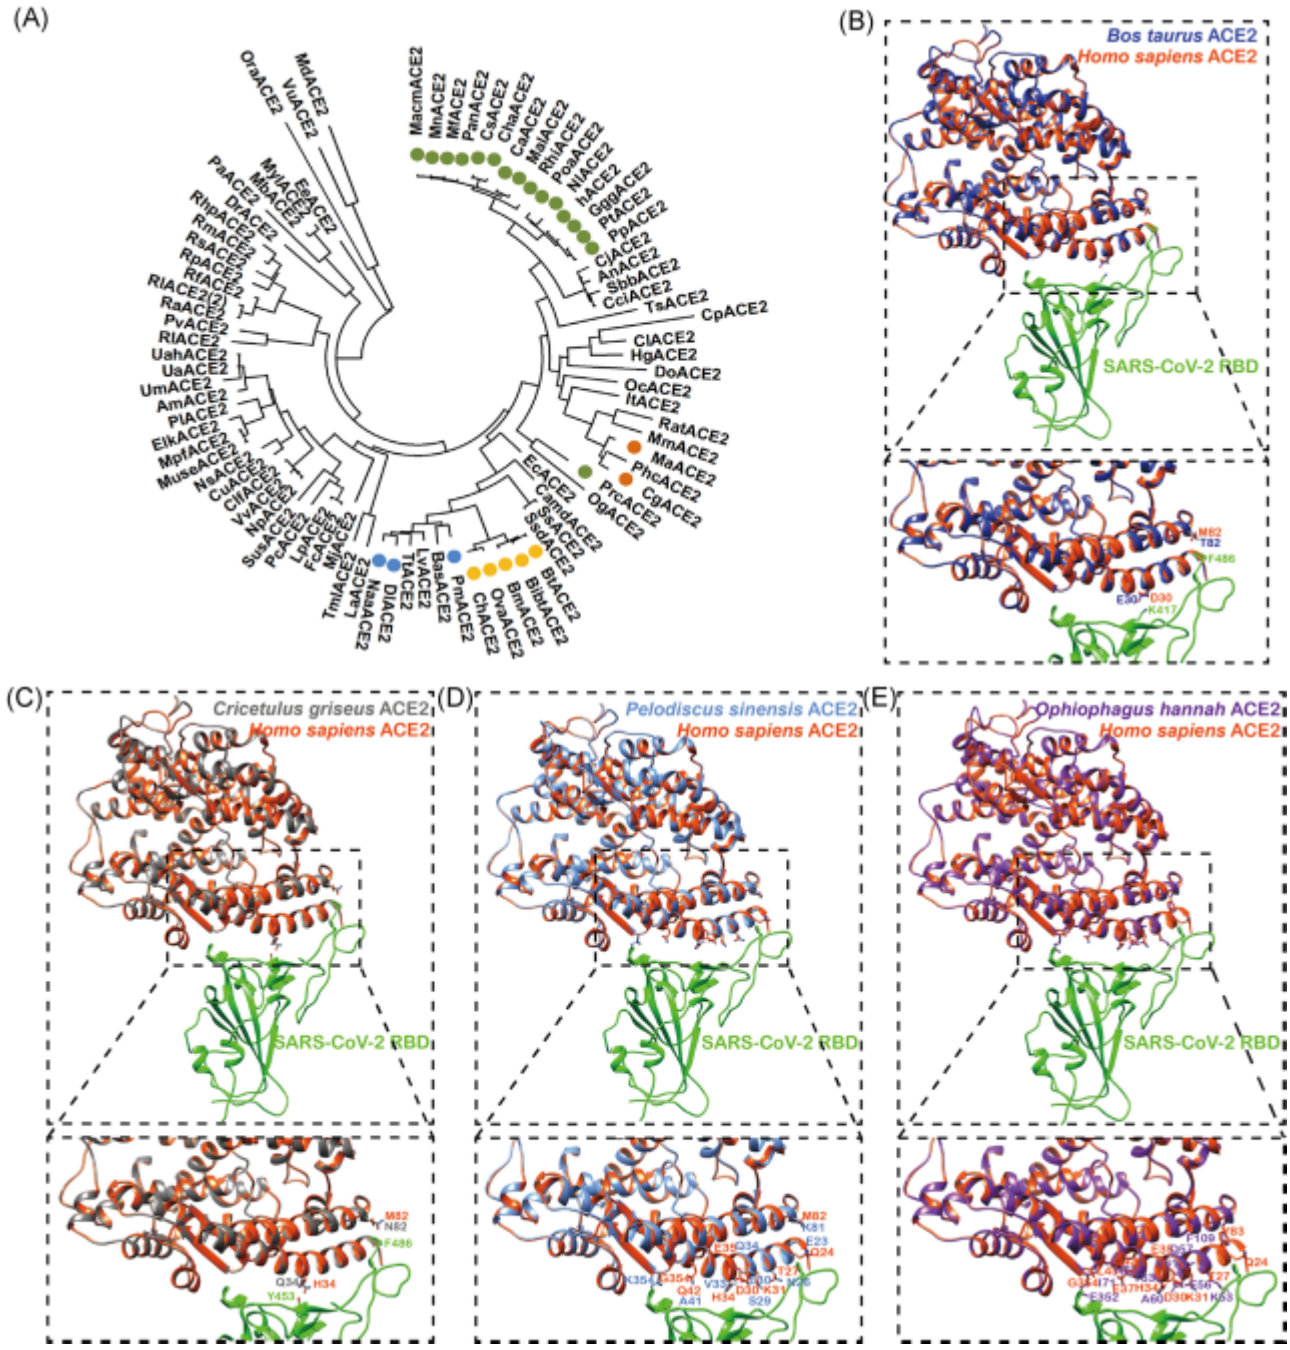

FIGURE 1 Structure simulation of SARSCoV-2 RBD with ACE2 from different species. A, Phylogenetic tree of mammalian ACE2. ACE2 proteins from a total of 85 mammals were analyzed by MEGA-X and the phylogenetic tree was constructed using a maximum-likelihood method. The green, yellow, orange, and blue represent ACE2 from Primates, Bovidae, Cricetidae, and Cetacea, respectively. B, Structural simulation of the protein complex of Bostaurus ACE2 and SARSCoV-2 RBD. Bostaurus ACE2, Homo sapiens ACE2, and SARSCoV-2 RBD are in medium blue, orange red, and green, respectively. C, Structural simulation of the protein complex of Cricetulus griseus ACE2 and SARSCoV-2 RBD. Cricetulus griseus ACE2, Homo sapiens ACE2, and SARSCoV-2 RBD are in dim gray, orange red, and green, respectively. D, Structural simulation of the protein complex of Pelodiscus sinensis ACE2 and SARSCoV-2 RBD. Pelodiscus sinensis ACE2, Homo sapiens ACE2, and SARSCoV-2 RBD are in cornflower blue, orange red, and green, respectively. E, Structural simulation of the protein complex of Ophiophagus hannah ACE2 and SARSCoV-2 RBD. Ophiophagus hannah ACE2, Homo sapiens ACE2, and SARSCoV-2 RBD are in purple, orange red, and green, respectively. ACE2, angiotensin-converting enzyme 2; MEGA-X, Molecular Evolutionary Genetics Analysis version X; RBD, receptor-binding domain; SARSCoV-2, severe acute respiratory syndrome coronavirus 2

3.2 | Structure simulation of the protein complex of SARS-CoV-2 RBD and Bovidae/Cricetidae/turtle/snake ACE2

Recently, the structure of SARS-CoV-2 RBD with human ACE2 has been resolved. To investigate whether Bovidae/Cricetidae ACE2 maintained the binding affinity with SARS-CoV-2 RBD, we simulated the potential structure of the protein complex. T82 and E30 in Bos taurus ACE2 kept the contact to F486 and K417 in SARS-CoV-2 S (Figure 1B). N82 and Q34 in Cricetulus griseus ACE2 maintained the contact to F486 and Y453 in SARS-CoV-2 S (Figure 1C). We concluded that Bovidae/Cricetidae ACE2 could associate with SARS-CoV-2 S (Figure 1B,C).

To investigate the potential association between SARS-CoV-2 and ACE2 from turtle and snake, we simulated the potential structure of turtle/snake ACE2 with SARS-CoV-2 RBD. The AA correlated to hACE2 Q42 is changed to A (A41) in turtle (Figure 1D). We also noticed that the AA correlated to hACE2 H34 is changed to A (A60) in a snake (Figure 1E). When the contact AA was mutated to smaller AA (A), the contact force for protein-protein interaction will be reduced. Moreover, the corresponding AA of K31 was changed to E (E30) in turtle and Q (Q57) in snake ACE2 (Figure 1D). K31 in hACE2 was critical for SARS-CoV RBD binding and ACE2-K31D mutant abolished its association with SARS-CoV RBD.[15] Taken together, turtle and snake ACE2 are unlikely to bind to S protein of SARS-CoV-2.

4 | DISCUSSION

SARS-CoV, MERS-CoV, and SARS-CoV-2 have caused severe human infectious diseases in the last 2 decades. These three human coronaviruses originated from bats, but the intermediate hosts were different. SARS-CoV came from the Paguma larvata,[16] and the intermediate host for MERS-CoV is Camelus dromedaries[17] The new coronavirus SARS-CoV-2 has recently caused a serious pandemic in China and other countries. However, it is not clear which animals are involved in the evolution of SARS-CoV-2 and which animals may be infected by SARS-CoV-2. RBD region in S protein of pangolin coronavirus is similar to that of SARS-CoV-2,[7,8] indicating the involvement of pangolin in the recombination of SARS-CoV-2. By analyzing the codon usage of SARS-CoV-2, people suggested that snake might be a potential host for SARS-CoV-2.[9] Another study indicated that turtle is a potential intermediate host for SARS-CoV-2 based on the key AAs in ACE2 for interacting with SARS-CoV RBD.[10] The late study raised the concerns of SARS-CoV-2 infection in the turtle aquaculture and pet turtle. Most of the coronaviruses hosts are mammals; with a few of exceptions are birds. Considering that all known hosts for coronaviruses are thermostatic animals, it is unlikely that reptiles will be infected with SARS-CoV-2.

There are 20 key AAs in ACE2 critical for binding S protein of SARS-CoV-2.[11] On the basis of these 20 AAs, we analyzed the corresponding AAs in ACE2 from a list of mammal, bird, turtle, and snake. We found that the ACE2 of turtles and snake lost the capability to associate with S protein (Table 1 and Figure 1D,E). These reptiles should be ruled out from the potential host list for SARS-CoV-2. Aves ACE2 was unlikely to associate with SARS-CoV-2 RBD because they lost the critical K corresponding to K31 in human ACE2 (Table 1). Pangolin ACE2 was predicted to recognize SARS-CoV-2 RBD less efficiently because it only preserved 14 of 20 critical AAs (Table 1). Interestingly, we found that ACE2 proteins from Primates, Bovidae, Cricetidae, and Cetacea were capable to recognize RBD of SARS-CoV-2 by maintaining the majority of key residues in ACE2 for associating with SARS-CoV-2 RBD. Swine ACE2 (CpACE2) with 15 of 20 matched critical AAs was shown to support SARS-CoV-2 entry.[6] Bovidae/Cricetidae ACE2 matched more AAs than swine ACE2, thus they should recognize SARS-CoV-2 RBD. It would strengthen our conclusion if we have biochemical evidence for the S-ACE2 interaction analysis for Bovidae/Cricetidae ACE2. On the basis of human ACE2 and SARS-CoV-spike complex structure model (PDB ID: 2AJF), we and others recently predicted that hamster ACE2 could associate with SARS-CoV-2 and hamster might be a candidate small animal model for SARS-CoV-2 infection.[18,19] Indeed, golden Syrian hamster (Mesocricetus auratus) has been established as a model to study the pathogenesis and transmission of COVID-19.[19] One of Cetacea, Neophocaena asiaeorientalis asiaeorientalis (Yangtze finless porpoise), lives in the middle and lower reaches of the Yangtze River and its lakes, where Wuhan located nearby.[20] It will be interesting to investigate whether Yangtze finless porpoise could be infected with SARS-CoV-2 or related coronavirus.

In conclusion, we found that Bovidae/Cricetidae ACE2 but not turtle/snake ACE2 could recognize SARS-CoV-2 RBD. More attention should be paid to Bovidae and Cricetidae in hunting the potential intermediate host for SARS-CoV-2.

ACKNOWLEDGMENTS

The authors would like to thank Dr Shan Gao for the discussion. This study is supported by grants from National Key Plan for Research and Development of China (2016YFD0500300), Shandong Academy of Medical Sciences Grant (2017-52), the Innovation Project of Shandong Academy of Medical Sciences, and Academic Promotion Program of Shandong First Medical University (2019LJ001). Molecular graphics and analyses performed with UCSF Chimera, developed by the Resource for Biocomputing, Visualization, and Informatics at the University of California, San Francisco, with support from NIH P41-GM103311.

CONFLICT OF INTERESTS

The authors declare that there are no conflict of interests.

Respiratory virus shedding in exhaled breath and efficacy of face masks

Nancy H. L. Leung[1], Daniel K. W. Chu[1], Eunice Y. C. Shiu[1], Kwok-Hung Chan[2], James J. McDevitt[3], Benien J. P. Hau[4], Hui-Ling Yen[1], Yuguo Li[5], Dennis K. M. Ip[1], J. S. Malik Peiris[2], Wing-Hong Seto[1,6], Gabriel M. Leung[1], Donald K. Milton[7,8] and Benjamin J. Cowling[1,8]✉

We identified seasonal human coronaviruses, influenza viruses and rhinoviruses in exhaled breath and coughs of children and adults with acute respiratory illness. Surgical face masks significantly reduced detection of influenza virus RNA in respiratory droplets and coronavirus RNA in aerosols, with a trend toward reduced detection of coronavirus RNA in respiratory droplets. Our results indicate that surgical face masks could prevent transmission of human coronaviruses and influenza viruses from symptomatic individuals.

Respiratory virus infections cause a broad and overlapping spectrum of symptoms collectively referred to as acute respiratory virus illnesses (ARIs) or more commonly the 'common cold'. Although mostly mild, these ARIs can sometimes cause severe disease and death[1]. These viruses spread between humans through direct or indirect contact, respiratory droplets (including larger droplets that fall rapidly near the source as well as coarse aerosols with aerodynamic diameter >5 µm) and fine-particle aerosols (droplets and droplet nuclei with aerodynamic diameter ≤5 µm)[2,3]. Although hand hygiene and use of face masks primarily targeting contact and respiratory droplet transmission, have been suggested as important mitigation strategies against influenza virus transmission[4], little is known about the relative importance of these modes in the transmission of other common respiratory viruses[3,5]. Uncertainties similarly apply to the modes of transmission of COVID-19 (refs. [6,7]).

Some health authorities recommend that masks be worn by ill individuals to prevent onward transmission (source control)[4,8]. Surgical face masks were originally introduced to protect patients from wound infection and contamination from surgeons (the wearer) during surgical procedures, and were later adopted to protect healthcare workers against acquiring infection from their patients. However, most of the existing evidence on the filtering efficacy of face masks and respirators comes from in vitro experiments with nonbiological particles[9,10], which may not be generalizable to infectious respiratory virus droplets. There is little information on the efficacy of face masks in filtering respiratory viruses and reducing viral release from an individual with respiratory infections[8], and most research has focused on influenza[11,12].

Here we aimed to explore the importance of respiratory droplet and aerosol routes of transmission with a particular focus on coronaviruses, influenza viruses and rhinoviruses, by quantifying the amount of respiratory virus in exhaled breath of participants with medically attended ARIs and determining the potential efficacy of surgical face masks to prevent respiratory virus transmission.

Results

We screened 3,363 individuals in two study phases, ultimately enrolling 246 individuals who provided exhaled breath samples (Extended Data Fig. 1). Among these 246 participants, 122 (50%) participants were randomized to not wearing a face mask during the first exhaled breath collection and 124 (50%) participants were randomized to wearing a face mask. Overall, 49 (20%) voluntarily provided a second exhaled breath collection of the alternate type.

Infections by at least one respiratory virus were confirmed by reverse transcription PCR (RT–PCR) in 123 of 246 (50%) participants. Of these 123 participants, 111 (90%) were infected by human (seasonal) coronavirus (n = 17), influenza virus (n = 43) or rhinovirus (n = 54) (Extended Data Figs. 1 and 2), including one participant co-infected by both coronavirus and influenza virus and another two participants co-infected by both rhinovirus and influenza virus. These 111 participants were the focus of our analyses.

There were some minor differences in characteristics of the 111 participants with the different viruses (Table 1a). Overall, 24% of participants had a measured fever ≥37.8°C, with patients with influenza more than twice as likely than patients infected with coronavirus and rhinovirus to have a measured fever. Coronavirus-infected participants coughed the most with an average of 17 (s.d. = 30) coughs during the 30-min exhaled breath collection. The profiles of the participants randomized to with-mask versus without-mask groups were similar (Supplementary Table 1).

We tested viral shedding (in terms of viral copies per sample) in nasal swabs, throat swabs, respiratory droplet samples and aerosol samples and compared the latter two between samples collected with or without a face mask (Fig. 1). On average, viral shedding was higher in nasal swabs than in throat swabs for each of coronavirus (median 8.1 $\log_{10}$ virus copies per sample versus 3.9), influenza virus (6.7 versus 4.0) and rhinovirus (6.8 versus 3.3), respectively. Viral RNA was identified from respiratory droplets and aerosols for all three viruses, including 30%, 26% and 28% of respiratory droplets and 40%, 35% and 56% of aerosols collected while not wearing a face mask, from coronavirus, influenza virus and rhinovirus-infected participants, respectively (Table 1b). In particular for coronavirus, we identified OC43 and HKU1 from both respiratory

P values for comparing the frequency of respiratory virus detection between the mask intervention were obtained by two-sided Fisher's exact test and (two-sided) *P* values for mask intervention as predictor of log_{10} virus copies per sample were obtained by an unadjusted univariate Tobit regression model, which allowed for censoring at the lower limit of detection of the RT–PCR assay, with significant differences in bold. Undetectable values were imputed as 0.3 log_{10} virus copies per sample. IQR, interquartile range.

respiratory droplet and aerosol samples collected without face masks, respectively. There was a significant reduction by wearing face masks to 1 of 27 (4%) in detection of influenza virus in respiratory droplets, but no significant reduction in detection in aerosols (Table 1b). Moreover, among the eight participants who had influenza virus detected by RT–PCR from without-mask aerosols, five were tested by viral culture and four were culture-positive. Among the six participants who had influenza virus detected by RT–PCR from with-mask aerosols, four were tested by viral culture and two were culture-positive. For rhinovirus, there were no significant differences between detection of virus with or without face masks, both in respiratory droplets and in aerosols (Table 1b). Conclusions were similar in comparisons of viral shedding (Table 1b). In addition, we found a significant reduction in viral shedding (Supplementary Table 2) in respiratory droplets for OC43 (Extended Data Fig. 4) and influenza B virus (Extended Data Fig. 5) and in aerosols for NL63 (Extended Data Fig. 4).

We identified correlations between viral loads in different samples (Extended Data Figs. 6–8) and some evidence of declines in viral shedding by time since onset for influenza virus but not for coronavirus or rhinovirus (Extended Data Fig. 9). In univariable analyses of factors associated with detection of respiratory viruses in various sample types, we did not identify significant association in viral shedding with days since symptom onset (Supplementary Table 3) for respiratory droplets or aerosols (Supplementary Tables 4–6).

A subset of participants (72 of 246, 29%) did not cough at all during at least one exhaled breath collection, including 37 of 147 (25%) during the without-mask and 42 of 148 (28%) during the with-mask breath collection. In the subset for coronavirus ($n = 4$), we did not detect any virus in respiratory droplets or aerosols from any participants. In the subset for influenza virus ($n = 9$), we detected virus in aerosols but not respiratory droplets from one participant. In the subset for rhinovirus ($n = 17$), we detected virus in respiratory droplets from three participants, and we detected virus in aerosols in five participants.

Discussion

Our results indicate that aerosol transmission is a potential mode of transmission for coronaviruses as well as influenza viruses and rhinoviruses. Published studies detected respiratory viruses[13,14] such as influenza[12,15] and rhinovirus[16] from exhaled breath, and the detection of SARS-CoV[17] and MERS-CoV[18] from air samples (without size fractionation) collected from hospitals treating patients with severe acute respiratory syndrome and Middle East respiratory syndrome, but ours demonstrates detection of human seasonal coronaviruses in exhaled breath, including the detection of OC43 and HKU1 from respiratory droplets and NL63, OC43 and HKU1 from aerosols.

Our findings indicate that surgical masks can efficaciously reduce the emission of influenza virus particles into the environment in respiratory droplets, but not in aerosols[12]. Both the previous and current study used a bioaerosol collecting device, the Gesundheit-II (G-II)[12,15,19], to capture exhaled breath particles and differentiated them into two size fractions, where exhaled breath coarse particles >5 µm (respiratory droplets) were collected by impaction with a 5-µm slit inertial Teflon impactor and the remaining fine particles ≤5 µm (aerosols) were collected by condensation in buffer. We also demonstrated the efficacy of surgical masks to reduce coronavirus detection and viral copies in large respiratory droplets and in aerosols (Table 1b). This has important implications for control of COVID-19, suggesting that surgical face masks could be used by ill people to reduce onward transmission.

Among the samples collected without a face mask, we found that the majority of participants with influenza virus and coronavirus infection did not shed detectable virus in respiratory droplets or aerosols, whereas for rhinovirus we detected virus in aerosols in 19 of 34 (56%) participants (compared to 4 of 10 (40%) for influenza and 8 of 23 (35%) for coronavirus). For those who did shed virus in respiratory droplets and aerosols, viral load in both tended to be low (Fig. 1). Given the high collection efficiency of the G-II (ref. [19]) and given that each exhaled breath collection was conducted for 30 min, this might imply that prolonged close contact would be required for transmission to occur, even if transmission was primarily via aerosols, as has been described for rhinovirus colds[20]. Our results also indicate that there could be considerable heterogeneity in contagiousness of individuals with coronavirus and influenza virus infections.

The major limitation of our study was the large proportion of participants with undetectable viral shedding in exhaled breath for each of the viruses studied. We could have increased the sampling duration beyond 30 min to increase the viral shedding being captured, at the cost of acceptability in some participants. An alternative approach would be to invite participants to perform forced coughs during exhaled breath collection[12]. However, it was the aim of our present study to focus on recovering respiratory

virus in exhaled breath in a real-life situation and we expected that some individuals during an acute respiratory illness would not cough much or at all. Indeed, we identified virus RNA in a small number of participants who did not cough at all during the 30-min exhaled breath collection, which would suggest droplet and aerosol routes of transmission are possible from individuals with no obvious signs or symptoms. Another limitation is that we did not confirm the infectivity of coronavirus or rhinovirus detected in exhaled breath. While the G-II was designed to preserve viability of viruses in aerosols, and in the present study we were able to identify infectious influenza virus in aerosols, we did not attempt to culture coronavirus or rhinovirus from the corresponding aerosol samples.

Methods

Study design. Participants were recruited year-round from March 2013 through May 2016 in a general outpatient clinic of a private hospital in Hong Kong. As routine practice, clinic staff screened all individuals attending the clinics for respiratory and any other symptoms regardless of the purpose of the visit at triage. Study staff then approached immediately those who reported at least one of the following symptoms of ARI for further screening: fever ≥37.8 °C, cough, sore throat, runny nose, headache, myalgia and phlegm. Individuals who reported ARI symptoms, within 3 d of illness onset and ≥11 years of age were eligible to participate. After explaining the study to and obtaining informed consent from the participants, a rapid influenza diagnostic test, the Sofia Influenza A+B Fluorescent Immunoassay Analyzer (cat. no. 20218, Quidel), was used to identify influenza A or B virus infection as an incentive to participate. All participants provided a nasal swab for the rapid test and an additional nasal swab and a separate throat swab for subsequent virologic confirmation at the laboratory. All participants also completed a questionnaire to record basic information including age, sex, symptom severity, medication, medical conditions and smoking history. In the first phase of the study from March 2013 to February 2014 ('Influenza Study'), the result of the rapid test was used to determine eligibility for further participation in the study and exhaled breath collection, whereas in the second phase of the study from March 2014 to May 2016 ('Respiratory Virus Study'), the rapid test did not affect eligibility. Eligible participants were then invited to provide an exhaled breath sample for ≥30 min on the same clinic visit.

Before exhaled breath collection, each participant was randomly allocated in a 1:1 ratio to either wearing a surgical face mask (cat. no. 62356, Kimberly-Clark) or not during the collection. To mimic the real-life situation, under observation by the study staff, participants were asked to attach the surgical mask themselves, but instruction on how to wear the mask properly was given when the participant wore the mask incorrectly. Participants were instructed to breathe as normal during the collection, but (natural) coughing was allowed and the number of coughs was recorded by study staff. Participants were then invited to provide a second exhaled breath sample of the alternate type (for example if the participant was first assigned to wearing a mask they would then provide a second sample without a mask), but most participants did not agree to stay for a second measurement because of time constraints. Participants were compensated for each 30-min exhaled breath collection with a supermarket coupon worth approximately US$30 and all participants were gifted a tympanic thermometer worth approximately US$20.

Ethical approval. Written informed consent was obtained from all participants ≥18 years of age and written informed consent was obtained from parents or legal guardians of participants 11–17 years of age in addition to their own written informed consent. The study protocol was approved by the Institutional Review Board of The University of Hong Kong and the Clinical and Research Ethics Committee of Hong Kong Baptist Hospital.

Collection of swabs and exhaled breath particles. Nasal swabs and throat swabs were collected separately, placed in virus transport medium, stored and transported to the laboratory at 2–8 °C and the virus transport medium was aliquoted and stored at −70 °C until further analysis. Exhaled breath particles were captured and differentiated into two size fractions, the coarse fraction containing particles with aerodynamic diameter >5 μm (referred to here as 'respiratory droplets'), which included droplets up to approximately 100 in diameter and the fine fraction with particles ≤5 μm (referred to here as 'aerosols') by the G-II bioaerosol collecting device[12,13]. In the G-II device, exhaled breath coarse particles (>5 μm) were collected by a 5-μm slit inertial Teflon impactor and the remaining fine particles (≤5 μm) were condensed and collected into approximately 1 ml of 0.1% BSA/PBS. Both the impactor and the condensate were stored and transported to the laboratory at 2–8 °C. The virus on the impactor was recovered into 1 ml and the condensate was concentrated into 0.2 ml 0.1% BSA/PBS, aliquoted and stored at −70 °C until further analysis. In a validation study, the G-II was able to recover over 85% of fine particles 0.05–5 μm in size and had comparable collection efficiency of influenza virus as the SKC BioSampler[13].

Laboratory testing. Samples collected from the two studies were tested at the same time. Nasal swab samples were first tested by a diagnostic-use viral panel, xTAG Respiratory Viral Panel (Abbott Molecular) to qualitatively detect 12 common respiratory viruses and subtypes including coronaviruses (NL63, OC43, 229E and HKU1), influenza A (nonspecific, H1 and H3) and B viruses, respiratory syncytial virus, parainfluenza virus (types 1–4), adenovirus, human metapneumovirus and enterovirus/rhinovirus. After one or more of the candidate respiratory viruses was detected by the viral panel from the nasal swab, all the samples from the same participant (nasal swab, throat swab, respiratory droplets and aerosols) were then tested with RT–PCR specific for the candidate virus(es) for determination of virus concentration in the samples. Infectious influenza virus was identified by viral culture using MDCK cells as described previously[14], whereas viral culture was not performed for coronavirus and rhinovirus.

Statistical analyses. The primary outcome of the study was virus generation rate in tidal breathing of participants infected by different respiratory viruses and the efficacy of face masks in preventing virus dissemination in exhaled breath, separately considering the respiratory droplets and aerosols. The secondary outcomes were correlation between viral shedding in nose swabs, throat swabs, respiratory droplets and aerosols and factors affecting viral shedding in respiratory droplets and aerosols.

We identified three groups of respiratory viruses with the highest frequency of infection as identified by RT–PCR, namely coronavirus (including NL63, OC43, HKU1 and 229E), influenza virus and rhinovirus, for further statistical analyses. We defined viral shedding as $\log_{10}$ virus copies per sample and plotted viral shedding in each sample (nasal swab, throat swab, respiratory droplets and aerosols); the latter two were stratified by mask intervention. As a proxy for the efficacy of face masks in preventing transmission of respiratory viruses via respiratory droplet and aerosol routes, we compared the respiratory virus viral shedding in respiratory droplet and aerosol samples between participants wearing face masks or not, by comparing the frequency of detection with a two-sided Fisher's exact test and by comparing viral load (defined as $\log_{10}$ virus copies per sample) by an unadjusted univariate Tobit regression model, which allowed for censoring at the lower limit of detection of the RT–PCR assay. We also used the unadjusted univariate Tobit regression to investigate factors affecting viral shedding in respiratory droplets and aerosols without mask use, for example age, days since symptom onset, previous influenza vaccination, current medication and number of coughs during exhaled breath collection. We investigated correlations between viral shedding in nasal swab, throat swab, respiratory droplets and aerosols with scatter-plots and calculated the Spearman's rank correlation coefficient between any two types of samples. We imputed 0.3 virus copies ml^{-1} for undetectable values before transformation to $\log_{10}$ virus copies per sample. All analyses were conducted with R v.3.6.0 (ref. [22]) and the VGAM package v.1.1.1 (ref. [23]).

Reporting Summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

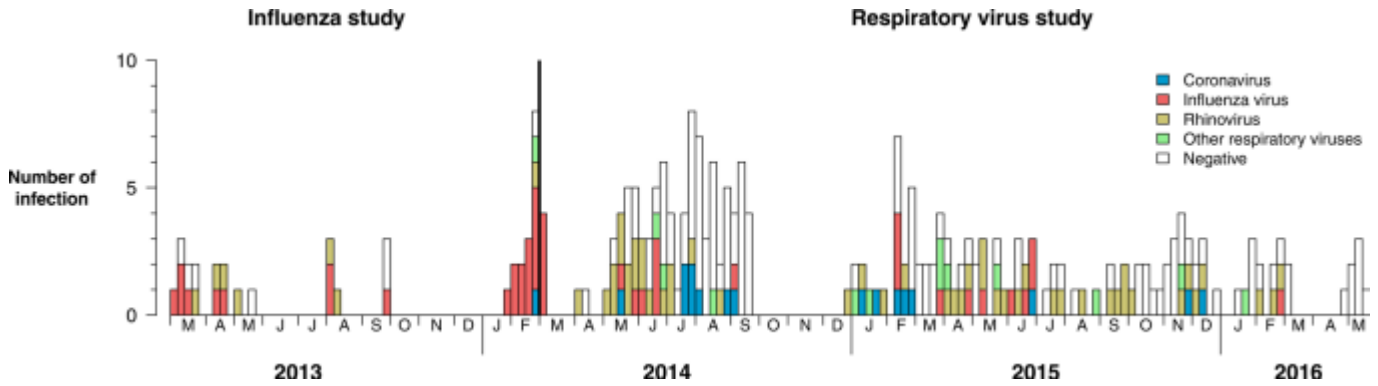
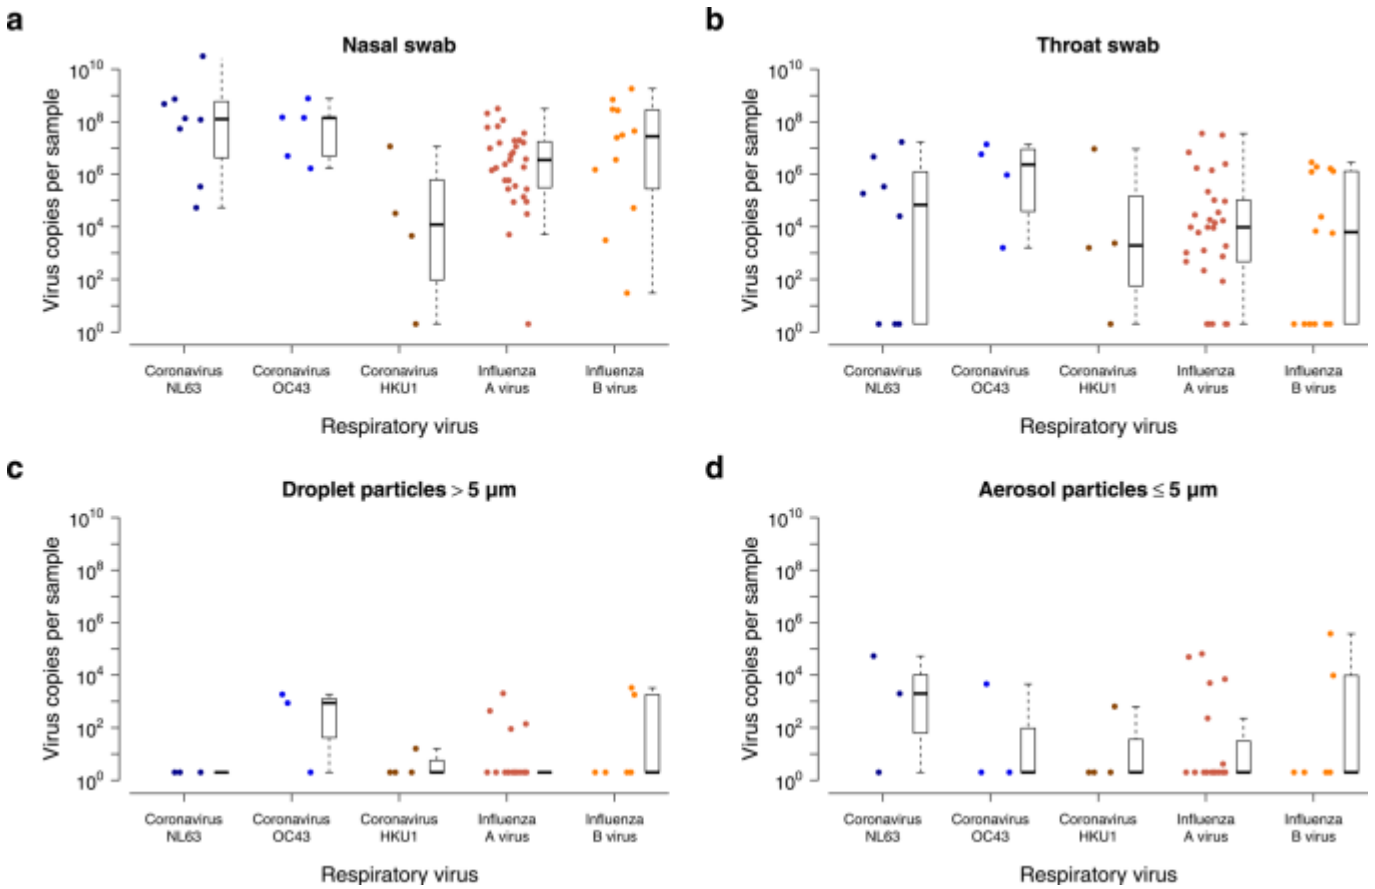
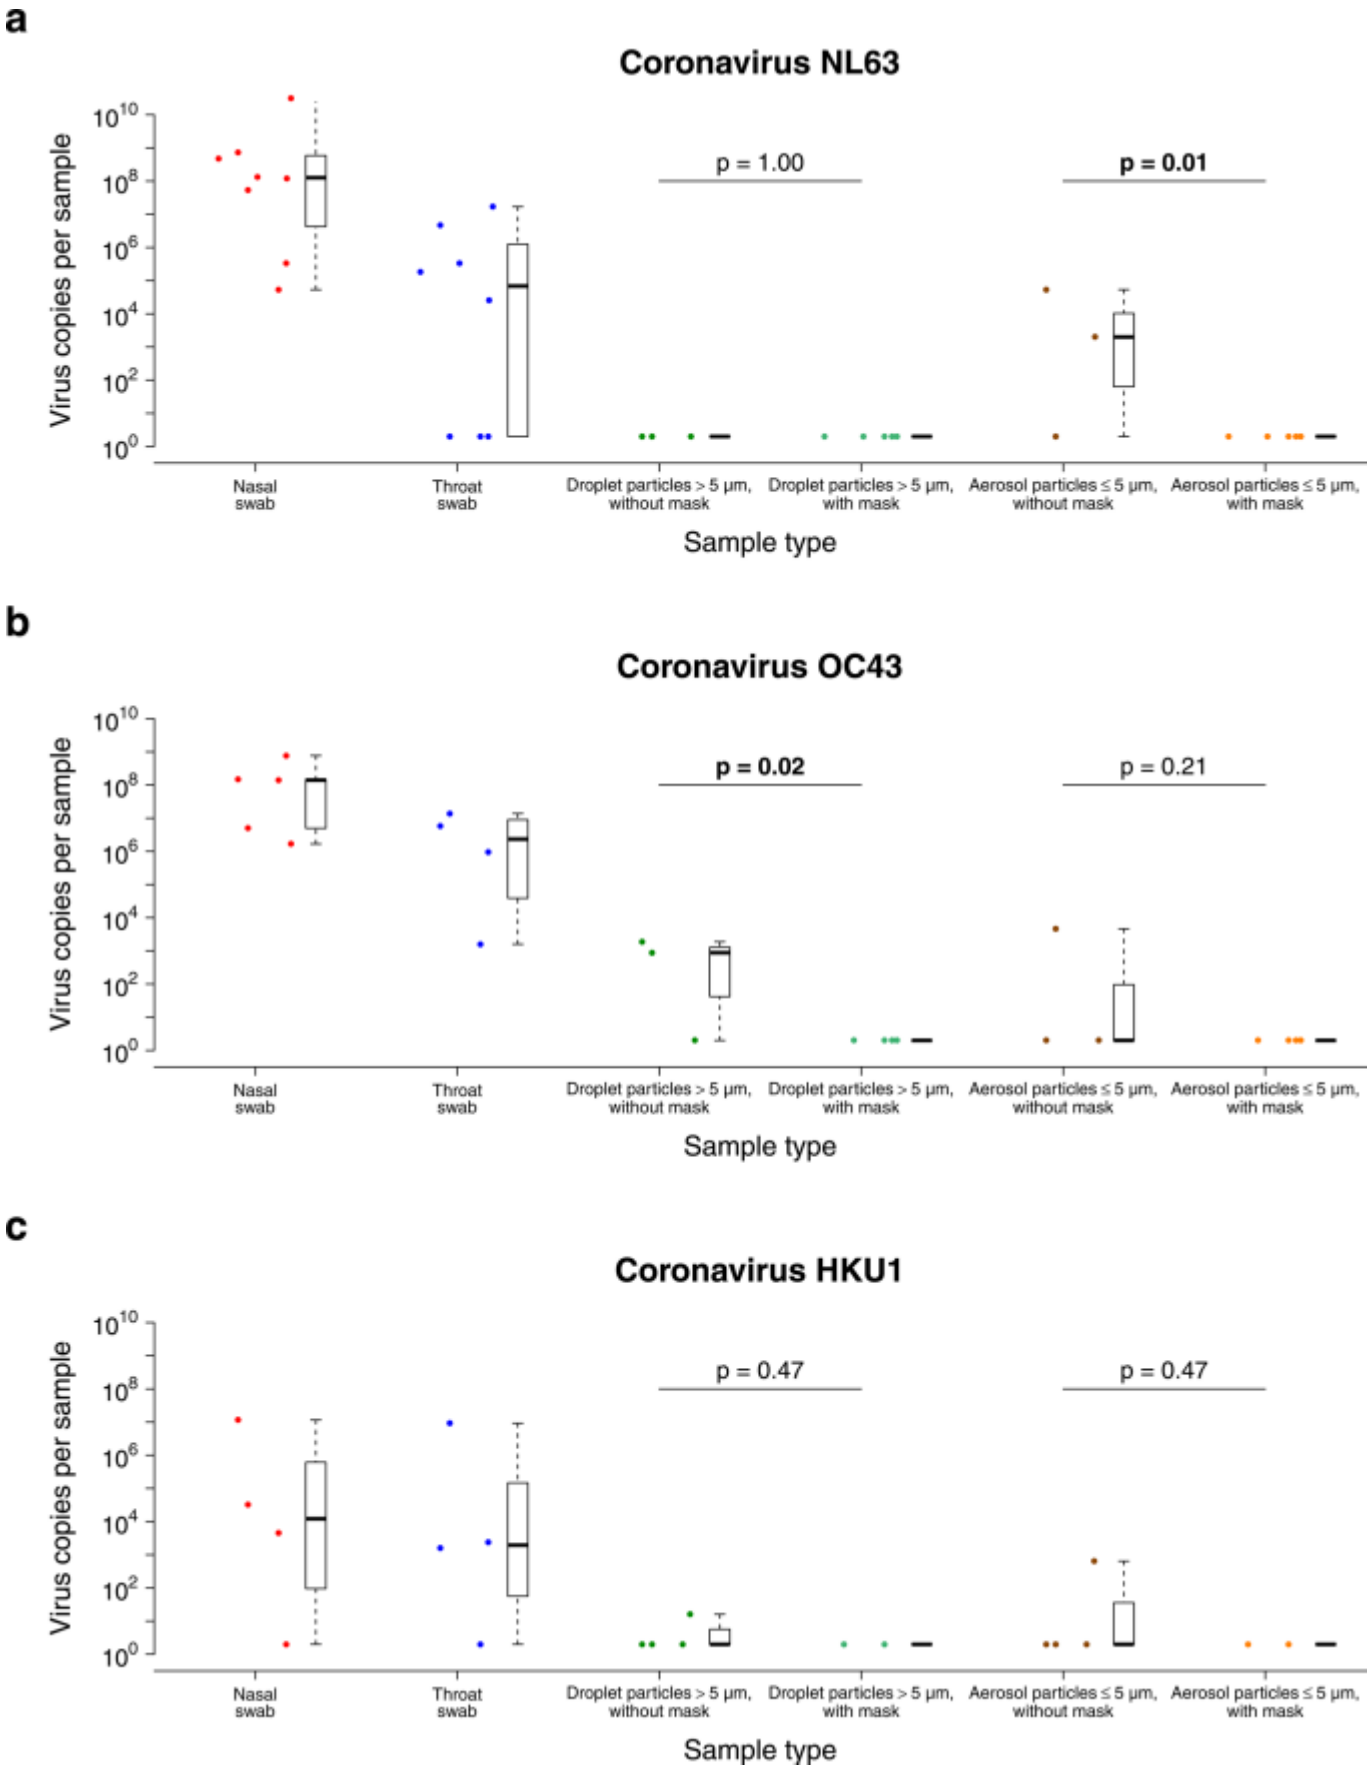
Extended Data Fig. 1 | Participant enrolment, randomization of mask intervention and identification of respiratory virus infection.



Extended Data Fig. 2 | Weekly number of respiratory virus infections identified by RT-PCR in symptomatic individuals who had provided exhaled breath samples (respiratory droplets and aerosols) during the study period. Blue, coronavirus; red, influenza virus; yellow, rhinovirus; green, other respiratory viruses including human metapneumovirus, parainfluenza virus, respiratory syncytial virus and adenovirus; white, no respiratory virus infection identified.

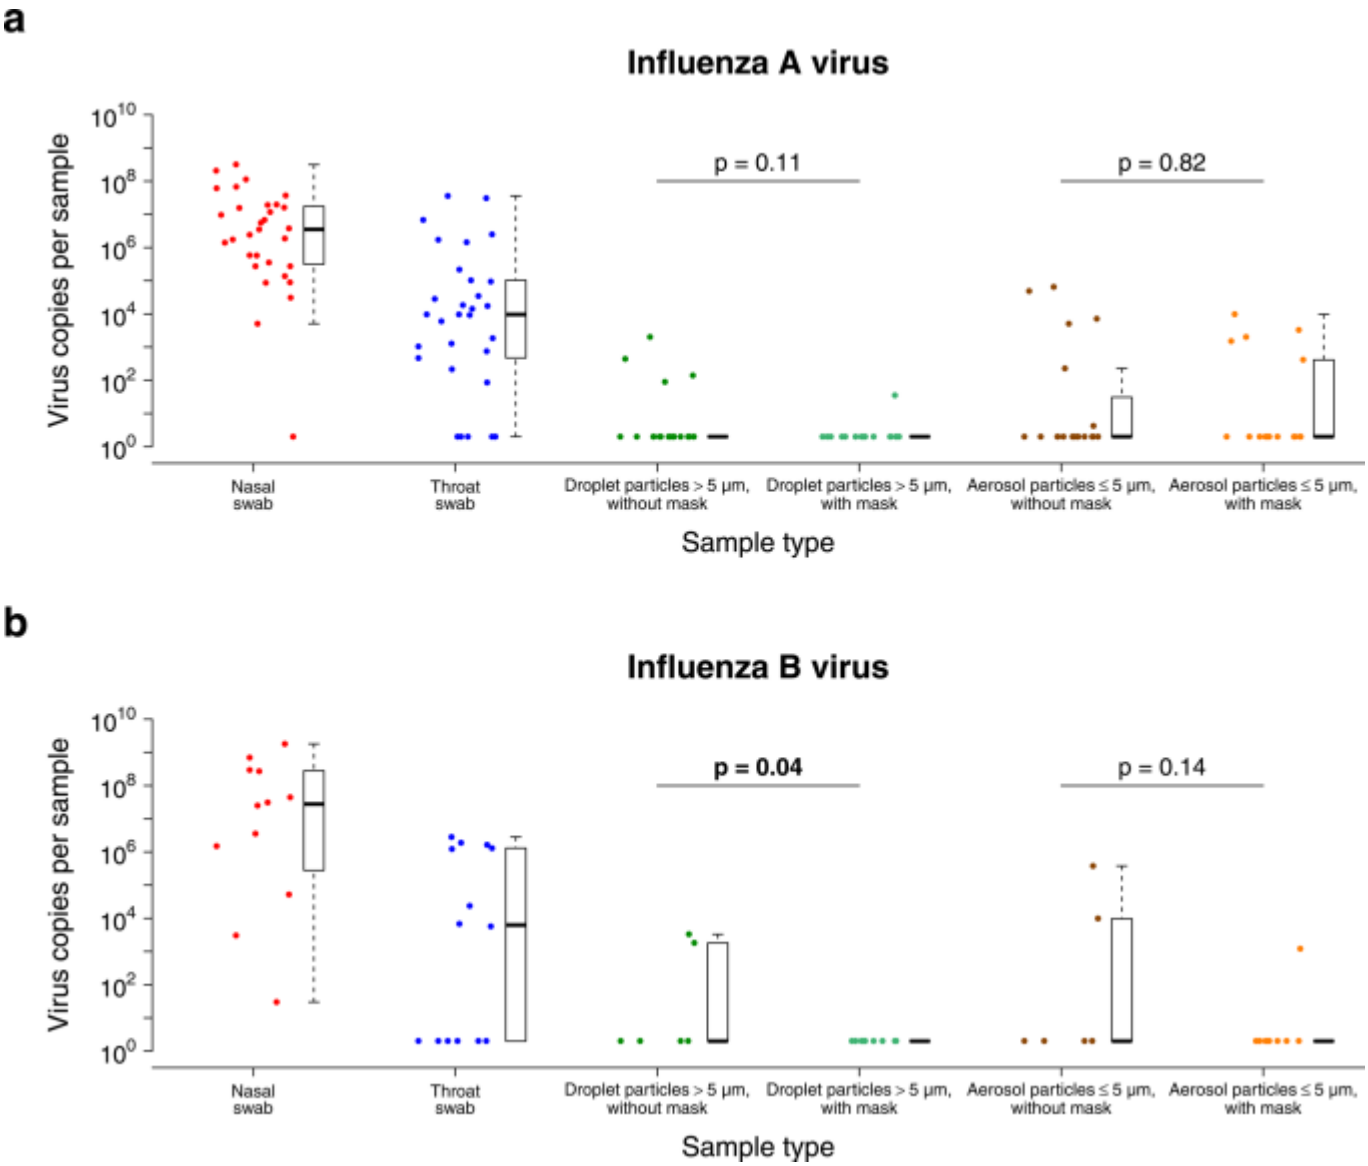


Extended Data Fig. 3 | Respiratory virus shedding in (a) nasal swab, (b) throat swab, (c) respiratory droplets and (d) aerosols in symptomatic individuals with coronavirus NL63, coronavirus OC43, coronavirus HKU1, influenza a and influenza B virus infection. For nasal swabs and throat swabs, all infected individuals identified by RT-PCR in any collected samples were included: coronavirus NL63 (n = 8), coronavirus OC43 (n = 5), coronavirus HKU1 (n = 4), influenza A virus (n = 31) and influenza B virus (n = 14). For respiratory droplets and aerosols, only infected individuals who provided exhaled breath samples while not wearing a surgical face mask were included: coronavirus NL63 (n = 3), coronavirus OC43 (n = 3), coronavirus HKU1 (n = 4), influenza A virus (n = 19) and influenza B virus (n = 6). The box plots indicate the median with the interquartile range (lower and upper hinge) and ± 1.5 × interquartile range from the first and third quartile (lower and upper whisker). Dark blue, coronavirus NL63; light blue, coronavirus OC43; brown, coronavirus HKU1; red, influenza A virus; orange, influenza B virus.

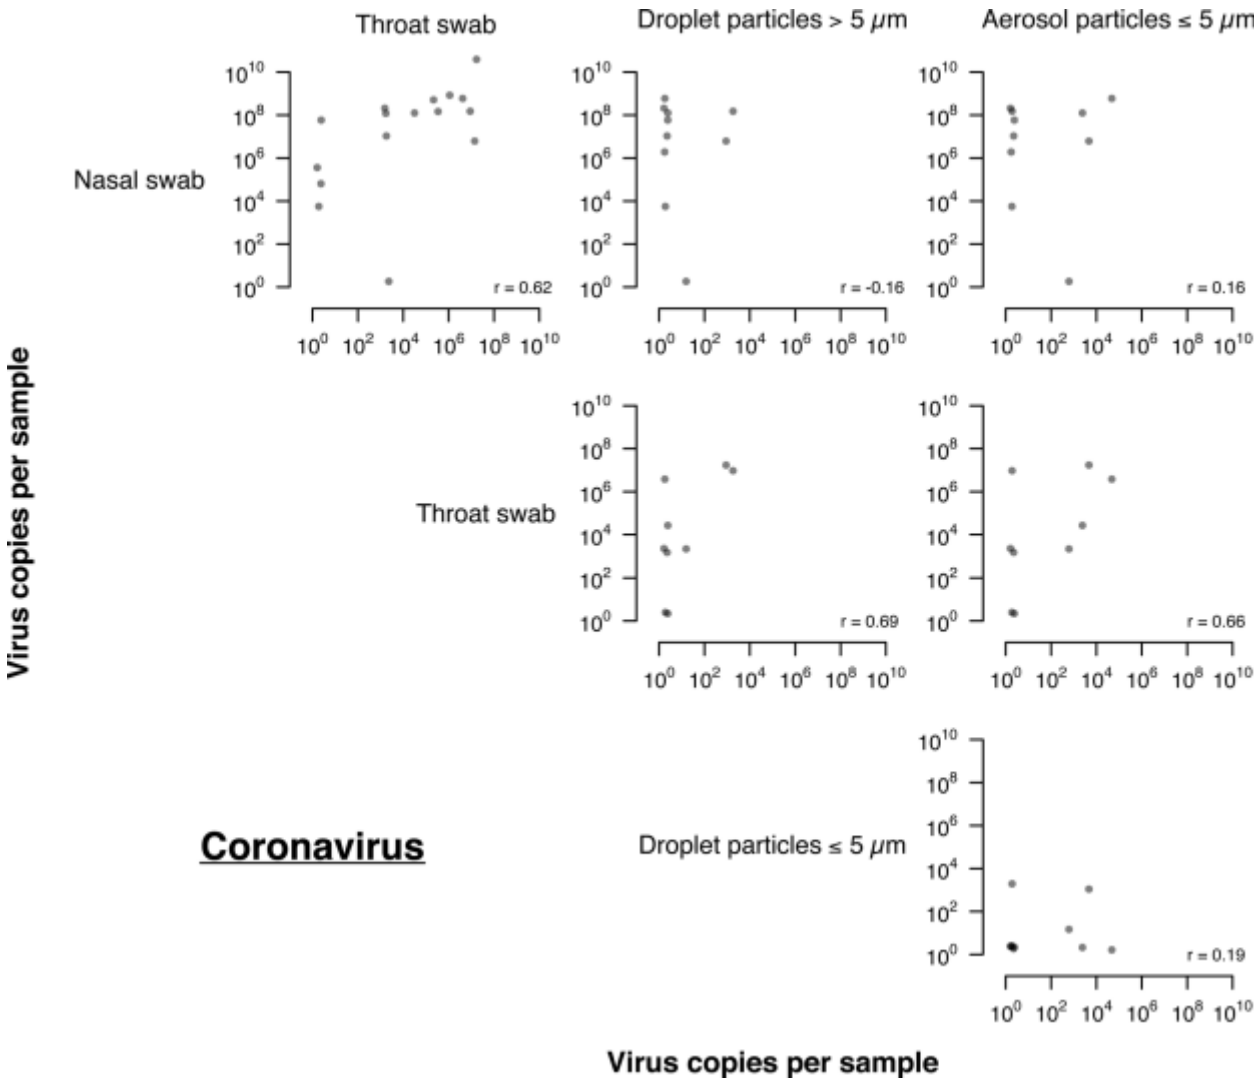


Extended Data Fig. 4 | See next page for caption.

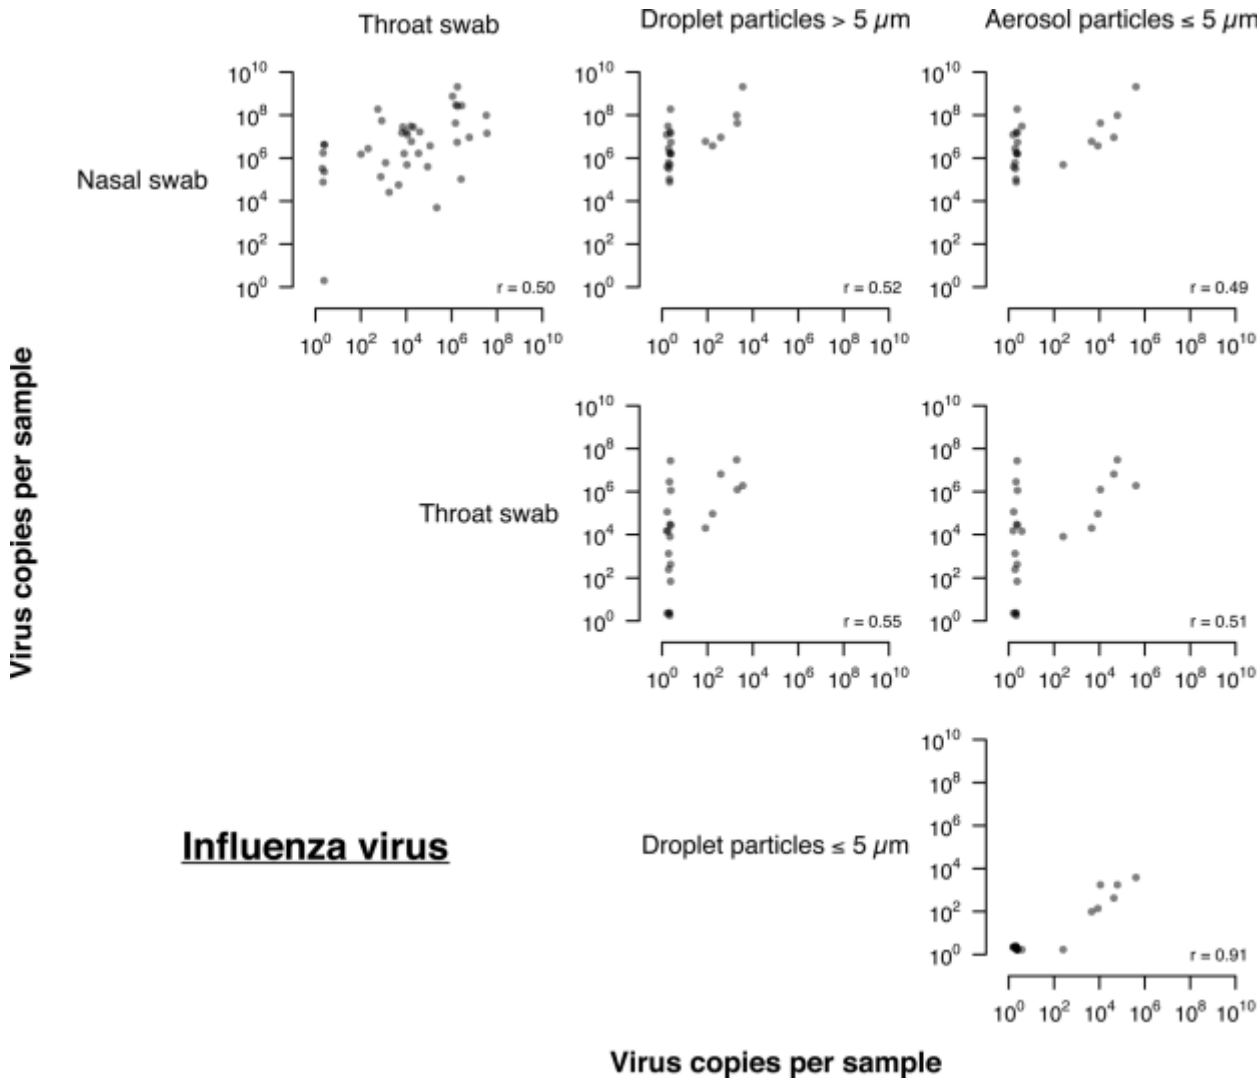
Extended Data Fig. 4 | Efficacy of surgical face masks in reducing respiratory virus shedding in respiratory droplets and aerosols of symptomatic individuals with seasonal coronaviruses including (a) coronavirus NL63, (b) coronavirus OC43 and (c) coronavirus HKU1. This figure shows the virus copies per sample collected in nasal swab (red), throat swab (blue), respiratory droplets collected for 30 min while not wearing (dark green) or wearing (light green) a surgical face mask and aerosols collected for 30 min while not wearing (brown) or wearing (orange) a face mask, collected from individuals with acute respiratory symptoms who were positive for coronavirus NL63, coronavirus OC43 and coronavirus HKU1 as determined by RT-PCR in any samples. *P* values for mask intervention as predictor of $\log_{10}$ virus copies per sample in an unadjusted univariate Tobit regression model which allowed for censoring at the lower limit of detection of the RT-PCR assay are shown, with significant differences in bold. For nasal swabs and throat swabs, all infected individuals were included (coronavirus NL63, n = 8; coronavirus OC43, n = 5; coronavirus HKU1, n = 4). For respiratory droplets and aerosols, numbers of infected individuals who provided exhaled breath samples while not wearing or wearing a surgical face mask, respectively were: coronavirus NL63 (n = 3 and 5), coronavirus OC43 (n = 3 and 4), coronavirus HKU1 (n = 4 and 2). A subset of participants provided exhaled breath samples for both mask interventions (coronavirus NL63, n = 0; coronavirus OC43, n = 2; coronavirus HKU1, n = 2).



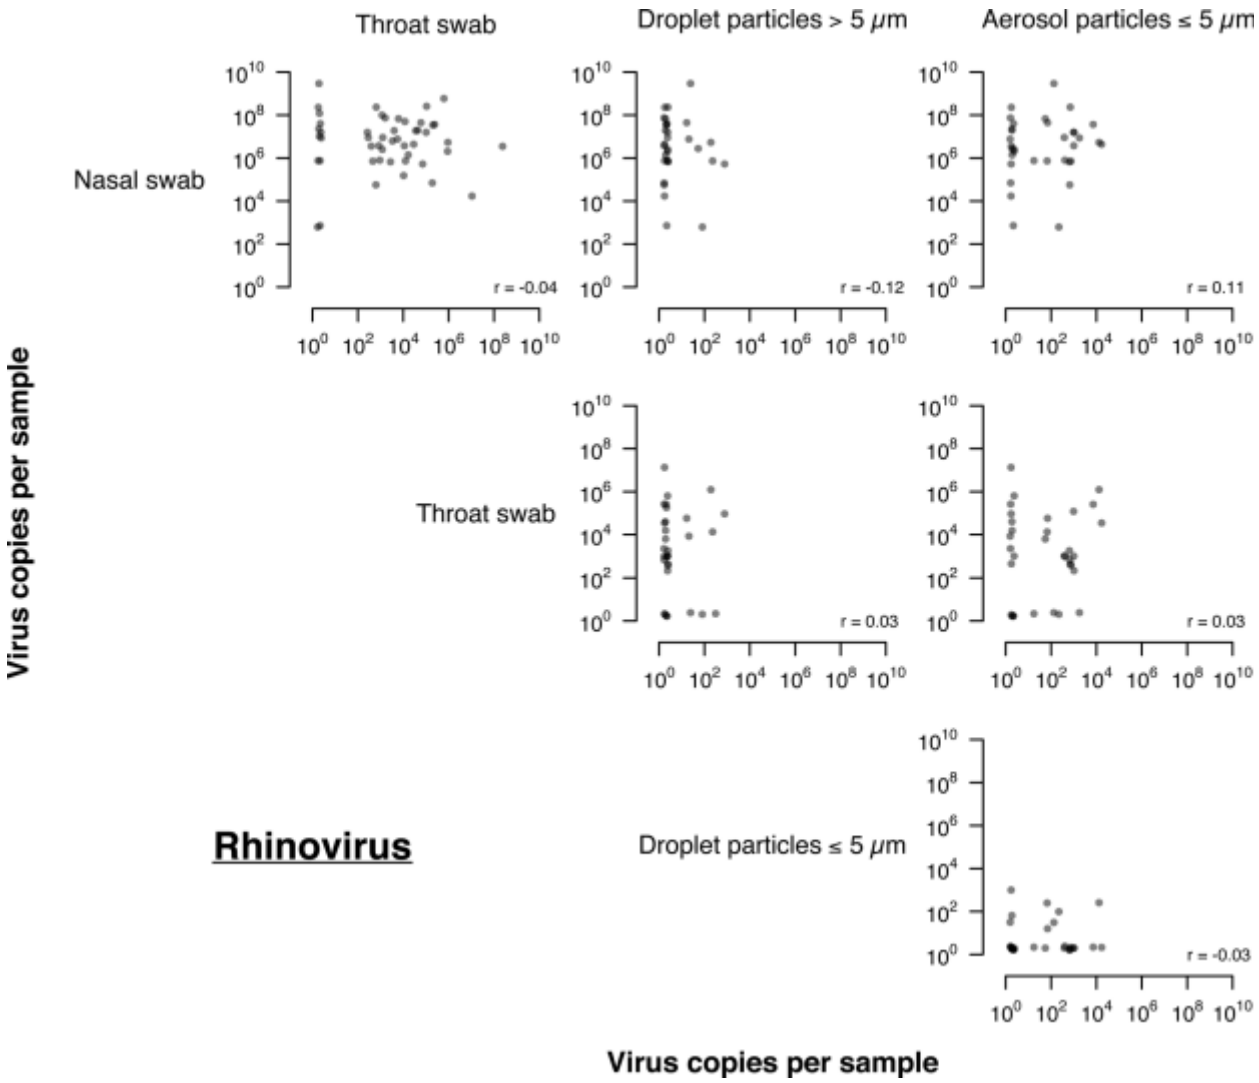
Extended Data Fig. 5 | Efficacy of surgical face masks in reducing respiratory virus shedding in respiratory droplets and aerosols of symptomatic individuals with seasonal influenza viruses including (a) influenza a and (b) influenza B virus. The figure shows the virus copies per sample collected i nasal swab (red), throat swab (blue), respiratory droplets collected for 30 min while not wearing (dark green) or wearing (light green) a surgical face mask and aerosols collected for 30 min while not wearing (brown) or wearing (orange) a face mask, collected from individuals with acute respiratory symptoms who were positive for influenza A and influenza B virus as determined by RT-PCR in any samples. *P* values for mask intervention as predictor of $\log_{10}$ virus log copies per sample in an unadjusted univariate Tobit regression model which allowed for censoring at the lower limit of detection of the RT-PCR assay are shown, with significant differences in bold. For nasal swabs and throat swabs, all infected individuals were included (influenza A virus, n = 31; influenza B virus, n = 14). For respiratory droplets and aerosols, numbers of infected individuals who provided exhaled breath samples while not wearing or wearing a surgical face mask, respectively were: influenza A virus (n = 19 and 19), influenza B virus (n = 6 and 10). A subset of participants provided exhaled breath samples for both mask interventions (influenza A virus, n = 7; influenza B virus, n = 2).



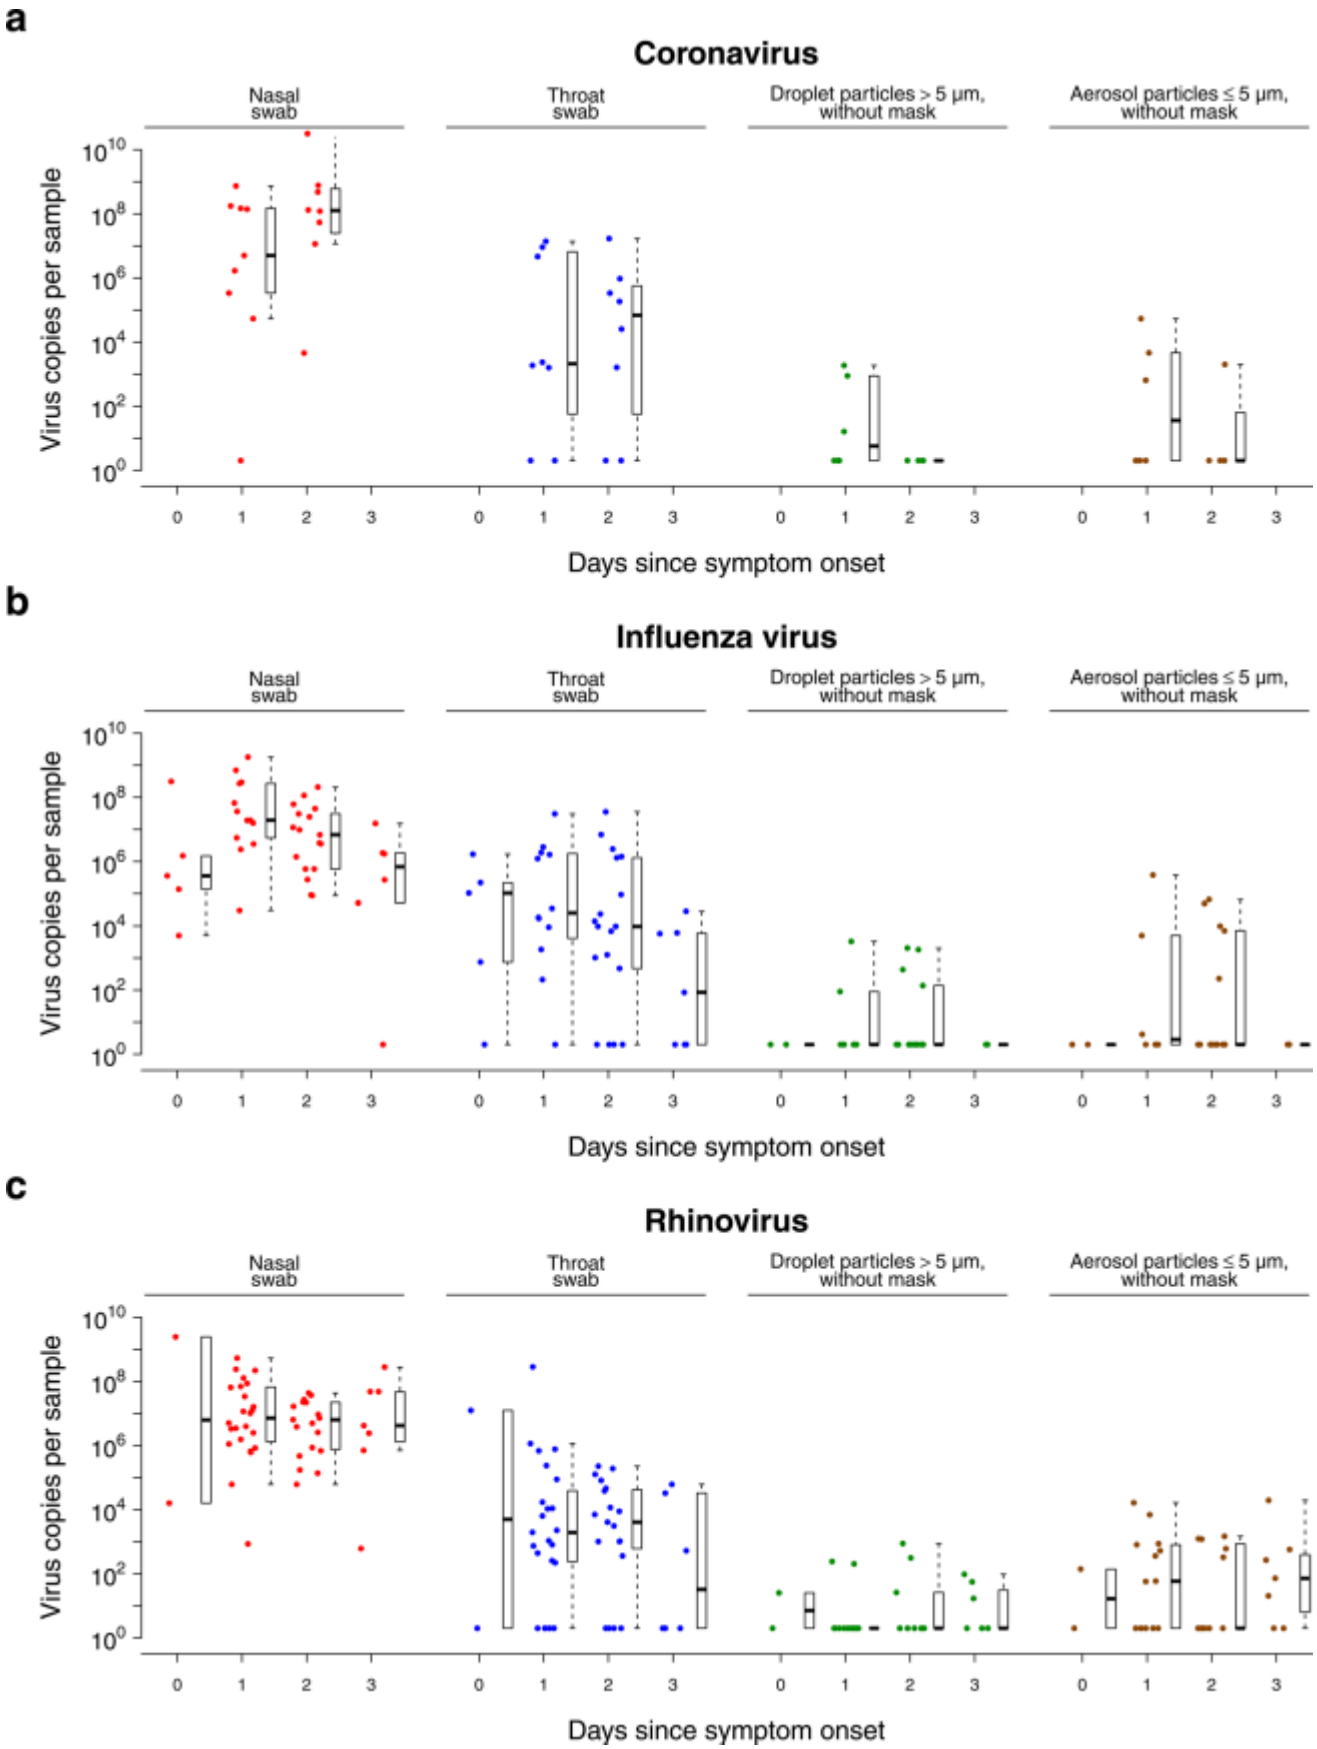
Extended Data Fig. 6 | Correlation of coronavirus viral shedding between different samples (nasal swab, throat swab, respiratory droplets and aerosols) in symptomatic individuals with seasonal coronavirus infection. For nasal swabs and throat swabs, all infected individuals were included (n = 17). For respiratory droplets and aerosols, only infected individuals who provided exhaled breath samples while not wearing a surgical face mask were included (n = 10). r, the Spearman's rank correlation coefficient.



Extended Data Fig. 7 | Correlation of influenza viral shedding between different samples (nasal swab, throat swab, respiratory droplets and aeroso in symptomatic individuals with seasonal influenza infection. For nasal swabs and throat swabs, all infected individuals were included (n = 43). For respiratory droplets and aerosols, only infected individuals who provided exhaled breath samples while not wearing a surgical face mask were included (n = 23). r, the Spearman's rank correlation coefficient.



Extended Data Fig. 8 | Correlation of rhinovirus viral shedding between different samples (nasal swab, throat swab, respiratory droplets and aeros in symptomatic individuals with rhinovirus infection. For nasal swabs and throat swabs, all infected individuals were included (n = 54). For respiratory droplets and aerosols, only infected individuals who provided exhaled breath samples while not wearing a surgical face mask were included (n = 36). r, the Spearman's rank correlation coefficient.



Extended Data Fig. 9 | See next page for caption.

Extended Data Fig. 9 | Respiratory virus shedding in respiratory droplets and aerosols stratified by days from symptom onset for (a) coronavirus, influenza virus or (c) rhinovirus. The figures shows the virus copies per sample collected in nasal swab (red), throat swab (blue), respiratory droplets (dark green) and aerosols (brown) collected for 30 min while not wearing a surgical face mask, stratified by the number of days from symptom onset on which the respiratory droplets and aerosols were collected. For nasal swabs and throat swabs, all infected individuals were included (coronavirus, n = 17; influenza virus, n = 43; rhinovirus, n = 54). For respiratory droplets and aerosols, numbers of infected individuals who provided exhaled breath samples while not wearing or wearing a surgical face mask, respectively were: coronavirus (n = 10 and 11), influenza virus (n = 23 and 28), rhinovirus (n = 36 and 32). A subset of participants provided exhaled breath samples for both mask interventions (coronavirus, n = 4; influenza virus, n = 8; rhinovirus, n = 14). The box plots indicate the median with the interquartile range (lower and upper hinge) and ± 1.5 × interquartile range from the first and third quartile (lower and upper whisker).

Reporting Summary

Nature Research wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Research policies, see Authors & Referees and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a	Confirmed	
☐	☒	The exact sample size (*n*) for each experimental group/condition, given as a discrete number and unit of measurement
☐	☒	A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐	☒	The statistical test(s) used AND whether they are one- or two-sided *Only common tests should be described solely by name; describe more complex techniques in the Methods section.*
☐	☒	A description of all covariates tested
☐	☒	A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐	☒	A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐	☒	For null hypothesis testing, the test statistic (e.g. *F*, *t*, *r*) with confidence intervals, effect sizes, degrees of freedom and *P* value noted *Give P values as exact values whenever suitable.*
☒	☐	For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☒	☐	For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☐	☒	Estimates of effect sizes (e.g. Cohen's *d*, Pearson's *r*), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection	No software was used.
Data analysis	All analyses were conducted with R version 3.6.0 and the VGAM package 1.1.1.

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors/reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Research guidelines for submitting code & software for further information.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A list of figures that have associated raw data
- A description of any restrictions on data availability

Anonymized raw data and R syntax to reproduce all the analyses, figures, tables and supplementary tables in the published article are available at: [Dryad link pending].

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences ☐ Behavioural & social sciences ☐ Ecological, evolutionary & environmental sciences

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	We estimated a priori the sample size to be 300 participants. The primary outcome of the study was the reduction in the exhaled virus concentration of normal tidal breathing by wearing face mask in terms of total virus by RT-PCR as a proxy for infectious virus particle. We expected that a 1-log reduction in exhaled virus particle by face mask intervention would have a clinically relevant effect in reducing the probability of transmission. Except for influenza, there was no quantitative data available from exhaled breath samples from respiratory virus-infected individuals before the present study. If the standard deviation of exhaled virus concentration was 1 log copies/ml (Milton et al., PLoS Pathog 2013), we would detect a difference of >1 log copies/ml in the mask vs control group as long as we have >15 participants with a specific respiratory virus. For example, if our study included 23 participants with rhinovirus detectable in exhaled breath without a mask, we will have 80% power and 0.05 significance level to identify differences in viral shedding in aerosols of 1.28 log10 copies associated with the use of face masks, assuming a standard deviation of 1.54 log10 copies based on data from nasal and throat swab (Lu et al., J Clin Microbiol 2008). We expected from 300 individuals with ARI, at least 150 to have a respiratory virus, and at least 20-30 to have each of rhinovirus, coronavirus, adenovirus and parainfluenza plus small numbers of other respiratory viruses, assuming the Viral Panel would detect respiratory viruses in 60% of participants including 10% by influenza (since we partly recruited during the influenza seasons) and the other 50% made up of rhinovirus, coronavirus, adenovirus and parainfluenza virus.
Data exclusions	As described in the Results section and Supplementary Figure 1, only participants who provided exhaled breath samples and randomized to mask intervention were included; and final analyses were performed only for participants with either coronavirus, influenza virus or rhinovirus infection, which had sufficient sample size for comparison between mask intervention.
Replication	Samples from a subset of participants identified with a coronavirus, influenza or rhinovirus infection were re-tested by RT-PCR with consistent results. R syntax is available to reproduce all the analyses, figures, tables and supplementary tables in the published article
Randomization	Prior to the exhaled breath collection, each participant was randomly allocated in a 1:1 ratio to either wearing a surgical face mask or not during the exhaled breath collection using a computer-generated sequence. The allocation was concealed to the study stuff performing the exhaled breath collection before allocation of the mask intervention.
Blinding	Blinding to the participant and the study stuff for the mask intervention was not possible. The study staff performing the statistical analyses was also involved in the data collection. We expected there would be minimal bias due to unblinding since data collection for questionnaires was done before randomization to mask intervention, and viral load from a sample measured by RT-PCR is an objective measurement

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involved in the study
☒	☐ Antibodies
☐	☒ Eukaryotic cell lines
☒	☐ Palaeontology
☒	☐ Animals and other organisms
☐	☒ Human research participants
☐	☒ Clinical data

Methods

n/a	Involved in the study
☒	☐ ChIP-seq
☒	☐ Flow cytometry
☒	☐ MRI-based neuroimaging

Eukaryotic cell lines

Policy information about cell lines

Cell line source(s)	Madin-Darby Canine Kidney (MDCK) cells
Authentication	European Collection of Authenticated Cell Cultures.
Mycoplasma contamination	We confirm that all cell lines tested negative for mycoplasma contamination.
Commonly misidentified lines (See ICLAC register)	Nil

Human research participants

Policy information about studies involving human research participants

Population characteristics	As described in the Results section, Table 1a and Supplementary Table 1, there were some differences in characteristics of participants with the different viruses. Overall, most participants were younger adults and 5% were age 11-17 years, but there were more children with influenza virus and no children in the subgroup with coronavirus infection. Overall, 59% were female, but there were more females among the subgroup with coronavirus infection. The majority of participants did not have underlying medical conditions and overall 9% had received influenza vaccination for the current season but only 2% among those with influenza virus infection. The majority of participants were sampled within 24–48 or 48–72 hours of illness onset. 24% of participants had a measured fever ≥37.8ºC, with influenza patients more than twice as likely than coronavirus and rhinovirus-infected patients to have a measured fever. Coronavirus-infected participants coughed the most with an average of 17 (SD 30) coughs during the 30-minute exhaled breath collection. The profile of the participants randomized to with-mask vs without-mask groups were similar.
Recruitment	As described in the Methods section, participants were recruited year-round from March 2013 through May 2016 in a general outpatient clinic of a private hospital in Hong Kong. As routine practice, clinic staff screened all individuals attending the clinics for respiratory and any other symptoms regardless of the purpose of the visit at the triage. Study staff then approached immediately those who reported at least one of the following symptoms of acute respiratory illness (ARI) for further screening: fever ≥37.8ºC, cough, sore throat, runny nose, headache, myalgia and phlegm. Individuals who reported ≥2 ARI symptoms, within 3 days of illness onset and ≥11 years of age were eligible to participate.
Ethics oversight	As described in the Methods section, the study protocol was approved by the Institutional Review Board of The University of Hong Kong and the Clinical and Research Ethics Committee of Hong Kong Baptist Hospital.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Clinical data

Policy information about clinical studies

All manuscripts should comply with the ICMJE guidelines for publication of clinical research and a completed CONSORT checklist must be included with all submissions.

Clinical trial registration	The present study was not registered in clinical trials registries, as it was a laboratory-based study of detection of viruses in exhaled breath and the effect of wearing surgical facemasks on virus detection. It was not a Phase II/III clinical trial.
Study protocol	Not available in clinical trials registries (as above). Study protocol will be made available to editors and peer reviewers if requested.
Data collection	As described in the Methods section, participants were recruited year-round from March 2013 through March 2016 in a general outpatient clinic of a private hospital in Hong Kong. Data collection for questionnaires and exhaled breath sample collection was done face-to-face with the participant by trained study staff at the same clinic on the day of participant enrolment.
Outcomes	As pre-specified in the study protocol, the primary outcomes of the study were the virus generation rate in the tidal breathing of participants infected by different respiratory viruses, and the efficacy of face mask in preventing virus dissemination in exhaled breath especially at the aerosol fraction. As pre-specified in the study protocol, one of the secondary outcomes was to provide indirect evidence for relative importance of different transmission routes of influenza and other respiratory viruses. In this regard, in the present manuscript we examined the correlation between viral shedding in nose swabs, throat swabs, respiratory droplets and aerosols, and factors affecting viral shedding in respiratory droplets and aerosols. As described in the Discussion section in the present manuscript about the limitation of our study, there was large proportion of participants with undetectable viral shedding in exhaled breath for each of the viruses studied, and therefore we were unable to examine the exhaled respiratory virus reduction proportion by chi-squared test, nor the exhaled respiratory virus reduction volume (i.e. viral load) by t-test and linear regression as pre-specified in the study protocol. Instead, we have used Fisher's exact test and Tobit regression for the same purposes respectively.

National Wildlife Rehabilitators Association

Position Statement:
Rehabilitating North American Bats during the SARS-CoV2/COVID-19 Pandemic

The newly emerging SARS-CoV2, which causes COVID-19 in humans, is currently a worldwide pandemic and has been diagnosed in people from every state and province in the United States[1] and Canada. A summary of the non-human animal SARS-CoV2 positive individuals as of 4/10/2020 is provided as an appendix at the end of this statement. Zoonotic transmission from these animals back to humans has not been reported.

Currently, it is thought that the newly emerging SARS-CoV2 virus originated from wildlife and possibly from East Asian pangolins, and/or East Asian bats[3]. Details about these theories are summarized at the end of this statement. SARS-CoV2 has not been found naturally in any wild bat. One preliminary study did show the ability to infect Egyptian fruit bats with SARS-CoV2 in a research setting, however, they did not shed enough virus to infect conspecifics[4]. There are over 1400 different species of bats[5], and it is unknown if this virus acts similarly in other species of bats. Many other coronaviruses use bats as a reservoir[6,7] and there is currently no evidence that introduction of SARS-CoV2 to North American bats would or would not cause population declines.

A certain percentage of humans can be asymptomatic shedders of SARS-CoV2[1]. Current expert understanding is that SARS-CoV2 is primarily transmitted person-to-person, and not a current zoonotic concern in any species[8].

Many species of North American bats are incredibly adaptable and live in and around human dwellings (houses, attics, flashing, backyard foliage and trees, etc.), even in dense human populations. Bats come into close proximity of many people every day.

Wildlife rehabilitators across the continent who are trained to work with bats are a valuable public health resource. Members of the public come into contact with bats regularly, and often are directly exposed to bats before contacting professionals. Wildlife rehabilitators direct these individuals to local public health departments, help walk individuals through learning about rabies risk factors and following all public health recommendations, and ultimately act as an advocate for the health of the finder and the bat.

The NWRA Veterinary Committee supports the continued admittance of bats for rehabilitation to wildlife rehabilitation professionals not only to ensure proper bat care, welfare, and conservation, but foremost as part of the solution to public health concerns surrounding bats. Without wildlife rehabilitators, it is highly likely the public will have more human-bat interactions

that lack the involvement of a professional to guide zoonotic concerns and take necessary biosecurity precautions. Wildlife rehabilitators also represent a valuable resource for sample collection for researchers and are encouraged to collaborate whenever possible.

The NWRA Veterinary Committee supports one-health initiatives to improve human health, animal health and environmental health. Furthermore, the NWRA Veterinary Committee supports evidence-based medicine and subsequent actions.

Restrictions on bat rehabilitation and release have massive implications for the thousands of bats that are rehabilitated in the US and Canada each year, and for the adverse human-bat interactions that will inevitably occur as untrained people continue to find bats in need of care. If SARS-CoV2 is able to be transmitted from humans to bats, it has likely already occurred due to the high number of human cases in the United States and the frequency that people interact with bats at their homes.

Furthermore, due to the COVID-19 outbreak, fewer resources are available at municipalities to handle wildlife cases resulting in additional risk for the public who may take it upon themselves to handle a bat, without appropriate PPE, thus potentially having a negative impact on the health and welfare of the bat and the health of the person who handled it. Wildlife rehabilitators' expertise is needed even more during this crisis to protect human and animal health.

RECOMMENDATIONS

1. We recommend that authorized wildlife rehabilitators should be allowed to accept and rehabilitate bats, following appropriate biosecurity and safety measures to prevent human-bat respiratory virus exposures.
2. New bat admissions should be quarantined for 14 days
3. There is no need to euthanize captive bats as a method of disease prevention
4. Limit the number of people who have access to areas where bats are housed and cared for.
5. Rehabilitators showing any clinical signs of Covid-19 such as fever, coughing, or shortness of breath should immediately cease working with bats and consult their doctor for testing and quarantine recommendations. Backup caregivers should be pre-arranged for bats and any other animals undergoing rehabilitation.
6. Working with the local or regional veterinary laboratories and state/provincial public health officials, samples should be collected from rehabilitated bats if feasible, and if/when testing for bats is available, the bats should be tested for Covid-19 prior to release if available. However, bats should not be delayed from appropriate release simply because testing is not available.

Because this is an emerging pathogen, new research may sway directives and this statement will be updated accordingly.

Appendix

Since the outbreak of severe acute respiratory syndrome (SARS) 18 years ago, a large number of SARS-related coronaviruses (SARSr-CoVs) have been discovered in their natural reservoir host, bats, and previous studies have shown that some bat SARSr-CoVs have the potential to infect humans.[6]

The coronaviruses found in the Malayan pangolin (*Manis javanica*) and the *Rhinolophus affinis* bat remain the current closest to SARS-CoV2 across the genome (~96%[6]); some pangolin coronaviruses exhibit strong similarity to SARS-CoV2 in the virus receptor binding domain (RBD), including all six key RBD residues.[3] However, bat coronaviruses are massively understudied[3].

Currently, it is thought that SARS-CoV2 virus originated from wildlife naturally[3], either via natural selection in the species in question before zoonotic transfer or natural selection in humans after zoonotic transfer from the species in question[3]. See the table below for current knowledge regarding positive test results suggestive of human to animal transmission of SARS-CoV2.

Summary below of current non-human animals that have tested positive for SARS-CoV2A[8]:

Species	Location	Antigen test results	Antibody test results	Symptoms	Possible source	Notes
Domestic dog	China	Weak positive	Positive	None	Owner had COVID-19	Elderly, died 3 d after release from unknown causes
Domestic dog[11]	Hong Kong	Positive		None	Owner had COVID-19	German Shepherd
Domestic cat	Belgium	Positive	--	Respiratory, vomiting	Owner had COVID-19	Unknowns around sampling
Domestic cat	China	Positive	--	None	Owner had COVID-19	
Tiger	NY, USA	Positive Confirmed by NVSL		Respiratory	Presumed asymptomatic keeper positive for COVID-19	Several big cats in zoo sick with respiratory signs
Domestic cats[12]	China	Positive (15)	Positive (11)	None? Not clear in report	Owned and stray (community acquired)	Tested 102 cats in Wuhan
Domestic cat	Hong Kong	Positive		None	Owner had COVID-19

This manuscript was compiled on April 12, 2020

The science around the use of masks by the general public to impede COVID-19 transmission is advancing rapidly. Policymakers need guidance on how masks should be used by the general population to combat the COVID-19 pandemic. Here, we synthesize the relevant literature to inform multiple areas: 1) transmission characteristics of COVID-19, 2) filtering characteristics and efficacy of masks, 3) estimated population impacts of widespread community mask use, and 4) sociological considerations for policies concerning mask-wearing. A primary route of transmission of COVID-19 is likely via small respiratory droplets, and is known to be transmissible from presymptomatic and asymptomatic individuals. Reducing disease spread requires two things: first, limit contacts of infected individuals via physical distancing and contact tracing with appropriate quarantine, and second, reduce the transmission probability per contact by wearing masks in public, among other measures. The preponderance of evidence indicates that mask wearing reduces the transmissibility per contact by reducing transmission of infected droplets in both laboratory and clinical contexts. Public mask wearing is most effective at stopping spread of the virus when compliance is high. The decreased transmissibility could substantially reduce the death toll and economic impact while the cost of the intervention is low. Thus we recommend the adoption of public cloth mask wearing, as an effective form of source control, in conjunction with existing hygiene, distancing, and contact tracing strategies. We recommend that public officials and governments strongly encourage the use of widespread face masks in public, including the use of appropriate regulation.

COVID-19 | SARS-CoV-2 | Masks | Pandemic

Policymakers need urgent guidance on the use of masks by the general population as a tool in combating SARS-CoV-2, the respiratory virus that causes COVID-19. Masks have been recommended as a potential tool to tackle the COVID-19 pandemic since the initial outbreak in China (1), although usage during the outbreak varied by time and province (2). Globally, countries are grappling with translating the evidence of public mask wearing to their contexts. These policies are being developed in a complex decision-making environment, with a novel pandemic, rapid generation of new research, and exponential growth in cases and deaths in many areas. There is currently a global shortage of N95 or FFP2 respirators and surgical masks for use in hospitals. Simple cloth masks present a pragmatic solution for use by the public. This has been supported by the United States and European Centres for Disease Control. We present a literature review on the role of simple cloth masks and policies in reducing COVID-19 transmission.

1. Components to Evaluate for Public Mask Wearing

In order to identify whether public mask wearing is an appropriate policy, we need to consider these questions:

1. Do asymptomatic or presymptomatic patients pose a risk of infecting others?
2. Would a face mask likely decrease the number of people infected by an infectious mask wearer?
3. Are there alternative face covers that will not disrupt the medical supply chain, e.g. homemade cloth masks?
4. Will wearing a mask impact the probability of the wearer becoming infected themselves?
5. Does mask use reduce compliance with other recommended strategies, such as physical distancing and quarantine?

Significance Statement

Governments are evaluating the use of non-medical masks in the community amidst conflicting guidelines from health organizations. This review synthesizes available evidence to provide clarity, and advances the use of the 'precautionary principle' as a key consideration in developing policy around use of non-medical masks in public.

Jeremy Howard prepared the initial literature list; Reshama Shaikh prepared the initial literature summaries; Frederik Questier did additional literature searches and summaries; Zhiyuan Li, Violet Tang, Lei-Han Tang, and Danny Hernandez did impact modeling; Zeynep Tufekci provided sociological research and analysis; Helene-Mari van der Westhuizen and Arne von Delft provided analysis of additional impacts; Christina Bax provided review and feedback; All authors contributed to the writing.

6. Are there any other potential benefits to universal mask wearing such as reducing stigma, signaling solidarity, and increased compliance with other measures?

We will evaluate each consideration in turn.

2. Transmission Characteristics of COVID-19

A primary route of transmission of SARS-CoV-2 is likely via small droplets that are ejected when speaking, coughing or sneezing. The most common droplet size threshold has a minimum at 5 µm to 10 µm (3, 4). There is much debate about whether these droplets should sometimes be considered an aerosol (5). An added complexity is that aerosols are not consistently defined in the literature.

Although earlier studies assumed that droplets were spread mainly through coughing, a more recent analysis has found that transmission through talking may be a key vector, with louder speech creating increasing quantities and sizes of droplets, which are associated with a higher viral load (6).

SARS-CoV-2 is highly transmissible, with a replication number estimated to be approximately 2.4 (7) although estimates vary (8) and will likely change as improved measurements of asymptomatic spread become available. Many COVID-19 patients are asymptomatic, and nearly all have a pre-symptomatic incubation period ranging from 2 to 15 days, with a median length of 5.1 days (9). Patients are most infectious during the initial days of infection (10–15), when symptoms are mildest or not present. This characteristic differentiates SARS-CoV-2 (COVID-19) from SARS-CoV, as replication is activated early in the upper respiratory tract (14, 16). High viral titers of SARS-CoV-2 are reported in the saliva of COVID-19 patients. These titers have been highest at time of patient presentation and viral levels are just as high in asymptomatic or presymptomatic patients (11, 16).

A consequence of these disease characteristics is that any successful intervention policy must properly address transmission due to infectious patients that display few or no symptoms and may not realize that they are infected.

3. Filtering Capability of Masks

Masks can be made of different materials and designs (17) which influence their filtering capability. There are rigorous standards evaluating masks used in healthcare settings but these focus on personal protective equipment (PPE) efficacy, that is, the ability of the mask to protect the wearer from infectious particles. N95 (the American standard; the equivalent in Europe is FFP2) respirators are recommended for health workers conducting aerosol-generating procedures during clinical care of COVID-19 patients. While it has been shown that N95 or FFP2 respirators perform well as PPE, they can become a scarce resource during a pandemic. Toner and Waldhorn (2006) (18) point out that shortages of N95 or FFP2 respirators should be anticipated, and say that if no other masks are available, surgical masks, which will provide droplet protection, should be used. One approach that has been studied for handling N95 or FFP2 respirator shortages is sterilization and re-use, which can be effective (19).

Masks can also be used for source control, which refers to blocking droplets ejected by the wearer, as well as PPE. Although we consider both of these as important, our focus in this paper is on source control, because if everyone is wearing masks to decrease the chance that they themselves are unknowingly infecting someone, everyone ends up being more protected.

Multiple studies show the filtration effects of cloth masks relative to surgical masks. Particle sizes for speech are on the order of 1 µm (20) while typical definitions of droplet size are 5 µm-10 µm (5). Generally available household materials had between a 49% and 86% filtration rate for 0.02 µm exhaled particles whereas surgical masks filtered 89% of those particles (21). In a laboratory setting, household materials had 3% to 60% filtration rate for particles in the relevant size range, finding them comparable to some surgical masks (22). In another laboratory setup, a tea cloth mask was found to filter 60% of particles between 0.02 µm to 1 µm, where surgical masks filtered 75% (23). Dato et al (2006) (24), note that "quality commercial masks are not always accessible." They designed and tested a mask made from heavyweight T-shirts, finding that it "offered substantial protection from the challenge aerosol and showed good fit with minimal leakage". Although cloth and surgical masks are primarily targeted towards droplet particles, some evidence suggests they may have a partial effect in reducing viral aerosol shedding (25).

When considering the relevance of these studies of ingress, it's important to note that they are likely to substantially underestimate effectiveness of masks for source control. When someone is breathing, speaking, or coughing, only a tiny amount of what is coming out of their mouths is already in aerosol form. Nearly all of what is being emitted is droplets. Many of these droplets will then evaporate and turn into aerosolized particles that are 3 to 5-fold smaller. The point of wearing a mask as source control is largely to stop this process from occurring, since big droplets dehydrate to smaller aerosol particles that can float for longer in air (26).

Anfinrud et al (6) used laser light-scattering to sensitively detect droplet emission while speaking. Their analysis showed that virtually no droplets were "expelled" with a homemade mask consisting of a washcloth attached with two rubber bands around the head, while significant levels were expelled without a mask. The authors stated that "wearing any kind of cloth mouth cover in public by every person, as well as strict adherence to distancing and handwashing, could significantly decrease the transmission rate and thereby contain the pandemic until a vaccine becomes available."

An important focus of analysis for public mask wearing is droplet source control. This refers to the effectiveness of blocking droplets from an infectious person, particularly during speech, when droplets are expelled at a lower pressure and are not small enough to squeeze through the weave of a cotton mask. Many recommended cloth mask designs also include a layer of paper towel or coffee filter, which could increase filter effectiveness for PPE, but does not appear to be necessary for blocking droplet emission (6, 27, 28).

In summary, there is laboratory-based evidence that household masks have some filtration capacity in the relevant droplet size range, as well some efficacy in blocking droplets and particles from the wearer (26). That is, these masks help people keep their droplets to themselves.

4. Mask Efficacy Studies

Although no randomized controlled trials (RCT) on the use of masks as source control for SARS-CoV-2 has been published, a number of studies have attempted to indirectly estimate the efficacy of masks. Overall, an evidence review (29) finds "moderate certainty evidence shows that the use of handwashing plus masks probably reduces the spread of respiratory viruses."

The most relevant paper (30), with important implications for public mask wearing during the COVID-19 outbreak, is one that compares the efficacy of surgical masks for source control for seasonal coronavirus, influenza, and rhinovirus. With ten participants, the masks were effective at blocking coronavirus droplets of all sizes for every subject. However, masks were far less effective at blocking rhinovirus droplets of any size, or of blocking small influenza droplets. The results suggest that masks may have a significant role in source control for the current coronavirus outbreak. The study did not use COVID-19 patients, and it is not yet known whether seasonal coronavirus behaves the same as SARS-CoV-2; however, they are of the same genus, so similar behavior is likely.

Another relevant (but under-powered, with n=4) study (31) found that a cotton mask blocked 96% (reported as 1.5 log units or about a 36-fold decrease) of viral load on average, at eight inches away from a cough from a patient infected with COVID-19. If this is replicated in larger studies it would be an important result, because it has been shown (32) that "every 10-fold increase in viral load results in 26% more patient deaths" from "acute infections caused by highly pathogenic viruses".

A comparison of homemade and surgical masks for bacterial and viral aerosols (21) observed that "the median-fit factor of the homemade masks was one-half that of the surgical masks. Both masks significantly reduced the number of microorganisms expelled by volunteers, although the surgical mask was 3 times more effective in blocking transmission than the homemade mask." Research focused on aerosol exposure has found all types of masks are at least somewhat effective at protecting the wearer. Van der Sande et al (33) found that "all types of masks reduced aerosol exposure, relatively stable over time, unaffected by duration of wear or type of activity", and concluded that "any type of general mask use is likely to decrease viral exposure and infection risk on a population level, despite imperfect fit and imperfect adherence". Overall however, analysis of particle filtration is likely to underestimate the effectiveness of masks, since the fraction of particles that are emitted as aerosol (vs. droplet) is quite small (26). Analysis of seasonal coronavirus compared to rhinovirus (30) suggests that filtration of COVID-19 may be much more effective, especially for source control.

The importance of using masks for health care workers has been observed (34) in three Chinese hospitals where, in each hospital, medical staff wearing masks (mainly in quarantine areas) had no COVID-19 infections, despite being around COVID-19 patients far more often, whilst other medical staff had 10 or more infections in each of the three hospitals.

Masks seem to be effective for source control in the controlled setting of an airplane. One case report (35) describes a man who flew from China to Toronto and then tested positive for COVID-19. He was wearing a mask during the flight. The 25 people closest to him on plane/flight attendants were tested and all were negative. Nobody has been reported from that flight as getting COVID-19. Another case study involving a masked influenza patient on an airplane (36) found that "wearing a face mask was associated with a decreased risk for influenza acquisition during this long-duration flight".

Guideline development for health worker personal protective equipment have focused on whether surgical masks or N95 respirators should be recommended. Most of the research in this area focuses on influenza. At this point, it is not known to what extent findings from influenza studies apply to COVID-19 filtration. Wilkes et al (37) found that "filtration performance of pleated hydrophobic membrane filters was demonstrated to be markedly greater than that of electrostatic filters." However, even substantial differences in materials and construction do not seem to impact the transmission of droplet-borne viruses in practice, such as a meta-analysis of N95 respirators compared to surgical masks (38) that found "the use of N95 respirators compared with surgical masks is not associated with a lower risk of laboratory-confirmed influenza." Johnson et al (39) showed that "surgical and N95 masks were equally effective in preventing the spread of PCR-detectable influenza". Radonovich et al (40) found in an outpatient setting that "use of N95 respirators, compared with medical masks... resulted in no significant difference in the rates of laboratory-confirmed influenza."

One of the most frequently mentioned papers evaluating the benefits and harms of cloth masks have been by MacIntyre et al (41). Findings have been misinterpreted, and therefore justify detailed discussion here. The authors "caution against the use of cloth masks" for healthcare professionals compared to the use of surgical masks and regular procedures, based on an analysis of transmission in hospitals in Hanoi. We emphasize the setting of the study - health workers using masks to protect themselves against infection. The study compared a "surgical mask" group which received 2 new masks per day, to a "cloth mask" group that received 5 masks for the entire 4 week period and were required to wear the masks all day, to a "control group" which used masks in compliance with existing hospital protocols, which the authors describe as a "very high level of mask use". It is important to note that the authors did not have a "no mask" control group because it was deemed "unethical to ask participants to not wear a mask." The study does not inform policy pertaining to public mask wearing as compared to the absence of masks in a community setting, since there is not a "no mask" group. The results of the study show that the group with a regular supply of new surgical masks each day had significantly lower infection of rhinovirus than the group that wore a limited supply of cloth masks. This paper lends support to the use of clean, surgical masks by medical staff in hospital settings to avoid rhinovirus infection by the wearer, and is consistent with other studies that show cloth masks provide poor filtration for rhinovirus (30). Its implementation does not inform the effect of using cloth masks versus not using masks in a community setting for source control of SARS-CoV-2, which is of the same genus as seasonal coronavirus, which has been found to be effectively filtered by cloth masks in a source control setting (30).

A. Studies of Impact on Community Transmission. When evaluating the available evidence for the impact of masks on community transmission, it is critical to clarify the setting of the research study (health care facility or community), the res-

piratory illness being evaluated and what reference standard was used (no mask or surgical mask). There are no RCTs that have been done to evaluate the impact of masks on community transmission during a coronavirus pandemic. While there is some evidence from influenza outbreaks, the current global pandemic poses a unique challenge. A review (42) of 67 studies including randomized controlled trials and observational studies found that simple and lowcost interventions would be useful for reducing transmission of epidemic respiratory viruses. The review recommended that "the following effective interventions should be implemented, preferably in a combined fashion, to reduce transmission of viral respiratory disease: 1. frequent handwashing with or without adjunct antiseptics; 2. barrier measures such as gloves, gowns, and masks with filtration apparatus; and 3. suspicion diagnosis with the isolation of likely cases". However, it cautioned that routine longterm implementation of some measures assessed might be difficult without the threat of an epidemic.

Seuesset al conducted an RCT (43)that suggests household transmission of influenza can be reduced by the use of non-pharmaceutical interventions, namely the use of face masks and intensified hand hygiene, when implemented early and used diligently. Concerns about acceptability and tolerability of the interventions should not be a reason against their recommendation (43). Cowling et al (44) investigated hand hygiene and face masks in an RCT that seemed to prevent household transmission of influenza virus when implemented within 36 hours of index patient symptom onset. These findings suggestthat non-pharmaceutical interventions are important for mitigation of pandemic and inter-pandemic influenza.

RCT findings by Aiello et al (45) "suggest that face masks and hand hygiene may reduce respiratory illnesses in shared living settings and mitigate the impact of the influenza A (H1N1) pandemic". A randomized intervention trial (46) found that "face masks and hand hygiene combined may reduce the rate of ILI [influenza-like illness] and confirmed influenza in community settings. These non-pharmaceutical measures should be recommended in crowded settings at the start of an influenza pandemic." The authors noted that their study "demonstrated a significant association between the combined use of face masks and hand hygiene and a substantially reduced incidence of ILI during a seasonalinfluenza outbreak. If masks and hand hygiene have similar impacts on primary incidence of infection with other seasonal and pandemic strains, particularly in crowded, community settings, then transmission of viruses between persons may be significantly decreasedby these interventions."

An observational study in Hong Kong on SARS (47) found "frequent mask use in public venues, frequent hand washing, and disinfecting the living quarters were significant protective factors (OR 0.36 to 0.58)". An important observation was that "members of the case group [infected with SARS] were less likely than members of the control group [not infected] to have frequently worn a face mask in public venues (27.9% vs. 58.7%)".

B. Implementation and Sociolological Considerations. For a novel diseasewhere much is unknown, it is important to examine the context of studies closely and also distinguish "absenceof evidence" from "evidence of absence"(2). We discuss estimates of cloth mask filtering performance in Filtering Capability of Masks and summarize modelling on population impact in Estimating Population Impacts.

Some of the concerns about public mask wearing have not been around primary evidence for the efficacy of source control, but concerns about how they will be used. We present someconsiderations for the translation of evidence about public mask wearing to diverse countries acrossthe globe, outside of the parameters of a controlled research setting:

B.1. Supply chain management of N95 respirators and surgical masks. There has been a global shortage of protective equipment for health workers, with health workers falling ill and dying of occupationally acquired COVID-19 disease(48). Public messaging encouraging mask use and depleting critical supplies have been a major concern. Some regions, like South Korea and Taiwan, have decided to promote surgical mask use on a mass scale and opted to address potential stock issues through rapidly increasing production of surgical masks. In regions where surgical mask supplies are scarce, cloth masks may be a pragmatic temporary alternative to surgical masks for the public.

B.2. Sociological considerations and anticipating population-level behavior changes. It is difficult to predict the behavior change that would accompany regulations encouraging public mask use. One concern around public health messaging promoting the use of face-covering has been that members of the public may use risk compensation behavior and neglect physical distancing based on overvaluing the protection a surgical mask may offer due to an exaggerated or false sense of security (49). Similar arguments have previously been made for HIV prevention strategies (50) (51) and other safety devices and mandates such as motorcycle helmet laws (52) and seat-belts (53). However, research on these topics finds no such increase in adverse outcomes at the population level but rather improvements in safety and well-being, suggesting that even if risk compensation occurs in some individuals, that effect is dwarfed by the increased safety at the population level (53, 54). Further, even for deliberately high-risk recreational activities such as alpine skiing and snowboarding, wearing a helmet was generally associated with risk reduction oriented-behavior (55), suggesting safety devices are both compatible with and perhaps encourage safety-oriented behavior. Even for high-risk recreational activities like alpine skiing and snowboarding, helmet use has greatly reduced injury rates (56).

In general, various forms of risk compensation theories have been proposed for many different safety innovations, but have been not found to have empirical support (57) at the population level. These findings strongly suggestthat, instead of withholding a preventative tool, accompanying it with accurate messagingthat combines different preventative measures would display trust in the general public's ability to act responsibly and empower citizens, and risk compensation is unlikely to undo the positive benefits at the population level (58).

At the height of the 2009 influenza epidemic in Mexico City it was found (59) that mandatory mask requirements increasedcompliance compared to voluntary recommendations. Voluntary compliance was strongly influenced by public perception regarding the effectivenessof the recommended measures.

For many infectious diseases,including, for example, tuberculosis, health authorities recommend masks only for those

infected or people who are taking care of someone infected. However, research shows that many sick people are reluctant to wear a mask if it identifies them as sick, and thus end up not wearing them at all in an effort to avoid the stigma of illness (60, 61). Stigma is a powerful force in human societies, and many illnesses come with stigma for the sick as well as fear of them, and managing the stigma is an important part of the process of controlling epidemics as stigma also leads to people avoiding treatment as well as preventive measures that would "out" their illness (62). Many health authorities have recommended wearing masks for COVID-19 only if people are sick; however, reports of people wearing masks being attacked, shunned and stigmatized have already been observed (63). Having masks worn only by the suspected/confirmed infected also has led to employers in high-risk environments like grocery stores and prisons, and even hospitals, banning employees from wearing one sometimes with the idea that it would scare the customer or the patients (64, 65). Further, in many countries, minorities suffer additional stigma and assumptions of criminality (66). In that vein, black people in the United States have reported that they were reluctant to wear masks in public during this pandemic for fear of being mistaken as criminals (67, 68). Even if it were possible to encourage only infected people to wear masks, given the lack of access to testing in many countries, it is not possible for many people to know for sure if they are infected or not (69). Thus, while this paper has shown the importance of masks for source-control – preventing asymptomatic and presymptomatic people from infecting others – it may not even be possible to have infected/sick people wear masks due to stigma, employer restrictions, or simple lack of knowledge of one's status without mask-wearing becoming universal policy.

Another important benefit of recommending universal mask wearing would be to serve as a visible signal and reminder of the pandemic, and given the importance of ritual and solidarity in human societies (70), it is plausible that visible, public signaling via mask wearing can potentially increase compliance with other health measures as well, such as keeping distance and hand-washing. Health, especially during an epidemic, is a form of public good in that everyone else's health behaviors improve the health odds of everyone else, and that it is non-rivalrous in that one person's health does not diminish the health of anyone else (71, 72). Visible signals play an important role in human societies (73). As such, signaling participation in health behaviors by wearing a mask as well as visible enforcement (for example, shops asking customers to wear masks) can increase compliance (74). Further, historically epidemics are a time of fear, confusion and helplessness (75, 76). Mask-wearing and even mask-making or distribution can provide feelings of empowerment and self-efficacy (77), which would in turn also suggest masks could increase compliance in other health-behaviors as well by increasing self-efficacy. In Hong Kong, for example, a community-driven focus on epidemic prevention started in the early days of COVID-19, and included community activists acquiring and distributing masks especially to those without resources and the elderly, even before it was officially declared a pandemic or before their own government had taken strong steps (78). Currently, Hong Kong has not only a relatively contained epidemic compared with many other countries, but a significant reduction in influenza cases as well which their health authorities attribute, among other factors, to the near-universal mask wearing and strong norms around it (79–81).

C. Universal or near-universal mask wearing. Estimating adherence to regulations for public mask wearing is a key input for modeling the impact of public mask wearing. Telephone surveys during the SARS-CoV-2 outbreak in Hong Kong reported enhanced adherence to public mask wearing as the pandemic progressed over three weeks, with 74.5% self reported mask wearing when going out increasing to 97.5%, without mandatory requirements (82). Similar surveys reported face mask use in Hong Kong during the SARS outbreak in 2003 as 79% (83), and approximately 10% during the influenza A(H1N1) pandemic in 2009 (84). This suggests that the public have enhanced awareness of their risk, and display higher adherence levels to prevention strategies than during other epidemics. Cloth masks could be an additional tool to enhance awareness of the importance of physical distancing in public places, serving as a visual reminder. Should masks be reserved solely for use in symptomatic patients, they become a symbol of illness and could lead to public stigmatization that discourages use, as has been described for patients with tuberculosis (61). Countries like the Czech Republic and Hong Kong offer interesting perspectives on the role of citizen advocacy and on the acceptability of face-covering in public.

D. Balancing potential harm of cloth masks with additional benefits for concurrent epidemic. Based on our detailed discussion above, cloth masks have not been shown to increase the risk of infection in people using them compared to not wearing any mask. While the focus of this article has been on preventing the spread of COVID-19 disease through public mask wearing, many low-middle income countries face concurrent epidemics of diseases like tuberculosis. Tuberculosis kills 1.5 million people globally per year, and in 2018, 10 million people fell ill (85). Face covering has been shown to also reduce the transmission of tuberculosis (86) and offer additional benefits to public mask wearing. Similarly, influenza transmissibility in the community was found to have declined by 44% in Hong Kong after the implementation of changes in population behaviors, including social distancing and increased mask wearing, enforced in most stores, during the COVID-19 outbreak (82).

It has been noted (87) that ensuring compliance with non-pharmaceutical interventions can be challenging: "Mask wearing is a promising non-pharmaceutical intervention to reduce risk of secondary transmission of viral URI [upper respiratory infections], but it is likely that adherence to mask wearing would occur only if there was a major pandemic that resulted in a heightened level of community concern and fear." Many regions have now passed laws to ensure compliance. The first RCT (2008) on mask use (88) "found compliance to be low, but compliance is affected by the perception of risk. In a pandemic, we would expect compliance to improve." The authors noted that "in compliant users, masks were highly efficacious."

5. Estimating Population Impacts

At the national and global scale, effective local interventions are aggregated into epidemiological parameters of disease spread. The standard epidemiological measure of spread is known as the reproduction number R_0 which parameterizes

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 12 April 2020 doi:10.20944/preprints202004.0203.v1

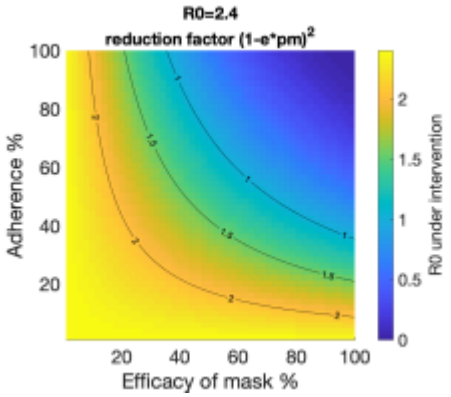

Fig. 1. Impact of public mask wearing under the full range of mask adherence and efficacy scenarios. The color indicates the resulting reproduction number R_0 from an initial R_0 of 2.4 (7).

the number of casesinfected by one case,in a completely susceptible population. R_0 determines the rate of growth, with a superlinear effect. The goal of any related healthcare policy is to have an aggregate effect of reducing R_0 to below 1.0.

Efficacy of face masks within local interventions would have an aggregate effect on the reproduction number of the epidemic. What is the magnitude of such an effect? The HKBU COVID-19 Modelling Group developed a transmission model that incorporated mask wearing and mask efficacy as a factor in the model (89). They estimate reductions in the basic reproduction number R_0 under common intervention measures. For wearing masks, they find that wearing masks reduces R_0 by a factor $(1 - ep_m)^2$, where e is the efficacy of trapping viral particles inside the mask, and p_m is the percentage of the population that wears masks. When combined with contact tracing, the two effects multiply.

A conservative assessmentapplied to the COVID-19 estimated R_0 of 2.4 (7) might posit 50% mask usage and a 50% mask efficacy level, reducing R_0 to 1.35, an order of magnitude impact rendering spread comparable to the reproduction number of seasonalinfluenza. To put this in perspective, 100 cases at the start of a month becomes31,280 casesby the month's end (R_0 = 2.4) vs. only 584 cases(R_0 = 1.35). Such a slowdown in case-loadprotects healthcare capacity and renders a local epidemic amenable to contact tracing interventions that can eliminate the spread entirely.

A full range of efficacy e and adherence p_m is shown with the resulting R_0 in Figure 1, illustrating regimes in which growth is halted entirely (R_0 < 1) as well as pessimistic regimes (e.g. due to poor implementation or population compliance) that nonetheless result in a beneficial effect in suppressing the exponential growth of the pandemic.

Yan et al (90) provide an additional example of an incremental impact assessmentof respiratory protective devices using an augmented variant of a traditional SIR model in the context of influenza with N95 respirators. They showed that a sufficiently high adherence rate (~ 80% of the population) resulted in the elimination of the outbreak with most respiratory protective devices.

Qualitative comparisons of outcomes between countries (91, 92) are suggestive of policy differences leading to differencesin diseasespread of up to three orders of magnitude. Although between-country comparisons do not allow for causal attribution, they suggestmask wearing to be a low-risk measure with a potentially large positive impact, with many countries with widespread use of masks in public keeping deaths below one in a million.

Abaluck et al (93) extend the between-country analyses from a cost perspective, estimating the marginal benefit per cloth mask worn to range from $3,000-$6,000. They also found that "the average daily growth rate of confirmed positives is 18% in countries with no preexisting mask norms and 10% in countries with such norms." and "that the growth rate of deaths is 21% in countries with no mask norms and 11% in countries with such norms."

6. Discussion and Recommendations

Our review of the literature offers evidence in favor of widespread mask use to reduce community transmission: non-medical masks use materials that obstruct droplets of the necessary size; people are most infectious in the initial period post-infection, where it is common to have few or no symptoms (10–16); non-medical masks have been effective in reducing transmission of influenza; non-medical masks have been shown to be effective in small trials at blocking transmission of coronavirus; and places and time periods where mask usage is required or widespread have shown substantially lower community transmission.

The available evidence suggeststhat near-universal adoption of non-medical masks when out in public, in combination with complementary public health measurescould successfully reduce effective-R to below 1.0, thereby stopping community spread. Economic analysis suggeststhat the impact of mask wearing could be thousands of US dollars saved per person per mask (93).

Interventions to reduce COVID-19 spread should be prioritized in order of their expected multiple on effective R divided by their cost. By this criterion experimentation with and deployment of universal masks look particularly promising. When used in conjunction with widespread testing, contact tracing, quarantining of anyone that may be infected, hand washing, and physical distancing, face masks are a valuable tool to reduce community transmission. All of these measures,through their effect on R_0, have the potential to reduce the period of lockdown required. As governments talk about relaxing lockdowns, keeping transmissions low enough to preserve health care capacity will be critical until a vaccine can be developed. Mask wearing may be critical to preventing a second wave of infections from overwhelming the health care system – further researchis urgently neededhere.

UNESCO states that "when human activities may lead to morally unacceptable harm that is scientifically plausible but uncertain, actions shall be taken to avoid or diminish that harm" (94). This is known as the "precautionary principle". The World Charter for Nature, which was adopted by the UN General Assembly in 1982, was the first international endorsement of the precautionary principle. It was implemented in an international treaty in the 1987 Montreal Protocol. The loss of life and economic destruction that has been seen already from COVID-19 is a "morally unacceptable harm". The positive impact of public mask wearing on this is "scientifically plausible but uncertain". This notion is reflected in Figure 1 - while researchersmay reasonably disagree on the magnitude of transmissibility reduction and compliance, seemingly

modest benefits can be massively beneficial in the aggregate due to the exponential character of the transmission process. Therefore, the action of ensuring widespread use of masks in the community should be taken, based on this principle (95).

Models suggest that public mask wearing is most effective at stopping spread of the virus when compliance is high. This is the same situation as we see with vaccines - the more people are vaccinated, the higher the benefit to the whole population including those who cannot be vaccinated like infants or immuno-compromised people. A common policy response to this conundrum is to ensure compliance by using laws and regulations, such as widespread state laws in the US which require vaccinations to attend school. Research shows that the strength of the mandate to vaccinate greatly influences compliance rates for vaccines and that policies that set a higher bar for vaccine exemptions result in higher vaccination rates. (96) The same approach is now being used in many jurisdictions to increase mask wearing compliance, by mandating mask use in a variety of settings (such as public transportation or grocery stores or even at all times outside the home). Early results suggest that these laws are effective at increasing compliance and slowing or stopping the spread of COVID-19 (91). We recommend that mask use requirements are implemented by governments, or when governments do not, by organizations that provide public-facing services, such as transit service providers or stores, as "no mask, no service" rules. Such mandates must be accompanied by measures to ensure access to masks, possibly including distribution and rationing mechanisms so that they do not become discriminatory but remain focused on the public health benefit. Given the value of the source control principle, especially for presymptomatic people, it is not good enough for only employees to wear masks, customers must wear masks as well.

It is also important for health authorities to provide clear guidelines for the production, use and sanitization or re-use of face masks, and consider their distribution as shortages allow. A number of countries have distributed surgical masks (South Korea, Taiwan) from early on while Japan and Singapore are now distributing cloth masks to their whole population. Clear and implementable guidelines can help increase compliance, and bring communities closer to the goal of reducing and ultimately stopping the spread of COVID-19.

Materials and Methods

A community-driven approach was used for building the paper list used in this literature review. A multidisciplinary community of researchers used online tools to review and actively discuss publications related to the question of the effectiveness and policy of public mask wearing.

PERSPECTIVE
Host-Microbe Biology

COVID-19: an Immunopathological View

Kamran Kadkhoda[a]

[a]Immunopathology Laboratory, Robert J. Tomsich Pathology & Laboratory Medicine Institute, Cleveland Clinic, Cleveland, Ohio, USA

ABSTRACT Since its emergence in December 2019, it took only a couple of months for an outbreak of the novel coronavirus disease 2019 (COVID-19) to be declared a pandemic by the World Health Organization (WHO). This along with the highly infectious nature of the disease and the associated mortality call for particular attention to the underlying (immuno)pathomechanism(s). The latter will inform case management and vaccine design. Unravelling these mechanisms can assist basic scientists, laboratory medicine practitioners, clinicians, public health practitioners, funding agencies, and health care policymakers in responding to the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic.

KEYWORDS COVID-19, SARS-CoV-2, immunopathology

Xu et al. (1) reported on a 50-year-old man with no known underlying conditions who presented with pneumonia. Despite the presence of lymphopenia and absence of neutropenia, all inflammatory cells observed on the lung biopsy specimen were mononuclear cells. Peripheral blood lymphocytes showed high levels of activation markers (HLA-DR and CD38) by flow cytometry. These cells were strongly perforin- and/or granulysin-positive $CD8^{ffi}$ T cells or were inflammatory Th17 cells. This had led to significant damage to the lung tissues as demonstrated by diffuse alveolar damage, indicating acute respiratory distress syndrome (ARDS). This is consistent with high-level surface expression of angiotensin-converting enzyme 2 (ACE2), the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) receptor, on pneumocytes (2). Unfortunately, the patient passed away, but it is important to note that methylprednisolone was started on day 8 after the onset of symptoms, while the catastrophic ARDS cascade was already under way. Interestingly, inhalational alpha interferon (IFN-ffi) was also instituted along with methylprednisolone. Since IFN-ffi can boost antiviral immune responses, it might have further played a role in the tissue damage in this case. On a related note, previous studies with macaques using SARS-CoV had shown that older macaques had stronger innate immune responses (including those related to IFN-ffi) compared with younger macaques. In contrast, expression of IFN-ffi, as an anti-inflammatory cytokine, was reduced in older macaques (3). It has recently been shown that interleukin-6 (IL-6) was also expressed significantly higher in patients who succumbed to coronavirus disease 2019 (COVID-19) than in survivors (4). Observations like this case made by a number of front-line clinicians since the inception of the COVID-19 pandemic have led to pointing fingers at immunopathology as the potential main culprit.

There have been several studies including the large epidemiological joint report by WHO and China (5) stating that the case fatality rate (CFR) is exceedingly low in pediatric patients especially in the very young (CFR of 21.9% for individuals over 80 years of age versus 0% for individuals under 8 years of age). This is a striking finding that further suggests an immunopathological component to this observation. Another observation is the seroprevalence of community-acquired coronaviruses among adults is very high (90 to 100%) (6), but this is not necessarily the case in pediatric patients (7). Additionally, there are antigenic commonalities among coronaviruses (CoVs); for in-

stance, similar to SARS-CoV-2, CoV-NL63 also uses ACE2 as the receptor (8). As individuals age, the chance of exposure to common community-acquired CoVs (229E, OC43, NL63, and HKU1) increases. As a consequence, with such background anamnesis, once individuals are exposed to novel (zoonotic) CoVs such as SARS-CoV-2, the fast and furious immune response does the damage (the original antigenic sin [OAS]). According to OAS, the initial antigen imprints an immune response so that subsequent exposure to related antigen(s) preferentially chooses the already-existing memory cells. The resultant response, although brisk and apparently strong (a high-titer IgG response would be faster than that of IgM), may be unduly insufficient and inappropriate to the point that it might be initially nonprotective. In the context of COVID-19, since ACE2 is highly expressed in the gastrointestinal (GI) tract (9), shedding the virus in the stool is prolonged (10); however, diarrhea is uncommon likely because virus-specific effector memory T cells typically home to the mucosal surfaces they had previously encountered with an infection with a common CoV, i.e., upper and lower respiratory tract. As a result, despite ARDS in the lungs, almost no significant intestinal damage occurs, if at all. To further confound matters, lungs also express high levels of CD32a (Fc! RIIa, typically on alveolar macrophages), whereas GI tissues express almost no CD32a protein (The Human Protein Atlas [https://www.proteinatlas.org/] [accessed March 2020]). It has recently been shown that SARS-CoV and the Middle East respiratory syndrome (MERS)-CoV take advantage of non- or subneutralizing antibodies and enter cells via surface CD32a receptors (Trojan horse mechanism) (11, 12). Therefore, another even more biologically plausible pathomechanism is the so-called antibody-dependent enhancement (ADE). ADE has also been shown in infection with dengue viruses, Zika virus, Ebola virus, and human immunodeficiency virus. ADE is not only triggered by neutralizing antibodies but also by nonneutralizing antibodies. Additionally, antibody affinity plays an important role in ADE (11, 13). The most important pathomechanism in COVID-19, therefore, could be ADE in which CD32a plays the central role. CD32a is expressed on the surfaces of monocytes and macrophages among other cells such as alveolar macrophages, and once aggregated by several IgG molecules, it transduces its signal through the associated immunoreceptor tyrosine-based activation motif (ITAM). This results in the release of proinflammatory cytokines including IFN-! , tumor necrosis factor alpha, interleukin-1 (IL-1), and IL-6 (14). This IL-6 overproduction is the justification for using IL-6 receptor antagonists such as tocilizumab in COVID-19 clinical trials. It should be noted, however, that activation of ITAM occurs through phosphorylation by certain members of Src family of tyrosine kinases such as Fyn and Syk. Interestingly, agents such as cerdulatinib have dual inhibitory function against Syk as well as against Janus kinase family members (such as JAK1/2) (15), the latter also play key roles in IL-6 receptor signaling (16).

To complete the picture, SARS-CoV nucleoprotein and RNA had previously been found within alveolar macrophages of nonsurvivors (17). These cells also express dendritic cell-specific intercellular adhesion molecule-grabbing nonintegrin (DC-SIGN; CD209 and also CD209L). These surface molecules have been reported to be coreceptors for SARS-CoV entry (18). In this way, alveolar macrophages can function as a local niche for the virus and thereby pass it on to other cells.

Findings similar to the aforementioned epidemiological finding have been made for MERS-CoV in which disease severity increases with age and severe disease has been uncommon among pediatric patients (19). Furthermore, along the lines of ADE, it has been known for decades that immunization of cats with spike protein of feline CoV leads to more severe future infections with feline CoV in cats (11). Therefore, ADE is perhaps more effective when the time intervals between CoV infections are just long enough so antibody titers drop to at least subneutralizing levels. This may explain why association of older age with severe COVID-19 is not always the rule. Infection of alveolar macrophages through ADE may explain their excessive activation and generation of local hyperinflammatory environment and the resultant systemic cytokine storm that may even fulfill criteria for secondary hemophagocytic lymphohistiocytosis and macrophage activation syndrome. The pivotal involvement of macrophages is further highlighted by the fact that very high levels of ferritin are seen in severe

Downloaded from http://msphere.asm.org/ on April 22, 2020 by guest

COVID-19 cases (20). Additionally, the fact that severe COVID-19 is associated with much higher viral load compared with mild cases further suggests that ADE could play an important role in severe cases (21). Another explanation for age-associated severity of COVID-19 may be attributed to C-reactive protein (CRP). It is known that CRP levels increase with age and that serum CRP levels in adults are higher than in children, with the highest median level observed in the elderly (22). Furthermore, it has been demonstrated that CD32a is the major biological receptor for CRP (23).

Furthermore, the course of COVID-19 is in general more severe in those with underlying conditions such as hypertension, poorly controlled diabetes mellitus, and cardiovascular disease among others (4). This may be attributed to the known increased expression of CD32a on monocytes and macrophages in these patients (24). However, it is a common assumption that immunocompromised patients are at increased risk of developing severe COVID-19. To challenge this assumption, a report from Italy (25) showed that 3 out of 111 liver transplant recipients who passed away due to COVID-19 had received their transplants 10 years prior to death. Interestingly, these patients were stable with very low trough concentrations of calcineurin inhibitors in plasma. They, however, were all male, older than 65 years, overweight, diabetic, and on treatment for hypertension. In contrast, in the same study, 3 out of 40 individuals who had recently received liver transplants and were on intense immunosuppression drugs (without the other risk factors mentioned for the former group) and who tested positive for SARS-CoV-2 experienced an uneventful course of COVID-19. The CFR in the former group was 3% in contrast to the overall CFR of ca. 10% in Italy. Abatement of IFN-ffi signaling by calcineurin inhibitors may explain these observations. IFN-ffi can also be largely produced as a result of CD32a activation (26). Similar observations in other immunocompromised patient populations with larger sample sizes will be paramount to further understand the role of immunopathology in COVID-19.

All in all, further corroborative research is urgently needed to find out why advanced age is a major risk factor for COVID-19 and whether immunopathomechanisms can potentially be harnessed early enough to prevent irreversible consequences. This may be ground-breaking and would not only change the current individual patient management but also potentially inform prudent vaccine design and recommendations as was the case with dengue virus vaccination. The implications of ADE will be immense if IgG serology is used to determine immune status for health care workers, as a positive result does not necessarily mean one is immune to COVID-19 (even with a test specificity of 100%). More importantly, ADE may cause harm if plasma from clinically resolved patients is used for treatment. A very careful balance between risks and benefits established through large multicenter randomized controlled trials will provide answers to all these questions.

Research Article | Infectious disease | Pulmonology

Newly emerging viruses, such as severe acute respiratory syndrome coronavirus (SARS-CoV), Middle Eastern respiratory syndrome CoVs (MERS-CoV), and H7N9, cause fatal acute lung injury (ALI) by driving hypercytokinemia and aggressive inflammation through mechanisms that remain elusive. In SARS-CoV/macaque models, we determined that anti–spike IgG (S-IgG), in productively infected lungs, causes severe ALI by skewing inflammation-resolving response. Alveolar macrophages underwent functional polarization in acutely infected macaques, demonstrating simultaneously both proinflammatory and wound-healing characteristics. The presence of S-IgG prior to viral clearance, however, abrogated wound-healing responses and promoted MCP1 and IL-8 production and proinflammatory monocyte/macrophage recruitment and accumulation. Critically, patients who eventually died of SARS (hereafter referred to as deceased patients) displayed similarly accumulated pulmonary proinflammatory, absence of wound-healing macrophages, and faster neutralizing antibody responses. Their sera enhanced SARS-CoV–induced MCP1 and IL-8 production by human monocyte–derived wound-healing macrophages, whereas blockade of FcγR reduced such effects. Our findings reveal a mechanism responsible for virus-mediated ALI, define a pathological consequence of viral specific antibody response, and provide a potential target for treatment of SARS-CoV or other virus-mediated lung injury.

Introduction

Severe acute respiratory syndrome coronavirus (SARS-CoV) causes fatal human respiratory disease (1–3). Patients with SARS (hereafter referred to as SARS patients) displayed the characteristics of acute lung injury (ALI), including diffuse alveolar damage (DAD), epithelial necrosis, and fibrin and hyaline deposition (4, 5). Most patients who die of SARS develop acute respiratory distress syndrome (ARDS), the most severe form of ALI (6, 7). Recent outbreaks of severe acute respiratory infections of emerging viruses, including Middle Eastern respiratory syndrome CoVs (MERS-CoV), highly pathogenic avian influenza viruses (e.g., H5N1 and H7N9), highlight the need to characterize the mechanisms responsible for virus-mediated ALI or ARDS.

Fundamental to ARDS is the acute onset of lung inflammation, which is intimately tied to monocyte/macrophage polarization and function (7, 8). Lung macrophages are highly plastic and heterogeneous cells that are resident in the lung interstitium and alveoli or recruited upon inflammatory stimuli. Inflammatory monocytes and resident tissue macrophages play critical roles in initiating and maintaining inflammation

during the acute stage of ARDS, as well as in the resolution phages of inflammation and recovery from ARDS. At steady state, resident macrophages are normally quiescent to prevent damaging the alveoli and are critically involved in normal tissue homeostasis. After tissue injury or during infection, resident macrophages become activated. Circulating monocytes can be efficiently recruited to the site of injury. Inflammatory monocytes/macrophages (IMMs) and resident macrophages undergo marked phenotypic and functional changes, and they can be classified into proinflammatory (M1 or classically activated) and inflammatory-resolving (M2, alternatively activated, wound-healing, or antiinflammatory) macrophages, with a continuum of macrophage polarization existing beyond these discrete categories (9). During acute infection, monocytes/macrophages often display a phenotype of classically activated macrophages. These cells mediate host defenses against viruses and also promote lung injury by producing nitric oxide (NO); ROS; IL-1, IL-6, and IL-8; and TNF. Simultaneously, some macrophages may become alternatively activated, exerting antiinflammatory function and regulating wound healing by producing matrix metalloproteinases (MMPs), growth factors, and antiinflammatory cytokines, particularly TGF-β. When the pathogen or inflammatory stimulus is eliminated, proinflammatory macrophages diminish. The predominant macrophage population assumes a wound-healing phenotype. At the final recovery stage, macrophages show a regulatory/suppressive phenotype, secreting increased levels of IL-10, which facilitates the resolution of wound healing and restores homeostasis. When the wound-healing response is well organized and controlled, the inflammatory response resolves quickly, and normal tissue architecture is restored. Disturbances in wound-healing response can lead to uncontrolled production of inflammatory mediators, contributing to a state of persistent injury (9–11). In patients who eventually died of SARS (hereafter referred to as deceased patients) and animal models, extensive lung damage is associated with high initial viral loads, increased IMM accumulation in the lungs, and elevated serum proinflammatory cytokine (IL-1, IL-6, IL-8, CXCL-10, and MCP1) levels (4, 5, 12, 13). While much is known about the terminal phase of SARS, little is known about the early immune events during the acute phase of infection. Studies defining macrophage heterogeneity and function during acute infection and ALI using nonhuman primate and patient specimens are limited, and the factors driving the hypercytokinemia and aggressive inflammation remain elusive.

During the SARS outbreak in Hong Kong, most patients (70%–80%) presented with abnormal chest radiographs, with approximately one-quarter of these individuals progressing to ALI. After 12 days, 80% of these SARS patients developed ARDS, coincident with IgG seroconversion (6). In a detailed analysis of antibody responses against SARS-CoV spike (S) glycoprotein, we reported that the anti-S neutralizing antibody (NAb) response developed significantly faster in deceased patients compared with recovered patients after the onset of clinical symptoms (14). It took an average of 20 days for the recovered patients to reach their peak of NAb activities, as opposed to only 14.7 days for the deceased patients. Moreover, the actual NAb titer is significantly higher in deceased patients compared with that in the recovered patients during the same time period (14). These findings suggest a role of anti-S antibodies in SARS-CoV–mediated ALI during acute infection. Consistently, preexisting serum antibodies against influenza antigens were found to associate with worse clinical severity and poor outcomes in patients during the 2009 influenza pandemic (15, 16). Moreover, multiple vaccine platforms and viral infection appeared to induce SARS-CoV–specific immune memory that enhanced lung inflammation following homologous challenge in mice and African green monkeys (17–19). The mechanism responsible for the immunopathologic reaction remains elusive. Recent studies suggested that T cells play a crucial role in protection of mice against lethal SARS-CoV infection (20–22). Enhanced pulmonary immunopathology in vaccinated and challenged animals reflects an inadequate Th1 response (22, 23). The role of virus-specific antibody response in SARS-CoV–induced lung injury has yet to be clearly defined. Therefore, we used vaccination and anti–S-IgG passive immunization strategies to evaluate the effects of anti-S antibodies on SARS-CoV–induced ALI in Chinese rhesus monkeys (*Macaca mulatta*). Our results now show that, in productively infected lungs, anti–S–IgG causes severe ALI by skewing inflammatory resolving responses during acute infection.

Results

Vaccine-induced S-specific immunity resulted in severe ALI in SARS-CoV–infected Chinese macaques. We initially compared the pathological changes in the lungs of rhesus macaques vaccinated with a modified vaccinia Ankara (MVA) virus encoding full-length SARS-CoV S glycoprotein (ADS-MVA) or control at 7 and 35 days after pathogenic SARS-CoV$_{PUMC}$ (1×10^5 tissue culture infectious dose of 50% [$TCID_{50}$]) challenge (24). Three healthy macaques were included as controls. Sixteen macaques were i.m. immunized twice: 8 animals with

ADS-MVA and another 8 animals with a control MVA (ADC-MVA) (Figure 1A) (24). Vaccination with ADS-MVA induced high levels of anti–SARS-CoV NAbs in all 8 macaques, with sera IC_{50} values ranging from 10,232- to 28,703-fold dilutions (Figure 1B). None of the macaques developed fever during or after vaccination (normal body temperature 37.8°C–38.1°C). The IC_{50} values of these sera were maintained, with an over-2,000–fold reciprocal serum dilution at 4 weeks after the secondary immunization, a time when all of the animals were i.n. challenged (Figure 1B). After viral challenge, all macaques developed fever between 1 and 5 days after inoculation (dpi) ranging from 38.6°C–39.2°C, and sera from control vaccinated macaques showed increased neutralizing activity after 14 dpi, indicating establishment of infection (Figure 1B). SARS-CoV RNA was readily detected on oral swabs from all control macaques examined at multiple time points using real-time reverse transcription PCR (real-time RT-PCR) but only in 3 of the 8 ADS-MVA–vaccinated macaques with lower NAb titers at 2 dpi (SL11, SE13, and SL14) (Figure 1C), suggesting reduced productive viral infection in the immunized macaques through S-specific immunity.

However, histological examination revealed acute DAD with various degrees of severity in 6 ADS-MVA–vaccinated macaques at 7 and 35 dpi, whereas most control macaques in the ADC-MVA group showed minor to moderate inflammation (Figure 1D). To better characterize the pathological changes, we adopted a 6-grade scoring system to describe the severity of the lung damage from least severe to most severe: 0, –; 1, +; 2, ++; 3, +++; 4, ++++; and 5, +++++ (Supplemental Figure 1; supplemental material available online with this article; https://doi.org/10.1172/jci.insight.123158DS1). In the control vaccinated group, 5 macaques showed minor inflammation with slight septa broadening and inflammatory cells infiltration that we scored as + (CL23, CE25, CE20, CE21, and CL19; Figure 1D, Supplemental Figure 1B, and Supplemental Figure 2). Two macaques showed moderate inflammation with more interstitial mononuclear inflammatory infiltration and were scored as ++ (CL26, CE24; Supplemental Figure 1C and Supplemental Figure 2). Only 1 macaque showed typical symptoms of acute DAD with extensive exudation and cell infiltration at 35 dpi (CL22, scored as ++++; Supplemental Figure 2). In the ADS-MVA–vaccinated group, 4 macaques showed typical symptom of acute DAD with extensive exudation and many-cell infiltration in alveolar cavities (SL11, SE12, SL16, and SL18, scored as ++++; Supplemental Figure 1E and Supplemental Figure 2). One macaque showed severe acute DAD with exudation, hyaline membrane formation along the alveoli, pneumocyte desquamation, and damaged alveolus filled with hemorrhage and inflammatory cells (SL15, scored as +++++; Figure 1D). One macaque showed early symptom of acute DAD (SL14, scored as +++; Supplemental Figure 1D), and the remaining 2 macaques showed moderate inflammation (SE13 and SE17, scored as ++; Supplemental Figure 2). The comparison of lung histopathological scores of 2 groups showed significantly enhanced lung injury in the ADS-MVA–vaccinated group at both 7 and 35 dpi compared with the control ADC-MVA group, suggesting that S-specific— but not MVA-specific — immunity promotes ALI during SARS-CoV infection (Figure 1E). Moreover, there is a moderate correlation between lung pathological scores and sera NAb titers at 0 dpi (Figure 1F), suggesting a role of S-specific antibody in enhancing SARS-CoV–mediated lung injury.
